bandwidth shared by those who share their nodes with their neighbors. One of the challenging questions related to intangibles (e.g. human knowledge, software, reputation, political support, and collaboration) is how to convert them into negotiable forms of value (Allee 2008). Since community contributions are provided for free, we estimate their value using their opportunity costs. We assume that the opportunity cost of volunteered time is $5 per hour, the donated hardware (e.g. used computers and access points) is $25 per unit, the technical support is $10 per hour and the shared access point is $50 per unit. This process is called value conversion through which we convert intangible inputs or assets into financial values (Allee 2008). The third column in this table presents the dollar value of volunteered hours per week for the investigated projects. For instance, Court Housing obtains voluntarily time of $5(1x5) and SeattleWireless obtains voluntarily time of $100 (20 hours x 5 dollars). Column four represents the money donations received so far by these networks. Column five represents the dollar value of the weekly technical support provided to these networks by community members. For instance, SeattleWireless obtains 5 hours of technical support whose money value is $50. Similarly, Court Housing has two community members who share their access points, with estimated money value of $100 and received two units of hardware donation of $50 value. Column six represents the money value, as estimated by respondents, of the OSS developed to the network.

Powell (2006) calls networks that depend on the contributions of volunteers a network of aid. However, we view CWNs as value networks composed of social and technical resources contributed by the community. They also generate social, economic and technical outputs for the community. In general, a value network is defined as a group of people who work together via relationships to create public goods or economic value (Allee 2008). We modeled community contributions in a bipartite graph: $G = (U, E)$, where $U = (V U R)$ where $V$ and $R$ are disjoint sets of vertices (nodes). In other words, there is no link either between any pair of nodes with the set $V$ or the set $R$. The set $V$ represents the investigated CWNs and the set $R$ depicts the types of contributors represented by their contributions. The set $E$ depicts the ties between $V$ and $R$. A tie is an ordered pair of nodes $(v_i, r_j)$. These ties represent different forms of community contributions. Each edge has a nonnegative capacity or weight $W$ for all edges $(v_i, r_j) \in E$, as shown in Table 1 and Figure 1. If there is no edge between two nodes $v_i$ and $r_j$ or the weight $w(v_i, r_j) = 0$, then the group of contributors $r_j$ do not support the network $v_i$. Figure 1 depicts the two sets described in our model: a set of CWNs (the red nodes) and a set of community contributions (the green nodes). The size $|R|$ of the set of contributions is 6. The set $R$ represents the inputs, or the dollar value, of community members, discussed earlier, which include money donation, time volunteered, sharing access points, developed software for the system, and provided technical support. The size $|V|$ of the CWNs set is 16 networks. In this model, the set $V$ represents the sinks, or CWNs, and the set $R$ represents the sources of values or set of contributors. Clearly, the rows, in Table 1, represent the sinks and the columns represent the sources of contributions. To illustrate more, Figure 2 demonstrates NYCwireless as a graph of a super sink and three sources of value.

One of the problems with respect to CWNs is finding efficient ways to summarize and visualize data about the transactions between their actors. Figure 1 depicts the investigated CWNs-by-contributions network. Visualizing such collective projects may uncover some of the hidden information about the interactions between their components. For instance, Figure 1 shows the “goingtogetherness” or “correspondence” of types of contributions, which represent contributors, and associated CWNs. This visualization depicts bundles of CWNs-contributions as clusters in the joint space. For instance, the SeattleWireless, Jawug, NYCwireless, Keur Sedaro, Digital el Paso, Cstle Square WiFi, Champaign-Urbana, and Pretoria Wireless are located close to each other. This togetherness indicates the similarity between these two groups of networks. We also visualized the tangible and intangible resources of these networks in forms of negotiable values. Figure 1 shows that hardware donation (HD) is located far away from the other types of contributions. The other five facets of contributions are located close to each other. We will provide more quantitative analysis to such togetherness in the following sections.
Figure 2 shows the NYCwireless as a super sink with three sources of values which are shared access points, technical support, and time. It receives weekly volunteered hours of $10 and $20 dollars of technical support and it has 200 dollars worth of shared access points between community members. It does not receive hardware donations, money donations, or free OSS form the community.

Although we provided monetary values for these facets of contributions in this study, this is not meant to measure the real value of the infrastructure. Instead, we used it only for modeling and analytical purposes in order to help researchers and practitioners to apply our method in their investigations. In other words, the main purpose is to provide a new approach to quantify, map and measure the assets of these networks or the community contributions used to build them. It is important to measure these resources so that network managers can manage them. We can also visualize how the wireless nodes are geographically distributed and to what extent these networks are embedded in their communities. Using this approach would be more useful for an in-depth case study that focuses on one, or few, network to have a clearer understanding and a thorough estimation of the resources and assets of this specific network.
5. EMPIRICAL ANALYSIS

The proposed graph theoretic model represents a valuable quantitative tool to address key issues related to the resources of CWNs. Following is an empirical analysis of community contributions with the help of this model.

5.1 A comparative study of CWNs

In this experiment we used the developed model to compare different CWNs based on the type and value of community contributions. In particular, we used the similarity function of the UCINET software to compare these networks using the sum of the weights, or the capacity, of their incoming edges or \( \text{in} (E) \). The similarity function measures to what extent two CWNs are similar in this regard. Table 2 shows the similarity between the investigated networks. A similarity of 1 means the two networks are identical (we compare the networks to themselves), and -1 means they are totally opposite to each other in terms of types of involved actors and their contributions. The similarity between the Court Housing and SeattleWireless networks, 0.94, means they are very similar to each other based on the types and value of community contributions. A high dissimilarity between two networks may indicate a good opportunity of collaboration between them. They could exchange knowledge, expertise or OSS. For instance, there are collaboration opportunities between the Champian-Urbana and Cape Town networks, as the similarity between them is -.92. We can also compare the set of contributions to each other using the same approach, and this one of our future work.

Another way to compare the similarity between CWNs is using the sum of the weights of the outgoing edges (or \( \text{out} (E) \)). The set of \( \text{out} (E) \) could be used to depict the number of nodes the network has, the number of users it serves or the opportunity cost of its services or value offerings. These potential measures will be addressed thoroughly when we study the outcomes (e.g., accruing social capital, generating human capital, and improving the business environment, achieving digital inclusion). In other words, we will address the dual version of this phenomenon which is considering CWNs as super sources of a pool of added values which feed, or benefit, multiple sinks (e.g., local community, developing organizations, municipalities, technology vendors), or subgroups of stakeholders of CWNs.

We can also use graph concepts to identify the maximum size of the CWNs-by-contributions network. This is a classical problem in graph theory known of the maximal complete bipartite graph or the maximal bicliques (Li, Sim, Liu, and Wong 2008). In our case, this graph should include all types of contributions or inputs.

Table 2. The similarity between
Figure 2 shows that the maximum complete bipartite graph, for the investigated networks, is of size \( k_{2,6} \). It includes two networks: Airstream and Red Libre De Ometepe. Both have affiliations with all the investigated set of contributors. The question arises here is: how can we increase the size of this graph? In other words, how can we enable other networks to affiliate with all possible segments of contributors and engage the community at large?

5.2. Classifying CWNs

The purpose of this experiment is to partition, or group, CWNs-by-contributions into classes based on the density of community contributions. Specifically, we identified CWNs which have high-density of contributions and presented them as close as possible to each other in one block called “the core.” We also obtained another set of CWNs which have very low-density of contributions in one group, called “periphery.” This approach is called “core-periphery” analysis (Hanneman and Riddle 2005). Others call it “Blockmodel,” through which the cells of the data matrix are sorted such that rows and columns that belong to the same class are organized close to each other (Borgatti 2008). We applied this type of analysis to the collected data to obtain an ideal image of high-density and low-density groups along the main diagonal. This approach uses the concept of graph density to classify CWNs-by-contributions. In particular, we partitioned the columns (types of contributions) and the rows (CWNs) into four groups based on the density of contribution for each group. In a directed graph with weighted edges, the term graph density refers to the average contribution of each group or partition. Table 3 shows that the bottom right block has the highest density, 26400.5 dollars, of contributions and the upper right block has the lowest density of contribution which is 283.6 dollars.

Density matrix

```
1   2
1 20143809 203654
2 1510263 26400626
```
A deep look at these blocks shows that the networks in the upper half (e.g. WUG, Keur Sedaro, etc.) have more shared access points, money donations and OSS. They also obtain less volunteerism of time, hardware donations, and free technical support from their communities. On the contrary, the networks in the lower half (e.g. SeattleWireless, Champaign-Urbana, etc.) have less sharing access points, money donations and OSS. They also receive more volunteerism of time, hardware donations, and technical support. The question is: why these two groups are different in terms of types and amounts of contributions they receive. We hypothesize that these different patterns between these groups could be due to the differences (e.g. social values, average income, education, etc.) between the contributors across these networks. We can also compare the density of each group to the density of the whole graph which is 12719.6 dollars. This density could be used to measure the level of community engagement in the investigated networks. Yet, we would like to emphasize that these facets of contributions are dynamic in terms of the number of contributors and the type of their inputs. This is because of the loose structure and nonprofit status of these networks, similar to other collectivities.

6. SIGNIFICANCE OF RESEARCH

Through the Internet, users share data, exchange massages and collaborate on research, and develop OSS (Lesser, Fontaine and Slusher 2000). In this study, we show how they build and share telecommunication infrastructures. In particular, we use graph theoretic approach to propose fresh perspective for understanding the role of communities in the development of their wireless infrastructures. In particular, we modeled, measured and analyzed the contributions of community members in a quantitative and compact manner. To measure community contributions in these collective projects, we construct the variables of OSS, money donations, technical expertise, voluntary work, node-sharing, and hardware donations. Identifying, mapping, measuring and evaluating these resources are important for a successful CWN endeavor. We also distinguish contributions of technical processes (e.g. developing OSS, providing technical support) from unskilled manpower. This would be useful if we study the role of CWNs in building technical expertise or human capital. Furthermore, we convert them into marketable values, using their opportunity cost, to help us aggregate them and measure the market value of these collective projects.

This study provides policy makers with important insights into CWNs as a potential solution for the digital inequality problem. The used analytical approach could be used to assess the socioeconomic benefits of such collective projects. Measuring such benefits may help researchers to obtain new insights into how to engage more participants. In particular, it may help community leaders to convince governments, OSS groups, students and developing agencies to contribute to this movement. The participation of government entities, for instance, may take different forms such as providing funds, deregulating the necessary spectrum, and/or providing the legal rights of communities and nonprofit organizations to collectively build, own, and run such telecommunication infrastructures. We also hope that the proposed model would expand the problem-solving abilities of practitioners when they use it to visualize, map, measure and manage the resources and outcomes of CWNs.

For academicians, our study provides an elegant analytical approach and a rich set of conceptual insights to guide current and future research on CWNs and similar collectivities such OSS groups, MySpace, Wikipedia, Facebook and other online forums and collaboration groups. In particular, our approach in treating CWNs as value networks is necessary to capture the complexity of relationships and transactions between their actors. Proposing such an approach, at this embryonic stage, is important in order to advance this intellectual stream. Another scientific contribution of this paper is providing an example of how to treat 2-mode network data and how to assess intangibles using their opportunity costs.

We believe that this perspective of treating the resources and assets of CWNs is illuminating but incomplete. Its main limitation is excluding important facets of community contributions such as boosting the publicity and awareness of the project. Another limitation is assuming that both CWNs and contributors are disjoint sets. In other words, we assumed that there are no relationships between individual CWNs and that groups of contributors do not intermix; however, this is not the case in reality. For example, volunteers may donate money, provide technical support, and/or develop software for the system. We isolate these inputs in order to distinguish financial contributions from nonfinancial contributions and cognitive contributions (e.g., technological processes) from
non-cognitive contributions (e.g. manpower). In addition, CWNs collaborate with each other in OSS development (e.g. their annual summit). We assume that these two sets are disjoint only for analytical purposes. Another important observation is that the agents of CWNs are spatially distributed and their cooperation may occur virtually or over time. Furthermore, the used data, Table 1, is correct only at the time of data collection, which is June of 2008. These networks are dynamic and their lack of commitments of participants. However, the adopted analytical approach should be useful in helping researchers resolve a number of critical issues related to CWNs. There is also methodological issue as the used SNA approach is limited only to small networks where we have confidence in the reliability of our observations, according to Hanneman and Riddle (2005).

It would be interesting if future work relates contributions of actors to their attributes such as their size, social values, income, age, gender, diversity, social cohesion and education. This may help answer questions such as why there is so much voluntary participation or money donation in specific networks compared to others. Another potential topic is focusing on one or few CWNs and study the one-mode, or micro, relationships (e.g. benefits, contributions, reciprocation, influence, solidarity, trust) between their actors. For instance, focusing on one network would help researchers to visualize and classify the contributors, beneficiaries, and isolates in a specific community. Our future work will focus on the dual version of the relationship between CWNs and their actors. In particular, we will investigate how CWNs, as macro-structures, create values for participants (e.g., volunteers, OSS developers, underserved communities) as micro-structures. We will use the adopted analytical approach to treat CWNs as sources of values. In particular, we will provide a careful analysis of the role of these networks in creating social capital and human capital.

7. CONCLUSIONS

This study presents a new direction in understanding the role of communities in developing their CWNs. In particular, In particular, it provides new insights into the role of communities, as macrostructures, in developing CWNs, as microstructures. We used graph concepts to model community contributions in the development of their wireless infrastructures. The proposed model is used to visualize, classify, and compare CWNs. The originality of our work lies in providing a generic approach to help practitioners and academicians to treat CWNs as value networks and systems of transactions. We considered both the tangible and intangible resources shared, mobilized or reproduced to build these networks. This study is an important step towards advancing this area as a research stream. It fills a gap between theory and practice for community activists, developing agencies, and researchers as it describes CWNs as systems of exchange. The phenomenal growth of this new form of collective actions is expected to completely revolutionize the telecommunication landscape and provide momentum to the digital paradigm. However, they need the attention of governments, developing and outreach organizations, technology vendors, students and researchers.

Abstract

Although there are a number of purported benefits of agile systems development methods over traditional forms, many in the Information Systems Development (ISD) community highlight the difficulties that the dynamic, turbulent nature of agile development environments may present. One prominent difference compared to traditional ISD projects is the emphasised presence of the customer in decision-making. Specifically, project management and decision-making can be significantly more challenging than in projects involving traditional development approaches. This paper describes a research-in-progress, that focuses on decision-making in agile projects, and aims to develop a better understanding of how agile teams present dynamic data to decision makers who may act “on the fly”, and in so doing lead to effective, high quality decision-making in agile environments. The goal of the paper with its three case studies is to develop a set of best practices for representing decision-making data in agile ISD projects.

Keywords: Agile IS project, Decision-making, Data presentation.
1 INTRODUCTION

This research captures one of the state-of-the-art development methods of today. The last 10 years or so has seen the emergence of a number of information systems development (ISD) methods, which have collectively been labelled as agile. Some of the most popular include eXtreme Programming (XP) (Beck 1999), the Dynamic Systems Development Method (DSDM) (Stapleton 1997), Scrum (Schwaber & Beedle 2002), Crystal (Cockburn 2001), Agile modelling (Ambler 2002), Feature Driven Design (FDD) (Coad et al. 1999), and Lean Software Development (LSD) (Poppendieck 2001), along with variants of each e.g. XP-Lite (Aveling 2004). These methods have been well received by those in ISD and there is strong anecdotal evidence to suggest that awareness and indeed use of these methods is highly prevalent across the community. However, use of these methods has a significant impact on the project’s decision-making processes.

Therefore, this research-in-progress paper aims to investigate and develop appropriate methods of data presentation to support high quality decision-making in agile information system projects with the means of qualitative multiple-case design (Benbasat et al. 1987).

In an agile development environment, the project manager’s role as a decision-maker is greatly reduced, and is more akin to that of a facilitator or coordinator (Nerur et al. 2005; Alleman 2002; Lindstrom & Jeffries 2004). Further, the development team makes most of the decisions, creating a “pluralist decision-making environment” (Nerur et al. 2005) due to the diverse backgrounds, attitudes, goals, and cognitive dispositions of the team members (Highsmith 2004; Chin 2004; Cockburn & Highsmith 2001). In agile projects, the organisation or team structure is “organic and flexible”, as opposed to traditional structures which are “mechanistic, bureaucratic and formalized” (Nerur et al. 2005); the project is completed through a series of iterations, each often as short as a few working days (Fowler & Highsmith 2001; Fitzgerald et al. 2006), resulting in more frequent, short-term decision-making; and software is valued over documentation (Fowler & Highsmith 2001) which was traditionally used as a vital decision aid. Significantly, the customer plays a more continuous and embedded role, and thus is intrinsically involved in most decisions (Griffin 2001; Farell et al. 2002; Beck & Andres 2004; Beck 2000). Moreover, developers are not confined to a specific specialised role and are encouraged to self-organise, interchanging and blending roles (Nerur et al. 2005) and involved in decisions that may fall outside their traditional skill areas.

One could assume that decision-making in an agile environment should be ad hoc, unstructured, and without discipline. Indeed, there is a common misconception that agile methods are centred around improvisation, and care-free deviation from rules and regulations. However, Beck dismisses this stating that agile “is not an excuse for unilateral behaviour” and he views agility versus discipline as a “false dichotomy” (Beck & Boehm 2003). In fact he argues that agility “is only possible through greater discipline on the part of everyone involved”. The need for discipline has been stressed by many key texts across a broad range of the agile methods (e.g. Schwaber 1996; Cockburn 2001; Schwaber and Beedle 2002; Beck and Andres 2004).

Next, we present the research objectives of our study. After that, the theoretical background for decision-making in agile IS projects is presented. Then we describe the research approach and the empirical cases of our study.

2 RESEARCH OBJECTIVES

As is often the case with new and emerging phenomena in ISD, agile method practice has led research, with the creation, promotion and dissemination of these methods almost completely due to the efforts of practitioners and consultants. Agile method research has gained momentum in more recent years,
but has been argued that the current body of agile method knowledge suffers from a number of conceptual problems such as a lack of clarity, parsimony, cumulative tradition, and theoretical ‘glue’.

One key weakness of agile method research is a lack of focus on how best to present data for decision-making in such an environment, particularly when many contribute to and are involved in the decision process. Indeed decision-making in this context is much different to that associated with traditional systems development, with many additional complexities, uncertainties and hurdles to overcome. There is a need to capture and represent metrics on the progress of the project, for example, estimates and bounds for stage delivery, dependencies and required resources for iterative development, timeline information on next stages, personnel information such as planned vacations, and external factors such as customer availability for development across iterations. Typically these are dynamic data, and are best represented either in tabulated formats with columns and column attributes, or in other aggregate representations such as appropriate graphs and charts. Indeed the latter has been shown to be particularly valuable in decision-making instances and scenarios involving key performance indicators. It follows that the format of presented data can be influential in decision-making scenarios. In agile development the customer plays a more continuous and embedded role, and thus is intrinsically involved in most decisions (Griffin 2001; Farell et al. 2002; Beck & Andres 2004; Beck 2000). This in contrast to more traditional approaches where customers do not get involved in day-to-day operational development; rather their involvement is limited to intermittent events such as prototyping sessions and release meetings.

It follows that data presented to decision makers in agile scenarios needs to be accessible to many people with varying roles and foci: considering the frequency of decisions in these environments together with the team-based approaches to decision-making endemic in agile projects and a need for timely decisions, it would seem sensible that data are presented to all actors in a manner that enables team interactions and facilitates the decision making process. One such manifestation of this may involve a single presentation technique to all involved, perhaps displayed on a computer screen or projection, that is easy to understand, displays interactions between variables, and allows data manipulation during the decision-making process. Such a presentation mechanism would not be solely output-based insofar as offering only data display, but would be pliable in terms of enabling decision-maker interaction with the data. In so doing the presentation mechanism could support the decision-making process.

In this study we seek to investigate decision-making efficacy in agile projects by exploring how best to present dynamic data to decision makers in team-based decision scenarios. The primary focus is in understanding the decision-making strategies in agile project management, supporting high quality decision-making through data presentation. The study will examine the decision strategies involved by project managers and teams in ensuring the success of agile projects in a context with both customer and IS teams consisting of diverse professions as the decision-making can not be studied outside its natural setting (see Benbasat et al. 1987). Furthermore, the study will investigate the appropriateness and value of various data presentation techniques to best support quality decision-making. In so doing, as output the study aims to develop a data presentation model for quality decision-making in agile projects involving the composition, structuration and presentation of relevant data.

The framework (Fig. 1) for the study is as follows:
Commensurate with the IS literature in this regard, we assume that decision makers will employ an effort-accuracy tradeoff in the decision-making process, and seek to reach an optimal decision with least effort. We also assume that the format of the data used in the decision-making process can support particular decision-making strategies: it remains to be seen whether such presentation formats can encourage quality decision-making by promoting superior strategies, but in so doing reduce the effort required for their use, and therefore provide a mechanism whereby decision makers are likely to employ such strategies.

Through an examination of the impact of data presentation on decision strategies used in the decision-making process, the study will provide a best-fit model of data presentation formats best suited to quality decision making in agile project management. Our research objective is thus: To investigate and develop appropriate and effective methods of data presentation to support high quality decision-making in agile information systems project management.

To realise the objective we will explore the decision-making strategies in agile project management, and investigate the effects of various data presentation formats on these strategies. Considering that there is substantial evidence in the literature that decision processes and employed strategies can directly impact decision quality, we strive to investigate decision making in agile development projects from a process perspective, with the aim of that identifying optimal decision strategies and the presentation formats underpinning them, so that decision quality can be maximised.

3 THEORETICAL BACKGROUND

Decision making is the performance of a task, that of making a particular decision (Bahl & Hunt 1984). Project managers and agile teams are faced with decision tasks on a daily and more frequent basis, with the occurrence of such tasks increased in agile development projects as a consequence of rapidly changing requirements, expectations, and their underlying data. Typically these tasks involve choice, with the decision makers presented with large amounts of data, and categories of data describable by various attributes that may influence the value of those data for decision-making. Decision makers in dynamic contexts need to assess various courses of action, various potentially good avenues of resource, or investigate the relativity of one potential decision over others, and make a choice. Such activities are multifaceted, and the process of quality decision-making includes aspects such as decision maker behaviours and strategies, the inherent timeliness of decisions particularly impactful in agile development scenarios, as well as data-related aspects such as data representation.
A decision strategy can be considered as a method (sequence) of operations for searching through a problem space (Payne et al. 1988; Todd & Benbasat 1999). Some strategies are better than others, insofar as leading to higher quality decisions. Benbasat and Todd (1996) argue that decision makers have “a series of pre-existing strategies which have been learned and stored in memory”, and to formulate a strategy, they make a selection “from a repertoire of pre-existing strategies which may be applied or adapted to the problem at hand.” They argue that the determination and application of a particular decision strategy is contingent upon the capabilities of decision makers as well as the characteristics of the problem (that is, the decision-making task) and the availability of decision aids as tools to support particular strategies. However, in choice-based decision-making scenarios, with decision makers choosing from alternatives, the use of particular decision strategies is dynamic, and decision makers are highly adaptive in strategy selection (Payne 1976; Kuo et al. 2004; Häubl & Trifts 2000). Decision making is the accomplishment of a decision task, where decision influences are assessed and where a decision choice is made. The application of strategies and decision-making approaches can be task-centred, with decision-making behaviours influenced by the nature of the task as well as other factors.

The choice and use of a particular decision strategy, or combination of strategies, is dependent upon many factors. The cognitive ability of the decision maker in conjunction with behavioural characteristics and decision styles can influence strategy selection and can impact decision making. Further, the nature of the decision-making task can lend itself to the employment of particular strategies: the use of accurate but more effortful strategies can arise in tasks where there is an importance attached to the decision outcome, and where decision-making time may be secondary to decision outcome. Also, data presentation formats may influence strategy selection, with particular display formats commensurate more so with higher quality strategies.

The cognitive ability of decision makers in conjunction with behavioural characteristics and decision styles can influence strategy selection and can impact decision making. Indeed many other person-centric and behavioural factors can be influential in the decision-making process, including self-efficacy, decision and management styles, team skills and others: a more thorough discussion is presented by Moldafsky and Kwon (1994). Decision makers perceive only that information relevant in order to achieve a specific goal within the problem space under consideration (Yadav & Khazanchi 1992). Zmud (1979) argues that whilst information requirements of decision makers are task-dependent as well as influenced by situational and individual characteristics, decision makers too often do not understand their information requirements, and demand too little or too much information. Further, he argues that decision makers are typically unable to make full use of the information provided or available in reaching a decision. Tasks best requiring the implementation of particular decision strategies for their resolution may only be optimally addressed if those strategies are recognisable as appropriate or useful by the decision maker. If decision makers possess the skills, intellect, and confidence to match particular behavioural strategies to particular task scenarios, and have the cognitive abilities required to choose and implement such strategies, then more optimal strategies may be implemented (Kuo et al. 2004; Eierman et al. 1995). Further, the nature of the decision-making task can lend itself to the employment of particular strategies: the use of accurate but more effortful strategies can arise in tasks where there is an importance attached to the decision outcome, and where decision-making time may be secondary to decision outcome. Also, data presentation formats may influence strategy selection, with particular display formats commensurate more so with higher quality strategies.

Studies have shown that modes of presentation of information to decision makers can be extremely influential on task performance (Garrity et al. 2005; Benbasat & Dexter 1986; 1985; Gershon et al. 1998; Jarvenpaa 1989; Hu et al. 1999; Kester et al. 2001; Lamberti & Wallace 1990; Marsden et al. 2002; Montazemi et al. 1996; Noyes & Garland 2003; Tan & Benbasat 1990). Vessey and Galletta (1991) found that individuals’ mental representations of the task space and the processes required to complete the (problem-solving) task were influential in determining the strategies employed in task completion. Literature from behavioural decision theory as well as consumer behaviour support
problem solvers’ use of processes and strategies that match the representation of the task (McClintock & Becker 1967; Barron 1974; Edwards 1961; Eierman et al. 1995; Gray & Wert-Gray 1999; Häubl & Trifts 2000; Payne 1982; 1976; Payne et al. 1988; Slovic et al. 1977). Further, there is evidence that individuals employ different decision-making and problem-solving processes and strategies for different types of task. Vessey and Galletta (1991) argue that matching the problem representation directly to the task positively impacts task performance, and that individuals’ skills have the greatest impact on performance when there is a close match between task representation and the task itself. Indeed they found that the former was largely unimportant in isolation and that the latter was substantially more important: where task representation alone was matched with the individual skills necessary for task resolution, there were no performance effects. Where individual skills supported the task itself, or both the task and its representation, there was significantly positive performance effects. As such, skill affected task solution rather than the acquisition of information alone. However, in this study the overall performance impact of individual skill-based differences were minimal compared to the effect of a fit between the task representation and the task problem. This study (involving the comparison of alternatives across a number of attributes) found that individuals prefer tabulated information to other representative forms.

It is clear that modes of presentation of information to decision makers can be extremely influential on decision making. Vessey and Galletta’s (1991) study involving the comparison of alternatives across a number of attributes found that individuals prefer tabulated information to other representative forms. Indeed Speier and Morris (2003) found that informational display format was influential in affecting decision performance. Further, Jarvenpaa (1989) found that display formats used in a multiattribute choice task were central in influencing decision strategies when the format was matched to the task, and that strategies which minimised the cognitive effort were preferred.

In this study we aim to examine the most appropriate data presentation formats to best support quality decision-making. In examining the usage, employment and selection of particular decision-making strategies, we aim to support decision making in agile projects by mapping presentation format to decision strategies, so as to promote the use of high quality strategies in the decision-making process, and thus positively impact decision quality. The study will examine a number of cases exploring how data are presented; investigate the decision strategies in use; map presentation format to decision process and strategies used; and produce a model for data presentation formats most likely to support and lead to high quality strategies in agile situations, and therefore superior decision-making.

4 RESEARCH METHODOLOGY & CURRENT PROJECT STATUS

To reach understanding of how teams act in agile IS projects; we apply experiential research methodology i.e. an integrated academic-practitioner team approach (Grant et al. 2001). With the methodology we aim to understand the "process behind the actual decisions being taken in the context of the inherent characteristics of entrepreneurs" (p. 66) in the teams of diverse professionals. The study will involve three case studies. Case studies are considered to be a suitable research approach for this study since it is exploratory in nature, with the intention of investigating decision-making in a real-life context (Stake 2000; Yin 2003) and they explore a phenomenon in its natural setting, applies several methods of data collection to gather information from one or a few entities (Benbasat et al. 1987). Empirical data will be collected over a 6 month period from December 2008 to May 2009.

Table 1. The Profiles of the Three Cases.

In this research, we will observe the meetings and collect literary material written by the project members. Further, we will collect emails and other notes that are written related to the project. To analyse the collected material, we will use discourse analysis (Potter, 1999) that supports naturally occurring talk and discussions, keeping in mind its context.

In addition, data collection will involve personal face-to-face interviews, a technique well suited to case study data collection, and particularly for exploratory research such as this because it allows expansive discussions which illuminate factors of importance (Yin 2003; Oppenheim 1992). The information gathered is likely to be more accurate than information collected by other methods since the interviewer can avoid inaccurate or incomplete answers by explaining the questions to the interviewee (Oppenheim 1992). The questions will be largely open-ended, allowing respondents freedom to convey their experiences and views, and expression of the socially complex contexts that underpin ISD (Yin 2003; Oppenheim 1992). The interviews will be conducted in a responsive (Rubin & Rubin 2005; Wengraf 2001), or reflexive (Trauth & O'Connor 1991) manner, allowing the researcher to follow up on insights uncovered mid-interview, and adjust the content and schedule of the interview accordingly. In order to aid analysis of the data after the interviews, all will be recorded with each interviewee’s consent, and subsequently transcribed, proof-read and annotated by the researcher. In any cases of ambiguity, clarification will be sought from the corresponding interviewee, either via telephone or e-mail. In relation to the interviews, supplementary documentation will also be collected, including project management plans, budgets and budget reports, meeting minutes and relevant e-mail communications.
Alternatively, we will carry out an interview done by questionnaires that will include both closed, semi-structured and open questions. With this choice we will ensure that we will reach also those respondents whose voice might otherwise remain unheard (Stapleton 2008).

Data analysis will use Strauss & Corbin’s (1998) open coding and axial coding techniques. Open coding is “the process of breaking down, examining, comparing, conceptualizing, and categorizing data” (Strauss & Corbin 1998). Glaser (1992) argues that codes and categories should emerge from the data, while with Strauss & Corbin’s approach (1998) these are selected prior to analysis. The approach adopted in this study is more akin to the latter, where the interview questions and subsequent analysis will be based on Payne’s (Payne et al. 1988) decision-making model. This will provide a list of “intellectual bins” or “seed categories” (Miles & Huberman 1999) to structure the data collection and the open coding stage of data analysis.

The second phase of analysis will use axial coding. Axial coding is defined by Strauss and Corbin (1998) as a set of procedures whereby data are put back together in new ways after open coding; whereas open coding fractures the data into categories, axial coding puts the data back together by making connections between the categories and sub-categories. As the data is coded, theoretical questions, hypotheses and code summaries will arise. These will be documented in analytic memos (Miles & Huberman 1999) to aid understanding of the concepts being studied and to refine further data collection. Miles and Huberman (1999 p. 72-74) offer advice on effective analytic memos, and these practices will be followed where possible.

As categories emerge, follow-up interviews will be arranged to elicit further, richer, more focused information. This will be done to confirm, extend, and sharpen the evolving list of categories. As categories become integrated, further data collection will not tend to cause any additional categories to emerge, but rather reinforce those already in existence. At this point, the categories will be deemed to be “theoretically saturated” (Strauss & Corbin 1998), and data collection ended.

Once the decision-making process is documented and analysed, the focus will shift to constructing decision-making scenarios involving underlying data presented in various formats to decision-makers. Revisiting the cases using a think aloud protocol, the study will investigate the impact of data presentation format on the decision-making process, in terms of the decision strategies used to reach decision finality. Using decision strategies as indicators of decision-making quality from a process perspective, the study will construct a model illustrating the relationship between data presentation format and decision-making processes in agile project management.

In all, the case study database will fulfil recommendations by Yin (2003) with its components of case study notes, case study documents, tabular material and a case study narrative.

The Cases

The primary operation of Pennysoft, a large, privately owned U.S. company, (employing 40000) involves the provision of financial services and investment resources. The company has been developing software at its site in Ireland since 1995, and currently employs around 300 people at this Irish site. The software products developed are supplied mainly to internal customers in the U.S. Many projects involve co-ordinating with several teams in the U.S. and India. In many cases, the requirements are generated in the U.S. with software development then taking place in both the U.S. and Ireland. In this study we analyse three systems development project cases within Pennysoft (Table 1).

Table 1 describes the three cases highlighting their differences. By including three cases in our study we will get a good conception of how decision-making is carried out in agile IS projects. As the chosen project teams involve several professions, we will get a conception of preferred data presentation as perceived by the team members. In addition, the team compositions reveal that there
are high-ranked people involved, such as a senior vice president (SVP) and vice presidents (VP) and this situation may influence the decision-making (see Stapleton 2008).

While we aim to examine the most appropriate data presentation formats to best support decision-making, we believe that the three cases offer good insight into real-time decision settings and environments.

Abstract

Open Innovation is a model used to describe how nowadays companies source and exploit new technologies, new products and services. Web-Based Intermediaries (WBIs) have entered the emerging innovation market and are expected to dramatically increase the number of innovation exchanges. However there are not yet clear theoretical guidelines supporting the design and management of such intermediaries. We use organizational sense-making theory and relative absorptive capacity (RAC) theory to analyze the factors that still hinder Open Innovation. From sense-making theory and RAC theory we draw directions on the services WBIs need to provide in order to effectively support an innovation market. Since information technology is critical to the success of a WBI, we also give directions on how ICT and KMS can be used in order to support these services.

Keywords: Open Innovation, ICT, Intermediaries, Sense-making, Relative Absorptive Capacity.
1 INTRODUCTION

The concept of Open Innovation (OI) was first proposed by Henry Chesbrough (Chesbrough 2003) and has quickly gained the attention of scholars and practitioners. While in the so-called closed innovation paradigm, research, development, and commercial exploitation of a new technology were performed mainly by large companies within their boundaries, today companies increasingly rely on outside innovation for new products and processes and have become more active in licensing and selling results of their own innovation to third parties (OECD 2008).

OI is strongly driven by globalization. The OECD has recently addressed the issue in a research project on “globalization and OI” (OECD 2008). The findings of this project show that increasingly companies link into global innovation networks with people, institutions, and other companies in different countries to source and/or exploit innovation. According to some authors a global, secondary market for technology is emerging (e.g. Chesbrough 2003, 2006, Lichtenhalter & Ernst 2008a, 2008b, OECD 2008).

Information Systems play a critical role in coordinating innovation markets. Large companies like Procter & Gamble and IBM have made major investments in proprietary platforms supporting the sourcing (Dodgson et al. 2006) or exploitation (Davis & Harrison 2001) of innovation.

In particular, Web-Based Intermediaries (WBIs) for OI provide virtual milieus to bring together buyers and sellers and to support their transactions. Yet2.com, for example, is a technology marketplace where it is possible to exchange patented inventions. Other WBIs, like Ninesigma, Innocentive or Yourencore provide access to broad networks of scientists, researchers and professionals which are potentially able to solve new technological problems proposed by companies (Tapscott & Williams 2007; Chesbrough 2006). These intermediaries are expected to dramatically increase the number of innovation exchanges (Fredberg et al. 2008; Lichtenhalter & Ernst 2008a, 2008b, OECD 2008). In fact, they enable firms to source (as well as exploit) innovation globally with limited investments in proprietary structures. However reducing transaction costs and information asymmetries through a broad availability of information is not sufficient to improve liquidity in the innovation market. Other factors hinder the development of an efficient market. Some of these factors are related to regulatory issues or cultural factors as the NIH syndrome (Laursen & Salter 2006, Lichtenhalter & Ernst 2008b). In this paper we focus on knowledge related factors. That is, we explore what factors hinder the ability of firms to recognize a valuable innovation among the many offered on the market, to find an external application suitable for a technology firms developed or to transfer the innovation from the provider to the recipient.

We argue that the difference between the context in which an innovation is developed and the context in which it is applied is a major cause of the difficulties that hinder OI. We use organizational sense-making theory (Weick, 1995, Weick & Sutcliffe 2001, Taylor & Van Every 2000, Weick et al. 2005) and relative absorptive capacity (RAC) theory (Lane & Lubatkin, 1998; Lichtenhalter, 2008b) to describe and explain the problems that arise when firms which share no substantial previous relation take part in the innovation market. From sense-making theory and RAC theory we draw directions on the services WBIs need to provide in order to effectively support an innovation market. Since information technology is critical to the success of a WBI, we also give directions on how ICT and KMS can be used in order to support these services.

This paper provides a theoretical framework for analyzing the role of WBIs and ICT in a OI context. It is the first paper using sense-making theory and RAC theory together to study OI.

The reminder of this paper is organized as follows: in section two we briefly discuss functions that intermediaries, and WBIs in particular, perform in facilitating OI processes according to the existing literature; in section three we present our theoretical framework; in section four we apply our framework to give directions on the implementation of ICT and KMS by WBIs to support OI processes. Directions for further research and conclusions follow.
2 THE FUNCTIONS PERFORMED BY WEB-BASED INTERMEDIARIES IN THE INNOVATION MARKET

OI comprises all the processes involving the external sourcing or the external exploitation of innovation. Existing research points out that firms are interested in the potentialities of OI and are practicing or are experimenting OI-oriented activities (OECD, 2004; Sheehan et al., 2004; Lichtenthaler & Ernst, 2008b). However, apart from some well-known success cases, the application of the OI principles is still limited (OECD, 2004; Lichtenthaler & Ernst 2008b).

In the literature it is often remarked that when the participating firms share a common background the innovation exchange is easier (e.g. Hertzfeld et al. 2006, OECD, 2008, Stock & Tatikonda 2008). On the other hand, studies on Absorptive Capacity (Lane & Lubatkin, 1998, Lichtenthaler 2008b) underline that dissimilarities between firms hinder innovation exchange. OI involves by definition the exchange of innovations across different contexts and backgrounds. OI strategies are often driven by the intention to get access to valuable sources of knowledge in other countries bringing together companies and institutions with different cultures (OECD, 2008). The increasing integration of different technologies in many industries increases the need for interdisciplinary research; spin-offs and licensing often lead to the commercialization of innovation in different markets (Fredberg et al. 2008, OECD 2008); innovation is exploited in companies with different business models (Chesbrough 2003, 2006). These differences, then, are expected to be a major challenge to the development of OI.

The emergence of intermediary markets for ideas and technologies may facilitate the exchange of innovation. The number of firms interested in buying or selling innovation on an open market seems to be increasing (Arora et al. 2001; Muthusamy & White, 2005; Chesbrough, 2007; Lichtenthaler, 2008a; Lichtenthaler & Ernst, 2008b). Intermediaries entered the market which are able to bring together solution seekers and problem solvers or buyers and sellers of intellectual property (Lichtenthaler & Ernst, 2008a; Lichtenthaler & Ernst, 2008b; Fredberg et al. 2008; OECD, 2008).

Firms may draw on the resources and capabilities of intermediaries to improve their proficiency in exchanging innovation (Makadok 2001; Foss & Ishikawa 2007; Lichtenthaler & Ernst, 2008a). Intermediaries can provide resources and capabilities for identifying exchange opportunities (e.g. through their network of resources) and for supporting the innovation transfer (e.g. through their R&D and market experts).

So far, innovation intermediaries have mainly concentrated in marketing and searching for technologies (Morgan & Crowford 1996), but they perform several other functions: identifying partners, helping package technology, selecting suppliers, providing support in deal making, adapt specialized solutions to the needs of user firms (Howells 2006, Lichtenthaler & Ernst 2008a). The functions performed by intermediaries can be seen as related to either of two phases in the innovation process:

1. The search for innovation phase comprises functions performed by intermediaries such as indentifying partners, selecting suppliers, evaluating alternative options;

2. The innovation transfer phase comprises functions such as supporting deal making, packaging the technology, adapting the innovation to the needs of the user firm, transferring related knowledge.

Several web-based intermediaries operate in the innovation market. Yet2.com, for example, is a marketplaces for IP which also offers intermediary services for the adaptation of technologies to the specific needs of the customer (Lichtenthaler & Ernst, 2008a). Ninesigma, provides access to a broad network of scientists, researchers and professionals which are potentially able to solve new technological problems proposed by companies (Tapscott & Williams, 2007; Chesbrough, 2007). Innocentive works like Ninesigma, but technological problems are more narrowly defined, are posted on the company web-site and can be solved by anyone who registers. Yourencore provides access to a network of retired scientists and engineers.
WBIs were expected to dramatically increase the number of transactions in the innovation market by expanding it to a global scale. They are able to provide wide and ubiquitous access to actors, technologies and information. However, few studies on the performance of these internet platforms have been conducted. The few existing studies suggest that some limits in the way WBIs operate make their services unsatisfying for their users. For example, in their study, Lichtenthaler & Ernst (2008b) on IP commercialization by industrial firms through WBIs, found that even if firms show a keen interest in the potential benefits of web-based technology marketplaces, still their attempts to use them were not satisfactory. The conclusions of the two authors suggest that even if WBIs are able to bring together a large number of potential buyers and sellers of innovation, they offer inadequate support in the selection and integration of innovation.

As a consequence, the research question addressed by this paper is: what kind of services and tools should WBIs provide in order to improve the effectiveness of innovation search and transfer?

This paper focuses on how ICT and KM tools could be used to improve the performance of web-based intermediaries in supporting the global innovation markets. Even if we acknowledge that changes in other areas of WBIs’ business models are needed, for example in the value proposition or in the approach to the value network, we focus on technological aspects since we deem that ICT and KM tools can significantly increase the effectiveness of web-based intermediaries if they are used consistently with the needs and structure of global OI processes.

3 A THEORETICAL FRAMEWORK BASED ON SENSE-MAKING AND RELATIVE ABSORPTIVE CAPACITY THEORIES

In this paper we draw on sense-making theory (Weick 1995, 2001, Taylor & Van Every 2000, Weick et al. 2005) and relative absorptive capacity (RAC) theory (Lane & Lubatkin, 1998, Lichtenthaler 2008b) to build a theoretical framework aimed at supporting WBIs in designing and implementing ICT and KMS based solutions. Our hypothesis is that services and tools would be needed to externally complement sense-making and relative absorptive capacity of firms participating in OI processes.

Probably the most common theoretical perspective on innovation exchange is absorptive capacity (AC) theory. Cohen and Levinthal (1990) argue that AC, i.e. a firm’s ability to acquire new knowledge, depends on its level of prior related knowledge and in the field. This definition implies that firms already possess substantial knowledge about an innovation. Through AC firms can advance their knowledge, but the theory does not explain how firms can create or exploit knowledge related to a completely new technology or market. OI posits a new challenge to firms: how to gain competitive advantage from knowledge developed in contexts different than the one where it is going to be used.

We argue that AC’s shortcomings are due to the fact that it focuses on the exchange of innovation within (more or less) homogeneous contexts. In an OI context it is necessary to understand how two potential, previously unrelated partners can be supported in:

1. Recognizing the opportunity for profitably exchanging innovation;
2. Transferring the innovation and adapting it to its new context of use.

While sense-making theory provides insight on the first problem, RAC theory can be used to address the second one.

When the innovation provider is unfamiliar with the context and/or the recipient is unfamiliar with the innovation, a sense-making effort is needed. Sense-making is a process through which circumstances are turned into a “plausible narrative” which substitutes for a rational decision process in order to take action. In the presence of new and complex problems, in fact, a rational decision process is often not feasible (Uren et al. 2006). As a first step in OI exchanges, the potential provider and recipient of technology need to make sense of the use that can be done of the technology in the new context. Sense-making will lead to a decision whether to undertake the exchange or not. Through the services
they provide WBIs are able to support sense-making. The better WBIs support their customers in making sense of a technology (from the seeker’s perspective) or of its potential context of use (from the provider’s perspective) the more it is likely that an exchange will effectively take place.

Lane and Lubatkin (1998) coined the term relative absorptive capacity to point out how the ability to acquire new knowledge also depends on the similarity between the source and the recipient of the exchanged knowledge. They suggest that two firms are more likely to effectively exchange new knowledge if they have similar: 1) knowledge bases; 2) knowledge processing systems and norms; 3) organizational structures; 4) dominant logics.

In order to successfully transfer an innovation, it is necessary to create RAC between the firms participating in the exchange. In our view RAC is not only a structural characteristic of the dyad of companies which determines if an exchange can be successful or not, but a “temporary capability” the two firms can build as a part of the exchange process. WBIs can provide tools and services which support RAC creation within the participating firms. But they can also provide tools and services which substitute for the capabilities firms are missing.

The simplest situation is that of a firm dealing with a familiar technology to improve well known business processes. In this case the best line of action is probably to develop and exploit the technology internally (see figure 1, quadrant 1). When considering external innovation sourcing or exploitation a firm can face one of the three situations represented in figure 1, quadrants 2, 3 and 4. The need to support sense-making and RAC formation depends on the asymmetries between the dyads of firms potentially interested in exchanging innovation. These asymmetries depend on two factors: familiarity and similarity.

“Familiarity” is, for a potential recipient, knowledge of the technology of interest which stems from direct experience. For a potential provider, familiarity represents direct knowledge of the recipient context of use. Familiarity provides a common ground for the mutual understanding of the potential buyer and supplier of technology. As the level of familiarity of the recipient with the technology the innovation is based on decreases, there is a greater need for a sense-making effort on the recipient side (quadrant 2). Familiarity with the innovation increases with the past experience a company has in using (and not necessarily developing) the technology. Similarly a greater sense-making effort is needed on the supplier side when she is not familiar with the potential recipient context of use. The level of familiarity increases if the two companies had previous contacts or one has previous experiences working with the business sector of the other, if personal relationships exist or if they are geographically close.

*Figure 1. Sense-making, RAC and OI.*
As maintained by Lane and Lubatkin (1998) two firms are similar if they have similar: 1) knowledge bases; 2) knowledge processing systems and norms; 3) organizational structures; 4) dominant logics. RAC theory implies that the level of similarity between the participating firms affects the need for support by a WBI when innovation has to be transferred. In particular the lower the similarity the stronger the need for RAC formation support (quadrant 3). If the two firms are familiar with each other, but they are not similar, problems are likely to arise when innovation has to be transferred (Lane & Lubatkin, 1998). Operative procedures and organizational structures need to be coordinated and differences in dominant logics can cause different priorities. The most complex situation, but also the most likely when OI takes place, is the one represented by quadrant 4. In this case, both a sense-making effort and a RAC formation effort are needed. The difficulties in the search and transfer phases sum up making the support of a wide range of intermediary tools and services critical.

In particular our focus is on the adoption and implementation of ICT and KMS to support the services provided by WBIs. In the following section the above described theoretical framework will be further developed and its implications for the choice of ICT an KM tools will be discussed.

4 IMPLICATIONS FOR ICT AND KMS IMPLEMENTATION BY WEB BASED INTERMEDIARIES FOR OI

4.1 ICT and KMS for enhancing sense-making

“Sense-making involves turning circumstances into a situation that is comprehended explicitly in words and that serves as a springboard into action” (Weick et al. 2005). In the absence of a single canonical view of the world, people must construct ‘plausible narratives’ to fill in the gaps (Uren et al. 2006). Sense making is about explaining phenomena through narratives, given that logical, causal explanations often fail in complex and dynamic contexts. In Weick’s words “we expect to find explicit efforts at sense-making whenever the current state of the world is perceived to be different from the expected state of the world”. Innovation management, then, is a field in which sense-making should have a prominent role, since by definition innovation changes the “states of the world”. Traditional decision support models are based on causal assumptions. For example, effort has been spent in developing quantitative methods for the economic valuation of innovations. The idea is that causal relations can be singled out which link the characteristics of an innovation with the economic value it is able to produce. Accordingly decision-makers will rationally chose the alternative which maximizes the expected returns. In a sense-making perspective the focus is different. It is important to figure out how the technology can be useful and what impact it is likely to have on the business. Sense-making is about the interplay of action and interpretation rather than the influence of evaluation on choice (Weick et al. 2005). According to Bettis and Prahalad (1995) the key problem for an organization is not to accurately assess scarce data, but to interpret an abundance of data into “actionable knowledge”.

We argue, then, that much of the effort spent by actors participating in OI processes, above all in early phases of the search for innovations or innovation applications, is a sense-making effort. In traditional innovation exchanges (e.g. R&D alliances, technology transfer projects, spin-offs), the sense-making effort can go unnoticed by an external observer, since sense-making processes are often carried out through informal interactions and only their formalized outcomes are visible (e.g. contracts, projects, agreements). In an OI context and in the presence of WBIs, however, these informal interactions are often limited. The sense-making problem must be explicitly addressed. The lack of tools supporting sense-making is, in our opinion, an explanation of the limited impact WBIs had so far on the growth of the innovation market. These tools must be implemented and managed by WBIs even if, to be effective, the involvement of potential buyers and sellers of innovation. Such an involvement can be thought as a pre-requisite that WBIs need to achieve in the earliest phases of their interaction with seekers and providers.
The model of sense-making process we use in this paper is the one proposed by Weick, Sutcliffe and Obstfeld (2005). According to the authors sense-making starts with chaos. People are immersed in a flux of events and activities. They may or they may not extract cues from this flow. If they do, the first phase of the sense-making process, namely *noticing and bracketing*, takes place. With reference to innovation, decision makers experience both a flux of information from inside their company and from external sources. When decision makers notice a potential match the sense-making process starts. The second phase is *labeling*, that is people use their experience and mental models to give a name to what they noticed and, so, to stabilize the “streaming of experience”. One recurrent observation is that ICT is used in OI processes in order to make innovations and innovation needs more visible to the participant actors. For example Tao and Magnotta (2006) describe a web-based system called “Needs Tracker” used within a large chemical company. Through this system employees can post the technological needs they noticed. The Needs Tracker helps to make the needs more visible and to rank them. It is also possible to propose solutions to a need. Similar functions are provided by Procter&Gamble’s website InnovationNet, described by Dodgson, Gann and Salter (2006). The company uses the web-site in the context of its Connect&Develop initiative (Huston & Sakkab, 2006) to foster collaboration among its employees and with external sources of knowledge. Artificial intelligence is used for data mining. The system acts in a similar way to Amazon.com, taking into account users’ interests and sending back information the user may be interested in. Data mining is also extensively used by a staff of 70 specialists systematically harvesting web pages, scientific literature and databases and global patent databases. “The change of the (technological) interface demands a change in the organizational ability to absorb, or assess the impressions from the outside” (Fredberg et al. 2008). In other words the use of ICT in these cases has changed the sense-making process by supporting the *noticing and bracketing* and the *labeling* phases. In general web-harvesting, i.e. using different, more or less intelligent, tools to search the Internet for relevant information and knowledge (Carlsson, 2003) can be understood as a means to support the *noticing and bracketing* and the *labeling* phases in the sense-making process. Internet-based toolkits for idea competitions (Piller & Walcher, 2006) are also a powerful means to make a technology need visible to potential solvers. They are used by WBIs such as Innocentive. From a sense-making point of view WBIs provide several traditional tools (e.g. newsletters or alerts) to address noticing, bracketing and labeling. However, the effectiveness of these phases can be improved by introducing innovative tools, e.g. Web 2.0 tools such as collaborative tagging (Golder & Huberman, 2006).

The third phase is *thinking retrospectively*. During this phase several cues noticed and labeled before are put together. A plausible narrative is created. Tools such as computer supported argument visualization have proven effective in supporting sense-making about ongoing scientific or professional debates (Shum, 2003). Similarly they can be used to trace debates about innovations or innovation applications. Knowledge mapping or knowledge cartography visually display the conceptual structure of ideas (Okada et al. 2008). By introducing these tools WBIs can support customers in understanding how an innovation could be adapted to a new context from several points of view: it is possible to link a technology to several actual or potential applications, to know about needed complementary competences and resources, to understand who possesses the necessary knowledge and to take into account intellectual property issues. This possibility can be very valuable since one of the problems pointed out by Chesbrough (2006) is the difficulty, for firms, of making sense of the interdependencies among different aspects of OI initiatives (technology, business model, intellectual property rights).

During the following phase, *supposing*, a tentative narrative is created to link the pieces together. Also in OI processes there is a need to build a tentative narrative to make sense of the potential applications of the innovation. Only through confrontation with other people, however, the narrative is rejected or becomes an accepted argumentation. *Socializing*, the fifth phase, explains why sense-making is a collective process: the explanation developed by an isolated individual is influenced by the interpretations of other people she is going to interact with if she is going to put her intentions into action. The subsequent actions will become experiences influencing a person mental models and, as a consequence, her future sense-making. As Web 2.0 tools become more common also in a business
environment (McAfee, 2006; Bardhan et al. 2008) the possibility to support the socializing phase of the sense-making process increases. In Web 2.0 tools the supposing and socializing phases are tightly intertwined, since it is possible to propose opinions, interpretations, points of view which are collaboratively discussed. Some WBIs are already introducing features based on the Web 2.0 approach. For example, Innocentive recently introduced a blog with all the (by now common) Web 2.0 functionalities like tags and feeds. In its “Innovation Community” section, YourEncore provides a full range of Web 2.0 tools like Wikis, forums and other tools to help clients collaborate with experts. These tools can be used independently from the other services, and are aimed at creating an ongoing discourse among the participants. A different way to support the supposing phase is through simulation and modelling or virtual prototyping tools (Dodgson et al. 2006). However, in this case a firm has already a good understanding of the innovation and of its applications. As a consequence, in our framework, simulation and modelling tools are better understood as tools for enhancing RAC. Malhotra (2001) suggests that Artificial Intelligence and Expert Systems could be used for supporting the supposing phase if designed to “encourage ongoing and continual re-assessment and modification of practices to ensure dynamic adaptability to the rapidly changing business environment”.

In the last phases of the sense-making process, action takes place and, in an organized context, it is likely to require communication with other people. The last phase, then, is called organizing through communication. In an OI context both socializing and organizing through communication require interaction with external actors. Both Web 2.0 tools and more traditional e-collaboration tools can be used to support the last phase of the sense-making process, that is organizing through communication. In particular e-collaboration tools such as whiteboards, document management systems, collaborative project management systems, file sharing can be used when translating the collaboratively created interpretation of the situation into action (Migliarese & Corvello, 2006; Fink, 2007; Kumar & Becerra-Fernandez, 2007).

4.2 ICT and KMS for enhancing Relative Absorptive Capacity

In Cohen and Levinthal’s approach, AC depends only on the previous related knowledge a firm possesses. As a consequence “a firm has an equal capacity to learn from all other organizations”. Lane and Lubatkin (1998), instead, argue that AC depends also on the similarity between the two firms exchanging knowledge. So it is better understood as relative absorptive capacity. While in Lane and Lubatkin’s paper RAC is described as a given attribute of the dyad, other research suggests that RAC can also be created for a specific exchange (Lichtenthaler 2008b).

If the knowledge exchange takes place without the intervention of an intermediary, only the characteristics of the participants (i.e. organizational form, processes and dominant logics) influence RAC. In the presence of an intermediary, however, the services and structures it provides can influence the capacity of the participating firms to exchange innovation. This is consistent with the idea that firms can draw on the resources and capabilities of intermediaries to improve their proficiency in exchanging innovation (Makadok 2001; Foss & Ishikawa 2007; Lichtenthaler & Ernst, 2008a). There are five modes an intermediary can contribute to the development of RAC:

1. Create a common knowledge base: intermediaries can provide firms with knowledge related to interdisciplinary (i.e. issues common to several technological domains) or complementary aspects (e.g. issues related to problems such as intellectual property rights, regulatory issues, electronic infrastructures) useful in more than one exchange;

2. Create field specific knowledge bases: intermediaries can collect, organize and package knowledge related to each specific domain to be provided to the partners once the exchange has been decided in order to speed up the development of a common domain specific knowledge base. This issue probably requires the intermediaries to be specialized in a limited number of domains;

3. Accelerate knowledge transfer: this is the most intuitive function an intermediary can provide for enhancing AC. The sooner knowledge is transferred, the easier is to proceed in the exchange;
4. Develop standard methods: by using standard methods provided by the intermediary (including standard documents, procedures and technologies) the participants can partially overcome the problem of different organizational processes;

5. Act as a temporary structure for innovation transfer: members of the participating firms and of the intermediary can work together as a temporary structure able to limit the problem of different organizational structures.

There is a fairly broad literature on tools supporting the creation of knowledge bases and on knowledge transfer. In fact these two aspects can be considered the central functions of a KMS (e.g. Robey et al. 2000).

With reference to the creation of RAC the first opportunity for intermediaries is to create a common knowledge base even before an innovation exchange is envisioned. Some pieces of knowledge can be useful for several different innovation exchanges. For example complementary knowledge such as knowledge about intellectual property rights or regulatory issues (Somaya et al. 2007). Also complementary technical knowledge can be used in several projects. For example knowledge related to soldering techniques is needed for different applications. Building searchable databases or preparing documents and tutorials related to these topics (in other words “packaging” the related knowledge) can support companies which at the moment of the exchange will be prepared to manage complementary aspects. Collaborative tools as document sharing, forums, blogs and wikis can also be used in order to create a common knowledge base, in particular with respect to more unstructured issues.

Since intermediaries are exposed to diverse knowledge in different exchanges, they gain relevant experience related to several specialist fields. The availability of expert individuals at an intermediary is much appreciated by customers. For example Yet2.com has recently shifted its services from marketing technologies to assisting its customers from a technological point of view (Lichtenthaler & Ernst 2008b). Such services can be made more efficient through the use of KMS. They can be used, in fact, to organize knowledge by specialist domain and make it available to customers. Automation of data retrieval and use (Robey et al. 2000) is complementary to the creation of knowledge bases. Besides capturing knowledge and making it easily accessible, also providing opportunities and tools for communication and discourse is important to speed up knowledge transfer (e.g. Robey et al. 2000). Collaboration tools such as Lotus Notes are still widely used to support collaborative work. Web 2.0 technologies provide further possibilities to cooperate and exchange knowledge (McAfee, 2006).

Creating standard methods is also a much appreciated feature of WBI. Innocentive, Yet2.com, Yourencore and the other WBI pay great attention in communicating to their customers how the methods they developed are able to make the exchange easier. They continuously modify their methods in order to adapt them to emerging customer needs. The methods developed by WBI are meant to coordinate the processes of innovation seekers and providers. For example Innocentive provides consultancy services and formats to firms seeking a new technology in order to formalize a technology need (which in Innocetive’s language is called “a challenge”). At the same time it provides solvers with interaction procedures consistent with the expectations of the seekers. The interaction takes place in a structured virtual room dedicated to the specific challenge. Structuring the innovation process through ICT and KMS, however, can also have drawbacks, since it is possible that established methods will not be revised and will become not adaptable to changing conditions (Robey et al. 2000).

Finally WBI can enhance RAC by providing virtual organizational structures for managing the innovation exchange. Organizational structures are virtual when they are temporary, geographically dispersed and based on electronic communication (Jarvenpaa & Leidner, 1999). Virtual organizational structures are especially common in R&D, due to the internationalization of research and to the frequent formation of R&D partnerships (e.g. Hagedoorn 2002). WBI, through their web-sites and their permanent structures are able to create temporary groups in which members of the provider and of the recipient organizations are involved. Such groups, guided by the norms and methods set by the intermediary, carry out the innovation exchange overcoming the difficulties created by differences in organizational structures.
5 CONCLUSIONS AND FUTURE RESEARCH

The enthusiasm about web-based intermediaries for OI is due to the promising features they show. In particular the possibility to bring together a large number of potential buyers and sellers of innovation, to act on a global scale and to provide structured and searchable information about innovation and innovation needs. The use of ICT and KMS by WBIs, however, seems to be limited to more or less advanced search techniques.

In the previous section we showed how a sense-making and an absorption effort are needed in OI exchanges. We argue that WBIs should provide tools and services able to support sense-making and the creation of RAC. Recent developments in the services, provided tools and business models of some web-based intermediaries for OI seem to support this hypothesis.

Since sense-making is an unstructured process, which produces unstructured outcomes (it produces sense, exactly), also the tools needed have been described by grouping them according to the phase of the process they support. The same tool, however, can be used in more than a phase. It is the way the user approaches the tool that makes the difference between phases (and, actually, also between sense-making and RAC creation). RAC creation, instead, produces structured outcomes that can be used also in future exchanges. So we grouped the tools for RAC creation according to the specific outcome they contribute to produce.

We expect that WBIs effectively supporting sense-making will experience a larger number of exchanges. On the other hand the percentage of successful exchanges will increase if RAC formation is effectively supported. The importance of sense-making and RAC creation support is likely to vary according to the context. In particular if the involved companies are familiar with each other and/or they show high levels of RAC the role of an intermediary will be less critical from a knowledge related point of view.

In this paper the two theories have been discussed separately. We presented OI processes as comprised of two sequential phases: recognizing the opportunity for profitably exchanging innovation and transferring the innovation and adapting it to its new context of use. While sense-making theory supports the analysis of the first phase, RAC theory supports the analysis of the second one. We have discussed OI processes considering an isolated exchange between firms which are characterized by low familiarity and low similarity. In this case the participating actors need to go through the whole sense making process and to spend a strong effort in building RAC. In practice, however, the two phases overlap. The same tools can be used to support both sense-making and RAC formation and there is not a temporal separation between sense-making and RAC creation. The difference is mainly in the use of the (often common) outcomes produced by the two processes. A database can be created and used both to support sense-making and RAC creation, but it is used differently (and probably using different functionalities) in the two cases. It is used in a structured and systematic way when supporting RAC, it is used in a less structured way when supporting sense-making.

The sense-making process influences the RAC creation process, by posing emphasis on same aspects of the innovation problem rather than on others.

If we consider repeated exchanges it is likely that much sense and RAC will be inherited from previous exchanges. In this case the sense-making process in a new exchange will build on the same knowledge made available during RAC creation in previous exchange which, in turn, had been influenced by the sense-making process.

In repeated interactions, sense-making and RAC creation intertwine and it is not possible to distinguish activities aimed at sense-making from activities oriented at RAC creation. This does not mean, however, that mechanisms to support both processes do not need to be devised and properly designed.
To our knowledge no other study has applied sense-making theory to OI. Decisions regarding OI, however, rely on highly ambiguous and uncertain data. As a consequence managers are more likely to use plausible narratives than rational methods when deciding to externally source/exploit innovation. In our opinion, then, sense-making support by WBIs is often more valuable than other forms of decision support. Few studies also exist on RAC in OI processes (Lichtenthaler 2008b). In this paper we considered RAC as a temporary capability which can be developed as a part of an exchange process relying also on the complementary capabilities of an intermediary. Supporting the rapid development of RAC is both a need for companies involved in global innovation exchanges and an opportunity for WBIs. The use of ICT to globally source or exploit innovation is still limited. In this paper we argue that a proper use of the available tools by web-based intermediaries can provide the innovation market with the needed liquidity, eventually enhancing OI on a global scale.

We suggest two main line of future research: 1) behavioral science research, and 2) design science research (Hevner & Chatterjee 2009). Future behavioral science research will, based on our two underpinning theories, describe and explain how ICT and KMS can enable and support sense-making and RAC formation. The intrinsically unstructured nature of the sense-making process makes the measurement of related constructs especially challenging. In the Absorptive Capacity field, instead, extensive research has been conducted which may provide insights into empirically examining the formation of RAC. Research aimed to the study of the performance of WBIs is needed, for example exploratory research involving interviews to WBIs’ personnel. This kind of research could also support the refinement of our framework. Future design science research will, based on our two underpinning theories, develop practical design knowledge for the design and implementation of WBIs. The design knowledge can be in the form of algorithmic or heuristic design propositions, design exemplars, design models or frameworks, and stories or narratives.

DIGITAL LIBRARIES AS INFORMATION ORGANIZATIONS
THE RE-UNFOLDING OF THE MEMORY/INFORMATION PARADOX

Marton, Attila, London School of Economics and Political Science, Houghton Street, WC2A 2AE London, UK, a.marton@lse.ac.uk

Abstract

Throughout history, libraries have played a key role in remembering the past continuously adapting to changes in societal communication and its technologies. Digital libraries prove to be the next step of unfolding the memory/information paradox which is the foundation of what makes a library a library. Libraries are again changing in order to remain libraries. The focus has begun to shift from being an archive of knowledge containers – the memory side of the paradox - to being an organizer of information taking the form of information organizations. In this sense, a library does not use an information system but rather is an information system. Contemporary developments in ICT seem to harbour the capability to transform the memory/information paradox into a solvable technical problem making libraries themselves an institution of the past. At a closer look, however, the paradox re-emerges provoking the dynamics behind the discussions of what a library actually is and does in the 21st century. The conceptual elaboration of contemporary libraries as information organizations serves as a sensitizing tool for the social science study of digital libraries but also as a key to introducing digital libraries into the Information Systems community.

Keywords: digital libraries, information organizations, information systems, information growth
1 INTRODUCTION

Those who cannot remember the past are condemned to repeat it. Libraries have a long standing tradition of organizing the past by using contemporary technological innovations of their time for, what we call today, data editing and ordering. As information organizations, the changes, libraries have gone through over the centuries, have been tightly coupled to the developments in communication technologies - be it the shift from manuscripts to print books or the diffusion of binary-based communication media into basically every aspect of social life (Bennett 2001). However, harbingers of the rise of the Internet, such as Weinberger (2007), proclaim the end of pre-ante categorizations of knowledge organized by professional librarians; instead, we all will join into running the limitless library of libraries – the Internet. More cautious voices denounce the Internet being The Alexandrian Digital Library as a mere myth arguing “[t]echnological progress has changed how libraries do their work, not why. […] technology will not substantially alter the business of librarians – connecting people with information” (Kuny and Cleveland 1996:1).

In the following paper, we will rephrase the “why libraries do what they do” as a paradoxical form of memory and information. This distinction will serve as a conceptual frame for observing historical as well as contemporary developments within the domain of librarianship which, in addition, will also serve to identify a library in difference to other forms of organizations. According to Luhmann (2006), a social system is observable, hence identifiable, because of its difference to its environment. It is a paradox. A library, for instance, is what it is, because it is what it is not at the same time. Paradoxa, however, are not solvable problems; they can merely be ignored, hidden, made fun of, or be a reason for creativity (Bateson 2000); in more general terms, a paradox can only be unfolded creating a dynamic that might lead into a self-organizational, autopoietic form (Maturana and Varela 1992, Luhmann 1996). Consequently, we shall see the techné of librarianship as ways of unfolding the memory/information paradox that finally led to the emergence of an autonomous organization – the modern library. Digital libraries may be seen as a phase of renegotiating the difference a library needs to maintain, in order to remain a library in a changing environment – the memory/information paradox is being re-unfolded.

The aim of the paper is to refocus the conceptual framework of a research-in-progress on digital libraries by formulating a problem rather than reporting on preliminary results. In order to make a first step from getting-a-sense-of to making-sense-of the data, it is necessary to conceptualize what makes a library observable as a library (and not as an archive, book store, bank, and so forth). Following Weick’s (2007:14) argument that “perception without conception is blind”, the aim of the paper is to enrich the observation of the phenomenon. Theorizing is to be seen as a sensitizing device by making assumptions and expectations explicit. Only with a conceptual map at hand, can an observer appreciate the richness of the observed, be open for surprises that were not captured by the map in the first place.

The second aim of the paper is to open up libraries and librarianship as a fruitful topic for IS research. The key viewpoint is the observation of libraries as information organizations based on following points: 1) libraries have always used information systems in their daily routines – be it shelf-, paper-, or data-based. Constructing and maintaining an information system is the core competency of any library. In other words, it is impossible to separate the organization library from the information system it uses. The library is the catalogue. 2) Opposed to other forms of organizations, like for instance profit oriented firms, libraries have a self-referential approach to what information is and how it should be organized which might contribute to similar discussions on information within the IS discipline (Boland 1987, Bryant 2008).

The paper begins with a brief outline of librarian history as a process of internal differentiation of, sometimes referred to as memory institutions (libraries, archives, museums) in relation to more general developments in communication technologies. Section three introduces the reader to points raised in the Library and Information Science community in relation to digital libraries. In section 4
the memory/information paradox will be elaborated in relation to developments in IT. Section 5 concludes the paper by arguing for the viability of the concept “information organization” in relation to future research efforts on digital libraries.

I would like to thank Jannis Kallinikos, Giovan Francesco Lanzara, Nathalie Mitev, Katerina Voutsina, Eleni Lamprou, and the anonymous reviewers for their constructive criticism and motivating support.

2 A BRIEF HISTORY OF LIBRARIES

A history of libraries can be constructed in relation to developments in communication technologies. In fact, it can be seen as a co-evolutionary relationship in terms of innovation and diffusion, meaning that the diffusion of new communication media (e.g. books) is coupled to librarianship developments (e.g. public libraries). Hence, the following outline should not be read as a unilateral cause-effect relationship but rather as a feedback loop between the library and its communicative environment mediated by certain technologies (Orr 1977).

2.1 Libraries in Ancient and Medieval Times

Following Niklas Luhmann’s communication model (Luhmann 1996), a communication technology separates the direct and mutual observation of communicative participants. Opposed to talking face to face, the utterance is de-contextualized and needs to be re-contextualized by the receiver in order to be (mis)understood. Hence, the written word gains a context-independent existence. That does not yet apply to the very first forms of pictographic writing like the hieroglyphs of ancient Egypt developed around 3000 B.C., since those do not mediate communication but rather representations of things. Pictograms allow for a wide range of phonetic, semantic, and grammatical interpretations that requires adequate knowledge in order to be read and, therefore, are hardly able to mediate something the reader did not already know. Consequently, the very early pieces of writing were memory devices rather than communication technologies (Esposito 2002:45-47). Consequently, libraries were storing what was deemed worth to be remembered. Still, “[…] there was no separation between book collections and archives; books and documents had the same outward appearance and required similar methods of storage” (Dahl 1958:11). At that time, libraries were simply storage compartments without any organizational autonomy. They were as undifferentiated as the papyrus rolls and cuneiform tablets they stored.

A crucial innovation in terms of communication technologies is the phonetic alphabet. The simplification of writing into a digital system\(^1\) of consonants in 2nd millennium B.C. Palestine and Syria, complemented with vowels roughly a millennium later in ancient Greece, allowed the text to become completely context free and autonomous (Borgmann 1999:45-47). While reading ideograms still relies heavily on the contextual knowledge and memory of the reader, the reading of a text based on a phonetic alphabet relieves the reader to have any contextual knowledge except how to pronounce the letters. In fact, a person can read such a text without understanding a single word. Although, alphabetic writing was firstly used as a support for mnemonic techniques (Luhmann 1998:511), it already allowed the mediation of content completely new to the reader, it allowed for the reader to be surprised – a very important aspect of information, as we will discuss further below. The classic example in terms of librarianship is, of course, the Great Library of Alexandria with an estimated amount of 743,000 scrolls collected through 3rd century B.C. Although its largest collection was still part of the temple of the muses – the Museion – we can already distinguish librarian practices and terms. For instance, “bibliotheka” was the word for the wooden or stone jars in which rolls were kept that also became the term for a collection of scrolls (Dahl 1958:18-20). The scrolls themselves were

---

\(^1\) In this sense, digital does not mean binary but rather the rendering of speech into a limited number of discrete characters.
already organized by a professional class of scholars according to subject criteria, however, the catalogue was merely an alphabetic inventory list of knowledge areas and authors (Orr 1977:126). In other words, while the scrolls themselves already harboured the potential for reading to shift from remembering to learning, the catalogue still required a lot of contextual knowledge by the librarian. One had to know what one was looking for. Opposed to being a storage compartment, the library slowly turned into a warehouse with an inventory list.

While the rudimentary communication technologies changed from the usage of papyrus to parchment over the centuries, evolving into standardized documents and codices in the Roman Empire around 2nd century B.C. (Landheer 1957:18), the basic setup of libraries did not change until the final stages of the Medieval era (Dahl 1958). Parchment was increasingly used for administrative records leading to the differentiation of libraries and archives. The import of paper production techniques from China finalized the evolution of the manuscript as a bounded entity. However, throughout the Medieval Ages, libraries (opposed to archives) were still part of religious institutions like monasteries or teaching mosques mostly dedicated to copying and preserving existing manuscripts. There was no need to change librarian routines of keeping an inventory, since a single library had to take care of a steady and rather small number of manuscripts. For instance, one of the largest monastery libraries – the Bobbio monestary library – had a collection of about 700 volumes in the 9th century (Dahl 1958:57). With the rise of universities around 12th century A.D. and the increasing number of quite large private collections throughout the Renaissance, the dominance of monastery librarianship came slowly to an end. However, the first major shift in librarianship was initiated a few hundred years later by the diffusion of the printing press and the rise of mass media.

2.2 Libraries and the Emergence of Printed Mass Media

The invention of moveable type printing by Gutenberg in the middle of the 15th century can surely be called revolutionary. Although this technology was already well established in China, it was not very successful because of the extensive number of ideograms (4-5000 different types) required to print a book (Dahl 1958:84). In comparison, the system of relatively few Latin letters turned out to be an enabler for the mass production of media. Only in the first 50 years after Gutenberg’s invention, 15-20 million books were produced (Weinberger 2007). Of course, this caused libraries to reorganize their items according to size rather than topic to save shelf space. Still, the printing press also brought qualitative changes along. Besides the standardization of the book in terms of size and structure (e.g. usage of titles, paragraphs, or page numbers), it was also necessary to standardize languages in order to minimize variety to reach as big an audience as possible – a process which led to the establishment of national languages from around the 16th century on. Most importantly, printing finalized the shift from what is known to what is new and interesting – from the oral tradition of repetition and devotion (Luhmann 1998:295-299).

The differentiation of books into a communication media rather than a memory device co-evolved with the emergence of libraries as autonomous organizations by gaining an educational aspect in addition to the preservation of knowledge (Landheer 1957:98). This was achieved by opening up the private collections of the aristocracy to the public in the 17th century. Of course, at that time the public was yet limited to a small elite (Dahl 1958:177). However, printing was not only dedicated to the production of books but also of pamphlets, leaflets, and newspapers that addressed a growing literate portion of the population. The final innovation that popularized the reading of books was the novel in the 18th century. Accompanied by the invention of the paper-making machine in 1799 and the power press in 1810, reading became a comparatively cheap undertaking (Dahl 1958:220). In England for instance, so called circulating libraries rented novels out and further promoted literacy in the population to an estimated amount of 5 million until 1850 (Shapiro and Varian 1999:95). Hence, the beginning of an internal differentiation of libraries into public libraries as opposed to national and research libraries can be observed in those times. It is also the beginning of the shift from memory to information.
The establishment of libraries as learning facilities for a wide range of people and the immense growth of books and other print media marks the era of the modern library from the mid 19th century on (Thompson 1982, Svenonius 2000:2). Obviously, books – being the prime collection item of any library – are quite useful for diffusion into a wider population as they are controlled by going through a publication process, mass produced, and easy to use. Still, the notion that books preserve knowledge and hence libraries need to preserve books was and still is very much alive which Ranganathan (1931:2) came to call a “tendency to hoard books”. The user-friendliness of libraries, propagated by the British Museum Librarian Panizzi in the 1850ies, towards open access to the items themselves collided with the need to store the items as efficiently as possible (Dahl 1958, Weinberger 2007). In general, public libraries allow direct access by ways of organizing the items themselves. Books are being shelved according to the categories they are assigned to; hence, the way books are displayed is already informative. The dominant system, especially in Anglo-American libraries, is the infamous Dewey Decimal Classification System (DDC) developed by Melvil Dewey in the 1870ies that classifies all the world’s knowledge into 10 main categories and 100 sub divisions per category (OCLC 2003). Admittedly quite an ambitious task, it produces some biased or even embarrassing classifications because of its Anglo-American roots and the limited number of categories. For instance, the 100 divisions for the main category “Religion” are mainly dedicated to Christianity while there is only one division for Islam. As ambivalent as these open shelf arrangements may be, they allow the user to browse through the collection, therefore, to find something without knowing exactly what to look for. The library, rather being an inventorized warehouse, becomes “walkable” for usage and discovery.

On the other hand, closed shelving applies to the immense growth of books allowing indirect user access via various retrieval systems. The shift from book catalogues to card catalogues is the main result. Card catalogues, first formulated by the Smithsonian librarian Charles Coffin Jewett in 1852 based on the work of Panizzi (Weinberger 2007:59), can organize an unlimited knowledge space since it is not bounded by the limitations of books. However, browsing through a library’s stock is not possible anymore, since the user needs to comply with the librarian way of describing items. The author catalogue is only usable when one knows exactly what one is looking for. From this perspective, a closed shelf library still remains a warehouse with an inventory that only answers questions like “Does the library have the book X by the author Y?” In order for a library to be used by patrons (this is the differentiating factor between a library and an archive) it needs to provide services enabling a user to find what he/she does not know (Ranganathan 1931, Thompson 1982:100ff). Subject catalogues are of limited help as they are mostly based on a controlled vocabulary, meaning that items are indexed according to a standardized set of categories a user needs to familiarize with. From this perspective, a library only provides a limited number of very specific paths for discovering items. In more general terms, librarianship refocuses from the problem of preserving knowledge to a problem of retrieval – of being informative in terms of its items (Orr 1977:125ff, Hjorland 2000).

Be as it may, while industrial mass production finalized the standardization of formats like books or newspapers, the card catalogue standardized how librarian items are to be described. Already to be found in Jewett’s conceptualization, the standardization allowed for the merging of catalogues into union catalogues, first on a national and ultimately on an international level. The consequences were, for instance, that from the early 20th century on, loaning books among libraries became possible. Another consequence was the establishment of national libraries as reference libraries distributing printed catalogue cards in order to maintain the nation wide but also international quality of the catalogues (Dahl 1958:255). Especially among national libraries, cooperation became a standard practice particularly after the Second World War.

The exponential growth in the mass production of books – what today would be called information growth (Kallinikos 2006) – being archived by libraries is, in fact, an immense problem. Various authors came to question whether libraries will be capable to not only store books but also to maintain a certain level of usability or whether we would witness the decline of libraries into unusability (Thompson 1982). Various technological innovations, like microfilming, may have had temporarily
solved the storage problem, but the biggest hope is put into computerization and digitalization not only in terms of storage and preservation but also in terms of access and retrieval (Schwartz 2000). First steps were the image scanning of catalogue cards later followed by OCR scanning accessible via various Online Public Access Catalogues (OPAC). Data-based catalogues are now able to use a wide variety of IT enabled search and retrieval functionalities such as Boolean operators or ranking and relevance feedback (Hahn 1998). However, the ultimate step is the digitalization of librarian items themselves which enables users not only to retrieve descriptions about specific items but rather to access the items themselves via the WWW.

3 ON DIGITAL LIBRARIES

The domain of Library and Information Science (LIS) observes and discusses changes of librarianship attributed to the rise of the Internet (Davis and Lagoze 2000); this includes changing user behaviour (Peterson Bishop 1999), the increasing importance of documentation and preservation of online communication, especially in science and research (Ercegovac 1997), and comparisons with new information service providers of which Google is the most prominent one (Schwartz 2000, Bjorner 2006). An indicator for the ongoing discussion is the lack for a standard definition of digital libraries (Meyyappan, Chowdhury and Foo 2000). Schwartz (2000), for instance, discovered 64 different definitions of digital libraries that vary from very strict characterizations to very loose ones. If we compare these definitions with a traditional definition of a library as, for instance, presented by Oppenheim and Smithson (1999:99); “The traditional library is defined as a specific place with a finite collection of tangible information and it is geographically constrained”, we may come to the conclusion that either the library does not change a lot or it changes tremendously. Either a library simply includes digital works into their collections and offers corresponding services or it leaves “the place” behind offering any document any time to anyone in any place (Covi and Kling 1996:672) – a library without walls.

A second very important issue is the relationship between librarianship and ICT. Digital libraries are often positioned between these two domains (Oppenheim and Smithson 1999, Schwartz 2000). The discussion unfolds along three major dimensions; digitalization and preservation of digital media, accessibility for library users, and interoperability of librarian cataloguing. The first point refers to the difficulties of not only digitizing analogue media but also to keep the digital content retrievable at any time. Decisions made during digitalization (e.g. file structure) have a huge influence on the preservation policy and vice versa. That is because digital documents are unable to “care for themselves” (Russell, Weinberger and Stone 1999:277), for digital media requires the appropriate hard- and software in order to be accessible (Bennett 2001, Kallinikos 2009).

Accessibility mostly refers to the interaction between the library and the library user. ICT does not only enable multi-dimensional search functionalities through the library’s repository but also new meeting points for face-to-screen interaction and collaboration. The discussion covers a wide range from usability in terms of screen- and interface design (Thong, Hong and Tam 2002) and the enhancement of the readability of texts on screen (Greene, Marchionini, Plaisant and Shneiderman 2000), the design of systems to improve the relevance of results of user enquiries (Marcum 2001, Tuominen, Talja and Savolainen 2003), to new tools for especially scientific users in terms of collaborative research and user behaviour (Wilensky 2000). The final point mainly discusses concerns regarding the interoperability between librarian standards of classification and metadata (Suleman and Fox 2001). Metadata standards play a key role in the future development of librarianship (Baker 2006), since they build the basis for search, retrieval, delivery, rights management, and preservation (Russell, Weinberger and Stone 1999).

Instead of observing the discussions surrounding the issue of digital libraries as a problem of developing and implementing the right technologies, we should rather treat them as indicators for the re-emergence of the more fundamental theme of what makes a library a library. In other words, the memory/information paradox needs to be re-unfolded in relation to a changing environment. As it will
be discussed further below, IT is one way to attempt a re-unfolding by transforming the paradox into a technical problem. The rest of the paper will be dedicated to further explore what is actually meant by memory and information in relation to the latest innovation in communication technology – binary-based media.

4 MEMORY/INFORMATION AND IT

The ways traditional libraries organize the items and their descriptions lies in the nature of the items themselves. Books, for instance, are bounded physical objects that can only occupy one place on a shelf at a time. As it is the case with the Dewey Decimal Classification System, the organization of the items turns into a system of either-or categories. Of course, all the books could have been piled up into an immense heap but, as a consequence, finding what one was looking for would turn into an event of luck. Therefore, having any order is better than having no order at all. In other words, one can find something because not everything is findable. Naturally, any classification system hides and distorts. This already begins with the collection policy of each library that is, in fact, a selection policy. In principle, that does not change with the introduction of a separated second-order search and retrieval system – the card catalogue. It only allows answers to very specific questions, on the one hand, by relying on the standardized attributes of books (the name of the author or title) and, on the other hand, by relying on librarian standard procedures of adding further descriptions such as keywords which are based on an existing pre-ante classification system. However, with the rise of ICT and ultimately the Internet, the established formats do not apply to new forms of online communication such as hypertexts.

In order to avert misunderstanding, digitalization should not be understood as the end of books or paper-based media in general. As Brown and Duguid (2000) argue, digitalization does not mean de-paperization. The paper-based domain of books and newspapers, on the one hand, and the binary-based online world, on the other hand, are not mutually exclusive but rather complement one another. Still, librarian 1st order categorization – organizing the books themselves – as well as 2nd order categorization through organizing descriptions of books – the catalogue – are based on the standardization of specific communication technologies as packaged media (Esposito 2002). Books, seen as containers of knowledge, have been organized the same way as any other mass produced good (Svenonius 2000:10). To some extent, this is still applicable to packaged digital media such as CD-ROMs or digitalized versions of books. However, the rise of hypertextual, networked media (Esposito 2002), of dynamic, unstable, borderless online digital media (Svenonius 2000:12) brought librarian collection practices back into the centre of attention2. So what is a library actually organizing – is it really simply books and the knowledge they contain?

4.1 What is a Library organizing?

Roughly in the middle of the 20th century, the incommensurable growth in mass printed media made librarians rethink the role of libraries similar to the situation today. The answer was the introduction of another difference – that is the difference between work and item. As Svenonius (2000:9) reports, the first explicit distinction was made by Julia Pettee – chief cataloguer of the Library of Union Theological Seminary in New York City – in 1936. She described a particular message content as a “library unit” and its embodiment in a medium as a “book”. In 1955, Ranganathan laid the foundation of what came to be the Functional Requirements for Bibliographic Records (FRBR). Ranganathan distinguishes between “work” as an expressed thought and “document” as an embodied thought. Finally in 1995, the International Federation of Library Associations and Institutions (IFLA) developed a four level model of work, expression, manifestation, and item (IFLA 1998). Work is

2 At a closer look, not even a book is as stable as it may seem if we, for instance, think of different editions and translations.
defined as a distinct intellectual or artistic creation – an abstract concept that is realized through an expression in the form of alpha-numeric, musical, or choreographic notation, sound, image, object, movement, etc., or any combination of such forms. The physical embodiment of an expression of a work is referred to as manifestation. Finally, an item is a single exemplar of a manifestation. For instance, Shakespeare’s Hamlet (work) is realized as various English versions and translations into other languages (expressions) which are published as hard-cover and paperback editions (manifestations) and one exemplare of each (items) is available in a library. Now, a peculiarity of modern libraries, since they are dealing with mass-media rather than unique archival records, is the organization of items (things) and works (abstract concepts) (Svenonius 2000:10). As Svenonius (2000:11) further elaborates in reference to Panizzi, this is quite an important distinction, since a user may know the work but not the peculiarities of different editions.

The introduction of IT into librarian services in the form of databases put a lot of emphasis on the item level. Information technology treats information like a thing that can be manipulated, ordered, and categorized at will, or at least so it seems (Buckland 1991). Of course, this notion is based on a very specific definition of information provided by Information Theory founded by the work of Claude Elwood Shannon (1993). Accordingly, information is a selection of a message out of a number of pre-selected messages based on the design of the communication channel between a sender and a receiver. The information value of the message sent derives from the number of messages it was selected from. Therefore, the informativeness of a message lies not in the message itself but in what else could have been sent. The basic measurement unit is a binary digit of 0 and 1. For example, sending the result of flipping a coin has an information value of 1 bit – 0 for head, 1 for tail. Shannon’s model is a basic input/output model of what comes in should come out at the other end as efficiently and undistorted as possible. However, in this model we do not find a differentiation between message or signal, on one hand, and information on the other hand. In other words, information and document – or in other words data and information - are one and the same (Lee 2004). Treating information as a countable thing, however, leaves the receiver completely out of the picture. In order to understand, the receiver needs to distinguish between noise and message which is based on her/his expectations. In fact, when pure noise complements the receiver’s expectations it is meaningful for her/him hence informative without the intention of a sender. Information lies in the eye of the beholder and is not a factual thing with an existence of its own. Consequently, even the absence of a signal may be informative for a receiver or as Bateson (2000:458) puts it: “The letter which you do not write can get an angry reply”.

Accordingly, books and catalogues may not be considered as containing information but rather having the potential of triggering the event of informing a reader and user. What books and catalogues contain is mere data that is organized in a way that is expected (by the author/publisher/librarian) to be potentially informative for somebody (an anonymous mass audience of readers, library users). However, the technological innovations in terms of data processing and ordering propel the librarian abilities to deal with items (things) but fail to notice the importance of organizing works (abstract concepts) as well (Svenonius 2000).

4.2 Memory and Information

The observer-related nature of information has been expressed by Bateson (2000:459) in his renown definition of information as being a difference which makes a difference. This concept has mostly been interpreted as information having an element of surprise or novelty (e.g. Luhmann 1996, Kallinikos 2006). In other words, a difference has to be informative for an observer and only then does information occur (Wildavsky 1983). Information has no existence of its own; it is a no-thing, an event that loses its informativeness for an observer the moment it is observed. This led Kallinikos (2006) to call information non-foundational and ephemeral, hence it can neither be stored nor produced. In short, information is not what triggers change nor what is changed but the change itself. Based on this concept, books contain potentialities for information for somebody. For instance, reading an English text without knowing English is of course possible but for the reader the work remains pure noise
without any meaning. Now, this is the crucial aspect that allows for a further elaboration of the shift of writing/printing from being mostly a memory device to a communication technology that mediates what the reader does not know. Mass media in general (e.g. TV channels, newspapers, radio channels) deal foremost with delivering exactly that (Luhmann 1996). Information, therefore, is closely attuned to learning rather than to knowing (Wildavsky 1983).

The same applies to the ways library items are organized and documented. Beginning with a mere inventory list, the documentation had no potential of informing a user. It only told where to find a specific scroll, manuscript, or book the user already knew about. To be precise, we cannot even think of a library being used at that point. A library was a memory or an archival function of mostly religious and later on secular institutions. Just as we cannot speak of users during those periods, in fact, neither can we speak of libraries as such. Only when the notion of education was introduced did the organization of library items start to turn into an informative system. Walking through an open shelf library or using a subject catalogue allowed the user to be surprised even when, admittedly, in a rather limited fashion. The crucial point, however, is that libraries started to reflect on how to make the immense amount of items or, in other words, data informative. Developments in ICT seemed to be the solution to all the problems (Thompson 1982). The paradoxical form of memory/information seemed to be, after all, only a technological problem soon to be solved by implementing state-of-the-art library information systems (LIS). As already mentioned further above, technology only deals with the problem of managing the immense growth of data but not the problem of information. “What is processed in information systems is only data (or potential information)” (Hjorland 2000:32). The problem of information is how to actualize information out of these immense pools of data (Wildavsky 1983).

At this point, we may return to the notion of memory in order to further specify the term. Memory should not be seen as a storage of past events; it is rather an expression of recursivity (Esposito 2002). It is the capability to observe sameness in difference, to construct repetition and hence what is already known. Information only occurs in comparison to what is remembered as well as forgotten. Memory is not a stock but rather the organization of observing information. Hence, we can formulate the memory/information paradox; memory is necessary to recognize information and information is necessary for the construction of repetition. Without memory everything and nothing is new and surprising. From a temporal perspective, we end up with the chicken and the egg: what was there first, memory or information - the observation of repetition or novelty? In order for an event to be observed as novel, it needs to be distinguished from what is repeated. From a factual perspective, we come to a tautology; in order to describe memory we refer to information and vice versa. By definition, a paradox does not offer a solution but rather the oscillation between the two sides of the form. In our case, the form is the library. It is the difference between memory and information. Consequently, librarianship is the self-observation of the form – the observation of the memory/information paradox based on the paradox – that oscillates between the two sides. In other words, memory is differentiated from information by applying the memory/information difference.

Similar to the argumentation on the potential information further above, books and catalogues do not remember but rather provide a potentiality for repetition and hence remembering as well. Memory and information are two sides of the same coin. Coming back to the difference between works and items, the organization of the fuzzy, abstract level of works by defining different items as being the same, is what makes a library an information organization. It constructs, like in every classification system, categories based on abstract definitions (works or keywords) to which physical items are assigned to. Sameness in difference and difference in sameness is just another way of phrasing the memory/information paradox. However, the self-referential closure of librarianship into an autonomous organizational form due to the mass production of books and the re-orientation towards

---

3 It is hard to imagine to read, for instance, a newspaper with the front-page title “nothing new happened today” or to watch a TV channel broadcasting the same shows, series, and movies every day.
being used is the key aspect that differentiates a library as an information organization in comparison to archives or museums which, so far, have remained mostly on the memory side of the paradox. In short, an information organization organizes the memory/information paradox in order for it to be a difference that makes a difference for an anonymous audience.

5 LIBRARIES AS INFORMATION ORGANIZATIONS – AN OUTLOOK

In this paper, libraries were introduced along the difference of memory and information in relation to developments of communication technologies. The emergence as an autonomous organizational form was outlined as a process of increased differentiation from its relevant environment that led to a shift from a focus on memory to a focus on information and retrieval – a form termed information organization. However, building an argumentation of libraries being information organizations based on the observational form of memory/information needs further development in order to being applicable to contemporary developments in librarianship. So far, the focus was on how libraries do what they do which is not a distinguishing characteristic anymore. Because of the converging, interoperable nature of binary-based media, libraries, archives, and museums become again less and less distinguishable when offering their services online. Additionally, other non-librarian organizations also provide information services online. Google, especially after launching their massive book digitalization project, seems to fulfil an equivalent function to what libraries were doing in the 20th century – connecting people with information. However, if we change the question of how into why a library does what it does, the difference becomes quite obvious. Google, like every commercial company, is a business oriented enterprise; consequently the reason why Google does what it does is simply profit. It seems a very trivial point to make, but rarely considered by harbingers of the end of libraries such as Weinberger (2007). The private sector has different goals than the public sector and fulfilling the role of an archival trustee in terms of provenance is not one of them (Jeanneney 2005). The Amazoogles of the Internet organize information to make money, but they are not information organizations in the sense of this article. In other words, digitalizing and indexing books is not what makes a (digital) library. What is it then?

Another point to be considered is that basically every organization can be observed according to the memory/information difference. Every organization “uses” information to make decisions, hence a relationship to memory is easily established (Wildavsky 1983, March 1991). After all, organizations do store and retrieve documents via an information system. Still, there is a difference between having a library and being a library – between using an information system and being an information system. Libraries are solely based on the dynamic relationship of memory and information. They establish a self-referential notion of the memory/information paradox leading to further differences (such as work and item) which in turn distinguishes librarianship from an IT centred organization of information-as-things (Buckland 1991). In order for libraries to remain libraries a re-unfolding of the memory/information paradox seems to be required which can be subsumed under the rather broad concept of digital libraries which, in fact, is not distinguishable from digital archives and museums anymore. The term information organization is expected to help to appreciate the peculiarities of these public information service providers in the next steps of the research. It directs the analysis towards contemporary changes without leaving historical developments behind.

Finally, the librarian memory/information distinction highlights different aspects than the predominant knowledge/information and data/information distinction in the IS field. The conceptualization of memory/information as a paradox expounds the limitations of IT – i.e. being capable to only solve problems - in a new light. The ways libraries re-unfold this paradox due to changes in societal communication and technological developments (mostly accomplished outside the domain of librarianship) is an excellent example for dealing with the increasing and boundary-crossing data-pollution and noise, basically every organization has to face.

A TRANSACTION COST THEORETICAL ANALYSIS OF SOFTWARE-AS-A-SERVICE (SAAS)-BASED SOURCING IN SMBS AND ENTERPRISES

Benlian, Alexander, Ludwig-Maximilians-University of Munich, Institute for Information Systems and New Media, Ludwigstr. 28, 80539, Munich, Germany, benlian@bwl.lmu.de

Abstract

This study seeks to better understand the factors contributing to the adoption of Software as a Service (SaaS) as on-demand sourcing option. Grounded in transaction cost theory (TCT), we developed a research model for assessing SaaS-sourcing at the application level. Four hypotheses with three TCT-based constructs (application specificity, environmental uncertainty, and usage frequency) and one contingency factor (firm size) affecting the adoption of SaaS-based sourcing were formulated. Survey data of 154 firms in Europe with 284 response items across different industries were collected to test the theoretical model. PLS-based structural equation modeling demonstrated that uncertainty emerges as the strongest factor for SaaS-adoption, while application specificity also contributes significantly. Differentiating between small and medium-sized businesses (SMBs) and enterprises, uncertainty represents the strongest driver for SaaS-adoption in SMBs, whereas application specificity is more important in enterprises. Finally, firm size is significantly and negatively associated with SaaS-based sourcing within, but not across the subgroups of SMBs and enterprises.

Keywords: Software as a service (SaaS), IT outsourcing, IT adoption, SMBs and enterprises

1 INTRODUCTION

On-demand software application delivery models are known since the late 1990s and have come in many forms and varieties such as Application Service Providing (ASP) or Business Service Providing (BSP). The common denominator of all these concepts is that this kind of demand-driven application sourcing model provides users and firms with network-based access to resources and expertise as well as to an integrated portfolio of complex applications that spans the complete virtual value chain of an enterprise (Kern et al., 2002a). While discussions on ASP-based outsourcing have become rather silent in recent IS management literature mainly due to the missing breakthrough success stories, a new acronym, called Software-as-a-Service (SaaS), has gained ground in the attention span of IS executives and is said to become a fundamental pillar of revenues for IT vendors in the next couple of years (Pettey, 2006). Although often discussed as an “old wine in new skins” concept, SaaS is promised to breach last barriers of adoption, as it offers more mature and comprehensive service packages on the customer side and the ability to support service-oriented multitenancy and a shared IT infrastructure to reap significant economies of scale on the provider side (Valente & Mitra, 2007).

Traditionally, the interest in on-demand based sourcing models was driven by a focus on core competencies, the attractive cost model for customers (i.e., turning fixed costs into variable costs), the benefits from cutting-edge technology and faster implementation times, transparent and predictable subscription pricing, and the possibility to flexibly balance the shortage of necessary IT skills (Kern et al., 2002b). Countering these benefits are the acknowledged risks of reliability (how can IT departments ensure that the business can access its applications?), security (how can it guarantee data privacy in line with regulations?), and process dependence (how can it make sure that quality of service is really achieved?) when outsourcing IT applications to a 3rd party (Kern et al., 2002a). Puzzled by these mixed point-of-views, researchers and practitioners have struggled to determine...
which side of the discussion will prevail over time. However, while many research and management papers have theoretically explored the meaning, characteristics, and economic implications of on-demand application outsourcing, only few have examined the drivers of SaaS-similar sourcing decisions on a substantial empirical basis, which may also be due to the immaturity of this research object. Specifically, what is missing in the existing literature is a solid and theory-based research model on the drivers of SaaS-based outsourcing which is assessed based on a broad dataset instead of a few isolated cases. Our study seeks to reduce this research gap. Key research goal of our study is to contribute to a heightened understanding in the drivers behind using SaaS-based sourcing models viewed through a transaction cost based lens. Concrete research questions are: (1) How do transaction cost based factors such as asset specificity, environmental uncertainty, and usage frequency explain the sourcing of applications via SaaS? (2) What is the role of firm size in the adoption of SaaS-based sourcing models? (3) How does SaaS-adoption look like on an application level today and in the future? Based on these questions, our research focus is not to compare SaaS-based sourcing with other types of outsourcing arrangements (e.g., licensing), but to explain why companies would agree or disagree to have their applications operated as service by an IT provider.

The following section reviews the literature from which our transaction cost theoretical framework is developed. A conceptual model and a series of research hypotheses are then formulated, followed by our research methodology, analysis, and the empirical results. The paper concludes with a discussion of findings and limitations.

2 TRANSACTION COST THEORY AND IT OUTSOURCING

Transaction cost theory (TCT) is embedded in the framework of the new institutional economics which was first introduced by Coase (Coase, 1937), who analyzed why firms exist and what firms do. One of Coase’s initial propositions was that firms and markets are alternative governance structures differing in their transaction costs (Coase, 1937, p. 389) – where by transaction cost Arrow referred to the “costs of running the system” (Arrow, 1969, p. 48). Accordingly, the transaction-cost approach is based on the premise that the existence of different organizational forms, whether they are markets, bureaucracies, or clans, is primarily determined by how efficiently each form can mediate exchange transactions between parties (Ouchi, 1980, p. 130). Over the past four decades, Williamson has added considerable precision to Coase’s general argument by identifying the types of exchanges that are more appropriately conducted within firm boundaries than via the market. To evaluate different governance or exchange arrangements, Williamson introduced characteristics or determinants of transaction cost differences of which asset specificity, frequency, and uncertainty are the most important ones (Williamson, 1985). In the IS research literature, transaction cost theory has particularly and comprehensively been applied in the context of IT outsourcing (e.g., Ang & Straub, 1998; Lacity & Willcocks, 1995). Wiener found in his literature synthesis on IT outsourcing that transaction cost theory has been the predominant theoretical approach to understand and explain IT outsourcing decisions (Wiener, 2006). Aubert et al. for example has investigated a transaction cost model on IT outsourcing using asset specificity, uncertainty, business and technical skills as determinants of the level of IT outsourcing (Aubert et al., 2004). Dibbern instead focused on the effect of human asset specificity on the sourcing of application services (Dibbern et al., 2005), while Loh developed an integrated governance model of IT outsourcing including various theoretical approaches (e.g., transaction cost theory and agency cost theory) to test his hypotheses (Loh, 1994). All of these studies provided consistent empirical support for the TCT framework.

Reviewing the IT outsourcing literature more closely focusing on on-demand based IT outsourcing, it is interesting to note though that drivers of on-demand outsourcing decisions have not been studied extensively so far. On the one hand, a number of theoretical research studies exist that propose definitions and classifications, and explore special characteristics (such as service quality or capabilities) of ASP-based sourcing models (e.g., Ma et al., 2005; Smith & Kumar, 2004). On the other hand, existing empirical studies very frequently limit their analysis to providing content-rich, but
less representative case studies on determinants of on-demand based IT outsourcing (e.g., Jayatilaka et al., 2003; Kern et al., 2002a). The number of research studies on the drivers of on-demand IT sourcing which are based on a solid empirical basis is thus rather small and limited to special aspects in the adoption in single countries and industries (Daylami et al., 2005). Based on these observations, the current IS literature is rather scarce on the assessment of more broadly valid and applicable adoption drivers of on-demand sourcing decisions. Drawing upon this empirical evidence, we seek to fill this research gap by examining TCT-based factors that may affect SaaS-based sourcing decisions.

3 HYPOTHESES DEVELOPMENT

Outsourcing of software applications is the handover of the development and maintenance of an application to an IT provider and is an alternative to internal development and maintenance. The essence of the transaction-cost based argument is that using an external IT vendor is not frictionless. When buying or leasing a service (such as SaaS) or a product, one incurs costs. If these costs become too high, relying on self-production is more appropriate. Transaction costs theory has two underlying assumptions. Bounded rationality is the inability of the human mind to find or process all the information about a transaction; therefore, it is conducted with a certain level of uncertainty. Opportunism is more than the simple defense of one’s interest or value maximization; it is self interest seeking with guile (Williamson, 1989). The combination of these assumptions results in information asymmetry. In order to strike a better deal, sellers will hide negative characteristics of their products, and buyers will not reveal how much they are willing to pay. Since both parties know that the other is opportunistic, each will engage in information seeking activities (e.g., having a product tested before buying it or asking for warranties). All these actions generate transaction costs. This is especially true for SaaS-based outsourcing in which an outsourcer’s handover of application data and process ownership may cause lower or higher levels of transaction costs compared to operating the application in-house. According to transaction cost theory, the factors determining the extent of transaction costs are grouped into three broad categories: (1) the specificity of the assets required for performing the transaction, (2) the uncertainty surrounding the transaction, and (3) the frequency of the transaction executed. As firm size seems to be a special factor in SaaS-based sourcing decisions due to the reasons mentioned in the introduction, it will also be included in our hypothesis development (4).

3.1 Application Specificity and SaaS-based Sourcing

Traditional transaction cost economics posit that transactions with high asset specificity (i.e., the degree to which assets can be redeployed elsewhere without losing value) are managed less expensively in-house, while the rest should be more efficiently outsourced (Williamson, 1989). Specifically, the theory suggests that when asset specificity is high, the assets involved in the transaction are so idiosyncratic and customized to the application context, that in-house production will bear lower transaction costs than outsourcing due to lower levels of so-called post-investment opportunistic behaviour (Klein et al., 1978). A number of prior research studies on IT outsourcing have employed asset specificity in their research models to explain outsourcing decisions with rather puzzling outcomes. While Nam et al. did not find any significant link between specificity and outsourcing (Nam et al., 1996), Aubert et al. discovered inconsistent effects of specificity (Aubert et al., 2004). On the other end, Dibbern showed that insourcing is more cost efficient and advantageous in creating strategic benefits through IS, if the provision of application services requires a high amount of firm specific human assets (Dibbern et al., 2005). In the case of SaaS-based application sourcing, application specificity is reflected in the degree that applications are customized to the individual requirements of the outsourcing company and thus comprise highly specific investments. Based on TCT thinking, it can be argued that the higher the degree of application specificity, the lower the level
of SaaS-based outsourcing, as integration and coordination costs for running a highly customized application system on the IT provider side outweigh the transaction costs for running the application in-house. These theoretical assertions lead to the following hypothesis:

**H1:** Application specificity is negatively associated with SaaS-based outsourcing.

### 3.2 Environmental Uncertainty and SaaS-based Sourcing

Analogous to asset specificity, environmental uncertainty surrounding a specific outsourcing relationship is posited to be negatively associated with the degree of outsourcing (Williamson, 1989). By the majority, prior research on IT outsourcing has supported this theoretical proposition. For instance, Nam et al. found that uncertainty towards potential opportunistic behaviour of the IT provider played a significant role in the decision to outsource. As expected, higher uncertainty and thus higher perceived risk lead to less outsourcing (Nam et al., 1996). Similarly, Aubert et al. found in their study that the level of uncertainty is the major deterrent to outsource IT operation activities (Aubert et al., 2004). Dibbern conceptualized environmental uncertainty in the IT outsourcing context as comprising business driven and technology driven uncertainty (Dibbern, 2004, p. 53-54). While business driven uncertainty refers to the extent to which the development of business related issues (such as pricing or processes) may be changed over time in the course of the outsourcing relationship by the IT vendor, technology-driven uncertainty captures the extent to which the required technical functions or features of the outsourced application may be changed over time. Based on these notions of uncertainty, one can hypothesize for SaaS-based outsourcing that when environmental uncertainty is high due to potential opportunistic behaviour of the IT provider regarding business- or technology-related activities, the outsourcer will prefer internal governance for highly risky activities. This leads us to the following hypothesis:

**H2:** Environmental uncertainty is negatively associated with SaaS-based outsourcing.

### 3.3 Usage Frequency and SaaS-based Sourcing

Theoretical ideas about transaction or usage frequency stem from the classical notion that an increasing number of transactions between two parties entails trust-building and routine which can be represented in a hierarchical governance form more efficiently than in a market governance form (Williamson, 1984). This is also backed up by classical organizational theory which argues that the higher the interdependence between organizational units, the higher the necessity to integrate both organizational units due to transaction cost savings (e.g., Thompson, 1967), which in turn can be attributed to routinization effects and economies of scale. Low frequency transactions with less complexity involved are thus likely to be organized through market interactions. In the context of IT outsourcing, Aubert et al. found that frequently used assets or skills in software development were used in-house, whereas infrequently and specialized assets and skills were contracted out (Aubert et al., 2004). Similarly, Hancox and Hackney synthesize from their findings in a study of private and public sector organizations that usage frequency indeed is negatively associated with the use of the market (Hancox & Hackney, 2000). Regarding SaaS-based sourcing, it can be argued that increased usage of an application system that requires different technical and human interfaces, skills and resources, as well as a high number of interactions (e.g., planning, adapting, and monitoring of task completion) will translate into increased coordination complexity between these different entities (Dibbern, 2004, p. 47-48). This will in turn induce the outsourcing decision-maker to rather opt for in-than for outsourcing due to transaction cost advantages. Hence, we can formulate the following hypothesis:

**H3:** Usage frequency is negatively associated with SaaS-based outsourcing.
3.4 **Firm Size and SaaS-based Sourcing**

Firm size is one of the most commonly studied factors in the IS and organization literature (e.g., Gremillion, 1984). Yet, different opinions exist as to the role that firm size plays in the process of adopting new technologies and innovations. On the one hand, large firms often possess more slack resources that can increase the openness for technology experiments – the so-called Schumpeterian resource advantages (Schumpeter, 1950). On the other hand, large firms tend to be less agile than small firms. This comparatively bigger structural inertia associated with large firms may entail more effort and cost for technology adoption (Duncan, 1976). In the context of IT outsourcing, Kern et al. developed the proposition – which is informed by transaction cost and resource based theory – that small and medium-sized companies (SMBs) are especially interested in more flexible application service providing mechanisms. This is mainly due to the fact that they can get access to strategic resources which are often prohibitively costly yet essential for SMBs to remain resource competitive against larger firms (Kern et al., 2002a, p. 171). Based on this theoretical assertion and the hypothesis that large firms show higher structural inertia, we argue that firm size will be negatively related to SaaS-based sourcing and thus deduce the following hypothesis:

**H4:** Firm size is negatively associated with SaaS-based outsourcing.

### 4 RESEARCH METHODOLOGY

#### 4.1 Data and Sample

To test the hypotheses suggested above, we designed a questionnaire and conducted a Europe-wide survey. The survey questionnaire was designed on the basis of a comprehensive literature review in the IT outsourcing context and based on interviews with IT managers. After several rounds of pretests and revisions, the survey was distributed in the biggest 6 European countries (Germany, France, UK, France, Italy and Spain) during the period of September through December 2007. The survey was conducted at the application type level, so that one company had the possibility to rate different application systems (i.e., Collaborative, Content, ERM, Human Capital, SCM, Production, Engineering, CRM applications) on the applicability and drivers of SaaS-based outsourcing.

The questionnaires were sent to 1,200 top or senior IT executives randomly selected from a directory of 3,000 firms in the finance, manufacturing, logistics, high-tech, energy, and TIME industry supplied by a market vendor (Bisnode Business Information Group). After we dropped 18 responses due to missing data and inconsistencies, a total of 284 usable responses from 154 different companies could be used for the analysis. We tested non-response bias with chi-square tests and found no statistically significant differences between early and late respondents on firm size and SaaS outsourcing levels (Pearl & Fairley, 1985).

#### 4.2 Operationalization of Constructs

Table 1 shows the operationalization of variables of our conceptual model. Besides one question, for which a percentage estimate on the SaaS adoption rate in 2007 and 2010 was requested, all other questions were asked from a scale ranging from 1 to 5, where 1 refers to the lowest score and 5 the highest score in the item scale. Measurement items of all variables were drawn from those of previous studies as depicted in Table 1.
4.3 Instrument Validation

Content validity was established through the adoption of constructs that had been used in former studies (see Table 1) and through pilot tests with IS practitioners of different industries. The reflective measurement models were validated using the standard procedures of current literature (Chin, 1998; Straub, 1989). Items of scales in a related domain were pooled and factor-analyzed to assess their convergent and discriminant validity. While convergent validity was determined both at the individual indicator level and at the specified construct level, discriminant validity – the extent to which different constructs diverge from one another and thus are distinct in nature – was assessed by analyzing the average variance extracted and inter-construct correlations. The results are illustrated in Table 2.

* All factor loadings are significant at least at the p<0.05 level

Table 1. Measurement of Constructs

Table 2. Assessment of Measurement Model: Factor Loadings and Reliability
All standardized factor loadings are significant, thus suggesting convergent validity (Bagozzi et al., 1991). To evaluate construct reliability, we calculated composite reliability for each construct. All constructs have a composite reliability significantly above the cutoff value of 0.70 (Hair et al., 1998). All reflective constructs also met the threshold value for the average variance extracted (AVE > 0.50). For discriminant validity of latent variables, the square roots of AVEs exceeded the inter-construct correlations that were negligibly low between the independent constructs.

5 EMPIRICAL ANALYSIS

5.1 Descriptive Results on SaaS-based Outsourcing on the Application Level

We analyzed the adoption levels in terms of the percentage of an application’s budget allocated to SaaS-based sourcing in 2007 and 2010. SMBs allotted around 5.7% of their IT application budget to SaaS-based outsourcing in 2007 overall and plan to spend as much as 14.8% in 2010. On the contrary, enterprises allocated only around 3.6% of their IT application budget to SaaS-based sourcing models. However, according to the results of our study, the adoption level of SaaS in enterprises will triple until 2010 to a level of around 11.1%. To gain a deeper understanding of current and future SaaS adoption, Table 3 shows the outsourcing levels of different SaaS-based applications in 2007 and 2010.

Table 3. SaaS-Adoption on the Application Level

Comparing the absolute adoption levels between SMBs and enterprises in 2007 and 2010 along all applications, a significant difference could be identified using t-tests (t-value_{2007}=3.49, p<0.001; t-value_{2010}=2.22, p<0.05). The implications of these descriptive results will be dealt with in the discussion section along with the following explanatory outcomes.

5.2 Analysis of the overall sample

We tested our research hypotheses with actual 2007 adoption rates by using PLS-based structural equation modelling (Chin, 1998; Lohmöller, 1989) based on SmartPLS (Ringle et al., 2005). In contrast to parameter-oriented and covariance-based structural equation modeling, the component-based PLS method is prediction oriented (Chin, 1998, p. 352). It seeks to predict the variations in the dependent variables of the model, which we want to achieve for the SaaS-based outsourcing construct in our study. Since PLS does not account for the covariances of all indicators, but only for those variances that have been specified in the model, it is closer to the actual data than the covariance-based procedure (Fornell, 1989). Due to the partial estimation of single elements in the causal model, fewer empirical cases are needed in PLS-than in covariance-based structural equation modeling to generate consistent and reliable results. To provide an aggregate view on the assessment of PLS-based models, the structural model is evaluated by looking at the percentage of the variance explained (R²) of all...
dependent latent variables. By examining the size and stability of the coefficients associated to the paths between latent variables, hypotheses, which were proposed during the model specification process, are finally analyzed for their significance. Standardized path coefficients and $R^2$ as major model-fit index are shown in Figure 1.

![Figure 1. Results of the Overall Model](image1)

![Figure 2. Comparison of Path Models SMBs vs. Enterprises](image2)
5.3 Comparing SMBs and Enterprises on the drivers of SaaS-based sourcing

Based on sub-samples of 169 SMBs and 115 enterprises, structural equation models were calculated. Analogous to the assessment of the full sample, standardized path coefficients and the share of explained variance ($R^2$) were analyzed and compared (see Figure 2). In the SMB sample, application specificity and environmental uncertainty have both strong negative and significant paths leading to SaaS-based outsourcing. The paths from usage frequency and firm size to SaaS-adoptions are also both negative and significant. A total of around 92% of the variance of SaaS adoption could be explained by TCT attributes and firm size. In the enterprise sample, 76% of total variance could be explained by the independent constructs in our research model. Paths from application specificity and firm size to SaaS-based outsourcing are both negative and highly significant. While environmental uncertainty is also negatively and significantly correlated with the dependent variable, the path from usage frequency is insignificant.

6 DISCUSSION

6.1 Major Findings and Interpretations

Finding 1: Environmental uncertainty emerges as the strongest factor for SaaS-based outsourcing, while application specificity also significantly contributes to SaaS-based application sourcing.

Linking the results of our empirical study to prior research, environmental uncertainty turns out to be the main deterrent of outsourcing on-demand IT applications as was also found out by Aubert et al. (2004). Most apparently, business and technical uncertainties still hinder IT executives and managers to take advantage of on-demand outsourcing options. Although asset specificity showed mixed results in its impact on the level of IT outsourcing in previous research, we found strong evidence that it can explain the level of IT outsourcing in the case of SaaS. This is also illustrated by our descriptive results on SaaS-based sourcing on the application level. While application systems, which supposedly have a lower degree of specificity in the sense that they are easier to transfer from one to another application context (such as CRM applications), show higher degrees of adoption, highly specific application systems (such as Operations & Manufacturing or Engineering applications) indicate very low adoption levels. Usage frequency as factor for SaaS-based sourcing showed inconsistent results. Obviously, the degree of interaction complexity and coordination intensity plays a more important role in the outsourcing decision for SMBs than for enterprises. This may be due to the fact that such organizational efforts attached to an outsourcing relationship engender a comparatively higher resource burden for SMBs than for enterprises. Overall, companies seem to be eager to acquire SaaS for applications that are not mission critical, involve relatively low data security and privacy concerns, and require little integration with on-premise applications. However, they still seem to be sceptical in application areas that involve transactions that are tied to mission critical processes including production and ERP and transactions between buyers and suppliers including ERP and logistics. Software vendors that shift from a traditional licensed model to SaaS will have to track the receptiveness of customers to the service delivery model in order to understand which applications will migrate when and position one’s own offerings early in the uptake.

Finding 2: While application specificity plays the strongest role in the adoption of SaaS-based applications in large enterprises, environmental uncertainty is the strongest factor for SaaS-based outsourcing in small- to mid-sized businesses.

As illustrated in Figure 3 with the comparison between the path models of SMBs and enterprises, the weights of the paths from application specificity and environmental uncertainty to SaaS-based
outsourcing are reversed in their magnitude in dependence of organizational size. Here it can be argued that uncertainty is a stronger driver or barrier in the SMB decision to outsource compared to application specificity and usage frequency. Before a SMB is ready to make a positive outsourcing decision, it wants to feel ensured that future changes in prices, processes, and technical issues are safeguarded through specific (e.g., contractual, reputational) mechanisms so that it is not worse off than before. This reasoning is in line with prior studies where uncertainty and risk factors also played a major role in explaining IT outsourcing (e.g., Aubert et al., 2004; Clemons & Row, 1992). By contrast, large enterprises are rather hindered to outsource by the idiosyncrasies and intricacies of their IT landscape. Large firms tend to have more fragmented IT legacy systems built over a long period of time, which is often further complicated by complex business processes. For that reason, application specificity may play even a more important decision factor in enterprises than in SMBs when it comes to carving out IT applications in the wake of a positive IT outsourcing decision. These results have several important implications for management. On the one side, IT managers of SMBs evaluating the adoption of SaaS-based sourcing models should concentrate on clarifying and safeguarding for potential sources of business and technology uncertainty. Integrating these aspects into contractual modalities (e.g., into the price model or SLA specifications) could be an important step for the success of the entire outsourcing deal. On the other hand, IT managers of larger enterprises should rather focus on addressing the ease or difficulties of integrating application system services delivered by SaaS-application providers into processes and the IT landscape of the outsourcer. An in-depth assessment of the application portfolio for its level of application specificity would therefore be a valuable preparatory step for actual outsourcing evaluations and negotiations. On the other side, SaaS-application providers should develop and establish authentic trust-building mechanisms to reduce outsourcers’ perceived uncertainty. Moreover, they should build up necessary skills and capabilities to help integrate their SaaS-based offerings into the outsourcers’ process and IT landscape.

**Finding 3**: Firm size is significantly and negatively associated with SaaS-based sourcing within, but not across the subgroups of SMBs and large enterprises.

In terms of firm size as a factor influencing the level of SaaS-based outsourcing, we could find that the organizational size had no significant impact in the overall sample. However, when analyzing the sub-samples for SMBs and larger enterprises individually, we could observe a consistent significant effect of firm size on SaaS-based sourcing. This means that within the SMB and enterprise sub-samples respectively, firms with a lower number of employees had a comparatively higher SaaS-adoption rate than firms with a higher number of employees. These results are not entirely in sync with the proposition made by Kern et al. (2002a) that smaller and medium-sized firms are generally more prone to adopt on-demand outsourcing options. Our research findings rather point to a more sophisticated picture which shows that effects emanating from the sub-group level cancel out each other on the full sample level. This phenomenon may suggest the existence of moderator variables which intervene in the relationship between organizational size and SaaS-based outsourcing. Our empirical findings also indicate that the absolute adoption levels in 2007 and 2010 are comparatively lower for enterprises than for SMBs indicating that smaller and mid-sized firm tend to take advantage of flexible software sourcing models more strongly than corporations. However, according to our descriptive analysis, the gap between the SaaS adoption levels in SMBs and in enterprises will not widen but narrow in the future. These results add to the findings above that, against the predictions of many IT providers, SaaS-based sourcing is not only a valid option for SMBs, but also for larger corporations.

### 6.2 Limitations and Future Research

As with any research, this study does have some limitations. First, since our dataset is cross-sectional in nature, we can only show associations, not causality. Furthermore, assessing estimated adoption rates of SaaS-based sourcing models in 2010 is an insufficient proxy for studying longitudinal processes which could probably uncover time preferences in the adoption behavior of companies.
Second, although this study included 6 different countries and industries with consistent results, the low sample size in specific categories did not allow us to apply inferential statistics to explore the differences and commonalities between different countries, industries, and application types. Third, the investigation of SaaS-based outsourcing on the application level turned out to be a relevant and appropriate approach to gain concrete insights into different application markets. Focusing on a small set of special IT applications would foster an even more thorough understanding in selected areas of SaaS-based application sourcing. Accordingly, future research directions are to increase the sample size in the abovementioned categories and to extend our study database over time to pave the way for a longitudinal study. With regard to our theoretical framework and empirical findings, we can derive three further recommendations for future research. First, extending our transaction cost theoretical framework by other theories (e.g., incomplete contracts or property rights theory) would add further insights into the drivers and barriers of on-demand outsourcing. Second, deepening the notions of application specificity and environmental uncertainty as important drivers of SaaS-adoption would add more insights for researchers as well as practitioners. Last but not least, digging deeper into the relationship between firm size and SaaS-based sourcing would uncover more clearly what moderator variables intervene in the relationship between organizational size and SaaS-based sourcing.

Abstract

Performance is a function of the alignment between information systems (IS) strategy and other business domains, including business strategy and organization structure. However, research has focused on the outcomes of that process, rather than the processes by which that alignment is developed. Using multiple case data, this paper investigates alignment in SMEs, explaining why different SMEs follow different paths to alignment. Four paths are identified, with the path chosen contingent on an SME’s market position. The four paths vary from simple, when the focus of the IS investment is on improving control, to complex, when the intent is to reposition the SME. The implications of these findings for management and research are explored.

Keywords: Alignment, small firms, paths, fit, SMEs.
1 INTRODUCTION

Information systems (IS) can automate to reduce costs and improve operational efficiency or IS may be adopted to informate and add value. Most small and medium-sized enterprises (SMEs) begin by automating, with some then seeking differentiation and using IS to add value. To achieve the latter, SMEs need an IS strategy that is aligned to their business strategy. However, for many firms, and particularly for SMEs, IS strategy is reactive to business pressures and the potential advantages of using IS strategically are often not considered.

While there is general agreement about the benefits of alignment, the process of aligning IS strategy with business strategy is problematic for many organizations (Avison et al 2004). In part, this is because little is known about the change processes in large organizations that lead to alignment (Sabherwal and Chan 2001, Smaczny 2001) and even less is known about the equivalent change processes for SMEs. Instead, research has focused on the characteristics of alignment, rather than on the process of aligning. In contrast, this paper investigates the different paths to alignment followed by SMEs. The paper begins by integrating the MIT90s model and the Focus-Dominance model (Levy and Powell 1997). The analysis shows that the alignment paths followed by SMEs are context-contingent.

The data analysis reports both qualitative and quantitative findings. Case descriptions illustrate the different paths to alignment in each of the four quadrants of the Focus-Dominance model. Quantitative analysis shows that the frequency with which those different paths are followed is context-contingent. The paths vary from simple, limited to a relationship between technology and management processes, to complex, involving changes in all five components of the MIT90s model. The reasons for adopting the different paths are discussed. The paper concludes with the implications for management and research.

2 LITERATURE REVIEW

Alignment is the process of developing fit among the key internal activities within an organization and between that internal fit and the external context and it enables firms to be competitive (Porter, 1987; Ciborra, 1997). Alignment, also termed fit, integration, bridge, harmony, fusion and linkage, enables IT investment returns to be maximised. The importance of strategic alignment has been discussed for the last 20 years (Earl, 1996). Yet, it remains a key concern (Luftman et al, 1996) and is consistently ranked among the most important issues faced by IT executives (Papp 2001, Tallon and Kraemer, 2003). A number of models of strategic alignment have been proposed. The two that have attracted most attention from researchers are the MIT90s model (Scott Morton, 1991) and the Strategic Alignment Model (Henderson and Venkatraman 1989). The MIT90s model argues that a successful organization has a high fit among its strategy, structure, roles and skills, management processes and technology, and between that configuration and its business environment.

More specifically, alignment in the MIT90s model is achieving synergy between strategy, structure, management processes, technology, and roles and skills, in order to sustain the quality of ‘interdependence’ and thus to achieve competitive advantage (Avison et al 2004, Hsiao and Ormerod 1998). Initially, it was assumed, at least implicitly, that there is only one transition path from one state of alignment to another. This is the ‘classic’ route of a change in strategy, followed by changes to structure, to which management processes, roles and skills, and technology are then aligned (Scott Morton 1991).

There is limited research on the process of aligning IS strategy and other business domains, including business strategy and structure. To examine this process or path to alignment, consider the following two studies. One analyses the experience of Flower and Samios, a small architecture firm (Yetton et al. 1994). The other analyses four cases in large organisations (Hsiao and Ormond 1998). Both use the
MIT 90s model to define the different paths to alignment. Together, they identify five different paths. The different paths start with different elements of the MIT90s model and move through the other four elements via a variety of routes. For example, Hsiao and Ormerod (1998) find two planned paths emphasizing the centrality of strategy – structural reconfiguration and process engineering, while the other two emergent paths – human renewal and IT transformation - lead with individuals and technology respectively. Yetton et al (1994) demonstrate three paths through the alignment elements.

The presence of different paths suggests that the choice of a path is context contingent. Consistent with this conclusion, Levy et al. (2001) show that the choices among different IS applications by SMEs are a function of their location in the Focus-Dominance model. Inspecting the different IS applications, some are adopted to implement a new strategy, some could not be implemented within the existing functional structures and some would require different competences to leverage them effectively.

The potential existence of multiple paths to alignment motivated the general question guiding this research: Are paths to alignment for SMEs context-contingent? This research begins to address the general observation that the process of alignment needs to be better understood (Sabherwal and Chan 2001, Smaczny 2001). Indeed, Cragg et al. (2002) report that many SMEs ‘have developed a high degree of alignment but we don’t know how that was achieved.’

Successful SMEs plan their growth and the systems required to support that growth (Salmeron and Bueno 2006, Street and Meister 2004). This planning is particularly important for mature SMEs, with owner-manager interest and enthusiasm being the prime driver of both the IS investment and its adoption (Premkumar and Roberts 1994). Whatever the motivation, SMEs invest incrementally in IS due to resource constraints (Levy and Powell 2005). Importantly, this incremental nature of IS investment allows mapping of the paths SMEs follow as a sequence of steps through the MIT90s model to implement that investment. Framed in this way, a path defines the sequence in which components in the MIT90s model are re-aligned. In the extreme, a new desktop environment might be purchased without any other changes. Assuming an SME is in alignment before the change, it would be in alignment after that change. This raises the interesting possibility of sub-paths to alignment in the MIT90s model, with the complexity of paths varying from simple (one or two components) to complex (all components) being re-aligned. The literature on alignment has implicitly, if not explicitly, focused on complex re-alignment. This paper shows that this assumption is inappropriate for the analysis of SMEs.

The Focus-Dominance model, in which two dimensions - the strategic focus on cost or value-add, and the level of customer dominance - defines an SME’s strategic market position, creating four scenarios in Figure 1 for IS investment: Control, Co-ordination, Collaboration and Positioning (Brown and Lockett 2004, Levy et al 2001, 2002, 2003).

*Figure 1. Focus-Dominance Model for SMEs (Adapted from Levy et al. 2001)*
Control: The focus of IS use in this quadrant is control. IS investment is treated as a cost of doing business, specifically, controlling the internal processes. These are operations-focused organisations in which IS has limited business value (Tallon et al 2000). Typically, their IS includes word-processing and accounting spreadsheets to control business expenses and revenues. Changes in structure are not required to achieve alignment because the new systems are implemented within the existing functional structure. In addition, the absence of any link to strategy is consistent with their internal operational focus (Tallon et al 2000). This behaviour is appropriate for SMEs, whose owners are not interested in growth and, instead, are specifically concerned with retaining control. The IS are simple, stand-alone and user-friendly. Thus, there is no requirement for changes in roles and skills, with the alignment process limited to changes in IS to support the new management processes (Quadrant 1 of Figure 2).

Co-ordination: IS investment is used to support communication and customer relationships. Owners are frequently interested in growth. They invest in IS to manage their customer base, when the number of customers exceeds the capacity of their manual systems. The new customer databases are typically supported by a local area network (LAN). Similar to the Control quadrant, the focus is still internal with no link to, or change in, the SME’s strategy. In addition, no changes to the individual roles and skills component are required. There are two reasons for this. One is that the systems adopted are not technically demanding (Levy et al. 2001). The other is that the IS knowledge of the owner, rather than the employees’ skills, is the driver of IS adoption (Premkumar and Roberts 1994). Thus, the dominant path is likely to be from management processes to technology to structure. To follow this path requires only limited restructuring to realise the benefits, with structural change supporting IS management (Bergeron et al 2001). This restricted path is presented in Quadrant 2 of Figure 2.

Figure 2. Focus-Dominance Model and Contingent Paths to Alignment
Collaboration: SMEs exchange real-time information with a small number of large customers. There is extensive use of EDI, with the SMEs often part of a customer’s Extranet (Levy et al. 2001). Customers are frequently the driving force behind the introduction of new IS. The proposed path to alignment is shown in Figure 2 with strategy driving technology, followed by management processes to support inter-organizational collaboration. This aligns an SME’s strategic information system, defined as the alignment between strategy, management processes and IS (Chatfield and Yetton 2000), with its customer’s strategic IS. The investment is managed within the existing structure and implemented without changes to roles and skills.

Positioning: SMEs integrate their IS and business strategies taking a dual internal and external perspective for the business (Tallon et al 2000). The owners are aware of IS-based opportunities for changes in business processes. The challenges here are the potential cost of the IS investment and the need for flexibility to support on-going change. Owners, who are both knowledgeable about IS and able to integrate it with the business strategy, are rare. These ‘dual focused’ SMEs focus simultaneously on operational efficiency and strategic positioning to improve performance through new market creation (Tallon et al 2000). Essentially, the path is strategy-led and enabled by new technologies (Croteau and Bergeron 2001). Bergeron et al. (2001) report a high correlation between strategic orientation and strategic IS. This relationship is supported by new management processes, to which roles and skills, and structure are aligned to position or re-position the SME. The suggested alignment path in this quadrant (Quadrant 4 of Figure 2) is more complex than in the other quadrants.

The above discussion examines paths to strategic alignment through the MIT’90s model, which are contingent on SMEs’ positions in the Focus-Dominance model. With different IS applications typically adopted in each quadrant of Figure 1 (Levy et al. 2001), the subject of this research is the different paths by which those applications are implemented and become embedded in SMEs. Formally, integrating the four paths identified in Figure 2:

Hypothesis 1: When investing in IS, the paths to alignment followed by SMEs are contingent on their strategic positioning in the Focus-Dominance model.

3 METHOD

This research reports both qualitative and quantitative analysis. The qualitative analysis investigates the paths to alignment followed by 27 SMEs. The quantitative analysis formally tests Hypothesis 1. As Lee (1991) argues, an integrated framework that includes interpretive and positivist approaches can provide robust understanding of phenomena. Lee proposes that observation of a situation can lead to an initial understanding that is then interpreted by the researcher based on their knowledge of the field. Finally, the research creates formal propositions that can be tested using positivist constructs. The outcomes from the propositions should then be reviewed in the empirical situation (Lee 1991).

Case studies are a powerful methodology for conducting the type of exploratory research proposed here. In particular, case research is effective when theory is relatively underdeveloped (Eisenhardt 1989). In general, this is true for research on the dynamics of alignment. Further, when the boundaries of the research are not clear, there is a need to investigate the issue within a real life context, collecting views from different sources (Yin 1994). However, while cases can be used to investigate a situation, generalisations based on one or two case studies are subject to a potential external validity threat. The multiple cases collected here ensure that common patterns are identified rather than risking generalisation from chance occurrences based on a single case (Eisenhardt 1989), with formal modelling to validate the patterns (Lee 1991).

Each case study was conducted over a one week period by a team of researchers and postgraduates, following the protocols developed by Levy et al. (2000, 2001, 2002). The organizations were not selected by industry, as there is little difference in SMEs’ strategic IS adoption across industries (Levy and Powell 2000). During the survey period, the SME owner, the senior management team and other employees took part in a series of standardized, semi-structured interviews, each lasting 1-2 hours.
The interviews cover the history of IS developments, business backgrounds, markets, and future plans for IS adoption. Pertinent issues are reported back to participants to allow them to correct misunderstandings, validate the findings and stimulate further discussion. The interview data identifying the choice of strategy, together with the number and importance of customers, classifies each SME’s strategic focus as cost reduction or value adding, and its customer dominance as high or low. Based on this data, each SME is classified within the Focus-Dominance model. The numbers of SMEs in each quadrant is shown in Table 1.

Table 1. Numbers of case studies in each quadrant of the Focus-Dominance Model

Having located each SME in the Focus-Dominance model, the next step identifies the alignment path. The changes the owners had put in place to implement each IS investment are used to map the paths taken. The interviews identify the nature of the IS, and changes in both the management processes, and IS-based training and recruitment. Changes in organizational structures are identified from organization charts, and the owners’ and senior managers’ descriptions of, and reasons for, structural change. Finally, a case description of each SME is written. Two of the authors inspected the sequence of steps defining the alignment paths followed by the SMEs. Based on that data, they independently coded the path followed by each SME. The two coders agreed on the classification of each SME’s path, demonstrating high inter-rater reliability.

The final step in the data analysis is what Lee (1991) calls third level understanding, where positivist, formal propositions are tested. To test Hypothesis 1, the frequency of agreement between the observed and expected paths to alignment for each SME is compared to the expected frequency under the null hypothesis that paths to alignment are not context contingent. If the four paths identified in Figure 2 are assumed to be both exhaustive (i.e. there are no other paths) and equally likely, then the critical value for the frequency of agreement, \( \theta \), would be \( \theta_c = 0.25 \). This would be a conservative test, given that there are many different potential paths through the MIT90s model. For example, there are 120 different potential five-step paths (Yetton et al. 1994).

In addition, the data in Table 1 suggests that the distribution of SMEs is not random across the four quadrants. Inspecting Table 1, the null hypothesis would be supported for 11/27 cases, when investing in IS, if the expected, non-contingent, path for all SMEs was specified as the path to alignment presented in the Control quadrant of Figure 4. So, \( \theta_c = 11/27 \), where that is the frequency of the most commonly adopted path, namely, management processes followed by technology, is adopted as the critical value to test Hypothesis 1 in the Results section below. This is a very conservative and demanding criterion – the probability that an SME adopts the path to alignment shown in Figure 2 for its location in the Focus-Dominance model must be greater than 40.7%.

4 RESULTS

The expected alignment path for each quadrant in the Focus-Dominance model is presented in Figure 2. The SMEs in the Control quadrant are characterised by a dominant path from management processes to technology adoption. This pattern accounts for 10 of the 11 cases here. The exception is Bird Designs, which needed to upgrade its staff skills to leverage its use of the new IS-based accounting systems. Therefore, its path included a link from management processes to roles and skills.

Chemical Analysis Co. illustrates the path to alignment followed in the Control quadrant. It followed the simple alignment path of management processes to technology. A small, family-run firm that
analyses soil samples for local authorities and utility industries, it was established by the owner in 1983, and grew steadily for 10 years. Growth then declined and it entered a steady state. The market is highly competitive. The owner invested in IS to reduce demands on senior management time, implementing a spreadsheet package for financial analysis, supported by a stand-alone accounting package. A specialist package was added to develop chemical analysis reports. The adoption of technology was reactive, focused on improving control over individual functions.

The dominant path in the Co-ordination quadrant in Figure 2 is management processes to technology, followed by changes in organization structure. This pattern explains seven of the eight cases in this quadrant. The exception is Regional Travel in which there is no link to structure: Its path is consistent with the dominant path in the Control quadrant in Figure 2. Regional Travel had not recognized the benefits from restructuring its informal approach to managing the organization.

Queensway Photographic Designers illustrates the path to alignment followed in the Co-ordination quadrant. It specializes in the development of large-scale photography for window and conference displays. The CEO owns the firm and is supported by a small management team. The firm works in a specialist niche, large-scale photographic printing, although it provides a wide range of photographic services. He has invested in technology to support that market niche, including a small administrative network, deploying accounting, word processing and order processing systems. For example, job costing was automated, using prior experience to quote prices. Job tracking was also implemented, with the system providing job progress information for customers. The owner is only planning sufficient growth to facilitate the sale of the business when he retires.

The complexity of or number of steps in the alignment path in the Collaboration quadrant is the same as for Co-ordination, but the path takes a different form. All cases here follow the dominant path, led by strategy, and followed by changes first in technology and then in management processes. Critical drivers include changes in major customers’ procurement, production and quality control systems.

Car Sign Design Co. (CSD) illustrates the path followed in the Collaboration quadrant. The owner established CSD in 1990 to produce graphic design liveries and signs, specializing in the automotive market. The firm employs 15 staff, with a plan to increase turnover 25% in 5 years. While only 10% of customers are in the automotive sector, they account for 80% of turnover. CSD works closely with major customers to ensure that orders are maintained in this highly competitive industry. The firm competes on quality and design innovation to develop and maintain the relationships. To do that, it has invested heavily in design and production technologies. CSD recognized early the value of the Internet to improve its competitive advantage by developing customer relationship management, particularly for the exchange of design information. New management processes were then developed to integrate order processing, accounts, design, production and delivery. CSD is now able to turn around design information quickly, with the new business processes supporting on-time order delivery.

Finally, the Positioning quadrant in Figure 2 identifies the need to align all five components of the MIT90s framework. In the three cases here, owner knowledge about opportunities from IS and the potential to exploit them is the key driver of strategic alignment. All three SMEs adopted the same path, beginning with their strategic objectives influencing their IS technology adoption, followed by changes in management processes and, finally, changes in roles and skills, and structure.

Mobile Phone Surveyors illustrates this path. The owner and CEO recognized early the potential growth in the mobile phone market. He positioned his firm to survey sites for the major mobile providers, developing a niche market that involves both negotiating with local authorities and recognising the public’s concerns over mobile phone masts. He and his team of surveyors have developed a specialised body of knowledge about the acceptability and viability of phone mast locations in the UK and overseas. His decision to adopt a knowledge management system to provide a repository for the surveyors’ knowledge was explicitly designed to support growth. Management processes were then implemented to co-ordinate and exploit that knowledge management resource. This was followed by changes to the organizational structure to support staff working as a team rather
than as individuals. At the same time, the owner recognized that he needed to train or recruit staff to use the new systems.

Aggregating across the four quadrants, 25 SMEs adopted the alignment path specified in Figure 2 for an SME in their strategic market position. Only two SMEs followed other paths. Hypothesis 1, *when investing in IS, the paths to alignment followed by SMEs are contingent on their strategic market positioning in the Focus-Dominance model*, is strongly supported. Table 2 reports that the probability of adopting the expected contingent paths, $\theta = 0.92$ or 92%, is significantly higher than expected under the null hypothesis that the alignment path is non-contingent, $\theta_c = 0.41$, ($\theta > \theta_c$, $p \leq 0.01$).

Table 2. Alignment Paths and Strategic Market Position

5 DISCUSSION

This discussion is organised under four headings. First, the findings are summarized. The relationships among the four alignment paths presented in Figure 2 can be illustrated by overlaying the Focus-Dominance classification upon the MIT90s model. Figure 3 highlights how the different paths to alignment involve different sub-parts of the MIT90s model. This supports Hypothesis 1 that the dynamics of IS alignment are contingent on an SME’s strategic market positioning. Second, the validity threats to the findings reported above are then examined. Third, the implications for research are explored, integrating the extant literature within the contingent model developed here. Finally, the implications of those findings for practice are reviewed.

![Figure 3. Understanding SME Classification through the MIT90s Model](image)

5.1 Findings

Figure 3 shows how the four paths relate both to each other and to the MIT 90s model. At the centre of the model is the basic relationship between management processes and technology to embed the IS investment in the SME. This is a control sub-model within the MIT 90s model. To also capture the benefits from increased co-ordination requires a more complex response by SMEs. Specifically, structural readjustment is required to manage the increased complexity.
Collaboration raises a different challenge. Here, there is a change from a cost- to a value add-based strategy. The control sub-model is developed into a strategic information systems sub-model, in which changes in strategy drive changes in both technology and management processes, and in the relationship between them. Finally, positioning requires changes in all the components of the MIT 90s model. The three sub-models are integrated with up-graded roles and skills. To implement alignment, the existing core competences of the SME would need to be significantly enhanced and new ones developed. This would be a major and high risk strategic change, for which many SMEs and their CEOs would not have the necessary skills and resources.

5.2 Validity Threats

The results are subject to four validity threats. The first threat concerns the representativeness of this sample of SMEs. The sample is not random. Potentially, it over-samples SMEs that are successful, and whose owners are engaged and knowledgeable managers, willing to be involved in a university-based research programme. This bias could affect both the relative numbers of observations across the four quadrants in Table 2 and the frequency with which SMEs select specific paths to alignment.

While a bias in the relative frequency of observations between quadrants is not a threat to the findings supporting Hypothesis 1, a bias in the frequencies with which paths are selected within a quadrant is a potential validity threat. It is reasonable to assume that the SMEs here are both more sophisticated and successful than randomly selected SMEs. In that case, the dominant paths identified above may be less frequently adopted by the typical SME and the findings may be subject to a potential validity threat.

The second validity threat concerns the scoring protocols for identifying the paths to alignment. Two of the authors coded the paths with 100% agreement. A potential validity threat exists as they were aware of the theory being tested, could have been aware of an SME’s location and, therefore, coded that SME’s path to be consistent with the theory. Against this potential threat, first, recall that the authors were coding the paths based on written case reports developed by teams involving others during a 1 week field study of an SME, including interviews with all its senior managers. There is substantial direct information on changes in components and, hence, the paths to re-alignment. Second, issues such as the timing of a restructure or of the acquisition of new technology are not typically subject to interpretation. Similarly, changes in management processes are well documented. However, managers’ descriptions of the timing of changes in roles and skills, and strategy may be open to interpretation.

The third threat is a potential internal validity threat, involving an alternative interpretation of Figure 3. Avison et al. (2004) show that a single large organization followed different paths to alignment for the different IS projects it implemented. Here, this suggests a more complex interpretation of Figure 3. SMEs in the Positioning quadrant could also follow a Co-ordination quadrant path to alignment when investing in IS to manage their customers more effectively. However, SMEs in the Co-ordination quadrant would not invest in Positioning interventions unless they moved to the Positioning quadrant. Similarly, SMEs in the Co-ordination and Collaboration quadrants could follow a Control quadrant path to alignment when investing in IS to improve their internal controls. Essentially, Figure 3 could be interpreted as presenting a hierarchy of paths to alignment, with SMEs in the Positioning quadrant able to follow the other paths as required, and SMEs in the Collaboration and Co-ordination quadrants able to also follow the path in the Control quadrant. This should be the subject of future research.

Finally, the paths identified in Figure 2 are not exhaustive. They do not include the path followed by Flower and Samios (Yetten et al. 1994). That path is technology, followed by roles and skills, structure, management processes and, finally, strategy. This was an emergent, rather than a formally designed path, and maybe infrequently used. Its potential existence does not invalidate the basic hypothesis tested here that the path adopted is contingent on an SME’s position in the Focus-Dominance model. Instead, it implies that an SME’s location in a quadrant does not uniquely define
the path adopted in that quadrant. However, there may only be an emergent and a formal path within the Positioning quadrant, with the paths in the other three uniquely determined.

5.3 Implications for Theory and Practice

Integrating this paper and earlier studies extends understanding of the contingent nature of an SME’s investment in and use of IS, and of the effect of its market position on its management of IS. It also provides guidelines for managers by describing the dominant path to alignment in each quadrant.

In terms of theory, the contingent model developed here allows re-interpretation and integration of the following three sets of findings, which initially appear to be inconsistent. First, benefit realisation depends on alignment between IS and business strategies (Hussin et al. 2002). Second, IS investment is frequently limited to supporting operations and transactions (Foong 1999). Third, organizations with more sophisticated IS tend to perform less successfully than those with less complex systems (Naylor and Williams 1994); the greatest alignment and highest performance are reported for systems to improve efficiency (King et al. 2000); and those that adopt a low-cost approach are unlikely to use IS strategically (Lesjak and Lynn 2000).

Twenty five of the 27 SMEs follow the expected paths to alignment in their quadrants and, therefore, potentially capture the benefits of alignment. However, for SMEs in the Control and Co-ordination quadrants, alignment between IS and business strategy is independent of their paths to alignment in Figures 2 and 3. These null relationships are not included in the typical models (Hussin et al 2002, Spanos et al. 2002) described in the SME literature.

Consistent with the literature (Foong 1999), IS investment is limited to operations and transactions for the 19 SMEs in the Control and Co-ordination quadrants. Also, these SMEs adopt a low-cost strategy, with the relationships between their IS and business strategies unchanged (Lesjak and Lynn. 2000). Finally, given that the complexity of the paths to alignment increases substantially from the Control to the Positioning quadrant, the greatest alignment and highest performance is likely to be achieved by SMEs in the former rather than the latter quadrant. So, findings, which appear on first inspection to be inconsistent, are consistent when integrated within the contingent model developed here.

The patterns in Figures 2 and 3 may also explain Cragg et al.’s (2002) finding that alignment is achieved by many SMEs but is not well understood. It is not well understood because SMEs do not follow the classic path to alignment. Instead, they frequently follow the much less complex paths to alignment in the Control and Co-ordination quadrants. These require only limited change management skills. For those SMEs, the path to alignment is not problematic and, therefore, is frequently realised but not recognised in the literature.

The different paths identify different levels of interventions to achieve re-alignment. It follows that SMEs in different quadrants require different levels of skill in change management to realise the benefits from completing their paths to alignment. However, only in the positioning quadrant is the path to re-alignment likely to prove a challenge to SME management. So, many SMEs are in alignment and capture the related benefits.

In contrast, the literature on large organizations’ IS use focuses on value-adding strategies and the repositioning challenge in the positioning quadrant. This raises the question of whether research on large organizations is limited in scope, and whether it should be extended to investigate organizations investing in IS to support existing management processes rather than focusing almost exclusively on the problems of strategic repositioning.

Turning to practice, Figure 3 documents the path to alignment for each quadrant. The appropriate intervention in the Control quadrant is shallow (See table 2), requiring limited changes in technology and management processes. In contrast, the intervention in the Positioning quadrant is deep, requiring significant change management skills and influencing all factors in the MIT90s model. Therefore, the risk to organization performance is low in the former and high in the latter quadrant.
Finally, few SMEs have the motivation and/or capacity to introduce the integrated systems needed to support IS-based innovation, even though strategic use of IS has become more important in flexible and dynamic markets. Improvisation is one way to respond to challenges in which the innovative use of resources, including IS, is critical (Ciborra 1997). However, while SMEs are typically assumed to be flexible and innovative, their use of IS is relatively inflexible (Levy and Powell 1997), with IS typically used as a means of support. Consistent with this, the dominant use of IS, in 19 of the 27 SME cases, is to support existing management processes.

6 CONCLUSIONS

While it is generally accepted that alignment is a critical enabler of organization performance, there is limited research into the actions or paths by which alignment is achieved. The research that does exist relates almost exclusively to large organizations. This paper adds to the limited literature on SMEs and their paths to alignment and, specifically, it maps the paths to alignment of 27 SMEs. It is hypothesized that the dominant path to alignment is a function of an SME’s market position in the Focus-Dominance model. Nineteen of the SMEs follow paths that are restricted to links among management processes, technology and structure in the MIT90s model. Five of the SMEs work closely with their major customers, whose IS systems strongly influence the SMEs’ IS options. Finally, only three SMEs follow paths to strategic repositioning, the focus of much of the IS alignment research in large organizations. This last finding suggests that either IS strategic choices have more limited impacts on SMEs than on large organizations, or that research on alignment in large organizations should consider other alignment mechanisms, including the less complex interventions identified in Figure 2 for the Control, Co-ordination and Collaboration quadrants versus the Positioning quadrant.

Abstract

Innovations are important for the development of firms and whole economies. Several theoretic approaches are therefore dealing with innovation and the motivation of firms to motivate. The Resource-based View of the Firm views innovations to be motivated by the use of slack resources while the Behavioral Theory of the Firm predicts problemistic search as an important motivation for innovative maneuvers. Recently, Pitelis proposes an integration of both theories to better explaining the motivation for innovation. This paper empirically tests the predictions from these theories using multiple case studies among small and medium enterprises. The results show that firms’ motivation to innovate is best explained using a combination of both theories.

Keywords: Slack Resources, Problemistic Search, Innovation.
1 INTRODUCTION

Innovations are an important driving force for the prosperity of economies and firms alike. Rapid technological change, increasing globalization, and shorter product cycles render the ability to innovate crucial for firms competing at the global marketplace. Therefore, lots of studies are engaged in innovation research for many years. Within this strand of research, several seminal contributions found problemistic search and use of slack resources as basic motivations for innovations.

The Austrian School of Economics (Schumpeter 1934) provides the central idea of the exploitation of opportunities by creating and adopting innovations that make a competitor’s position obsolete. Superior firm performance, in turn, can only be achieved by continuous innovation. Building on that, the Resource-based view of the firm (RBV) (Penrose 1959) proposes the achievement of a sustained competitive advantage by employing novel services of resources controlled by a firm. Thus using organizational slack to innovate and employing novel services of resources is a key consideration of the RBV. In contrast, the behavioral theory of the firm (BTF) (Cyert & March 1992) is engaged in innovations and focuses on problemistic search as the driving force behind the creation of innovative solutions.

Pitelis (2007) in a recent article discusses the approaches of the RBV and the BTF in terms of their assumptions and predictions regarding the motivation for innovation and the followed-up search strategies for innovation. RBV and BTF provide quite different explanations for innovations while Pitelis proposes an integration of both theories. He calls for the test of the theoretical predictions, among others, with case studies to provide more insights. We follow this call and ask the following research question:

- How to explain different search strategies for innovations and which theory or combination of theories best explains the emergence of innovations?

To address this question, we used case studies among small and medium-sized enterprises (SMEs) that are known as very innovative and successful in their markets.

The remainder of the paper is structured as follows: Section 2 deals with the theoretical foundation that is followed by section 3 explaining the used methodology. In section 4 the case study environment and the case study sample is described. Section 5 presents the case study results. Key findings, limitations, and future research are summarized and critically discussed within section 6.

2 THEORETICAL FOUNDATION

This section first introduces the Behavioral Theory of the Firm, then the Resource-based View and finally the derived propositions.

2.1 Behavioral theory of the firm (BTF)

The classic work of organizational theory, A Behavioral Theory of the Firm’ of Cyert and March (1992) aims to reveal the perception of the business firm being a so-called black box. They seek to provide insight within the internal processes of economic decision making of contemporary organizations as a unit faced with an ever-changing environment (Prietula & Watson 2000).

Cyert and March assume that search within organizations is mainly stimulated by a certain problem. Thus it is strongly related to their concept of problemistic search (Pitelis 2007). Problems are either identified by failure to achieve a certain goal or by the threat of failure in the upcoming future. As long as a specific problem is not solved, an organization will continue to search for a satisfying answer as the declared goal. Thus problemistic search is undertaken as long as the actual performance is below a certain aspiration level. This so-called negative attainment discrepancy induces problemistic search.
problematic search can be defined as search that is motivated by a
certain problem internal or external of an organization and aims at finding an appropriate solution. The
concept of problematic search implies that firms that have not been successful in the past generate
more innovations than more prosperous ones. This assumption could not be verified concerning
important technological improvements in particular. Therefore organizational slack resources were
included in the attempt to predict innovation decisions as these have proven to result in major
technological changes and are in many cases available in successful firms that do not suffer from
shortness (Cyert & March 1992, p. 189). Thus slack resources provide a source of excess funds
enabling search for innovations that would not be realized in times of shortness.

As a consequence the authors distinguish between two types of innovation. The problem-oriented
innovation, developed due to short-run problems and those that are designed to solve major
organizational problems on a long term basis out of slack resources. In conclusion, both, successful as
well as lesser successful firms are innovating (Cyert & March 1992, p. 189). In both cases
(problemistic search and slack search) the existence of a problem (i.e. performance below aspiration
level) is the engine that drives innovation. This is also indicated by the theoretical model forwarded by
Greve (2003a, p. 686) who puts “performance minus aspiration level” as explanans for problematic
search and in a “dotted line” connection also for slack search. The latter also points to the fact that
slack search was introduced into the BTF in a further step to better predict innovation decisions and as
such sometimes appears as sort of an exogenous variable that is not readily explained by the existence
of a problem. In contrast organizational slack is a central tenet of the RBV depicted in the following
section.

2.2 Resource-based view of the firm (RBV)

The starting point for RBV is the assumption of the heterogeneity of resource endowments across
firms that explain performance variations (Peteraf 1993). Thus, a firm’s competitive position results
from bundles of unique resources (Rumelt 1984) that are not perfectly mobile (Spanos & Lioukas
2001). The RBV, therefore, explains sustainable competitive advantage (SCA) by means of the
resources controlled by a firm. The firm itself is viewed as a collection of productive resources guided
by the administrative function (Penrose, 1959) required for market competition. These resource
bundles are found to be immobile, firm-specific, and are developed in a path-dependent way (Teece
1993). The growth of a firm depends on exploiting existing resources and developing new ones
(Penrose 1959; Wernerfelt 1984). “Resources are defined as those tangible (or intangible) assets that
are tied semi-permanently to the firm” (Spanos & Lioukas 2001, p. 909) where “the subdivision of
resources may proceed as far as is useful for the problem at hand” (Penrose 1959, p. 74).

Regarding the core concept “resource”, a basic idea of Penrose (1959, p. 67) is that the same resource
can render many different services. Although important, it is not the resource per se but its use in
productive processes that leads to eventual value. With subsequent operations knowledge of the
services a resource can render is accumulated. With this knowledge the exploitable opportunity set of
the firm is enhanced and excess resources can be put into different services (Penrose 1959). These
slack resources, then, enable innovation and even motivate its use for innovative purposes as long as
the management pursues profit maximization and excess resources can be put into service at no extra
cost (Pitelis 2007) which is a different engine driving innovation than depicted by the BTF.

2.3 Propositions

Pitelis (2007) in his effort to combine BTF and RBV identified several similarities as well as
differences between both theories. The BTF starts from the observation that intrafirm conflict is
paramount (Pitelis 2007, p. 478 f.). This leads to search activities to resolve the conflict. This
problemistic search, then, leads to the discovery and implementation of innovative solutions.
Therefore it can be hypothesized that relatively unsuccessful firms are more likely to innovate (Pitelis
Innovation takes place both in case of immediate problems to be solved and as a means to alleviate conflict in other cases (Pitelis 2007, p. 483). Therefore we formulate:

Proposition 1: Both intrafirm conflicts and the presence of immediate problems lead to innovations to resolve the problem or conflict, respectively.

In the RBV intrafirm conflict is not in focus, and innovations are enabled by slack resources through newly discovered and exploited services rendered possible by the resources of a firm (Penrose 1959). That points to the importance of intrafirm learning for the RBV. Through learning new uses of resources are discovered and exploited. Thus, in growing firms, excess resources are present leading to perennial search for innovation (Pitelis 2007, p. 483). In contrast BTF predicts the use of slack resources to solve major organizational problems on a long term basis (Cyert & March 1992, p. 189). Following the argumentation of Penrose and Pitelis we state:

Proposition 2: There is a continuous search for innovative solutions through learning new uses of resources.

The integrated view of Pitelis (2007, p. 479) “predicts excess resources/slack-motivated and problemistic search-induced innovation, depending, however, on moderating factors such as the immediacy of the problem faced, the degree of maturity of the line of business, and the firm’s productive opportunity”. Thus we formulate:

Proposition 3: Both problemistic search and continuous search for innovations can be observed simultaneously.

3 METHODOLOGY

One form of empirical studies is case studies which are suited for an in-depth investigation of a phenomenon and thus ask how- and why-questions (Yin 2003). In the following sections, case studies carried out among small and medium-sized enterprises (SME) are presented, focusing on the emergence of innovations. Case studies have to be prepared and carried out thoroughly in order to achieve the necessary rigor. During design and preparation it is important to make the research question, propositions and unit of analysis explicit (Yin 2003; Dubé & Paré 2003). The research question employed for this research is: How to explain different search strategies for innovations and which theory or combination of theories best explains the emergence of innovations? How and why questions are considered appropriate for case studies (Yin 2003). The propositions used in the cases are theoretically grounded as depicted in the previous section.

After the definition phase the case study partners were identified by using the assessment of the general managers of two local investment promotion agencies of the most innovative SMEs of their area of discretion of Heilbronn-Franconia. In order to carry out a case study we developed case and interview protocols, and discussed the approach within the research community prior to the actual interviews. Afterwards, the adapted documents are used for the case studies (Yin 2003; Eisenhardt 1989). After this preparation phase the contact phase was commenced. This phase started with calling the identified companies by phone to verify the contact information, to provide preliminary information regarding the objectives of the planned case studies, and to schedule an appointment.

After scheduling the meetings in each case two researchers visited the firm and performed the interviews. The procedure was as follows:

- The objective and the procedure of the case study were explained.
- The semi-structured questionnaire was applied to cover a wide variety of contextual variables.
- The interview was tape-recorded.
- Data was complemented by company reports and academic literature.
- Performing a wrap-up session among the researchers to summarize the essential items.
- Transcription of the tape-recorded interviews.
The interviews lasted in average two hours. The transcripts of the cases were compiled into a case protocol comprising 61,563 words in total. The unit of analysis is the firm, its resources and the approach towards innovation. Therefore the Chief Executive Officers of the firms were interviewed. To evaluate the transcribed interviews NVivo was applied. NVivo is software designed to support qualitative data analysis and simplifies rich text handling through facilitating sorting, arranging and classifying information. A main feature of the software that was utilized in the actual cases is the creation of specific categories, so-called tree nodes. NVivo allows to directly attributing phrases or paragraphs abstracted from the transcriptions to those nodes, following a certain rule for codification developed in advance. This functionality makes it easier to compare answers to specific questions across the case study partners and to trace back constructs and hypotheses to individual answers. After finishing the case studies a final presentation was created and both sent by e-mail to the contact partners and presented within a workshop.

In the following paragraph, the case studies presented are discussed in terms of the requirements of a positivist method. According to Yin (2003) construct validity can be improved by several tactics. The first is the use of multiple sources of evidence, which provides multiple measures for the same phenomenon. In our case studies we carried out interviews in five different firms using top manager as key informants who represent the firm and who’s perceptions can be assumed to be closely related to objective measures (Tallon & Kraemer 2007). In addition, we had access to several documents related to company background. Lastly, Yin recommends maintaining a chain of evidence. This was done by deriving constructs and hypotheses from literature, and employing NVivo which allows us to trace back from conclusions to initial research questions. Internal validity means that a relationship between two variables may be inferred as causal or not. To ensure internal validity, pattern matching may be used (Yin 2003), which involves qualitative but logical deduction (Lee 1989). In our case studies we compared the statements collected with propositions derived from literature in order to detect support or non-support for theoretical propositions. External validity means the generalizability of the findings. Case studies can be used to test a theory. A case study can confirm, challenge or extend a well-articulated theory and is similar to the use of an experiment, because one instance of both methods is sufficient to reject propositions (Lee 1989; Yin 2003). To support a theory several instances are needed. Reliability means the consistency and stability of the study across researchers and time. Yin proposes a case study protocol and a case study database to ensure reliability. A protocol is needed to guide the researcher in a standardized manner. In our case studies this protocol consisted of a proposal containing focus areas, research questions and propositions derived from literature. Furthermore, it consisted of a semi-structured questionnaire, and a set of slides covering research objective, motivation, research model, unit of analysis, and methodology. Besides the protocol, NVivo was used to cover the interview transcripts which allow easy checking for cross-references to other interviews.

4 CASE STUDY DESCRIPTION

4.1 Case study environment

In total we conducted five case studies with interviewees of small and medium-sized enterprises that operate within different classic industries (see Table 1). All five companies of the sample are located within the region of Heilbronn-Franconia, a part of Germany’s third biggest federal state Baden-Wuerttemberg down south. Heilbronn-Franconia measures 4,765 square kilometers and is home to about 900,000 inhabitants. Baden-Wuerttemberg as a whole hosts a well-diversified domestic industry, even though two emphases can be noticed measured by the number of employees: the process engineering sector and the automotive sector. SMEs dominate the overall corporate landscape. On average around 99 per cent of all companies within Baden-Wuerttemberg (and Heilbronn-Franconia as well) can be attributed to this category. SMEs generate about 40 per cent of the volume of sales and provide 50 per cent of the jobs within Baden-Wuerttemberg (Brenner 2008).
An extraordinary feature of Heilbronn-Franconia is a remarkable density of world niche market leading companies. In Kuenzelsau, a town with a population of about 15,000 people situated within the area, the highest concentration of this type of firms in relation to the number of inhabitants within Germany could be identified by a recent survey of a German manager magazine (WirtschaftsWoche, 2008, 19: 53-83). The largest town of the Heilbronn-Franconia district is Heilbronn with about 120,000 people living there. Although being rural and agrarian-oriented Heilbronn-Franconia features good transport connections as being part of the Stuttgart metropolitan area.

4.2 Case study sample

Table 1 summarizes some characteristics of the sampled firms. While TransDrive, InVitro and ProtoType were proposed interview partners of the local investment agency working within the wider Heilbronn area, SafeEx and TechDat were suggested by the agency responsible for the northern part of the region investigated. The managing directors of both agencies were asked to rank their selected firms based on their subjective impression on the innovativeness of the firms considered. Although TransDrive and SafeEx exceed the upper boundary for SMEs in terms of employees as defined by the European Union (i.e. 250), these firms are considered as SMEs by their CEOs because still operated in a family tradition with strong local roots. All figures relate to the headquarters of the firms investigated located within the region Heilbronn-Franconia.

5 CASE STUDY RESULTS

5.1 Problemistic search

“Problemistic search occurs as a response to an organizational problem” (Greve 2003b, p. 54) so that “an innovation is a solution that will be implemented if it is matched with an organizational problem” (Greve 2003b, p. 96) in both cases: immediate problems and intrafirm conflicts (Pitelis 2007).

Proposition 1 state that according to the BTF both intrafirm conflicts and the presence of immediate problems lead to innovations to resolve the problem. An example for immediate problems being a driver for a firm’s innovative activity is SafeEx, a provider for high-quality industrial safety technology for applications in explosion-hazardous areas. With Airbus as an important customer SafeEx strives to meet the special requirements of the aviation industry. When Airbus urgently needed to have a possibility to connect cables in a way that guarantees watertightness even at temperatures at
around minus 60 degree Celsius, the engineers of SafeEx managed to combine well-known materials and technologies in an entirely new way. The result was a cable connection system designed to meet the demands put on the material by the conditions occurring at maximum heights. The related quote from SafeEx is presented in Table 2. Additionally quotes of the managing directors of InVitro and ProtoType on proposition 1 are listed:

<table>

<td>External event: Customer request</td>
</tr>
<tr>
<td>InVitro</td>
<td>“Between the manager of R&amp;D and the operations manager an increased tension could be noticed. […] This got out of control leaving me highly dissatisfied. […] As a consequence we have redesigned the organization chart.”</td>
<td>Internal event: Intrafirm conflict</td>
</tr>
<tr>
<td>InVitro</td>
<td>“Sometimes we are forced by external suppliers. […] The electronics is already 10 years old and out-dated and we can’t buy it anymore. Because of that we have bought ahead enough components for our restage. […] And now we have to figure out if our product (= electronic pipette, the authors) needs to be up-dated.”</td>
<td>External event: Environmental change</td>
</tr>
<tr>
<td>ProtoType</td>
<td>“Pricing pressure has never been a driver of innovation. By experience I know that it’s different. […] you notice a question or a problem e.g. raised from production and then you reflect about a possible solution.”</td>
<td>Internal event: Problem detection</td>
</tr>
</tbody>
</table>

Table 2. Immediate Problems

The statements of our case study partners show, that an important driver of a firm’s innovative activity is the pressing need to search for solutions for internal and/or external problems. Being faced with a certain problem all forces are concentrated on turning a deficiency fastest possible into a benefit for the organization, it’s customers, and/or further stakeholders. We could detect four types of “immediate problems”.

(1) External event – customer request:
External problems can be formulated in the sense of a typically urgent customer-specific order that involves finding solutions for specific requirements. This is termed “customer project” and is an externally initiated impulse to search for innovation. It is categorized as an immediate problem because the formulation and acceptance of customer-specific orders almost always comprises a short timeline, because the customer presses to get e.g. the product as fast as possible. In particular, if the customer is an important one, failing to find a solution jeopardizes e.g. market shares and sales of a firm imposing a major problem.

(2) External event – environmental change:
Also externally stimulated are changes in the market or technological environment of the firm causing immediate problems to be solved. Typical examples are shortages in specific raw materials or components due to sudden increases of demand exceeding supply, technological progress rendering obsolete specific components that are no longer produced, technological progress pressuring for reorganize the implemented production technology, and market exit or severe production problems of key suppliers without having direct substitutes. In some cases, in particular regarding technological progress, the problem becomes an immediate one, because a firm did not react in time and now faces an immediate problem. All this requires immediate action to replace e.g. a certain technology by another within a short timeframe to not disrupt production.
(3) Internal event – conflict:
Internally stimulated are immediate problems caused by conflict situations. Similar to the statement regarding technological progress mentioned above, the situation might become critical because there was no appropriate reaction in time and then suddenly must be resolved. The conflict situation in our case was resolved by changing the organizational design which in contrast to the other cases described is not primarily directed towards the innovation of a product.

(4) Internal event – problem detection:
In some cases problems along the business process are detected by firm-internal stakeholders. These are immediate problems if they cause a disruption of the process and thus jeopardizing its outcome. In contrast to simply “repair” a situation by restoring it to the previous state and thus do not change anything, an innovation comes up if the immediate problem is resolved not by “repair” but by coming up with an alternative solution.

The motivation to innovate by resolving immediate problems in any of the above mentioned types of immediate problems is based on negative attainment discrepancy as described in section 2. Furthermore those problems are “immediate” in a sense that they will cause negative effects on performance if unresolved in time. Intrafirm conflict as stated by BTF is one type of immediate problems but not the only one, and externally as well as internally motivated events could be revealed.

5.2 Continuous search for innovation

Superior firm performance can be achieved by continuous search for innovation (Schumpeter 1934) that builds on using organizational slack to innovate by employing novel services of resources (Penrose 1959) through learning. This is expressed in proposition 2 (“There is a continuous search for innovative solutions through learning new uses of resources”). An example for proposition 2 is TechDat, a firm providing data base services for technical data for the automobile industry. One idea of TechDat was not just to check incoming invoices by an information system for the management of vehicle fleets, but to add additional functions to this already available system. Building on both the knowledge of the information system including possible extensions and on market knowledge already available, these additional functions were laid out to streamline the process of car maintenance by avoiding the print-out of different forms at each maintenance step, automatically listing recommended maintenance measures according to the specifics of the car, and to provide a report covering the complete maintenance process. Thus TechDat developed an online tool for managing all maintenance procedures of a fleet without any printing required. This includes the registration of a certain vehicle at a garage, plausibility checking according to the car’s manufacturer’s specifications as well as the approval. At the end of the process the fleet manager can generate a detailed report for a review if needed.
The following table depicts specific quotes from TechDat and other cases centering on the search for innovative uses and therefore referring to proposition 2:

<table>

<td>Internally initiated search for improvement</td>
</tr>
<tr>
<td>TransDrive</td>
<td>“We are already today thinking about what sort of products we could offer in about 10 to 15 years. These products are often beyond the scope of transmission systems.”</td>
<td>Internally initiated search for improvement</td>
</tr>
</tbody>
</table>

Table 3. Search for innovative uses

At first look the data collected from the cases revealed that most firms, independent from the specific industry, looked for new combinations of their resources in order to better serve their markets. However, reading the transcriptions thoroughly shows that this search for innovative uses was not always rigorously and formally applied. Rather the search for innovative uses was internally initiated and based on ideas derived from recognizing potential for optimization of current practices, for example.

Furthermore the observed innovations are all incremental in nature. Depending on the degree of newness and the pace innovations can be classified as either being incremental or as radical if achieving noticeable breakthroughs. Whilst the term incremental relates to only slight changes such as simple product improvements breakthrough innovations can be defined as novel and unique advancements that have the potency to substantially shift the patterns of a market or even create a new one (Zhou & Yim & Tse 2005). However, the innovations mentioned by the interview partners of the sampled companies were incremental in that the firms exploit their deep knowledge in certain technologies and markets to create improvements. This is close to Penrose’s assumption that novel services of already available resources are implemented and thus innovations are created.

All firms in the sample follow a long-term strategy of growth that favors benefits in the long run over short-term profits. This does not mean that short-term profits are not important but they do not play an outstanding and dominant role.

To sum up, in the cases reported above learning about new uses and extending products and services to new application fields without having an immediate problem or conflict is the main driving force of the innovations as predicted by the RBV. Thus proposition 2 is supported.
5.3 Both problemistic search and continuous search for innovations are present

The third proposition deals with both problemistic search and continuous search for innovations which can be observed simultaneously. The term “simultaneously” can be understood twofold:

(1) As simultaneously occurring within the same firm which will be addressed in the next section and
(2) as simultaneously occurring regarding one innovation which will be addressed in this section.

An example for simultaneous problemistic and continuous search is InVitro, the producer of laboratory equipment. It was one of the first firms offering a battery operated pipetting aid for all pipettes from 0.1ml to 200ml. Instead of pipetting manually laboratory technicians now attach glass made pipettes directly to this innovative device. The product features a 5-stage speed key for the selection of the ideal pipetting speed as well as an easily readable color display. It resembles a bit like a pistol nowadays. When it was introduced to the market the shape was similar but much more angular and unhandy. Nevertheless the product was quite successful on the market. Every once in a while users mentioned that the shape of the instrument is not beneficial to fit all different sizes of hands. However stimulated by a certain problem but without high pressure of time the developers of InVitro reassessed the design of the pipetting aid within a slack period in order to provide a better fit for all laboratory technicians. The developers of InVitro conducted several ergonomic studies to find out, how to change the shape of the instrument in order to make pipetting more convenient. Finally they managed to improve the design of the device for a faster, safer and absolutely precise pipetting. The new product shape was even awarded a prize for its exceptional design.

Table 4 contains some quotes on the topic of the combination of problemistic and continuous search for innovation within the development process of the sampled firms.

<table>
<thead>
<tr>
<th>Case</th>
<th>Exemplified quotes</th>
<th>Remarks</th>

</thead>
<tbody>
<tr>
<td>InVitro</td>
<td>“In the past it (= the pipetting aid, the authors) was an angular shaped part, a bit like a pistol. […] We have conducted a few ergonomics studies. Now it fits both female as well as male hands, small and big hands.”</td>
<td>Internal initiative triggered by external sensing</td>
</tr>
<tr>
<td>SafeEx</td>
<td>“Our task is to strategically develop the product portfolio initiated by suggestions from the customers. […] it has to become more and more complete. There are quite a few useful components that do not exist yet.”</td>
<td>Internal initiative triggered by external sensing</td>
</tr>
<tr>
<td>ProtoType</td>
<td>“We redesign our internal development process on a systematic basis when we detect an error occurring repeatedly at the same stage. Then we think about how to stop this problem. That is one way how an innovation can come up.”</td>
<td>Internal initiative triggered by internal sensing</td>
</tr>
<tr>
<td>TransDrive</td>
<td>“Our customers force us to innovation by asking for lower costs or the like.”</td>
<td>Internal initiative triggered by external sensing</td>
</tr>
</tbody>
</table>

Table 4. Simultaneous search

The data showed, that in some cases both, problemistic search as well as continuous search for innovations, is present. All the cases present internally initiated innovative activities that refer to detected problems either externally occurring such as usage problems, or internally occurring such as repeated errors e.g. in development or production. The difference to the innovations mentioned in section 5.1 is that these problems are not immediate in a sense that they have to be resolved within a
short time to avoid performance problems. The difference to the innovations mentioned in section 5.2 is that innovations of this section are problem-induced, either internally or externally articulated.

6 CONCLUSION AND FURTHER RESEARCH

Before concluding we discuss the limitations of our study. First, we employed the theoretical lenses of BTF and RBV thereby acknowledging that those aspects of innovation addressed by these theories are visible to us while other aspects are faded out. Second, we used the abstract definition of innovation offered by Schumpeter to allow for a cross-sectional investigation, thus neglecting the more micro-level of innovation with its manifold characteristics and complementarities.

From the cases presented in the previous section we have found support for the propositions to several degrees.

While all firms of our sample used slack resources to innovate either on a continuous basis or triggered by a detected problem, there is no firm in the sample that exclusively used problemistic search to resolve immediate problems.

We have found two firms that are ProtoType and SafeEx, reacting to immediate problems, using slack resources for innovations and combining both approaches. Thus these firms cover the whole bandwidth of motivations and for explaining this behavior both RBV and BTF arguments are needed.

For TransDrive we did not find evidence for problemistic search in case of immediate problems but the use of slack resources for continuous innovation and the combined motivation (see section 5.3).

In contrast, at InVitro we found the combined motivation (see section 5.3) plus the problemistic search in case of immediate problems.

Finally, TechDat was found to only make use of slack resources for continuous innovation.

These findings point to the argument of Pitelis that a combination of RBV and BTF approaches to explain innovation is best suited to analyze the innovation behavior of firms. Only applying BTF or RBV arguments, respectively, are not sufficient.

Nevertheless, all firms of our sample economize on their long-year experiences with certain technologies whether they resolve immediate problems, searching for new applications, or looking for innovations triggered by usage problems, for example. That is, according to Penrose, firms look for novel services of their resources regardless what the original motivation was.

Although a statistical generalization is not possible when using case studies our cases provide evidence for Pitelis’ argument to combine both approaches. The following table summarizes the results.

Table 5. Summary
For this study we decided to select the top performing firms based on their perceived innovativeness (see section 4) rather than to restrict the sample to only IT innovators to test the general arguments of the theories involved. The next step in research will apply the insights of this study to a sample of IT innovators to test for possible differences in the explanation of search strategies. In this context more in-depth studies are needed to better understand in which situations and under which conditions firms use problemistic search, slack resources, or both. In particular, the time horizon of strategies and also the ownership structure is a promising field of future research to further clarify the call of Pitelis to investigate the contexts and motivations of innovation.

Abstract

Near Field Communication (NFC) technology allows for the implementation of novel contactless payment systems in stationary retail. In this paper, we quantitatively analyze the impact of such systems on a retailer's payment costs on the example of real-world data from a Swiss food retailer. Our results indicate that the introduction of contactless payment under current card fee models would in virtually any case significantly increase the payment costs due to the substitution of low cost cash payments for expensive card payments. This increase might be balanced out by a substantial growth in sales, a reduction in operating costs, or a reduction of card transaction fees.

Keywords: Near Field Communication, Retail, Contactless Payment, Mobile Systems.
1 INTRODUCTION

The term “Near Field Communication” (NFC) denotes a wireless communication technology that operates at 13.56 MHz and is compatible to the international industry standards ISO/IEC 14443 and ISO/IEC 18092. The integration of a NFC module into mobile phones or PDAs enables these devices to act as contactless smartcard as well as to read from and write onto such cards. Possible applications include the use of NFC devices for mobile payments, as electronic tickets, for the participation in loyalty programs, and for the storage of rebate coupons. The fact that NFC compatible devices can hold a large number of virtual smart cards in the form of secured applications allows for providing their owners with access to a wide variety of contactless services without the need to carry numerous plastic cards. In recent years, most manufacturers of mobile phones have developed corresponding prototypes. The Nokia 6131 NFC phone has, to date, been the only NFC-compatible device freely available on the market, while all others were available to technology trial organizers only.

In recent years, numerous trials of NFC-based payment have been conducted world-wide. The first publicized example was started in August 2005 in the Dutch town of Kerkrade (KPN 2005). In November 2006, the first trial to implement an EMV-compliant payment process and to use the SIM as secure element for the storage of the NFC application was conducted in the French Strasbourg. This brought the contactless payment process closer to the conventional payment process called “Chip and PIN” as it is practiced in Europe (NFC Forum 2006). In November 2007, the French cities of Caen and Strasbourg saw the launch of the first trial to include all mobile network operators and all banks of an entire country (Balaban 2007).

Against this background, our contribution specifically considers the use of NFC as a novel technology for the realization of payment systems in stationary retail. Retailers are currently confronted with several challenges in regard to their relationship with their customers. According to Chu and Morrison (2002), 75% of retailers view waiting lines at the checkout as the most important factor for improving the customers’ shopping experience. Measurements by large payment system providers seem to indicate that NFC might be able to significantly speed up the payment related part of the checkout process. The payment system providers claim to have measured contactless payments as being 20% to 63% faster than cash transactions and 20% to 53% faster than magnetic stripe based card transactions (cf. Table 1). Additionally, Visa states that the implementation of their contactless solution has lead to a waiting line reduction of up to 23% (Visa 2008).

Table 1: Transaction times for the payment by cash, magnetic stripe cards and contactless cards

According to Visa and MasterCard their contactless solutions also leads to a growth in sales for adopting retailers. This would come about by means of an increased number of transactions and larger average expenditure by those customers that pay contactless. MasterCard states that PayPass users visit stores accepting contactless payment cards 33% to 52% more often than other customers, and that they spend 28% to 42% more per purchase than they did previously (MasterCard 2008). Visa, on the other hand, claims that customers using their contactless payment solution PayWave spend 22% more than those using cash (Visa 2008). Both companies attribute this increase in spending to the elevated transaction convenience and the fact that the shoppers’ expenditure is not curtailed by the amount of cash they carry.
It is understood that the before mentioned figures should be interpreted with care since the detailed data underlying these published transaction times has not been made available for scrutiny. Furthermore, the studies by payment service providers ignore the financial impact that the implementation of a new payment technology would have, due to the occurring transfer of payment transactions between payment methods. Since each of these methods (e.g. cash, debit cards and credit cards) is subject to its own individual cost and fee structure these transfers would mean a change in the payment costs that retailers have to bear. The most significant transfer would probably occur from low cost cash payments to more expensive card payments, which would lead to an increase in payment costs for retailers. This increase in costs might however be recouped in part or neutralized entirely by the growth in sales promised by the payment system operators. Other means of preventing a cost increase for the retailers are a general reduction in card fees or a special rate for small payments.

Our research concerns itself with the following question: how would the implementation of NFC-based contactless payment affect the payment costs of stationary retailers? For this purpose, we assess the financial impact of novel payment technologies with the help of a mathematical model. We subsequently illustrate its practical use on the example of a data set of payment transactions provided by a Swiss operator of small supermarkets and convenience stores. Moreover, we analyze the influence of a growth in sales on payment costs as well as the impact of reduced transaction fees.

2 RELATED WORK

In their recently published review of literature focusing on mobile payment, Dahlberg et al. (2008) classify 73 relevant publications, in accordance to the stakeholders and issues that they focus on. While 29 publications focus on the technological aspects of mobile payments and 20 on the consumer, only five papers focus on mobile payment providers (Kreyer, et al. 2003, Vilmos and Karnouskos 2003, Karnouskos 2004, Vilmos and Karnouskos 2004, Zmijewska and Lawrence 2005) and four center on retailer-related issues (van der Heijden 2002, Ondrus and Pigneur 2004, Mallat and Tuunainen 2005, Teo, et al. 2005). The literature review’s authors state that the number and diversity of mobile payment publications focusing on retailers are disappointing, and further claim that quantitative studies are needed in order to contribute to a better understanding of merchant adoption. This paper contributes to filling this gap by analyzing the financial impact that the implementation of NFC-based mobile payment will have on retailers and by indicating to mobile payment providers how mobile payments will have to be priced so as to make this technology a viable alternative for retailers.

Not all of the work on mobile payment is however related to this paper without qualification. The term “mobile payment” not only describes payment by means of a mobile device at a point of sale in a retail store, which is the focus of our work. It also includes three other usage scenarios: the use of mobile devices for the payment of mobile content (e.g. mobile phone ringtones), the settlement of purchases made in online stores and its use for consumer to consumer payments (Kreyer, et al. 2003). As this paper is focused on payments in stationary retail, the publications that focus on the other mobile payment scenarios loose some of their relevance.

Mallat (2004) provides a review of literature dealing with information technology adoption and acceptance and discusses the usability of the applied theories in explaining the adoption of mobile payment. While Dewan and Chen (2005) isolate factors which will influence the adoption of mobile payments, Mallat (2007) discusses the inherent advantages of mobile device based payments in comparison with other payment technologies, and how these will advance mobile payment adoption. Amin (2007) studied the attitude of Malaysian bank customers towards mobile credit cards, while Kristoffersen et al. (2008) researched the consumer perception of mobile-based micropayments. Klee (2006) analyzed the time-saving of switching from one payment method to another based on large quantities of POS data. Her results show that debit card payments take on average 30% less time than check payments. A comparable study for contactless and mobile payments is not available.
Several publications have discussed aspects of the costs of payment. Worthington (1996) compared the costs incurred through payment by various methods and emphasized the importance of costs in the adoption of new payment methods. Ardizzi (2004) discussed cost structures and efficiency of payment systems on the basis of the Italian credit card system. Bean (2006) analyzed past developments of card payment fees and made suggestions on how to lower them. Huchzermeier and Van der Heyden (2007) concluded that payment costs are too high due to the inefficiency of the payment card market. They suggest that more retailers should become payment scheme operators, thereby becoming competitors to the established payment systems. Guibourg and Segendorff (2007) made an estimate of the Swedish bank sector’s payment costs and concluded that there are large cross subsidies between the profitable card payments and the unprofitable cash payments. Finally, Papaefstathiou and Manifavas (2004) evaluated the transaction costs for micropayment systems and underlined the importance of transaction costs for the success of electronic micropayment systems. There were, however, no publications on the financial impact that the implementation of a payment instrument or transfer between payment methods would have on a retailer.

We are not aware of any publications that describe the financial impact of payment method and payment technology adoptions on retailers. This seems to constitute a neglected field of research. The publications closest to the methodology of this thesis are a series of articles which analyzed the financial impact that discounts for shoppers who pay cash, instead of using a credit card, would have on retailers (Gordon, et al. 1977, Ingene and Levy 1982, Grant, et al. 1985). The fact that confounded the matter was that retailers would have to give discounts to all cash-paying customers, regardless of whether they had originally intended to pay with credit cards or not. Comparable publications dealing with the financial impact of new payment methods or payment technologies do not exist.

3 METHODOLOGY

We developed a mathematical model in order to measure the financial impact that the decision to adopt a new payment technology would have on a stationary retailer, which we shortly describe in this section. The main input parameters of the model are the concerned retailer’s revenue structures, its current payment method specific costs and fees, and the anticipated transfers of transactions and revenue between payment methods caused by the implementation of the new technology.

Revenue structures. This paper refers to the allocation of payment transactions and revenue to the different amount ranges and the various payment methods accepted by a retailer as revenue structures. The empirical data that our analysis relies on was gathered from a survey among Swiss retailers in autumn 2007. In the following, we will set the focus on one specific data set from a Swiss operator of small supermarkets and convenience stores. Its large share of micropayment transactions – defined as all payment ≤ 15 CHF1 – makes its industry segment particularly suitable for the implementation of a new payment technology that specifically addresses small value transactions. This choice was made, because it is the card scheme operators declared intention to use contactless payment to target the market for small amount payments (MasterCard 2008).

Payment method specific costs. Each payment method is subject to its own individual cost and fee structure. Cost elements can be based on the number of transactions and the revenue. Card payment fees are considered confidential by, both, retailers and payment scheme operators. Approximate average card fees for the Swiss market were, however, obtained from the Swiss Association for Electronic Payment Transactions (cf. Table 2). The cash costs that we use in our calculations originate from company-internal figures of two large Swiss retailers, which both calculated cash payment costs independently of each other and came to similar results.

---

1 The separation between micro- and macropayments is not consistent in prior academic studies and usually varies between 5 and 20 €. We therefore chose 10 € (approximately 15 CHF) as mean value.

Substitution effects. This paper refers to the transfers of payment transactions and revenue between payment methods, caused by the implementation of a new payment method, as “substitution effects”. The substitution effects are an unknown factor in the mathematical model which cannot be determined in advance. Additionally, they will differ between different countries and amongst retail industry segments, due to various influence factors. For this reason, we developed three distinct scenarios that cover various possible outcomes of the adoption process (cf. Table 3).

- Scenario 1 illustrates the transfer of payments from cash to credit cards in the micropayment ranges between 0 and 15 CHF. It assumes that 25% of all cash transactions for less than 15 CHF will be replaced by credit card payments.
- Scenario 2 represents the transfer of payments from cash to debit and credit cards in all amount ranges. 30% of the cash-based micropayments are assumed to be transferred to debit and credit card payments in equal shares. A smaller share of cash-paid macropayments (defined as all payment > 15 CHF) are also expected to be transferred: 20% of the cash payments between 15.01 and 50 CHF and 10% of those above 50 CHF are also assumed to be replaced by debit and credit card payments in equal shares. The transfer rates are assumed to be lower for macropayments, because these amount ranges already feature a higher card payment share than micropayments.
- Finally, scenario 3 includes the same substitution effects as scenario 2, however, it incorporates the possibility of retailer-operated store cards becoming more prominent due to the added convenience of contactless technologies. In contrast to the first two scenarios, scenario 3 not only includes the transfer of cash payment to other payment methods, but also the transfer payments from debit and credit cards to retailer-operated store card schemes.

Table 3. Specification of substitution scenarios

Payment costs consist of two elements: The payment method specific transaction-based costs \(C_{\text{Pay}}\), which have to be paid for each transaction and the payment method specific revenue-based costs \(C_{\text{Re}}\), which are proportional to the amount of a transaction. The multiplication of the transaction-based costs with the number of transactions settled with a payment method \(i\) \((\text{Tr}_{\text{old}_i})\) and the multiplication of the revenue-based costs with the revenue paid for with that payment method \((\text{SR}_{\text{old}_i})\)
results in a retailer’s costs for its use. The sum of payment costs for all payment methods accepted by a retailer equals that retailer’s current total costs of payment \( C_{\text{old}} \).

\[
C_{\text{old}} = \sum_{i=1}^{n} \left( C_{\text{TB}_i} \cdot Tr_{\text{old}_i} + C_{\text{RB}_i} \cdot Sr_{\text{old}_i} \right)
\]

The application of the substitution scenarios permits to give estimates of the future distribution of transactions onto payment methods and the new payment costs \( C_{\text{new}} \) caused by the implementation of the new payment technology. This model uses substitution effects, in the form of percentages to articulate which share of transactions \( ST_{\text{ji}} \) and revenue \( SSR_{\text{ji}} \) are transferred from one payment method to another after the introduction of the new payment technology. A payment method does not necessarily have to be solely a beneficiary or benefactor of a new payment technology. It is possible that a new payment technology may cause it to receive a share of the transactions \( ST_{\text{ji}} \) and revenue \( SSR_{\text{ji}} \) from some payment methods, while at the same time forfeiting a share of its own transactions \( ST_{\text{ji}} \) and revenue \( SSR_{\text{ji}} \) to others. The difference between the old payment costs and the new payment costs constitute the financial impact of the new payment technology:

\[
C_{\text{new}} = \sum_{i=1}^{n} \left( (C_{\text{TB}_i} \cdot Tr_{\text{old}_i} + \sum_{j=1}^{n} (Tr_{\text{old}_i} \cdot ST_{\text{ji}}) - \sum_{j=1}^{n} (Tr_{\text{old}_i} \cdot ST_{\text{ji}})) + (C_{\text{RB}_i} \cdot Sr_{\text{old}_i} + \sum_{j=1}^{n} (Sr_{\text{old}_i} \cdot SSR_{\text{ji}}) - \sum_{j=1}^{n} (Sr_{\text{old}_i} \cdot SSR_{\text{ji}})) \right)
\]

When interpreting our results, it should be noted that our approach comes along with a number of modeling assumptions, which might limit its applicability in practice. First, we arbitrarily separate micropayments \( \leq 15 \text{ CHF} \) and macropayments \( >15 \text{ CHF} \) and restrict the growth in sales to the first. It is, however, possible that a new payment technology could lead to increased sales among large amount transactions as well, even if it might do so to a smaller extent. Secondly, we assume that payment costs increase linearly to the growth in sales, i.e. the transactions caused by the implementation of the new payment technology have the same average value than the previous micropayment transactions. Thirdly, the model does not account for infrastructure investments that are necessary on the part of the retailer. These are excluded for two reasons: On the one hand, the investment costs are complex and strongly dependent on a retailer’s existing point-of-sale and payment terminal infrastructure, and can thus not be generalized. On the other hand, card fees constitute a more significant amount of money than hardware does. Finally, the model does not account for cost savings which might be possible through the acceleration of the check-out process. If a new payment technology could accelerate this process, it might lead to a reduced need for cashiers and checkouts. This could decrease the retailers operating costs and refinance a part of the possible additional costs. These potential savings were not integrated into the model due to the high uncertainty with regard to their realization and to the level to which they are dependent on store formats and sites.

4 EVALUATION

4.1 Case Description

The retailer that we consider in the following is one of the largest food retailers in Switzerland with approximately 600 small supermarkets and convenience stores, and an annual revenue of 1 billion CHF. In their case, the 40 million annual sales transactions are mostly micropayments, i.e. 61.61% of all transactions are valued at less than 15 CHF, while only 2.8% are above 50 CHF (cf. Figure 1). With regard to revenues, on the other hand, micropayments amount to 24.93% only, whereas macropayments account for 75.07%. The large number of micropayments represents a significant potential for a novel payment technology focused on the convenient settlement of small value
transactions. While a large share of the customers’ purchases are probably planned based on specific household needs, supermarkets and convenience stores can also incite their customers to make spontaneous purchases. A new convenient payment method which frees the shoppers from having to carry cash could thus lead to a significant growth in sales through higher spending per purchase.

Figure 1. Distribution of transaction volume across payment ranges

As Figure 2 illustrates, the shares of cash payment in the micropayment and the macropayment area differ strongly. 82.84% of the sales transactions in the respondent’s stores are paid in cash, 16.81% with debit cards, and only 0.33% with credit cards since the supermarket operator only accepts credit cards in those stores that are located in tourist areas. Cash cards are not accepted. The retailer neither offers gift certificates nor a self-operated store card. While 99.6% of the micropayment transactions are settled in cash, the same holds for only 55.94% of the macropayment transactions. With higher payment amounts, the card payment quota increases amongst micropayments and decreases amongst macropayments. This is in part due to the fact that some commercial customers, such as restaurants, are allowed to pay on account (i.e. 0.01% of transactions).

Figure 2. Payment method use by payment range

4.2 Payment Costs

The company’s current average payment costs amount to 0.09 CHF per transaction, and 0.44 CHF per 100 CHF of revenue. The financial impact with regard to the implementation of NFC based payment that we calculated from our model in the three substitution scenarios is given in Table 4. The figures show that the implementation of NFC based contactless payment would cost the retailer additional money in the occurrence of any of the three proposed scenarios. Scenario 1 causes the lowest costs, because cost increases are limited to micropayments. Scenario 2 causes the highest additional costs since a significant share of large value payments are moved from cash to the more expensive debit and credit cards. An occurrence of scenario 3 would be less expensive than scenario 2 for two reasons: Firstly, some of the cheap large value cash payments are transferred to the even cheaper private label payment card. Secondly, some of the more expensive credit and debit cards are considered to be transferred to a private label card as well, and thereby reduce the cost increase.
In all three scenarios, the costs for micropayments would increase by between 290% and 366% when compared to the company’s current payment costs. The costs for macropayments on the other hand would not increase in the occurrence of scenario 1, and increase by only 22.16% and 12.95% in the occurrence of scenarios 2 and 3, respectively. This is due to the fact that (a) our scenarios assume a higher substitution rate for lower amount payments, and (b) that the current card payment share is higher in the macropayment range, thus already causing higher payment costs for macropayments.

Table 4. Payment cost before and after NFC implementation

According to these results, it seems that the implementation of NFC based contactless payment would, in any case, substantially increase payment costs. Adopting retailers would thus either have to achieve additional sales that enable them to recoup some of these costs, or be willing to relinquish a share of their return on sales to the payment scheme operators. Otherwise, the retailer would have to make the implementation of contactless payment depend on a reduction of payment fees. These reductions could be applied globally onto all payments or be restricted to small amount payments.

4.3 Growth in Sales

One way of neutralizing increased payment costs is additional earnings achieved through growth in sales. The model underlying the presented results restricts the growth in sales to the micropayment area. This assumption is based on the premise that micropayments are much more likely to be characterized as spontaneous purchases whose number could increase due to a more convenient shopping environment than macropayments. The growth in sales necessary to cover for higher payment costs is dependent on a retailer’s margin, which determines his earnings. The lower a retailer’s margin, the greater the additional sales need to be in order to produce the additional earnings necessary to outbalance additional payment costs. The contour lines (i.e. isobenefit curves) in Figure 3 describe these interrelations for the three substitution scenarios. All growth in sales/return on sales combinations below the lines would lead to a negative financial impact on the retailer, while all combinations above the lines indicate a positive impact of the NFC implementation.

- On the occurrence of scenario 1, a return on sales of 3.3% or lower would not enable the respondent to cover the increased payment costs through a growth in sales at all. At a margin of 4% the retailer, for instance, would have to increase his micropayment sales by 112%. A 50% growth in sales, which surmounts the sales increases proposed by MasterCard and Visa (MasterCard 2008, Visa 2008), would only suffice to cover the additional cost of payment if the retailer’s margin is 4.8% of revenue or more.
• In the event of scenario 2, a return on sales of 3.4% or lower would not enable the respondent to cover the increased payment costs through a growth in sales at all. At a margin of 4.5% the retailer would have to increase his micropayment sales by 126%. A 50% growth in sales would only suffice to cover the additional cost of payment if the retailer’s margin is 6% of revenue or more.

• On the occurrence of scenario 3, a return on sales of 2.3% and lower would not enable the respondent to cover the increased payment costs through a growth in sales at all. At a margin of 3% the retailer would have to increase his micropayment sales by 165%. A 50% growth in sales would only suffice to cover the additional cost if the retailer’s margin is 4.5% of revenue or more.

Figure 3. Growth in Sales Necessary to even out Payment Cost Increase

The curves representing scenarios 2 and 3 resemble each other because both scenarios influence payment transactions in all amount ranges and have similar substitution effects. The difference between them is the enhanced role of the store card in scenario 3, responsible for the lower necessary growth in sales rates for all possible return on sales rates. On the other hand, the curve representing scenario 1 stands out due to its different shape and the fact that it intersects the curve representing scenario 3. This is due to the fact that scenario 1 aims only at micropayments thus representing a very different setting. When interpreting the necessary growth in sales rates in Figure 3, it has to be kept in mind that micropayments represent only 24.93% of the respondent’s revenue. A growth in sales of 100%, restricted to micropayments, thus only equates to a total growth in sales of 24.93%.

4.4 Card Fee Reduction and Micropayment Discount

The costs caused by the implementation of NFC could also be partially or fully balanced out by an overall reduction of payment fees or a special discounted fee restricted to micropayments. Should the implementation of contactless payment not lead to a growth in sales at all, the supermarket operator would have to negotiate fee reductions of 84.03% (scenario 1), 51.42% (scenario 2), or 46.26% (scenario 3). If the implementation of contactless payment were to lead to a growth in sales, the answer to the question concerning necessary card fee reductions becomes more complex. In this case, the reduction necessary is, as is the growth in sales discussed beforehand, dependent on the retailer’s margin. This is due to the fact that a growth in sales also leads to an increase in payment costs, due to the higher number of transactions and the increased revenue.

If the retailer’s margin is lower than the average payment costs of the new transactions, the reduction of fees that is necessary increases when compared to a situation without growth in sales. If, on the other hand, the retailer’s margin is higher than the average payment cost incurred by the new transactions, the reduction necessary to balance out the cost of contactless payment implementation becomes lower. Figure 4 shows the necessary card fee reductions in a highly optimistic case of 50% growth in sales – restricted to micropayment sales – for all three substitution scenarios.

If we assume that fee reductions are given only for micropayments, the retailer would have to negotiate for discounts of 92.47% (scenario 1), 123.13% (scenario 2), and 106.47% (scenario 3) if the implementation of contactless payment does not lead to any growth in sales at all. On the occurrence
of scenarios 2 and 3 without any growth in sales, the payment scheme operators would actually have to subsidize the retailer for each micropayment transaction, so that the retailer is able to pay the additional costs for macropayments with this income. This clearly does not seem to be a realistic outcome for negotiations between payment scheme operators and retailers. The cost increases on the occurrence of scenarios 2 and 3 could however be neutralized by a micropayment discount, provided that the implementation of contactless payment leads to a growth in sales. As depicted in Figure 5 (also in case of 50% growth in sales), the necessary micropayment discounts become dependent on the retailer’s return on sales in the case of additional sales incurred by the implementation of NFC based contactless payment.

![Figure 4](image-url)

**Figure 5.** Necessary micropayment discount in case of 50% growth in sales

5  
**CONCLUSION**

This paper concerned itself with the question of how the implementation of NFC-based contactless payment would affect the payment costs of stationary retailers. As our numerical results indicate, the introduction of NFC based contactless payment under current card fee models would in virtually any case significantly increase the payment costs for retailers. This is due to the transfer of payment transactions and revenue from low cost settlement with cash to more costly card payments. Ceteris paribus these increased costs would lead to a reduction of the retailer’s profit. While the results in this paper are based solely on the analysis of one retailer’s data, the authors validated the results using the data from three further retailers which led to consistent results.

There are, however, various means to recoup a share of the additional costs. Firstly, the implementation of NFC-based payment could cause a growth in sales due to the elevated transaction convenience and the fact that the shoppers’ expenditure is not curtailed by the amount of cash they carry. However, the growth rates necessary to neutralize the increased costs are substantial.
Secondly, a reduction in card fees for all transactions or, alternatively, a discount restricted to small amount payments could reduce or neutralize the payment cost increase as well. In the event of the proposed substitution scenarios occurring, the overall reduction in card fees would have to lie between 46.4% and 84%, while the micropayment discount would have to amount to between 92.5% and 123.1%. A discount beyond 100% implies that the payment scheme operators would have to subsidize the retailer for each micropayment transaction, so that the retailer is able to pay the additional costs for macropayments. This clearly does not seem to be a realistic outcome for negotiations between payment scheme operators and retailers. If the implementation of contactless payment were to lead to a growth in sales, the answer to the question concerning necessary card fee reductions becomes more complex. In this case, the reduction necessary is, as is the growth in sales discussed beforehand, dependent on the retailer’s margin. If the card scheme operators are not willing to agree to lower card fees, the implementation of a retailer operated store card constitutes an alternative.

While lower transaction fees would make the processing of small payments a less attractive source of revenue for the payment service providers, the launch of such a service could become a means to save costs, especially for the issuer banks, which retain a large share of the card fee revenues. In general, a cardholder’s issuer bank is also the institute at which he has his bank account and where he obtains cash at ATMs. The transfer of payments from cash to NFC-based cards would very likely result in less cash withdrawals, thus leading to a reduction in cash provisioning costs for issuer banks. Banks could seek further savings by delivering payment cards to NFC devices over the air instead of sending plastic cards by postal service. These possible savings should be a part of the considerations when pricing NFC-based payment services.

Additional costs that cannot be compensated by a growth in sales, lower fees or operating cost savings have to be considered as the retailer’s price for the implementation of NFC based contactless payment. Each retailer has to decide individually, whether the implementation of contactless payment is worth this price. Criteria favoring retailers to spend money on the new payment technology are increased customer convenience due to faster payment transactions, quicker check-out processes and possible added value through other contactless customer services such as loyalty cards, coupons or seamless combinations of different services.

Abstract

This paper presents the results of a survey conducted amongst European retailers on their plans and 
perceptions with regard to novel applications based on Near Field Communication (NFC) technology. 
Whilst the survey showed that retailers did evaluate the possible applications differently, none of them 
clearly stood out as the most beneficial one. NFC based services were on average conceded to be able 
to accelerate the checkout process at the point-of-sale. This is an important acknowledgment, as 65% 
of the respondents consider waiting lines which can occur at the checkout to hold the largest potential 
for an improvement of their customers’ shopping experience. While the rate of agreement is somewhat 
smaller than in the case of process acceleration, retailers also concede that NFC applications could 
make shopping more convenient for their customers. On the other hand, none of the NFC-based 
applications seemed to yield cost saving potentials to the responding retailers. The most surprising 
result of the survey was the respondents’ low expectations in regards to customer acceptance. This is 
in clear contrast to the reports on NFC trials which generally describe participants as enthusiastic 
about the technology.

Keywords: Near Field Communication, Retail, Payment Systems.
1 INTRODUCTION

1.1 Background

Retailers are currently confronted with several challenges in regard to their relationship with their customers. Shoppers expect retailers to sell quality products and to provide them with good service levels within their stores. However, they also expect the retailers’ prices to be as low as possible. The last several years have seen fierce price competition, which has forced retailers to cut costs wherever possible. Apart from the optimization of supply chain activities, through initiatives such as Efficient Consumer Response (ECR), retailers have also reduced the number of employees in their outlets. This cutback has led to a lower employee to customer ratio in retail stores, which in turn created new problems e.g. longer waiting lines at the point-of-sale (POS) and difficulty for customers in finding store personnel for assistance.

Today, 95% of retailers consider waiting lines at their checkouts as the most serious problem to be solved in order to improve service for their customers (Chu and Morrison 2003). A long term study conducted by Zenith Management Consulting states that 92% of retailers have problems meeting their customers service expectations (Cowgill 2006). This assessment is confirmed by a survey of 1,000 US retail customers, conducted by the Verde Group, according to which the biggest perceived problems that shoppers encounter in retail stores are a lack of support by store personnel and long lines at the checkouts. A third of the respondents stated that they could not find store representatives when they needed help, or that representatives did not have enough product knowledge to be able to assist them. 6% of the respondents declared that they have left retail stores without purchasing anything, precisely because of these problems (Verde Group 2007).

These problems can lead to various negative consequences in the short, medium and long term: Crowded stores, and the necessity to wait at the checkout, cause shoppers to take a place in the waiting lines as soon as possible. Additionally, they reduce their shopping to that which is absolutely necessary, so as to be able to leave the store at the time they intended to. This can directly lead directly to a decline in sales for the retailer. On the other side, negative experiences have an influence on shoppers in their future choice of a store (Harrell and Hutt 1976). Long waiting lines and bad service can thus cause a retailer to lose customers permanently.

One cause for the long waiting lines at checkouts is the slow payment process, which prevents the cashiers at checkouts from starting to scan the next customers purchase (Chu and Morrison 2003). The most time-consuming payment process is cash, which to some extent is promoted by retailers through restricted card acceptance and the instatement of minimum amount rules for card payments. A wide-ranging switch from cash to electronic payment could increase the tempo of the payment process and shorten waiting lines in retail stores. In addition, offering customers the opportunity to use the payment instrument of their choice constitutes a service contribution. A study conducted by the German EHI Retail Institute in 2003 and 2004 found that card acceptance significantly influences the shoppers’ decision on where to shop. According to this study, 56.4% of debit and credit cards owners stated that they were influenced by card acceptance when choosing a store. Card acceptance also leads to enhanced spending. 22% of the credit card users stated that they spend more when paying by credit card instead of cash (S-CARD Service 2004).

A further problem for retail customers is the phenomenon of ‘consumer confusion’, a catch phrase for the fact that consumers can be overwhelmed by the range of products that retailers offer in their stores (Rudolph and Schweizer 2004). While the German hard discounter Aldi has only 200 products (Brandes 2004) in each of its stores, a Wal-Mart Supercenter has 142,000 products (Wal-Mart 2007) to choose from. Consumer confusion, which can result from this abundance, might in turn limit the shoppers’ willingness to spend money. This problem could be tackled either by reducing the number of products in the stores, thereby combating the problem at its roots, or by improved assistance for shoppers with their buying decision. Since assistance by store personnel already seems to be too
scarce, mainly because of cost reasons, other means of assistance, e.g. with the help of new technological solutions, could alleviate the problem.

1.2 Research questions

Against this background, this contribution concerns itself with the use of 'Near Field Communication (NFC)' technology in retail to address the before-mentioned issues. NFC stands for the integration of contactless smart card technology into personal devices, such as mobile phones, PDAs and personal computers. The integration of NFC hardware into a personal device enables it to act as a contactless smart card, as well as to read from and write onto such cards. These abilities make it possible for NFC compatible devices to be used as replacement for physical plastic cards (Ecma International 2005; NFC Forum 2006). The possible applications include the use of NFC devices as payment cards, electronic tickets, for the participation in loyalty programs and for the storage of rebate coupons. When compared to contactless smart cards, NFC devices have some advantages which are due to their user interfaces (keyboard and screen), their connection to mobile networks, their large memory and the close connection that people have built up towards their personal devices.

The implementation of NFC-based payment services could help retailers to tackle the problem of long waiting lines at their checkouts by accelerating the payment process. The adoption of NFC-based loyalty applications and rebate coupons could further contribute to this effect. In addition, NFC devices could be used by customers to obtain information on products without the need for assistance by store personnel. This could represent an interesting solution for retailers, since it would reduce the need for assistance by store personnel, which retailers have to pay for, using instead mobile devices, which would be provided by their customers. On the other hand, however, the adoption of NFC would still require significant investments in infrastructure, such as compatible payment terminals.

The standardization of NFC is being driven by the NFC Forum, which was founded by NXP, Sony, and Nokia in 2004. According to its website, the NFC Forum had 146 members, as of November 2008; only 1 (Groupe Casino, France) of these is a retailer. This could indicate that retailers are insufficiently represented in the organization which could in turn lead to an inadequate observance of their expectations in the standardization process. This paper aims to increase the knowledge on the attitude and expectations of the retail industry towards NFC technology. For this purpose, this paper considers the following research question: How do stationary retailers evaluate NFC?

In the following, we present the results of a survey among European retailers. The respondents were, amongst others, asked to evaluate various NFC applications in regard to their ability to increase the speed of the check-out process, improve the shoppers’ convenience, and increase the customers’ loyalty towards retailers. Section 2 provides an overview of our methodology. Section 3 discusses our survey results. The paper closes with a summary of our main findings.

1.3 Related work

The search for scientific publications on Near Field Communication does not lead to a large number of results. The technology has as of yet not received a lot of attention from researchers due to the recency of its emergence. There is however a considerable amount of works on the closely related subject of mobile payment. In their recently published review of literature concerning mobile payment, Dahlberg et al. (2008) classify 73 relevant publications in accordance to the stakeholders and issues they focus on. While 29 publications focus on technological aspects of mobile payments and 20 on the consumer, only five papers focus on mobile payment providers (Kreyer et al. 2003; Vilmos and Karnouskos 2003; Karnouskos 2004; Vilmos and Karnouskos 2004; Zmijewska and Lawrence 2005) and four center on retailer related issues (van der Heijden 2002; Ondrus and Pigneur 2004; Mallat and Tuunanen 2005; Teo et al. 2005). The literature review’s authors state that the number and diversity of mobile payment publications focusing on retailers are disappointing and claim that quantitative studies are needed in order to contribute to a better understanding of merchant adoption. This paper
contributes to filling this gap by surveying the retailers’ evaluation of NFC based applications including mobile payment.

While there are numerous publications on NFC trials and on the potentials of the technology published by proponents of the technology, these sources usually do not meet an academic level of rigour and completeness and therefore suffer from a lack of credibility. Additionally, since their authors have a stake in the success of the technology they might also be regarded as potentially biased.

2 DATA COLLECTION

Based on an extensive review of articles in trade magazines, press releases, and technology white papers on NFC and its applications in the retail industry, a survey was conducted among European retailers between October 2007 and April 2008. The research question was further operationalised, which resulted in the following sub-questions:

• How do retailers evaluate the different possible NFC applications?
• Do some of the applications seem more appealing to retailers than other applications?
• Which changes do retailers expect NFC to bring to their stores?
• Which NFC applications are retailers planning to implement?
• Which payment methods would retailers like to see implemented into NFC devices?

The survey was conducted by means of a questionnaire consisting of five parts (technology adoption, accepted payment methods, payment method preferences and costs, customer services offered today, and customer services planned for the future). It was originally designed in English, but was later translated into German, French, and Italian in order to facilitate the respondents’ participation. The questionnaire was sent to potential respondents by e-mail if possible, by ground mail and fax if requested. Due to feedback concerning the questionnaire format from the first respondents, the questionnaire was later also migrated to a specialized online platform (www.unipark.de) which made the participation more convenient for the further respondents.

In order to generate contacts to be sent the questionnaire we made use of the 2007 version of the Deloitte Global Powers of Retailing report (Deloitte 2007), which is published annually and, among other data, contains a list of the world’s 250 largest retailers. Of the 89 European retailers among the top 250, 6 are not stationary retailers, but operate mail order businesses and were thus excluded from the survey. A further 16 retailers were not contacted due to language barriers. The remaining 67 retailers were contacted by phone. 14 of the 67 companies stated to not participate in any research activities whatsoever, while 12 companies refused to participate in this survey, due to time issues, confidentiality issues or lack of interest in the topic. The remaining 41 companies asked to be sent the questionnaire. After up to two reminders, 16 (39%) of the companies sent the questionnaire back, while 25 (61%) did not answer.

In order to broaden the scope of our explorative study, a further 22 companies were contacted, whose type of business was not covered by the top 250, e.g. an operator of duty free shops at airports and a fast food chain. Of these 22 contacts, 5 refused to participate in the survey due to time issues or a lack of interest in the subject. The remaining 17 contacts were sent the questionnaire. After up to three reminders, 4 (23.5%) of the contacts sent back the questionnaire, while 13 failed to do so (76.5%).

*Table 1. Statistics concerning questionnaire respondents (based on Deloitte, 2007)*
Overall, 57 questionnaires were sent out to different retailers, and 20 were returned. This represents a response rate of 34.5%. The 20 respondents include 4 of the 10 largest European retailers, 7 of the top 25, and 16 of the 89 included in the mentioned Deloitte ranking (cf. Table 1). While 50% of the respondents’ companies have annual revenues of more than €5 billion, 40% are between €1 billion and €5 billion, and the remaining 10% between €100 million and €1 billion.

As depicted in Figure 1, the number of stores operated by the respondents varies between 1-20 and more than 1,000. A strong majority of the respondents (75%) operate more than 1,000 check-outs. The adoption of a technology which requires new hardware at each check-out would entail significant investments on the part of these retailers. While most of the respondents’ companies operate stores of different formats, supermarkets are the most common among them with a share of 50%. This seems to give those companies that during the interviews showed most interest in NFC solutions which can accelerate the check-out process a disproportionate weight in the survey’s results. However this is attenuated by the fact that 35% of the respondents operate department stores, which on the other hand showed a greater interest in NFC solutions that support the shopper on the store floor (cf. Figure 2).

During the initial phone calls with retailers, it was always attempted to contact the person that is, or that would be responsible for implementing NFC based solutions in the company’s stores. The respondents were all heads of departments or managers of relevant projects. While some of the companies linked NFC technology directly to payment terminals and the departments responsible for these devices, others classify it as a technology related to RFID and the departments driving these technologies. The responding companies have attributed the responsibility for the operation of their payment terminals to different departments. The most common responsible is the IT department followed by the finance department and general store management. Due to NFC’s closeness to RFID, two of the respondents designated their logistics department as closest to NFC. Finally, one of the responding retailers disposes of a dedicated innovation group, which is responsible for all major innovations that are tested and implemented by the company. The head of this department also answered to the questionnaire (cf. Figure 3).
3 RESULTS

3.1 NFC Application Evaluation

The respondents were asked to evaluate five NFC-based applications that are also discussed in the majority of related works on NFC: payment, loyalty applications, rebate coupons, the retrieval of product information, and mobile device based self scanning. Each application was evaluated in regard to six criteria on a five point Likert-type scale. The scale enabled respondents to answer to statements concerning the NFC applications in a spectrum reaching from “strongly disagree” to “strongly agree”. During the evaluation, these answers were replaced by points:

- strongly agree: 5 points
- agree: 4 points
- neither agree nor disagree: 3 points
- disagree: 2 points
- strongly disagree: 1 point

The criteria for the evaluation of the NFC applications were their ability to (a) accelerate the check out process, (b) make shopping more convenient for the customer, (c) increase the user quota when compared to conventional (e.g. barcode based) implementations of the application, (d) reduce the retailers’ costs when compared to current solutions, (e) increase customer loyalty, and lastly (f) the expected consumer acceptance. These criteria were chosen, because they represent the possible influences that seemed most crucial to the interviewed retailers.

In two cases, the questions in regards to the procurement of product information deviated from those of the other NFC applications, due to the facts that it would not constitute a part of the check-out process, and that, according to interview results, it was expected that product information solutions were less established than the other applications. Instead of its effect on the speed of the check-out process, the respondents were asked to judge the potential of NFC based product information to reduce the customer’s need for store personnel assistance. Furthermore, instead of being asked to judge its ability to increase the user quota when compared to current solutions, retailers were asked whether they thought the solution could increase the consumers’ knowledge of products they buy. An overview of the respondents' evaluation of NFC application is given in Figure 4.

Ability to Accelerate the Check-Out and Payment Process

On average, the respondents agreed with the statements that NFC applications could benefit their stores by accelerating the check-out and payment process. In the case of NFC coupon applications, that agreement is considerably weaker than in the cases of payment, loyalty applications, and self scanning applications.

As stated before, the fact that NFC based product information procurement would support the shopper on the store floor instead of becoming part of the check-out process gave reason to deviate from a check-out related question. Instead, the questionnaire asked, whether NFC based product information
procurement was expected to reduce the customers’ need for assistance by store personnel. The respondents were on average unsure whether this would be the case or not.

**Ability to Reduce Costs**

The respondents were asked whether NFC based solutions would help them to reduce payment transaction costs and issuance costs for loyalty cards and coupons. The questionnaire also asked whether NFC device based solutions would constitute cheaper alternatives to current self scanning and kiosk based product information solutions.

On average, the respondents disagree with the statements that NFC based payment, loyalty applications, and coupon solutions are going to reduce their costs of providing the respective services. Self-scanning and the procurement of product information based on NFC enabled mobile devices receive a less negative assessment. However, these two applications also do not seem to represent big cost savers to the respondents.

**Ability to Increase Customer Loyalty**

The respondents answers concerning their opinion on the ability of NFC applications to increase their customers’ loyalty show, that they are on average unsure whether NFC application can have such an effect or not. The average answers differ less than in the previous two questions concerning check-out acceleration and cost reduction.

**Ability to Increase Customer Convenience**

As the results show, the respondents’ belief that NFC solutions could make shopping at their stores more convenient for their customers is slightly weaker than their belief in their ability to accelerate the check-out process. However, with the exception of NFC based product information retrieval, retailers on average tend to agree that NFC solutions could make shopping more convenient.

**Ability to Increase the Shoppers’ Use of Customer Services**

The respondents tend to agree, that NFC based payment and self scanning could increase the number of electronic payments and the use of self-scanning solutions. On the other hand, they tend to disagree, that NFC based loyalty application and coupons could increase the participation ratio of loyalty programs or the use of coupons by customers.

In the case of the NFC based product information procurement application, the questionnaire again deviated from the standard question. Instead, the questionnaire asked, whether NFC based product information procurement was expected to be able to increase the customers’ knowledge of the products they buy. The respondents, on average, tended to agree to the statement. However, the agreement was not very strong.

**Expected Customer Acceptance**

The retailers’ opinions as to the acceptance of the different NFC application by their customers differ only slightly. Retailers are on average neither convinced that NFC based services would be greatly appreciated by their customers, nor that they would be rejected. This clearly contradicts the statements made by companies that have conducted NFC trials. These statements generally speak of enthusiastic consumers and high approval rates concerning NFC technology. This divergence means that either the statements issued by trial organizers are too optimistic, or that the retailers that participated in the survey lack the appropriate enthusiasm, because they have an inaccurate picture of their customers’ preferences. Anyhow, retailers and trial organizers which usually include NFC hardware vendors and service providers clearly have different views on the shoppers’ preferences. If these hardware vendors and service providers wish to make these retailers their customers, they will have to convince them that customers will be fond of NFC.

3.2 Plans in Regards to NFC

When asked which of the listed NFC applications they were currently planning to implement, 40% of the respondents stated that they were currently planning to implement NFC based payment. NFC based self-scanning and coupons applications followed with two respondents each. An NFC based loyalty application and a product information service based on the technology are currently only planned by one respondent each (cf. Figure 5). This significant lead in planned implementations of NFC based payment is rather surprising when the previous evaluations of the different applications are taken into consideration. While NFC based payment received relatively good evaluations throughout all criteria, there was no exceptionally high rating when compared to the other applications.

Figure 5: Planned NFC services

A possible explanation for this predominance of payment could however be found in the answers to another question: The respondents were asked to point out, which of the possible NFC applications they considered to be the killer application that would drive the technology’s introduction in the retail industry. A clear majority of 70% think of payment applications as the driving force of NFC in the retail industry. Two of the respondents on the other hand think that loyalty applications will be the
initial driver. One respondent stated that both payment and loyalty applications together would drive the technology’s adoption. Coupon Applications and the support of internal logistics applications were picked by one respondent each, and finally one respondent stated that NFC would be driven into the retail industry by another application, but did not state which. NFC based self-scanning and product information solutions on the other hand were not mentioned by any of the respondents (Figure 6). The role as NFC killer application that is attributed to payment could in part be due to the fact that retailers would only have to upgrade their payment terminals in order to accept contactless and NFC based payments. The remaining infrastructure would be provided by the payment system operators. Loyalty and coupon applications on the other hand would require higher investments from the part of the retailers, because the issuance of loyalty cards and coupons would require them to also invest into infrastructure for the delivery, the processing, and the authentication of loyalty cards and coupons.

![Figure 6: Potential NFC killer application](image)

3.3 Payment Method Preferences

Finally, the questionnaire asked for the payment methods currently accepted by the respondents, their payment method preferences, which payment methods they would like to see implemented as NFC based payment methods, and whether costs to the retailer or convenience for the customer are more important in the decision to accept a new payment method. As Figure 7 illustrates, the only payment method accepted by all respondents is cash. While debit cards and credit cards are also accepted by a large majority of 95% and 85%, only 35% of the respondents accept the stored value cash cards and a private label card operated by their own company. While, 40% of the respondents allow for on account payments, this method of payment is restricted to regular, commercial customers.

![Figure 7: Accepted payment methods](image)

The respondents’ preferences as to the payments methods their customers settle their purchases with are dependent on the amount that the customer has to pay for. Cash is clearly the preferred payment method for payments up to 10 EUR, while debit cards are the preferred method of payment for amounts above 10 EUR. Whilst cash payments decrease in popularity with increasing amounts, all
card payment increase in popularity with increasing amounts. The only exceptions to this rule are the prepaid stored value cards, whose popularity decreases for amounts above 100 EUR (cf. Figure 8).

![Graph showing payment method preferences for different amounts](image)

**Figure 8: Payment method preferences**

When asked which payment methods they would like to see implemented as NFC enabled payments methods, most respondents favored debit cards (80%) before credit cards (75%). As Figure 9 illustrates, the preferences of the respondents as to which of the payment methods they would like to see NFC enabled seems related to the share of respondents that currently accept them based on conventional cards in their stores.

![Graph showing accepted payment methods and favored NFC payment methods](image)

**Figure 9: Accepted payment methods and favored NFC payment methods**

When asked, whether transaction costs or the effects on their customers’ convenience would influence the decision on adopting a new payment method in their stores stronger, most answers stated that both factors were equally influential. As Figure 10 illustrates, the other answers are almost equally distributed over the remaining options. This seems to indicate, that for a new payment method to reach wide adoption the payment method in question has to provide both, a reasonable transaction price to the retailer, and the ability to increase the customers convenience when shopping.
CONCLUSIONS

This paper presented the results of a survey amongst European retailers conducted between October 2007 and April 2008 in order to find out how retailers evaluate NFC. The respondents agreed that NFC based payment had the potential to speed up the payment part of the check out process. They did however attribute this capability to NFC based loyalty applications and self scanning as well. Coupon applications were also attributed the same quality though the rate of agreement was lower in its regard. None of the proposed NFC applications is seen as a potential cost saver by the responding retailers. The respondents seem to expect that the implementation of NFC will rather cause additional costs. This feeling is particularly strong in the case of loyalty applications and payment. The respondents are unsure whether the implementation of NFC applications in their stores will lead to an increase in their customers’ loyalty towards their company. The answers differ only slightly in between the different applications. The responding retailers, on average, agree that NFC based payment constitutes a more convenient way for their customers to settle payments with. However, NFC based self-scanning, loyalty applications and coupons are evaluated to be almost as beneficial to the shopper’s convenience. NFC based product information applications are perceived to be the least beneficial for the customers’ convenience.

The respondents are not convinced that their customers will be enthusiastic about NFC based services. They only expect a moderate acceptance of NFC on the part of their customers. Retailers are, on average, neither convinced that NFC based services would be greatly appreciated by their customers, nor that they would be rejected. This clearly contradicts the statements made by companies that have conducted NFC trials. Retailers and trial organizers which usually include NFC hardware vendors and service providers clearly have different views on the shoppers’ preferences. If these hardware vendors and service providers wish to make these retailers their customers, they will have to convince them that customers will be fond of NFC.

None of the NFC applications clearly stand out as the NFC application yielding the largest to the improvement of the shopping process. While payment is highly ranked among the different applications in regards to its potential to increase the speed at the check-out and to bring additional convenience to the shopping process, other applications are evaluated similarly. The NFC application which the highest number of the respondents is currently planning to implement is payment. 8 respondents (40%) stated that they were currently planning to implement NFC based payment. This number is four times higher than that of the next most current answers. This result was somewhat surprising due to the fact, that payment had not been evaluated significantly more beneficial to retailers than the other applications. A possible explanation for this predominance of payment could however be found in the answers to another question: A clear majority of 70% think of payment applications as the driving force of NFC in the retail industry.

The respondents’ preferences as to the payment instruments that their customers use to pay for their purchases with are clearly dependent on the amount to be settled. While cash is clearly preferred for
the settlement of small amounts, debit cards are the preferred payment method for larger purchases. The majority of the respondents would like to see both debit and credit cards implemented as NFC payment instruments. In order for such NFC-based payment services to be adopted by a large majority of the responding retailers, such services will have to be convenient for shoppers and feature an acceptable price tag.

Abstract:
Wireless Field Force Automation (WFFA) is a wireless solution designed to support field staff such as service personnel, repair or installation employees, technical teams, or medical workers. Certain companies try to provide their field workers with this sort of solution to improve their productivity, their effectiveness and to reduce administrative costs, but more than 50% of these projects fail. This paper discusses the Critical Success Factors (CSF) contributing to the success of these projects. To do this, an exploratory qualitative study was conducted with ten experts in the field. The results of this study show that eight CSF are important in this kind project and that conversely to traditional, sedentary Information Systems, successful WFFA requires taking into consideration a new CSF called “management of mobility” that integrates device management, helpdesk support and mobile device fleet management.

Keywords:
Field Force Automation, field workers, Mobile business, Mobile B2E applications, Critical Success Factors, mobility
Introduction

Advances in mobile technologies, particularly the development of data transmission bandwidths in wireless networks\(^1\), mobile applications\(^2\) (Alag, 2006) and mobile devices\(^3\) have prompted the development of mobile technologies for business\(^4\). Despite their slow growth, when compared to consumer mobile technologies practitioners and researchers predict that business applications will have an enormous impact in the future (Lehmann et al., 2004). The consulting firm Strategy Analytics (2005) predicts that business use of wireless data will grow by 20 percent in North America, Western Europe and Asia/Pacific to surpass $22 billion in 2009.

Mobile business technologies target several diverse populations such as sales force, executive staff, and field workers. This last group represents those individuals that can most benefit from mobile technologies (Barnes, 2004; Rodina et al., 2003). Mobile technologies that support the field force are called Wireless Field Force Automation (WFFA). In 2004, Redman estimated that the number of WFFA users would reach 4 million by 2008 and that the market for wireless FFA would be worth roughly $400M in North America alone. The same 2005 Strategic Analytics study predicts a 16 percent WFFA growth in North America, Western Europe and Asia/Pacific with the market eclipsing $1 billion in 2009. The benefits claimed by WFFA systems are improved field force productivity, reduced costs, increased revenues and improved customer satisfaction (Evans, 2002; Rodina et al., 2003).

Despite the growing popularity of wireless FFA in organizations, the failure rate for these projects is high, above 50% (Bush et al. (2005) cited in Scholl et al., (2007)), and surprisingly few researchers have studied the Critical Success Factors (CSF) in WFFA project implementations. Existing studies concentrate on very specific or limited CSF factors such as lack of buy-in or user implication, inappropriate technological choices (Djemai et al., 2008), lack of training, or poor project management.

The goal of this research is to simultaneously and globally investigate the CSF of WFFA projects by using an exploratory study resulting in a description of the different factors contributing to success.

The contributions of this paper are both theoretical and practical. At the theoretical level, this paper extends classical critical factors (traditionally adapted to sedentary systems) to the mobile context, particularly to WFFA projects, and proposes a new critical factor called “management of mobility”. At the practical level, the CSF, identified in this study, provide useful guidelines for project managers, IT managers, integrators and consultants in order to successfully implement WFFA.

This paper is organized as follows. The first section presents WFFA by defining it and presents those CSF found in the existing Literature. The second section presents our

---

\(^1\) The bandwidth has evolved from 9.6Kbits/s in generation 2 to 171Kbits/s in generation 2.5 and to 2Mbits/s in the third generation.

\(^2\) Mobile application is the software installed in the mobile device. This software has evolved from a disconnected mode to connected “always-on” mode.

\(^3\) Mobile devices have evolved from mass-market devices to rugged-devices, adapted to the job conditions of field workers.

\(^4\) Mobile technologies for business refer to the concept of mobile business or mobile e-business.
research methodology, followed by results and discussion, and the final section presents our conclusions.

2 Wireless Field Force Automation

Terms such as “Fully Mobile Wirelessly Connected” (FMWC) or “Mobile Workforce Management” are used to identify Wireless Field Force Automation (WFFA) and these terms are inter-changeable. There are also several definitions of wireless FFA that vary from author to author (for more details please refer to the appendix). A review of these definitions highlights the different angles from which the subject is approached. Some focus on technological aspects (Gorlenko and Merrick, 2003; Rodina et al., 2003), others on their characteristics (Barnes, 2004; Olofsson and Emborg, 2004) others on their target users (Barnes et al., 2006; Rangone and Renga, 2006; Rodina et al., 2003), and still others on their objectives (Olofsson and Emborg, 2004). We propose the following definition that synthesizes all of these perspectives:

Wireless FFA is a class of information systems functioning in real time applied in order to support and manage (scheduling, supervising and reporting by) a field force, remote from their base of operations and who do not carry out any sales activities.

2.1 Critical Success Factors for WFFA implementations

(Rockart, 1979) defines CSF as “the limited number of areas in which results, if they are satisfactory, will ensure successful competitive performance for an organization”. Unlike the crowded Information Systems research field where much ink has been devoted to investigating CSF (Plant and Willcocks, 2007), little research has concentrated on CSF for WFFA. In order to address this lack we have chosen to analyse the existing literature using Nah and Delgado’s (2006) classification of CSF for ERP systems as a framework for identifying the critical success factors for WFFA projects. Change management, technological factors and communication emerge as being particularly important, change management having been widely studied as compared to the other factors.

Change management: Front and back office staff reductions and changing roles are the principle areas of potential WFFA impact on the employee and they may incite people to resist change (Vas and Vande Verle, 2000; Westelius and Valiente, 2006). According to Vas and Vande Verle (2000), resistance may occur at different levels (managers, technicians, dispatchers, team managers and regional directors) and may be expressed either tacitly (by inertia, covert acceptance) or explicitly (sabotage, argumentation). These results make change management an important factor for success and thus have been studied from both static and dynamic perspectives. Static perspective research tries to identify factors that can facilitate transition. These factors include:

---

3 The synthesis of the body of existing literature relating to CSF in WFFA projects is based on (Nah & Delgado, 2006)’s classification of CSF for ERP systems. They proposed an interesting classification that groups CSF for ERP projects into seven categories: (1) business plan and vision, (2) change management, (3) communication, (4) ERP team composition, skills and compensation, (5) project management, (6) top management support and championship, (7) system analysis, selection and technical implementation.
• Training both field and back office employees is an important factor for managing change (Westelius and Valiente, 2006; Scholl et al., 2007).

• Business Process Reengineering (BPR): Scholl et al. (2007) identified several factors that may inhibit BPR efforts such as: extant process design inadequacy for work in the field (i.e. manager and/or team exclusion in the conception of new work processes), inappropriate compensation schemes and levels in fieldwork, lack of standard operating procedures, and managerial concerns and issues with regard to field operations.

• Getting people’s Buy-in: according to Bush et al. (2005), success or failure depends mostly on the “Buy-in” of field workers. Two factors may lead to this; first, the degree of process change and workers understanding the associated evolution of work processes due to WFFA implementation, and second, the perception of technology enablement as a means to satisfy worker’s individual needs and the resulting advantages for their work.

In contrast to the static perspective, the dynamic perspective responds to questions related to conducting change in WFFA projects. (Vas, 2005) adopted a longitudinal study for evaluating preponderance factors and their evolution before and after the adoption of wireless FFA. He found that organizational context facilitates the implementation of WFFA in the pre-adoption stage, but inhibits its acceptance in the post-adoption stage.

**Technological Factors:** technology can contribute to the success of WFFA projects and neglecting these factors may cause problems such as lack of flexibility, synchronization, and local decision-making authority, and may lead to cumbersome work order management reporting, or ineffective information organization and poor ergonomics. Effective technological choice can explain the failure or success of WFFA projects. Technological choices are studied according to strategic and functional perspectives. From the strategic perspective, choices are made according to their degree of process transformation and modification of existing procedures within the company (Chen et Kamara, 2008; Scholl, 2005). However, from a functional perspective, choices are made according to technical criteria (Djemai et Favier, 2008). Technical choice includes the choice of architecture (data-based or voice-based), software and its package, wireless network and mobile devices.

**Communication:** Scholl et al. (2007) underline the importance of alliances between managers and field workers who are the stakeholders in wireless FFA projects. They point out how their separation leads to frustration and conflicts for both groups. Synthesizing this body of literature, we conclude that it underlines three factors: change management, technological factors and communication. Among these, change management has been widely studied as compared to other factors.

### 3 Research Methodology

The purpose of this study is to investigate the critical factors effecting WFFA system implementation. To address this objective, we adopt a qualitative exploratory approach. Two factors motivate this choice. First, mobile technology is a young technology in its initial phase of development (Lyytinen and Yoo, 2002). Second, there is little empirical research on WFFA (Barnes et al., 2006; Scornavacca et al., 2005).

---

6 (Hammer & Champy, 1993) define BPR as “the fundamental rethinking and radical redesign of business processes to achieve dramatic improvement in critical, contemporary measures of performance, such as cost, quality, service, and speed”.

---

Proceedings ECIS 2009
When these two conditions are fulfilled (new area and little empirical research), interviewing experts is desirable (Evrard et al. 2003). For our study ten WFFA experts were interviewed: one Business Development Manager, one Mobile Solutions Leader, one CEO of an editing company, 4 CEOs of WFFA integrators, and 3 stakeholders in WFFA projects (2 Directors of Operating Methods and one Telecommunications Manager). The interviewees were asked about WFFA technology, evolution, WFFA impact and barriers. The interviews lasted between 40 and 60 minutes. Audio recordings of the interviews were made and the data was later transcribed. Data analysis was carried out using thematic analysis following the suggestions of Miles et al. (2003). We use Nah and Delgado (2006) classification of CSF to codify data.

4 Results and discussion

The Critical Success Factors found in this study are classified into eight themes: action plan and vision, change management, project team composition, project management, top management support and sponsors, communication, technological factors, and management of mobility.

4.1 Action plan and vision

In this factor group it is important to determine the objective and ROI project before launching the WFFA project.

4.1.1 Objective setting

Clearly established objectives are considered a key to success in WFFA projects. The objectives may be quantitative or qualitative and may vary from one firm to another. For one of the companies studied, the objectives are improved productivity and increased technician responsibility. As stated by one Director of Operating Methods “It’s important for us to provide our technicians with mobility tools to avoid returning to the central station and eventually making a round-trip and for the workload.” At another company, the objective is to improve customer satisfaction.

4.1.2 Justification of ROI

It is important to set operational indicators that facilitate ROI calculations. The most popular indicator is an increase in the number of interventions done per day. In the case of Elyo the number of intervention is increased from 8 to 12 per day and the ROI is attained in 6 months. In some cases ROI is difficult to determine, particularly when objectives are qualitative, for example when the objective is to increase customer satisfaction. “As we prepare the specifications for a project, we analyse each operational process to identify the potential gains. In parallel to the technical solution, we build an administrative tool that allows us to access a maximum of information so that we can track ROI indicators. We only finished deploying the system in February of this year, so the feedback is relatively recent, but we already have very interesting data. These are rough indications, but at the same time they serve as benchmarks, dare I say, for comparison amongst our different operations units. They allow us to
measure where we are in relation to our initial desired target. The trend is very
good.” Director of Operating Methods.

4.2 Change management

The majority of respondents argue that managing change in WFFA projects is relevant
because of potential impact on field workers and state that training, business process
reengineering, and involving users in the project enhances successful change
management.

4.2.1 User training

The majority of respondents agree on the importance of training in managing change,
for example one Telecommunications Manager states that: “Everything is
accompanied by training, for instance, when we deploy an application, it’s always
proceeded by a day of training.” In WFFA projects, there are two kinds of training,
familiarisation with a specific mobile device and software application training. The
first is necessary when a field force has paper process experience but has never used
mobile equipment. The later is always necessary. “What kind of training should be
pursued? If you know that you have field workers coming from a paper culture, you
need to not only provide applications training, but also hands on instruction for using
the (mobile) terminal...Typically, with portable telephones there are occasional
breakdowns. How can I correct the problem? This sort of event isn’t a pure
applications issue, so it needs to be dealt with in the training.” Mobile Solution
Leader.

Training quality can be measured by the number of post-training hotline calls coming
from field workers; the better the training, the fewer the calls. “A poorly trained...
person...will call us everyday and will slow us down, (because) they will require extra
help. That’s proof that the training was ineffective, or that there is a problem in
transferring the information... If the training is successful, there won’t be calls to the
hotline...however, (there is always the possibility that) despite the training, the
number of calls increases (and this is a problem)” CEO of WFFA integrator.

4.2.2 Business process reengineering

WFFA significantly impacts existing business processes. Firms must examine and
adapt their processes in relation to this technology, otherwise the project will fail.
"Repeating existing procedures doesn’t work, changes must be accepted." clarifies one
Business Development Manager. Rewriting or creating processes can also facilitate the
development of specifications lists, as mentioned by one Director of Operating
Methods “When we rewrote our processes we also wrote the specifications list...
100% of our processes were revisited”.

4.2.3 Implication of users

As proved by previous research, user implication is highly relevant to WFFA project
success. “In the appropriation of tools, if we don’t listen (to workers) they reject the
tool, and if they reject it the system falls apart.” explain one Director of Operating
Methods. In addition, these users must be integrated at all stages of a WFFA project, as mentioned by another Director of Operating Methods “The users were integrated in absolutely all stages of the project, even before the specifications list was developed. The technicians were involved in the choice of the final solution after they tested two operational prototypes. These (prototypes) had been field tested for three weeks under real work conditions. The choice was made based on feedback from these experiences. The impact of this test period was huge and gave the project enormous visibility. It really excited the workers who ended up using the system.”

4.3 Communication

The majority of participants emphasize the importance of communication in the success of WFFA. Several classical tools such as internal supports or internal newspapers, meetings…may be used to implement an effective communication but the creation of a network of representative (persons designated in each operational entity) who build a good internal communication appear to be the most efficient tools.

4.4 Team composition

The roles, processes and responsibilities of field workers are determined by Operating Methods Direction. Thus when a WFFA project is undertaken (a project that will strongly impact field work), the project team needs to include representatives from both Information Systems and the Operating Methods Division. Levels of responsibility and involvement vary depending on the phase of the project. At the beginning of a project the two teams interact, but once deployment is finished, the Operations team is left in charge of follow-up and the evolution of the applications.

4.5 Project management

Deployment methodology and financial guarantees are the two project management factors stressed by the participants.

4.5.1 Methodology of deployment

All participants emphasize the importance of deployment methodology in the success of a WFFA project. Globally, they stress five phases:

1. Buy or develop: in this phase the enterprise must choose between an off-the-shelf or a tailor-made solution. With off-the-shelf solutions, the company buys a pre-existing mass marketed application. A tailor-made solution allows the company to develop a specific application that fits their field worker’s tasks. According to Chen et Kamara (2008) these alternatives fall under the category of mobility strategy.

2. Integration or specification: This selection is driven by the “buy” or “develop” choice. In the first case (buying off-the-shelf software) the company opts for gap analysis software to integrate a non-custom-made solution into their existing Information Systems. In the second custom software case, they opt for functional specification software.

3. Pilot phase: This generally takes from two to four weeks. The objective is to provide the solution to a selected group of users who test it and verify its usability.

4. Pre-deployment phase: This generally lasts anywhere from several weeks to a year. At this stage, it is important to select the appropriate population that will test the solution. The goal is to validate all of the WFFA solution components before deployment to the global population.
5. Final deployment: This phase entails global deployment of the solution. A progressive approach is important in order to identify errors or defects and to correct them. As suggested by one participant, “progressive deployment will detect a problem with ten terminals, will redetect new things when we go to fifty terminals, will redetect new hazards at 500 terminals and at a thousand. This is an approach that increases the volume progressively ... while mastering (the system) and reclassifying the process.” CEO of WFFA integrator.

4.5.2 Financial guaranties
Like Information Systems, mobility projects run the risk that estimated budgets may be exceeded and projects will be abandoned. Guaranteeing that the budget estimated in the early stages of the project will not be exceeded is critical to the success of WFFA projects. “(It is vital in order to) assure the operational life of the project because that’s where there’s a major rejection risk. In addition, there are market zones that allow us to be sure that things won’t change economically. We are committed to ... maintaining a fixed price.” CEO of WFFA integrator.

4.6 Top management support and sponsors
Top management implication is also necessary in WFFA projects. “(This aspect) is fundamental because it is truly a project of managing change” explains one Director Operating Methods. The importance of this implication is proportional to the size of the future user group, especially when there are more than 50 users, and when the WFFA project affects the firm’s core business.

Technological sponsors also play a crucial role in the success of WFFA projects especially when there is a large population of field workers that need to be federated. “For example, team leaders help motivate the others (concerning the project) and can be helpful (in passing on messages from top management)” explains a Mobile Solution Leader.

4.7 Technological factors
Effective choice of technological components is considered as the most important aspect in a WFFA project. These choices concern system architecture, software, middleware, mobile devices and telecommunications network (for detailed discussion about these choices and decision criteria please refer to Djemai et Favier (2008) study). “When we put together a project like this, we decide to use a certain number of different components and even if we think that everything is moving in the right direction, it’s important, when choosing middleware and applications, to choose, for example, the right terminal and not make a mistake. After that we have to choose the appropriate telecommunications operator, the correct transmission speed and why, etc...” Mobile Solutions Leader. This aspect can, however, be problematic, as one participant states, “The problems we most often encounter are technical...otherwise stated, the rejections (on the part of the field workers) that we experience are linked to the computing process” Mobile Solutions Leader. This may be explained by the fact that the technology is still maturing.

Owing to the heterogeneity of technology in WFFA solutions and differing development standards, successful communication between purchased components is...
vital. Integration management is an alternative that facilitates and optimises the choice and integration of technological components. “We define each offer in regard to the (existing/available components), they are totally interdependent” CEO of WFFA integrators. In addition, integration management assigns responsibility for and guarantees the correct functioning of the chosen solution(s). If this role is not fulfilled, it is difficult, if not impossible, to identify the origin of function errors and the responsible party.

4.8 Management of mobility

This emergent and increasingly important factor is the result of the growing mobility of field workers who spend the majority of their time outside of their organization. They work alone and remotely from their base of operations, making receiving support difficult if a problem should emerge in the field. This problem does not arise for sedentary workers or workers operating in a local mobility context as they can get support at any time from their colleagues or from their Information System Department. As explained by one CEO of WFFA integrators: “We are working with people who... are all alone (in the field). With a traditional IS, when a problem arises the head of IS is available (to help). (In a remote context) the technician is alone and faced with a malfunctioning machine. He doesn’t have the time to determine what works and what doesn’t, he must respond quickly and make it work...he’s got to figure out the solution by himself.” Several services exist to remotely support field workers and to manage problems. Helpdesk support, device management and applications support are critical factors that are proper to the mobility context and deserve further examination, as follows.

4.8.1 Mobile device management

When mobile devices break down, field workers cannot receive information related to their work and as a result are unable to do their jobs. Quickly providing the fieldworker with functional replacement mobile devices is critical in this kind of project. This activity is called “mobile device management” and integrates several other services like “managing breakdowns, returns, transport and forwarding, (and) management of stock security” according to the CEO of an editing company. These activities can be accomplished by creating an internal maintenance and repair service for mobile devices, or by externalizing the function to integrators who take charge of device management. “We get calls until 16h (four o’clock) in the afternoon. The next morning, before 9 am, the on-site user should have a terminal that is in the final phase of configuration and is being synchronized to pick up from the moment the system broke down. We try to limit this kind of correction, preferring rather to make an “anticipated exchange” containing advanced specialized software that allows the user to avoid breakdown in the event that there is a technical problem... (and this reduces the down time to) virtually zero” CEO of WFFA integrators.
4.8.2 Helpdesk support

Corporations must provide helpdesk support for their field force users on those occasions when they encounter use, login or start-up problems. As one respondent stated, “if the (field worker) can’t enter data into an application, he can call the hotline”. The participants agree that 70 to 80 % of the problems encountered in the field consist of workers who have pushed the wrong keys, mishandled their equipment, or who encounter login or start up difficulties. These problems can generally be resolved remotely in a few minutes by a specialist in the back office.

Two kinds of helpdesk exist, a start-up helpdesk and a recurrent helpdesk. The first supports users for six months following system deployment. The later provides ongoing support for users and is particularly helpful during the release and installation of new software. In addition, the helpdesk can anticipate and react to lingering problems in the field and warn mobile device service management about their existence.

4.8.3 Mobile device fleet management support

When a company wants to install a new application or release a new software version, historically, they needed to physically recover all the devices concerned and install the upgrades. This was very difficult and costly with field force workers in far-flung regions or in several countries. In addition, bringing mobile devices to a central location implied that field force work halted for the several days required to collect the devices from their field locations.

This problem is addressed by device fleet management support or tele-distribution7. “It’s imperative to create new applications for deployment that are capable of verifying what’s happening on a terminal (and to enable the installation or upgrade of existing software). For us this is the biggest challenge for the mid and long term, and it’s extremely important.” explains a Mobile Solutions Leader. This kind of service is relevant to the success of WFFA projects, especially when the company has equipped a large number of field workers with WFFA and this field force is geographically dispersed. “Device management is a critical factor of project success if you have hundreds of regional or international collaborators” Mobile Solutions Leader.

5 Conclusion

In our research we explore critical factors for success in WFFA projects. The eight most prominent keys to success that we identify in WFFA projects are action plan and vision, change management, project management, top management support and sponsors, communication, technological factors, and mobility factors.

This paper reveals that, in addition to classical CSF outlined by Nah and Delgado (2006), “mobility factors” are also critical to WFFA project success due to the dispersed localization of field workers. Mobility factors integrate three sub-elements; helpdesk, mobile device management, and mobile administration. These sub-factors

---

7 Tele-distribution is a kind of middleware (a sort of software) that acts as a communications and command center for multiple applications, content types, and devices (Sabat, 2002).
can be integrated either separately or simultaneously by a company wishing to undertake a WFFA project. The paper provides useful guidelines for IT consultants, firm IT managers and project managers in the implementation of a WFFA system. If the factors presented in this study are taken into account, the likelihood of a successful implementation is greatly improved.

As with any research, this paper has certain limits that can serve as an starting point for future research:
- The CSF in WFFA are studied without consideration to company size or sector. A comparative study of projects carried out in companies of differing sizes and in different sectors is an interesting avenue for further research.
- In this paper the factors aren’t classified by degree of importance, however, this is an interesting subject for further research. Quantitative research is necessary in this type of investigation.
- This study has not explored the pre-adoptions or post-adoptions pattern of CSF importance or shifts in importance between these stages. (Vas, 2005) has undertaken this sort of analysis, but only for change management factors. Thus a longitudinal investigation of the evolution of all factors identified in this study is an interesting area for future research.

Appendix

Some definitions of WFFA proposed in the existing literature:

• FFA is the association between software and hardware, which are used by a specific number of staff, who are responsible to build relationships with customers, maintain expensive corporate and government assets and gather critical data that keep organization running (Rodina et al., 2003).

• FFA is a generic term for mobile applications used in real-time support orders, scheduling, supervising and reporting in the field (Olofsson and Emborg, 2004).

• Wireless FFA is usually used to describe mobile employees, remote from their base of operations, utilizing wireless technologies to perform their specific business tasks (Barnes et al., 2006).

• FFA applications are used by employees such as field service teams, technical teams, or more generally, staff that do not carry out any sales activity (Rangone and Renga, 2006).

• Compared to traditional FFA applications, Wireless FFA offers a substantially increased scope for benefits – particularly through real-time, location independent network connectivity (Barnes, 2004).

• Fully Mobile Wireless Connected (FMWC) is defined as Information and Communication Technologies are assumed to have high potential for improving field operations Gorlenko, and Merrick, 2003) cited in (Liu et al., 2007)).

Abstract

The IT productivity paradox raised the issue of finding appropriate measures for capturing the business value of information technology. While the topic is much discussed on the general IT level, there is little research on the specific investments in innovative mobile and ubiquitous technologies. In this paper, we apply a case study research methodology in order to identify the specific characteristics of mobile and ubiquitous technology investments and the subsequent requirements on appropriate measures for the IT business value of mobile-integrated business processes. The results are discussed with respect to the existing propositions from general IT business value frameworks. The outcome is a set of requirements on IT business value measures tailored to the specific characteristics of mobile-integrated business processes. We see the result also as a first step in the development of a suitable measurement framework which could be applied by both researchers and practitioners, especially ex ante in mobile business process reengineering.

Keywords: Mobile-Integrated Business Processes, IT Business Value, Performance Measurement
1 INTRODUCTION

While in the past the adoption of mobile and ubiquitous technologies has mostly followed a technology-driven approach (Köhler and Gruhn, 2004), organizations increasingly expect measurable business returns from their mobile technology investments (Basole, 2004). In order to demonstrate the returns that the mobile technology delivers to business, companies are required to define appropriate measures to capture the realized business value outcomes. While the topic of IT impact on organizational performance has been extensively discussed in literature in connection with the *IT productivity paradox* (e.g. Brynjolfsson 1993; Brynjolfsson and Hitt, 1994; Dewan and Kraemer 1998), little research has been conducted on appropriate measures for capturing the specific returns of mobile and ubiquitous technology in business process reengineering (Van der Heiden and Valiente, 2002).

The research objective of this paper is to contribute to theory building in the area of *mobile-integrated business processes (MIBP)* by deriving a set of requirements on appropriate business value measures for MIBP. For this, we analyse the findings from four case studies. In order to relate the business value measures to the specifics of MIBP, we explore typical characteristics of MIBP investments and derive the requirements in relation to each characteristic. The outcome is a set of requirements that need to be considered when assessing the business value of MIBP.

In the context of this paper, the term *mobile business processes (MBP)* refers to any business process which is partly or completely mobile and thus cannot be fully supported by the use of stationary IT (Gumpp and Pousttchi, 2005). The term *mobile-integrated business processes (MIBP)* refers to any MBP that is fully supported by mobile or ubiquitous IT (Pousttchi and Thurnher, 2005). Typical examples of MIBP in this respect are mobile service, mobile sales and logistic processes where applications on mobile devices, RFID-based systems, dispatching software, backend systems or whatever is needed for full support are all seamlessly integrated and allowing in the best case a bidirectional real-time information exchange from any part of the process.

The paper is structured as follows: In section 2 we examine the existing literature on IT business value measures and MIBP. In section 3 we describe our research approach and the context of the applied case studies. In section 4 we then identify the specific MIBP characteristics based on the findings from the case studies, derive the requirements on the MIBP business value measures and compare them to propositions from general IT business value models. In section 5 we draw conclusions and discuss the limitations.

2 LITERATURE

2.1 Research on IT business value measures

The need for appropriate measures of IT business value has been a major topic in IS literature for almost twenty years. The topic received particular attention in conjunction with the debate on the IT productivity paradox which claimed that a direct relation of IT investments and productivity outcomes cannot be empirically shown (Brynjolfsson, 1993). While the original paradox actually addresses the macroeconomic level, it also initiated the IT business value research on the organizational level (e.g. Mahmoud, 1993; Barua et al., 1995). Most studies on the organizational level are able to prove a positive correlation of IT investments and organizational performance, but show at the same time a significant variance over the complete sample (Brynjolfsson and Hitt, 1994; Mukhopadhyay et al., 1995).

The process models of IT value explore this effect by looking at different levels of business value (Soh and Markus, 1995; Weill and Broadbent, 1998). They conclude that only through internal user
adoption, the application to business processes and a positive external environment, the IT expenditures will ultimately lead to positive organizational performance (Soh and Markus, 1995, Kohli and Hoadly, 2006). Based on these findings, they suggest assessing business value outcomes at each level separately with a particular focus on the intermediate level (Seddon et al., 2002). Measures at the intermediate, as opposed to firm-level measures, have the advantage to provide insight on how value is created (Davern and Kauffman, 2000) and they are less affected by external factors such as competitor actions or general market developments (Kohli and Hoadly, 2006).

In contrast to the models that focus on the organizational level of measurement, Mooney, Gurbaxani and Kraemer look at the degree of transformation that is created (Mooney et al., 1996). They distinguish three dimensions of IT business value based on the degree of process change: automation, information and transformation. Based on this distinction, they define different measures and demonstrate how business value increases as IT permeates the organization. Their approach basically follows and summarizes an earlier model from Venkatraman who distinguished seven different categories of potential benefits from IT-enabled business transformation (Venkatraman, 1994). Two other central aspects with respect to business value measures are explored by Barua, Lee and Whinston (Barua et al., 1996). First, the IT impact can typically not been measured in isolation and, second, there may be dependencies and conflicting business value impact. They maintain that without the understanding of the complementarity, of the (inter-)dependencies and the conflicts, wrong measures may be applied or business value outcomes may be wrongly measured.

IT business value measurement frameworks have also been developed in the corporate environment. One of the most recognized ones is published by Svard and refers to the value dials concept established through Intel's IT Business Value program (Svard, 2006). In this program, over 350 IT projects were reviewed over a three year period from 2002 to 2004. The result is a set of 18 general measures for IT business value in four categories: headcount management, expense avoidance, revenue increase and working capital. Especially notable is also Svard's definition of business value which is explicitly requesting to represent IT business value in monetary terms. He refers to business value as the benefit for business groups represented in dollar terms which are a result of IT solutions or services. Academic papers in turn define business value typically more general as the contribution of IT to firm performance (Tallon et al., 2000).

While these general requirements on IT business value measures certainly include important aspects that are also valid for MIBP, they, however, do not consider the specific characteristics of MIBP investments and its consequences on particular requirements for MIBP.

### 2.2 Research on IT business value of MIBP

Dedicated research on the specific characteristics of MIBP investments and IT business value measures is rare up to now. As with static IT, the business value of implementing mobile and ubiquitous technologies can typically not be assessed in isolation but only in conjunction with respective process improvements (Van der Heiden and Valiente, 2002). The MIBP literature mainly describes two broad beneficial effects of mobile technology: (1) improved process efficiency, and (2) improved process effectiveness (e.g. Gebauer and Shaw, 2004). Also convenience is suggested as a third potential benefit (Basole, 2004). Most existing papers derive exemplary MIBP benefits based on observations in certain industries, for certain process types or in relation to specific MIBP capabilities. Examples of benefits in specific industries can be found for the building and construction industry (Löfgren, 2006; Gump et al., 2005), healthcare (Scheepers and McKay, 2004), utilities (Nah et al., 2005), intervention forces (Bazijanec and Pousttchi, 2004) and the financial services sector (Hastreiter, 2006). Benefits of specific MIBP types have been explored, e.g., for dispatching processes (Botzenhardt and Pousttchi, 2008). Effects of specific MIBP capabilities like real-time order assignment have been analysed by Habermann (Habermann, 2005). However, it can be contended that none of the studies provides an overarching business value framework and dedicated requirements on business value measures for MIBP.
Another valuable source for examples of achieved business value may also be the various whitepapers from mobile software vendors (e.g. Aventeon, 2008, Cognito, 2008). These whitepapers certainly provide a deep insight in the process improvements and achieved business values, but naturally tend to overestimate business value potentials and underestimate the drawbacks (Van der Heiden and Valiente, 2002).

Specific research on MIBP assessment methodologies is rare up to now. Deibert and Rothlauf (Deibert and Rothlauf, 2006) suggest a set of quantitative indicators (e.g., error rate or stock size) and qualitative indicators (e.g., process and stakeholder goals) for measuring the process performance. However, these indicators remain at the level of process improvement and do not relate to any measurable business value impact. Earlier, Gumpp and Pousttchi (Gumpp and Pousttchi, 2005) provided a structural framework for the implementation of mobile and ubiquitous technologies in business processes and the assessment of its impacts (Mobility-M framework). However, the benefits assessment in this framework is relying on informational added values and thus also lacking concrete measures to capture the achieved business values.

3 METHOD

3.1 Case study research

For our analysis, we apply a case study approach (Eisenhardt, 1989; Yin, 1994). We consider case study research as especially appropriate in this situation as we are aiming to contribute to theory building in a new research area. The case study research allows us to build our requirements on existing practice and leverage the expert knowledge of experienced practitioners (Benpasat et al., 1987).

Following Eisenhardt's process steps for building theory from case study research (Eisenhardt, 1989), we defined the initial research question and selected a group of organisations that seemed suitable to contribute to the research question. In order to achieve a broad understanding of the topic, we selected four organisations for which their M(I)BP is at the heart of their business and which show a high level of maturity with respect to business value assessment. This certainly does not lead to a representative result, but provides insight in advanced practices with regard to the research question. To be most diverse, we selected the organisations from different industries, countries and company size. For data collection, we applied a combination of different methods (Yin, 1994). We reviewed internal documentation, company presentations and conducted semi-structured personal interviews, both face-to-face and telephone-based. In each organization, we spoke in person to at least one person from the IT and the business side who have been involved in the mobile technology implementation phase.

3.2 Applied Case Studies

Case Study 1: Utility Company, Ireland

For the first case study we investigated a major Irish Utility Company in the area of network management and metering. In three phases, over the last 4 years, more than 1,000 technicians have been equipped with a mobile solution. Typical tasks of the mobile technicians are the maintenance of network components and services around meter reading and exchange. Compared to the previous decentralized planning, the dispatching of work orders is now handled through a central dispatching system, which also results in significant organizational changes. The central dispatching system also proposes a preferred task order based on criteria such as priority, specialization of the technicians, and availability of required equipment.
Case Study 2: Logistics company, Netherlands

For the second case study we investigated a Dutch logistics company with an own fleet of 300 and an additional 450 associated trucks. All own trucks have been equipped with ruggedized PDAs. The associated trucks had to commit themselves to use the same mobile software, so that the dispatching can be uniquely controlled through a central tour planning solution. The software on the mobile device provides an order management application, barcode scanning and integrated navigation module. Initially, the mobile solution was implemented with the goal to reduce the vehicle cost through saved kilometres and toll costs, but the efficient real-time management of new orders, and especially the provision of information problem reports on an integrated webpage, have also proven to be a differentiator in the market and resulted in an extended customer base for the logistics company.

Case Study 3: Airport operating company, Europe

For the third case study we investigated the service unit of a company in the airport operating sector. The company provides both logistics and facility maintenance services. In total, about 30 processes have already been mobile-integrated or being currently rolled out. More than 1000 mobile workplaces are impacted. The MIBPs include the maintenance of equipment, technical asset control as well as a series of processes around loading and unloading of the aircrafts. Many technical assets have also been equipped with RFID tags to ensure efficient data exchange. While the first processes were mobilized mainly to comply with legal requirements, mobile integration has increasingly become a source of business value for the company. The mobile process engineering does not only allow for real-time coordination and seamless data transfer but also for the accurate recording of start and end-time of orders which is basic for an accurate service charging to the airlines.

Case Study 4: Sales company, Germany and Austria

For the fourth case study, we investigated a specialized sales company that is offering sales and merchandizing services for major product companies especially in the cosmetics industry. The company has about 200 mobile sales consultants equipped with a scan-enabled mobile device. Main intention of the mobile solution besides the improved coordination of customer visits is the creation of a central market intelligence system. The documented data from the field will be analysed to improve the sales process, but also the optimal product positioning and best display method. The generated knowledge will be provided as extra service. Also a new consulting arm for innovative display methods is planned, where the company can run specific campaigns and document the results directly on the mobile device including photos and recorded testimonials from the shop owners.

4 REQUIREMENTS ON MIBP BUSINESS VALUE MEASURES

In this section, we derive the requirements on business value measures of MIBP based on four specific MIBP characteristics that have been rated by both the interviewed experts from the business and IT side as major impact factors on the definition of their MIBP business value measures.

• Close relation of MIBP investments to the business side
• Dependency of MIBP impact on organizational changes
• Significance of mobile employee independence
• Consideration of the innovative nature of MIBP

In the following, we describe each characteristic and derive the associated requirements on the business value measures. To raise the theoretical level, we also compare each requirement with propositions from existing IT business value literature. The outcome is a set of six requirements that should be considered when defining a suitable measurement framework for business value of MIBP (Figure 1).
Specific characteristics of MIBP from case studies

Requirements on MIBP business value measures

Figure 1. Analysis model for deriving the requirements on MIBP business value measures

4.1 Close relation of MIBP investments to the business side

The first characteristic states the close relation of MIBP investments to the business side. In all regarded cases, the investments are to a large extent sponsored from budgets outside of the IT department. Business managers are also over proportionally involved in the MIBP planning, implementation and control processes. As a consequence of their sponsorship, the business side normally associates clear expectations on the concrete technology contribution to defined business objectives. Typical business objectives in that sense are, for example, cost savings for central coordination, reduction of rework efforts or an increase of mobile work productivity. In some cases the business objective is even more concrete in the sense that it determines a concrete value target like 10 % cost savings or achieving 100 Euro of additional revenue per customer. To prove that the technology can really fulfil its expectations, the business value measures need to be set up in direct relation to the concrete objective for which the technology is deployed. Concerning the business objectives also the expected time of the business value realization is relevant. The business side typically expects almost immediate results from the MIBP implementations. This is clearly another major impact factor on the definition of appropriate business value measures and the time horizon for actual business value measurement.

<th>Business objectives and expected realization time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Utility Company</td>
<td>All direct project costs sponsored from business side. Project lead by business side with IT support.</td>
<td>Improving dispatching capabilities with expected savings of at least 300k Euro per year. Reintegration of outsourced services saving a min. of 100k Euro. Realization of business value for back office expected for first year, total project payback within 24 to 30 months.</td>
</tr>
<tr>
<td>Logistics Company</td>
<td>Specific MIBP project outside normal IT budget. Project lead by IT side, high involvement of drivers during design phase.</td>
<td>Reducing kilometres by 5%, resulting in vehicle cost savings of 800 Euro per truck per year. Not planned, but achieved has been an extent ion of the customer base and orders by 18%.&quot;Immediate&quot; impact of mobile technology investment expected, payback within 18 month.</td>
</tr>
<tr>
<td>Airport Operating Company</td>
<td>Partly sponsored from business side. Infrastructure updates within IT budget. Project lead by IT with close relation to business side.</td>
<td>Fulfil legal requirements, reduce overall process expenses by defined percentage, improve service level to airlines to justify agreed price increase. Single projects embedded in MIBP, concrete payback horizon based on strategic plan.</td>
</tr>
<tr>
<td>Sales Company</td>
<td>Specific MIBP project outside normal IT budget. Dedicated project team from business and IT side.</td>
<td>Increasing sales by 20% through optimized product selection and improved product display Realization of business value within two years, also depending on implementation of business intelligence system</td>
</tr>
</tbody>
</table>

Table 1. Overview of case study findings in relation to the first MIBP characteristic

Based on the close relation of MIBP investments to the business side, we derive the first two requirements on MIBP business value measures.

Requirement 1: MIBP business value measures should be defined in relation to the business objectives for which the technology is deployed

Proceedings ECIS 2009
Requirement 2: MIBP business value measures should be considering the time horizon of the expected realization

Within the IT business value literature, the relation of measures to concrete goals is a central demand for realizing business value outcomes. Kohli and Hoadly state that the technology investments are typically initiated in the context of certain strategic objectives. Measures should therefore be defined in close relation to the strategic goals in order to show if the original goal has been achieved to the extent expected (Tallon et al., 2000; Kohli and Hoadly, 2006). Hitt and Brynjolfsson contend that the focus of an IT initiative, i.e. productivity, customer value or profitability, determines which measures are attended to (Hitt and Brynjolfsson, 1996). Regarding the measurement of business value outcomes, the literature typically mentions that it has to happen over a longer period of time (Wagner, 2003), especially in dynamic environments (Chan, 2000). The specific requirement of a short time horizon is mentioned by Svard, particularly in situations where there is also high pressure on the business side to deliver fast results (Svard, 2006).

4.2 Dependency of MIBP impact on organizational changes

The second MIBP characteristic derives from the awareness that the business value of MIBP can only be realized when companies also possess the flexibility to incorporate the required organizational changes. Only in very few cases, for example the logistics company's vehicle cost reductions, the mobile technology implementation leads to immediate business value effects. In most case, especially when the MIBP is intended to transform the existing process, the organisational changes are condition to the realization of business value outcomes. The utility company for example realized business value only after completely restructuring the dispatching function from a decentralized to a centralized structure. The business value measures consequently need to consider this complementarities. They also need to comprise the complete effect that is generated through the technology and the organizational changes which in turn means that also all related costs, including expenses for process reengineering and organizational changes, need to be considered in ROI calculations. Clear aim of the companies is to ensure traceability and credibility of the business value assessment. Therefore they typically define their business value measures at the internal level. This avoids the dilution of the results through external effects, which often cannot be influenced.

<td>Measuring the weekly product sales depending on new product assortments and re-positioning in the stores</td>
</tr>
</tbody>
</table>

Table 2. Overview of case study findings in relation to the second MIBP characteristic

Based on these cognitions, we derive the third requirement on MIBP business value measures.

Requirement 3: MIBP business value measures should be defined at the internal organizational level, assessing the complete business effect of the MIBP

In the IT business value literature, the complementary of IT investments with organizational changes is central aspect in all process and BPR-related models. Kohli and Hoadly for example state that the IT
effect in IT-enabled BPRs is typically not to measure in isolation (Kohli and Hoadly, 2006). The IT implementation often creates business value only in combination with coordinated structural changes (Brynjolfsson, 1993) and must be changed in a coordinated manner to improve business performance (Barua et al., 1996). For the business value measurement, the process models typically suggest to set up separate measures at each organization level (Soh and Markus, 1995; Weill and Broadbent, 1998), however it is widely suggested to use the intermediate level, i.e. the internal process or organizational level, for assessing business value outcomes (e.g. Kohli and Hoadly, 2006).

4.3 Importance of mobile employee independence

As the cases show, it is crucial to respect the fact that the mobile employees are often self-employed or at least a high share of their income depends on performance. So it should be in their natural interest to improve their performance through mobile technology support. However, in reality we can also see many cases where the productivity of the mobile employee is even decreasing. The reason is to be found in the on-site work process which is sometimes loaded with additional verification and documentation needs resulting in significant business value gains at the back office level. To reach acceptance in these cases, a potential negative business value for the mobile employees needs to be considered in their performance schemes. This necessarily requires the separate measurement of business value outcomes for the mobile work process and the back office. The separate measurement becomes even more crucial in cases where the mobile process is outsourced. If the additional effort is not reflected in the price per work task, the external service provider is not likely to adopt the new technology, thus the associated business value impact at the back office is inhibited. In an outsourcing scenario even a small productivity increase for the mobile work process may often not be enough as the expenses for mobile devices and process changes are often to be carried by the external service provider. A distinct assessment of the added value is also necessary for business partners or customers. It is for example contingent for setting accurate prices for new service offerings. Furthermore, from the experiences in the case studies, it can be concluded that the measures should be agreed upon by all stakeholders to ensure that objectives are well understood by all parties involved and the measurements receive broad long-term support.

<table>

<td>Utility Company</td>
<td>70% of work orders currently handled by internal employees (25% performance bonus), 30% outsourced</td>
<td>Internal work force involved from the beginning of the project. Measured lower productivity in some areas.</td>
</tr>
<tr>
<td>Logistics Company</td>
<td>45% of all tours through own fleet, 55% outsourced. External drivers paid based on structure of tour.</td>
<td>Measures mainly provided from business side, aligned with major external transport organizations.</td>
</tr>
<tr>
<td>Airport Operating Company</td>
<td>Central solution provided to different business departments. Outsourcing in certain areas, e.g. cleaning.</td>
<td>Measures aligned within project team, service level measures defined in coordination with airlines.</td>
</tr>
<tr>
<td>Sales Company</td>
<td>Mobile sales personnel typically self-employed, but strongly connected to company. Average performance bonus between 20% and 40%.</td>
<td>Measures defined within project team and in accordance with mobile sales personnel. Extra payment scheme for additional work tasks that are supported by the new MIBP.</td>
</tr>
</tbody>
</table>

Table 3. Overview of case study findings in relation to the third MIBP characteristic

Based on these finding, we derive the next two requirements for MIBP business value measures.

Requirement 4: MIBP business value measures need to assess the outcomes separately for different stakeholders in the process

Requirement 5: MIBP business value measures need to be agreed with all stakeholders prior to the invest to ensure later acceptance
The separate business value measurement for different stakeholders is not a typical requirement in IT value frameworks. It is especially important in MIBP due to the high share of self-employment and outsourced work tasks. The stakeholder agreement in turn is a central topic in various concepts (e.g. Svard, 2006; Ward and Daniel, 2003). For implementation of the stakeholder agreement prior to the investment, Ward and Daniel for instance suggest to create a dedicated benefits realization plan that a priori determines the business value measures and also defines the measurement points (Ward and Daniel, 2003).

4.4 Consideration of the innovative nature of MIBP

Throughout the cases, it can also be observed that business value measures for MIBP have a specific importance in the phase of assessing the business value potential prior to the investment, i.e. when building the business case. This is due to the innovative nature of MIBP for most companies. While the companies are able to estimate the impact of automating existing processes quite accurately, they face problems when the MIBP really leads to a new process design or effectiveness increases. Depending on the intended degree of innovation, also the consideration of realization risks will become a central element for assessing the business value potential.

<table>
<thead>
<tr>
<th>Case Study</th>
<th>Degree of intended process innovation</th>
<th>Business Value realization risk</th>
</tr>
</thead>
<tbody>
<tr>
<td>Utility Company</td>
<td>High. Strong transformational character of new process. New role for many back office employees, reduction of staff in call center.</td>
<td>High realization risk as centralization of dispatching is imposing a role change for many coordinators. Risk is incorporated in time horizon of business value measures.</td>
</tr>
<tr>
<td>Logistics Company</td>
<td>Low. Basically automation of previous paper-based process. New is option to control tour in real-time.</td>
<td>Low realization risk internally as stricter tour control is supported by most drivers. Higher risk of integrating external drivers.</td>
</tr>
<tr>
<td>Airport Operating Company</td>
<td>High. Often new roles with more responsibility for mobile workers.</td>
<td>Business Value realization risk is reduced by earlier involvement of staff in MIBP definition.</td>
</tr>
<tr>
<td>Sales Company</td>
<td>Medium degree of innovation. Base process of sales people is not changed, but extended with new work tasks.</td>
<td>Medium realization risk. To ensure acceptance, the mobile workers get paid extra for the new work tasks.</td>
</tr>
</tbody>
</table>

Table 4. Overview of case study findings in relation to the forth MIBP characteristic

To cope with the specifics that arise from the innovative nature of MIBP, we derive the sixth requirement on MIBP business value measures.

Requirement 6: MIBP business value measures should regard the degree of intended innovation and consider the corresponding realization risks especially when the MIBP has a transformational character.

In the IT business value literature, the importance of measures for the assessment phase prior to the investment is for example highlighted by Davern and Kauffman (Davern and Kaufman, 2000) who also conclude the measures need to be suitable for the estimation of business value and the subsequent tracking of achieved results. The business value dimension model by Mooney, Gurbaxani and Kraemer (Mooney et al., 1996) also helps in the assessment phase. Based on the degree of intended change, automational, information and transformational, the business value expectation can be set. The consideration of business value realization risk in the measurement process is considered for example by Peppard, Ward and Daniel in his distinction of problem-based and innovation-based interventions (Peppard et al., 2007).

4.5 Resulting set of requirements on MIBP business value measures

Based on the analysis of the specific MIBP characteristics, we derive a set of six distinct requirements that need to be considered when defining appropriate MIBP business value measures, which is shown in Figure 2.
5 CONCLUSION

The research objective of this paper was to develop a set of requirements on appropriate business value measures for MIBP. Based on the case studies of four different companies with distinct experiences in the implementation of mobile and ubiquitous technologies, we identified four central characteristics of MIBP and derived six subsequent requirements that need to be considered when defining business value measures of mobile-integrated business processes.

Comparing these requirements with existing IT business value frameworks, it can be concluded that especially the short time horizon and the separate assessment of the business value outcomes for different stakeholders stand out and can be seen as very particular for MIBP. Furthermore, it can be concluded that the complementarity of mobile technology and organizational changes is central for the definition of MIBP business value measures. The complementarity points to the fact that mobile and ubiquitous technology can only unfold its potential in connection with associated business process changes and organization flexibility. The innovative nature of MIBP also demands for the development of a business value concept that especially supports companies in the phase of evaluating the business value potential and designing MIBP that have a true transformational character. This will be an essential issue for realizing the true potential that MIBP offer.

This paper only represents a first step in the development of a business value framework for MIBP. In order to ensure the applicability for all types of MIBP, the research needs to include a wider range of cases, especially in areas such as warehouse optimization, facility management, construction or healthcare solutions. The eventual framework will also require an extension with regard to the public service sector where business value is rather created through improved offerings to the people rather than cost savings or revenue increases. The result is especially intended to be used ex ante and to provide an improved third quadrant to the Mobility-M, enabling better investment decisions within the process model for mobile business process reengineering.

OPEN PROCESS INNOVATION: 
A MULTI-METHOD STUDY ON THE INVOLVEMENT OF 
CUSTOMERS AND CONSULTANTS IN PUBLIC SECTOR BPM 

Niehaves, Björn, European Research Center for Information Systems, University of Münster, Leonardo-Campus 3, 48149, Germany, bjoern.niehaves@ercis.uni-muenster.de 

Abstract 

Open Process Innovation – drawing from the literature on Open Innovation and Business Process Management (BPM) – promotes the study of how to systematically make use of knowledge that lies outside of an organization’s boundaries for process innovation initiatives. Open Innovation has been heavily studied for product innovation, however, process innovation has not yet been researched from such perspective. Against this background, we seek to investigate into variables that impact on the qualities of Open Process Innovation taking the example of the public sector domain. This paper examines how personnel resource scarcity exerts influence on the involvement of i) customers (here citizens and local companies) and ii) consultants (here management and software consultants) in public sector BPM. Our multi-method analysis shows that personnel resource scarcity has consequences for BPM-related collaboration schema as it restricts the involvement of customers. Based on our findings, implications for theory and practice are discussed, including implications for studies on BPM maturity or on business process design. We call for a governance-theory perspective on process innovation as a fundamental basis for understanding and designing the institutions that shape collaboration in open process innovation. 

Keywords: Open Process Innovation, Business Process Management, Governance, Public Sector
1 INTRODUCTION

External actors play an increasingly important role in public sector reforms. Various approaches seek to modernize, improve or restructure public administrations, be it practices in context of New Public Management (Pollitt and Bouckaert 2004), Electronic Government (Lenk 2004), or business process management (BPM). Despite the distinct phrasing, all of these approaches overlap in several elements. The central goals of local government reforms are on the one hand concerned with cost reduction (Asgarkhani 2005) and the increase of efficiency (Ridder et al. 2005) and, on the other hand, with customer orientation (Reichard 2003). Due to the high pressure, the diversity of demands, and new areas of responsibility, local governments increasingly rely on innovation networks (Rethemeyer 2007). Various external actors are involved in reform processes, such as software and management consultancies (Pratchett 1998) or individual citizens (Wollmann 2000). Here, Open Innovation can be regarded as a management paradigm addressing related challenges (Chesbrough 2003a, 2003b) as it studies the role of external actors in extending the pool of capabilities of a (government) organization (Feller et al. 2008).

Open Process Innovation can be regarded as a management perspective on process innovation which promotes the study of how BPM activities could be more successful when making use of BPM knowledge which lies outside of the organizational boundaries. Research on process management maturity discusses two major types of external actors for BPM collaboration, customers and BPM experts (for instance, Rosemann et al. 2006). Against this background, we seek to investigate into variables that impact on the qualities of Open Process Innovation taking the example of the public sector domain. This paper addresses the following research question:

*Does personnel resource scarcity exert influence on the involvement of i) customers (here citizens and local companies) and ii) consultants (here management and software consultants) in public sector Business Process Management?*

In order to achieve this research aim, we undertook a comprehensive multi-method study. First, within a 22-months time frame, 16 interviews were conducted with experts in local government BPM in Germany. As a second step, a quantitative analysis of BPM-collaboration with customers and consultants was carried out, taking into account the answers of 357 local governments.

The paper is structured as follows: Section 2 builds the theoretical foundation of our analysis. Subsequently, the discussion of the research methodology applied takes into account issues of method selection, interviewee selection, and data collection and analysis. Following the result discussion, we seek to reflect on the implications for theory and try to open up new vistas for BPM practice. The final section contains conclusions.

2 THEORETICAL FOUNDATION

2.1 Policy Networks and Collaboration

Against the background of a mounting policy and system complexity in the public sector, governments have to increasingly rely on resources of knowledge, capacity, and expertise outside of their own organizational boundaries (Rhodes 1997). As Rethemeyer (2007: 201) puts it, “[c]ontemporary government cannot function unless it can leverage the knowledge and expertise of vast networks of public and private sector organizations.” Here, policy networks can be regarded as structures in which stakeholders of public policy carry out decision-making. Policy networks might be understood as “sets of public agencies, legislative offices, and private sector organizations (including interest groups,
corporations, and non-profits) that have an interest in public policy within a particular domain” (Rethemeyer 2007: 201). Despite its importance, little research has yet elaborated the role of networks in the area of BPM (a related study on collaborative e-Government is Gil-Garcia 2007). While only few public sector reform studies take an actor-oriented spin (for instance, Sarker et al. 2006; Kuhlmann et al. 2008), an explicit BPM network approach is not to be found in current literature.

2.2 Open Innovation

The paradigm of ‘Open Innovation’, first described by Chesbrough (2003a, 2003b), tries to address the high demands of innovation processes. Companies find themselves exposed to constantly rising pressure due to higher competition, increase of acceleration and rising customer demands. Research and development divisions are often dysfunctional in coping with such increased pressure. Hence, in contrast to ‘Closed Innovation’, companies focus on acquisition of external knowledge, e.g. by know-how buy-in or the support of universities. This results in blurring enterprise boundaries, in particular the boundaries of processes in product and service development. In each development phase, external knowledge can be integrated as well as knowledge can be extracted and brought to market as independent products. The outside-in process extends the knowledge base of a company, whereas the inside-out process aims at commercialisation of ideas and sale of intellectual property. The coupled process describes work in alliances of complementary partners, where give and take is crucial to success (Gassmann and Enkel 2004). While Chesbrough (2003a, 2003b) originally examines private sector product innovation, the approach can be applied to the public sector as well. Here, various forms of collaboration can already be found, including collaboration with consulting companies (Pratchett 1998) or individual citizens (Wollmann 2000).

2.3 BPM and Process Innovation

BPM describes the efforts of an organisation to manage its processes, for instance, to monitor, analyse and optimize them. BPM can be considered to subsume fields like process innovation, optimisation, improvement or reengineering (Hung 2006, Hammer & Champy 1993, Davenport 1997, Zairi 1997, Breyfogle 2003). BPM habitually includes methods to automate tasks, define processes as a sequence of work steps, and to define responsibilities (for a comprehensive overview of IS and process innovation see Tarafdar & Gordon 2007). Major characteristics of public administrations, in contrast to private companies, are a high density of legal rules and a larger variety of goals: guarantee of proper legislation and jurisdiction, promotion of economic development, defence of public rights or environmental protection are only some of them (Lenk et al. 2001). For BPM in local governments, these issues imply more complex processes that contain a multitude of decision points and that are rarely well structured.

External actors play an integral role in BPM (de Vreede 1998; Dean et al. 1995; den Hengst & de Vreede 2004, Magdaleno et al. 2008) and especially in models of BPM maturity. For instance, Fisher (2004), Rosemann & deBruin (2005) and Rosemann et al. (2006) develop BPM maturity models with the intent to assess and evaluate BPM activities in organizations. Habitually, five stages are differentiated from one another, ranging from an initial state with uncoordinated and unstructured attempts to optimized BPM being core part of strategic and operational management and incorporating customers, suppliers, distributors and other stakeholders. Following these frameworks, openness – in terms of systematically involving stakeholders in BPM activities – is a major characteristic of high BPM maturity, while the heavy reliance on external expertise – here consultants – is a characteristic of low BPM maturity (Rosemann et al. 2006; see also Fisher 2004, Rosemann & deBruin 2005). Against this background, we seek to investigate into the question of other variables than that of BPM maturity – in the context of this paper personnel resource scarcity – exert influence on BPM-related
collaboration with consultants and customers (in our public sector study: citizens and local companies).

2.4 Open Process Innovation

Accordingly, Open Process Innovation can be regarded as a management perspective on process innovation which promotes the study of how BPM activities could make use of BPM knowledge that lies outside of the organizational boundaries. While such understanding opens up for an analysis of a variety of potential BPM-collaborators (for an overview, for instance, Niehaves & Kobayashi 2009), we focus in our analysis on BPM-related collaboration with consultants (management and software consultants) and customers (citizens and local companies) on the level of an individual process.

3 RESEARCH DESIGN

3.1 Qualitative Method

Method selection. A series of 16 semi-structured expert interviews was conducted within a 22 months-timeframe. Here, qualitative expert interviews allowed for gathering rich data and for building up a deeper understanding of the phenomenon under investigation. The involvement of external actors in public sector BPM initiatives has not yet been studied intensively – neither with qualitative nor quantitative means. Against this background, we sought to reflect insights derived from the literature analysis as a first step for a subsequent quantitative study.

| Period of data collection | June 2006 to March 2008 |
| Duration per interview | Average of 65 Minutes |
| Transcribed pages | ~ 150 pages |
| Transcribed words | ~ 95,000 words |

Table 1. Data Collection Fact Sheet

Interviewee selection. Interviewees include public officials that are responsible for BPM-related reforms in German local governments. The researcher’s professional network and recommendations by other study participants have been the basis for potential interviewee identification (snowball sampling). Regarding the size of the administration represented in this study, the set is representative (regarding the German setting) as it covers small(est), medium-sized and large(st) organizations. Moreover, it covers data from public organizations from all parts of Germany. Thus, reflections on a representative organization size and geographical distribution have been major criteria for the interviewee selection.

Data collection and analysis. The interviews were semi-structured, meaning that a part of the interview was shaped by questions derived from the literature analysis, while an additional free part allowed for an open discussion of other relevant aspects brought up in the interviews. All interviews were tape-recorded and transcribed afterwards resulting in 150 pages of transcript, comprising about 95,000 words (for details see Table 1). The transcripts were then analyzed and coded against the background of the variables/constructs in the research model.
3.2 Quantitative Method

Data Collection. The quantitative part of our study was carried out in 2008 and covers 357 cases of German local governments in the sample. A questionnaire was posted online and a random sample of 8,000 government officials, each responsible for (BPM) reforms in a single local administration, were invited to participate in the study. Out of about 12,250 local governments in Germany, thus, ~65% have been contacted and ~3% answered the questionnaire. The answers comprise local governments in 13 out of 13 large-area federal states – plus Berlin. An additional non-response analysis did not reveal any biases in the study participants.

Data Analysis Technique. In order to study the impact of personnel scarcity on BPM collaboration schema, the two samples test of significance (also known as independent samples t-test) was chosen. Such statistical test examines the difference between two sample means and here indicates if an independent variable (grouping variable for the samples) exerts influence on a specific dependent variable (for details regard this statistical test see, for instance, Argyrous 2005).

As for this study, the independent variable (grouping variable) is the personnel resource scarcity of an organization while the dependent variable represents the importance of a particular actor in BPM networks. Regarding the independent variable, the degree of agreement on the statement of “There is a lack of personnel resources to conduct desirable reforms in our public administration” led to two different groups (not agree; agree). Regarding the dependent variable, the study participants were asked “How important was ACTOR_X for business process management in your local public administration in the last five years?”. The questionnaire allowed for an answer by five degrees of importance, ranging from 5 (="Very important") over 4, 3, 2 to 1 (="Not important at all"). Consequently, a code 5 means that the actor is at the core, while a code of 1 indicates that the actor is in the periphery of a network. Following the results from our literature review and our qualitative part of the study, here, four external actors were analyzed for their importance in BPM networks: citizens (customers), local companies (customers), management consultancies, software consultancies. Accordingly, for example, the answer to the question of “How important were citizens for business process management in your local public administration in the last five years?” was included with a 5-point likert scale in the group-comparative independent samples t-test. Therefore, four dependent variables (each actor) were analyzed for their dependence on personnel resource scarcity.
4 RESULTS

4.1 Qualitative Study Results

External Experts in Public Sector BPM. Business Process Management (BPM) activities cover a broad variety of issues ranging from selecting process modeling methods, defining process documentation standards, implementing IT support for BPM activities, establishing a process-oriented culture, BPM training, BPM governance to concrete process analysis, optimization, and design (Rosemann et al. 2006). Such topics might be very challenging as they require comprehensive, but very specific BPM know-how. Against the background, that BPM activities are comparably new to the public sector, the majority of public organizations do not feature this know-how and their staff is most frequently better educated in other areas, such as law, regulations, or task-specific aspects, rather than in BPM. Here, a public official states:

Due to the size of our organization, we often don’t have the necessary in-depth know-how [for BPM reform issues]. Our staff has to deal with a broad range of topics rather than being a very expert [...] in BPM. Therefore, we might sometimes run into situations in which we have to seek for support by professionals, by external experts.

Thus, the need for BPM specific know-how often requires that local governments seek external BPM expertise. To give an example, a public official identifies BPM-related communication action as a potential field which requires support from outside of the organization:

Process design and implementation heavily relies on effective internal communication. Against this background, several departments in our organization have already carried out communication analyses, tried to identify potential to improve BPM-related communication, and provided specific training for the department heads and staff members. Here, we did receive support by an external expert.

Citizens in Public Sector BPM. When it comes to innovating those processes which feature points of interaction with organization-external entities citizens are seen as a potential cooperation partner. A public official argues:

20 years ago, we could observe an attitude among our colleagues like ‘The government is in charge and has to define what is to be done’. However, this attitude changed pretty much. Today, we perceive our administration as a public service provider. And as we provide services to our customers, we don’t want to be disconnected, but to stay in close contact with them. This also means that we do want to exchange ideas with the citizens.

The administration understands itself as a service provider to its customers, the citizens. In that role, innovation of external business processes, here service innovation, is considered as a mean to enact citizen-oriented service design. Another argument to involve citizens in process management activities is concerned with the acceptance of BPM-related change efforts:

[Process innovations […] need to be accepted by the stakeholders. I’m not sure, if it’s efficient to involve that many people, but I do know that if you want to implement successfully, you have to have the people on board. My experience shows that it’s way easier to achieve acceptance for certain change processes in case you’ve involved people beforehand than in case you’re just ordering to do something.

Proceedings ECIS 2009
To sum up, the interviewees identify the necessity to involve citizens in BPM activities. However, the arguments provided—customer-orientation in service design and acceptance of BPM-related change effort—do apply mainly in the context of innovation external rather than internal business processes.

Personnel resource scarcity and the involvement of consultants. The involvement of external experts is seen from a critical perspective, especially with regard to employee motivation:

In general, we prefer to involve internal know-how and internal ideas. Employees have a totally different identification with those ideas they have created themselves than to those ideas that came from others, for instance, external experts.

However, the interviewees identify a multitude of factors, related to a lack of resources, which necessitate the involvement of external experts. A major argument is that of a lack of BPM-specific know-how among the local government employees. This argument becomes even stronger in case of a lack of personnel resources as the public administration employees are already working long hours and do not have the time to educate themselves in BPM. A public official formulates:

Many of our employees, including myself, are engineers. We’re experts on different content than [BPM] reforms and we, thus, have to familiarize ourselves with specific reform know-how … but that’s besides everything else we do.

Additionally, arguments are found that BPM projects often exceed the personnel capacities available in the local government. Such capacity deficit necessitates the involvement of external expert, here consultants:

In my opinion, it is very important to involve know-how and to get capacity support by external experts. Regarding the in fact little personnel resources we have available, it wouldn’t be possible to conduct such large [BPM] projects on our own.

We’ve just completed a large organizational redesign project where we had wide-ranging support by a consulting company. That project would have been far too capacity-intensive for the personnel resources available within our own organization.

When considering different ways to achieve necessary BPM know-how, public administration might have two basic option: first, to hire new people or to educate existing staff (internal solution), second, to hire external experts, consultants. Here, arguments are found that economic necessities might support that external experts are involved instead of hiring additional staff: BPM know-how is often too specific and too expensive to have experts working as employees in the local government. A public official argues:

We look for cooperation with external experts in case we aren’t able to solve a specific problem on our own … or if it’s just cheaper to involve external expertise.

For the future, I do believe that cooperation [in process-related reform activities] will increase. This is due to pure economic necessity and we won’t have too many other options.

To sum up, the qualitative data indicates that a limitation of personnel resources makes it necessary to involve external experts, meaning to hire consultants. To local governments, such cooperative solution to BPM efforts tends to be more cost-efficient than hiring new employees with such BPM expertise or to comprehensive educate existing staff in BPM.
Personnel resource scarcity and the involvement of citizens. Regarding the effect of a lack of personnel resources on citizens cooperation in service innovation, a public official states:

*One of the main reasons to not involve citizens [in our BPM activities] is that we’re not able to manage too many projects at the same time. We have 80 employees working in our organization [...] The big project we’re working on at the moment is concerned with shared service structures. Before that, it was the implementation of a managerial accounting system and this involved the work of all the employees of our administration. Thus, we’re only able to operate with the limited personnel resources available and this in fact means doing one project after the other.*

Here, it becomes clear that the involvement of citizens requires personnel capacity and that such cooperation effort has to be seen in the context of increasing legitimacy and transparency of public services and the administration.

### 4.2 Quantitative Study Results

The independent samples t-test and additional descriptive analyses were processed applying the SPSS 16.0 software package. Table 2 shows the Independent Samples t-Test Group Statistics, Table 3 provides the Independent Samples t-Test Results.

**Table 2. Group Statistics**

The results show that the influence of personnel resource scarcity, here the group-difference, is significant for both customer groups (citizens and local companies) at 0.95 confidence level! However, group-differences are not significant for consultants (neither management nor software consultancies). The lower and upper limits of the 95% confidence interval (last two columns, Table 3) span the range in which the difference between the population means is to be expected. If such interval does not include the value of 0 (here: applies to both customer groups), we can reject the hypothesis that the population means were equal. This reads as: With a confidence of 95%, we can assume that the importance of customers (both citizens and local companies) is different in organizations depending on personnel resource scarcity.

*Table 3. Independent Samples Test*

### 5 DISCUSSION

The independent samples t-test reveals that there is a significant group difference in the importance of customer (both citizens and local companies) in public sector BPM depending on the scarcity of personnel resources in the organization. Customers play a less important role in BPM networks of organizations in which personnel resources are perceived scarce. Against the background of the qualitative study results, we understand that, in general, the involvement of customers in process innovation is regarded as a desirable action. Such insights confirm the BPM maturation of an organization towards and intelligent operating network where processes are innovated on the basis of an extensive involvement of stakeholders (for instance, Rosemann et al. 2006). Personnel resource scarcity, however, is a (new) variable to be considered in the BPM maturity and governance discussion. A limitation of personnel resources has an impact on the cooperation schema in BPM initiatives. Literature on BPM maturity (for instance, Rosemann et al. 2006; see also Fisher 2004, Rosemann u. de Bruin 2005) discusses the importance of external actors in BPM. Here, the heavy reliance on external expertise is identified as a characteristic of early maturity stages while the involvement of stakeholders, especially customers, is regarded as a characteristic of high maturity. However, personnel resources do have an impact on this picture. Here, we can interpret that the involvement of customers in process innovation, and thus the maturation of BPM initiatives, is hindered by personnel resource scarcity. This opens up for follow up questions of how customer collaboration in BPM can be designed more resource-efficiently.

Taking a governance-theory perspective (Williamson 1975, see also Rowley et al. 2000), potentially fruitful avenues for future research could include the study of how to design the institutions that govern the involvement of customers (and other actors) in process innovation. How could institutions of open process innovations be designed in order to allow for a more effective and efficient involvement of customers? For instance, such studies could include the design of business process modelling methods or toolsets – in terms of design science (Hevner et al. 2004; Niehaves 2007a) – in order to reduce transaction costs of collaboration. Such might not primarily focus on the optimization of business processes on a very detailed level, but rather provide a more general understanding of the
processes, their aims, and their context. Here, modelling could take place on a higher degree of abstraction, containing modules or building blocks instead of detailed description of each minor step. This approach ensures an increase of transparency and, hence, legitimacy. In addition, management-oriented studies could examine methods for improving quality and costs of customer-collaborative BPM, for instance, drawing from methods of open innovation (Chesbrough 2003a).

Moreover, we consider it potentially fruitful future research to examine the effect of personnel resource scarcity – and other variables – on the involvement of additional external actors (for instance other local governments (Becker et al. 2003; Algermissen et al. 2005) or superordinate organizations such as central governments (Niehaves 2007b)) and, thus, to provide a more holistic picture on BPM networks and Open Process Innovation. Too, a comparison of Open Process Innovation in the public and private sector could be regarded prolific future research (for network structures and innovation in the private sector see, for instance, Capaldo 2006).

6 SUMMARY

BPM requires specific expertise and knowledge, assets which might not be available inside of an organization, here local governments. These organizations may seek to involve external actors in their BPM activities. Here, Open Process Innovation – drawing from the literature on Open Innovation and Business Process Management (BPM) – promotes the study of how to systematically make use of knowledge that lies outside of an organization’s boundaries for process innovation initiatives. Open Innovation has been heavily studied for product innovation, however, process innovation has not yet been researched from such perspective. Against this background, we investigated into variables that impact on the qualities of Open Process Innovation taking the example of the public sector domain. This paper specifically examined how personnel resource scarcity exerts influence on the involvement of i) customers (here citizens and local companies) and ii) consultants (here management and software consultants) in public sector BPM. Our multi-method analysis shows that personnel resource scarcity has consequences for BPM-related collaboration schema as it restricts the involvement of customers. Such insight opens up for future research. Here, we call for a governance-theory perspective on process innovation as a fundamental basis for understanding and designing the institutions that shape collaboration in Open Process Innovation. How can organizational BPM benefit from knowledge outside of the organizational boundaries without immense increase of transaction costs? Determinants/Institutions could be addresses, for instance, by management-oriented studies as well as by design science studies (e.g., on the design of business process modeling methods or tools). Too, the analysis of the influence of other variables on BPM collaboration, also taking into account other actors than customers and consultants, can be considered potentially fruitful future research.

ACKNOWLEDGEMENT

The author thanks Michael Räckers, Burkhard Weiß, and Jörg Becker for helpful comments and support as well as the ECIS editors and three anonymous reviewers for insights and helpful recommendations. This work would not have been possible without the support of our graduate students Shaoxian Zhou, Andreas Krause, Robin Trenkner, and Robert Malsch.

Abstract

Inactivity is the most widespread health risk factor in modern societies today, causing not only individual health problems but also immense costs for the healthcare systems. This emphasizes the need for improving population-wide impact of activity interventions, with particular attention to cost-effectiveness, scalability, and delivery channels. In this paper, we present the theory-motivated design (drawing on the transtheoretical model) and empirical test of an IT-based physical activity programme (Personal Health Manager, PHM). In order to be as cost-effective as possible, the PHM was designed to have only few face-to-face contacts and to deliver supervision through the internet.

Our design and implementation proved to be successful in a pilot test with 88 employees of an automotive company. The PHM increased participants’ activity, motivational readiness for change, functional capacity and transported the feeling of being well taken care of. Enhanced supervision did not increase performance. The results are first evidence that internet-mediated supervision can be successful in promoting physical activity and provide a starting point for investigating the role of face-to-face-contact and service levels in physical activity programs. The PHM and similar designs are also relevant to practice as the semi-automation makes them eligible for large-scale corporate or public health programs.

1 INTRODUCTION

Physical activity and exercise are widely recognized today as key factors in maintaining and restoring health (Wagner & Brehm 2008). Many health problems and diseases are associated with certain habits, among them lack of physical activity. For the US, it is estimated that about 12% of yearly deaths can be ascribed to lack of regular physical activity (Pate et al. 1995b). Furthermore, it is assumed that about one quarter of the population of the western industrial nations are suffering from metabolic syndrome (Whaley et al. 1999). The metabolic syndrome as a term for the simultaneous occurrence of multiple risk factors (all linked to physical inactivity) is presumed to be a warning signal for the development of coronary heart diseases. However, only about 10 to 20 percent of the adult population in western industrial nations can be described as active enough to achieve health protecting effects. Inactivity therefore is the most widespread risk factor in the population, causing not only individual health problems but also immense costs for the healthcare systems (Wagner & Brehm 2008).

The prevalence of inactivity and its economic consequences emphasize the need for improving population-wide impact of activity interventions, with particular attention to cost-effectiveness, scalability, and delivery channels. As a conclusion of a review of physical activity interventions, Eakin (Eakin 2000) points out the need for research on non-physician delivery of activity intervention and on cost-effective ways of activity consulting and the conduction of follow-ups. In a recent review, Marcus et al. (2006) confirm and detail these research demands: “Further research should pursue better understanding of the minimal amount of face-to-face contact necessary for behaviour change and related cost-effectiveness issues. Questions concerning the most effective channel or combination of channels (e.g. print, telephone, or internet) for intervention delivery must be answered […]”. The development or internet- and IT-based programmes seems even more appropriate as the diffusion of internet access across all social classes and ages has been rising constantly over the past years (Statistisches Bundesamt 2008).

This research takes up these issues from an information systems point of view. Drawing on the transtheoretical model, we designed an IT-based physical activity programme for currently inactive people, combining both automatic and face-to-face services. The programme was implemented and tested in a three month pilot test in cooperation with the health promotion department of a German automotive company. In this article, we will focus on the participants’ side and perception of the programme. Key questions are if a physical activity intervention with supervision mainly delivered through internet-mediated channels is effective in increasing physical activity behavior, and if participants perceive this supervision as appropriate and satisfying.

2 THEORETICAL BACKGROUND: THE TRANSTHEORETICAL MODEL APPLIED TO PHYSICAL ACTIVITY

The transtheoretical model (TTM) is an integrative framework for understanding how individuals progress toward adopting and maintaining health behaviour change (Prochaska et al. 1998). The TTM uses stages of change to integrate processes and principles from various theories of intervention and psychotherapy, hence the name “transtheoretical”. Originally developed in the context of addictive behaviour, it has been widely applied to physical activity (e.g. Marcus & Forsyth 2003, Marcus et al. 1998b, Marcus et al. 2000, Velicer et al. 2006, Prochaska et al. 2008, Sarkin et al. 2001).

The TTM describes intentional behaviour change as a temporal process that unfolds through a series of five sequential stages. Progress through the stages is impacted by 10 processes of change. Other constructs affecting progress through the stages are the decisional balance, reflecting the individual’s relative weighting of pros and cons of changing, as well as self-efficacy, reflecting the situation-specific confidence in practicing the new behaviour as intended (Prochaska & Velicer 1997).
2.1 Stages of Change

The stage construct represents a temporal dimension, a characteristic that sets it apart from any other construct used in many social-cognitive theories. According to DiClemente et al. (DiClemente et al. 1991), the construct is in between temporally stable personality traits and dynamically changing personality states – the stages can thus be both stable and dynamic. The original concept assumed a unidirectional progress through the stages. This has been replaced by a cyclical or spiral approach: The stages can be passed through repeatedly, allowing for both remaining on a certain stage as well as relapsing to a prior stage (Prochaska et al. 1992).

The following paragraph describes the five stages of change (Keller et al. 1999) and their adaption to physical activity (Marcus et al. 1992).

1) Precontemplation: Individuals in precontemplation have no intention to change. This can be due to ignorance about the consequences of their current behaviour, but can also be a consequence of resignation after having failed to change repeatedly. For physical activity: Individuals do no physical activity and do not intend to start in the next six months (“not thinking about change”).

2) Contemplation: Individuals in contemplation intend to change. They think about a certain behaviour and weigh pros and cons. Ambivalences arise. For physical activity: Individuals do no physical activity but intend to start in the next six months (“thinking about change”).

3) Preparation: Individuals in preparation have decided to change. They have designed an action plan and have taken first steps to change. For physical activity: Individuals do some physical activity but not at levels meeting the recommended level1 (“doing some physical activity”) and they may or may not intend to become more physically active.

4) Action: Individuals in action have been practicing the new behaviour for a short time (up to six months). The risk for relapses is especially high on this stage. For physical activity: Individuals participate in recommended amounts of physical activity but have done so for less than six months and may or may not maintain this level of physical activity (“doing enough physical activity”).

5) Maintenance: Individuals in maintenance have been practicing the new behaviour for more than six months and have reached a relative stability. The risk for relapses decreases. For physical activity: Individuals have participated in recommended amounts of physical activity for six months or longer (“making physical activity a habit”).

2.2 Processes of change

The processes of change are covert or overt activities that people use to progress through the stages. Prochaska et al. have identified ten processes of change reflecting two main categories: cognitive and behavioural processes (Prochaska et al. 1988). For many behaviours, cognitive processes seem to be especially relevant in early stages (contemplation, preparation), whereas behavioral processes are mainly applied in later stages (action, maintenance) (Prochaska et al. 1994). Specifically for exercise behaviour, Marcus, Rossi, Selby et al. (Marcus et al. 1992) have identified the cognitive and behavioral processes displayed in Table 1. The question if some processes of change are of more or less importance on different stages of change in exercise behaviour has not been answered yet.

---

Comparative analyses indicate that both cognitive and behavioral processes are relevant in all stages (Marcus et al. 1992), being applied more often the higher the stage is (Marshall & Biddle 2001).

*Table 1: Processes of change in exercise behaviour (Marcus et al. 1992)*

### 2.3 Further constructs in TTM: self-efficacy and decisional balance

Self-efficacy (Bandura 1997) is the individual situation-specific confidence a person has that he or she can cope with high-risk situations without relapsing to their unhealthy behaviour. For exercise, it reflects the confidence in doing physical activity even if confronted with certain barriers. Self-efficacy is assumed to be lower in early stages than in higher stages (Lippke & Plotnikoff 2006), (Marshall & Biddle 2001).

The decisional balance reflects the individual’s relative weighing of the pros and cons of changing. The perceived pros increase in the first three stages and then remain on an almost equally high level throughout the last two stages. In contrast, the cons decrease throughout the last three stages (Keller et al. 1999), (Marshall & Biddle 2001).

### 2.4 Implications for the design of the Personal Health Manager

We use the theoretical foundations of the TTM for designing the PHM following a theory-based design approach (Briggs 2006, Leimeister et al. 2009a). Following the TTM, interventions must be adapted to the specific stages of change the targeted persons are in (Loughlan & Mutrie 1997). Helping people to progress one stage in the course of the program seems a reasonable goal (Prochaska et al. 1998). Past research suggests that movement from the early to the more advanced stages of motivational readiness for physical activity adoption is also significantly associated with changes in functional capacity (maximum oxygen uptake, VO2 max) (Marcus et al. 1998a).

In the case of the PHM, we target people engaging in physical activity less than once a week or not at all. According to the definitions above, those people would be in the early stages of change, namely precontemplation, contemplation and preparation (I1). Processes of change act as independent variables that people need to apply to move from stage to stage (Prochaska et al. 1998). They therefore provide important guides for interventions for every stage that should be addressed in the design of the PHM (I1.1). Self-efficacy in our targeted stages is still low, and should be increased (I1.3). The communication in these stages should emphasize the pros of physical activity (I1.4). Another effective way of adapting interventions to participants apart from targeting them according to a certain variable (e.g. stage of change), is tailoring them to the individual. A combination of both approaches has been found to increase physical activity (Marcus & Forsyth 2003) and should be addressed in the PHM (I2). Figure 1 shows an overview of the described relationships. All implications are presented in Table 2.

3 DESIGN OF THE PHM

3.1 Procedure

As most physical activity interventions, the PHM program will be subdivided into a start phase (SP), an activity phase (AP) and an end phase (EP). The start and end phase consist of mainly singular activities, such as informing the participants on the procedure of the intervention or the end of the intervention, training them on the topic or collecting evaluation data. The collection of evaluation data (e.g. medical data) mostly requires face-to-face contact. We will therefore design most activities of the start and end phase as face-to-face contacts.

In our opinion, the most interesting phase for testing alternative delivery channels is the activity phase. We have two reasons for this: First, supervision in the activity phase is very time and resource-consuming. Supervision of the participant in the activity phase requires the supervisor to perform mainly repeated activities, such as checking the participant’s performance, giving feedback, answering questions, motivating and reminding over a longer period of time. Second, supervision in the activity phase is very important to help participants stick to physical activity. Partial automation or IT-support for supervising processes and their delivery through the internet or other media therefore hold great potentials for reducing cost and increasing the scalability of activity interventions.

As a preparation for the design, we first analyzed and documented the basic supervision activities delivered in offline physical activity programs. We then identified potentials for automation or IT-support in these activities using a four step approach assessing priority (frequent, time- and cost-intensive activities with high possible savings are considered first), quality standard and customer experience (customer still should perceive individual supervision), technical feasibility, and required parties in the activity (for instance, registration for the PHM could be performed by the participant interacting with a system in absence of a supervisor). With this background information, we started designing elements of the physical activity programme to meet the requirements derived from TTM. The design was done in multiple iterative steps, and was reviewed and refined by an interdisciplinary team with backgrounds in information systems, sports medicine, business and communication (Knebel et al. 2007). A prior, much simpler prototype had previously delivered promising results in field tests (Leimeister et al. 2009b). The following sections provide an overview of the design elements addressing the requirements from TTM.
3.2 Addressing precontemplation, contemplation and preparation (I1)

In the early stages, people usually have little knowledge or experience with physical activity. The content of all information should therefore be basic knowledge about physical activity presented in a simple way (D1). How this content should be communicated is detailed in the following sections.

3.3 Addressing processes of change, self-efficacy and pros of physical activity (I1.1-I2)

For physical activity, all of the processes are important in all of the stages of change (see section 2.2). However, it is hardly feasible to emphasize all processes at each contact with the individual, and thus key processes are usually selected based on a person’s stage (Marcus et al. 1998a). In our design, we focused on the cognitive processes and on 4 of the behavioural processes. Some elements seem appropriate to address more than one process, or address self-efficacy and the pros of physical activity as well. Table 3 shows the variables from TTM (implications from 2.4; I1.1-I2) and the PHM design elements addressing them (D1.1-D2).

3.5 Schedule

Start phase: Participants start the PHM activity program with a 90 min training, covering importance of physical activity, benefits, risks and advice on how to become more active, as well as how to use the PHM internet platform. The training is accompanied by print information material. All participants take a fitness test.

Activity phase: After the fitness test, the participants get access to an online exercise plan containing endurance and strength units. The plan contains instructions and also a documentation tool. To reach the weekly activity goal, participants must have performed and documented all planned exercise units. They perform their exercise following the plan autonomously, using a heart rate monitor to check the intensity. Exercise can take place at home, outdoors, or at the gym. In specific situations the participants are contacted by a supervisor: First, in a monthly phone call, second, if the supervisor notices major irregularities in the participant’s activity documentation (for example not reaching the weekly goal multiple times, documentation about not being satisfied etc), or third, if the participant himself actively requests information. This enables the supervisor to interfere where it is most necessary and motivate potential dropouts to continue with their activity. E-Mail information on exercise and diet are sent out to all participants twice a week.

End phase: At the end of the programme, the participants repeat the fitness test and take part in a closing event.

4 PILOT TEST

4.1 Evaluation goals

We have two major evaluation goals. First, to evaluate the overall effectiveness of our design. This will be answered by comparing the output variables described in Figure 1 (motivational readiness, activity level, functional capacity) before and after the program. We will also consider the subjective
impressions of the participants concerning the semi-automatic nature of the PHM. Second, we aim to evaluate the effectiveness of those design elements supporting active supervision in the activity phase. This will be answered by comparing two test groups, one receiving active supervision in the activity phase (premium group), and one not receiving active supervision in the activity phase (basic group).

Our data collection is therefore guided by the following research questions:

- Do the PHM participants progress in their motivational readiness for change? Is this effect stronger for the premium group?
- Are the PHM participants more active? Is this effect stronger for the premium group?
- Does the functional capacity of the PHM participants increase? Is this effect stronger for the premium group?
- Do the participants feel positive about the PHM? Is this effect stronger for the premium group?

### 4.2 Test setting

The pilot test was conducted in cooperation with the worksite health promotion of a major German automotive company. To make participation as easy as possible for the employees, all fitness tests and all administrative issues took place at the corporate gym, the initial trainings and closing events at a university site at a small distance from one of the major company buildings. The elements of the program were implemented as described in the schedule in the previous section (total duration: 4 months, April-July 2008). The participants were randomized into two groups. The basic group received all designed services in the start and end phase, but only passive support in the activity phase (e.g. by providing them with an activity documentation tool). The premium group received all the services the basic group received and in addition to that active support in the activity phase (Figure 2).

![Figure 2: PHM implementation for basic and premium test group](image)

### 4.3 Data collection and measures

**Motivational readiness** for physical activity adoption was assessed using the five-item motivational stage measure for physical activity by Marcus & Rossi (1992) both at the beginning and at the end of the PHM programme. To capture **functional capacity**, we measured the maximum oxygen uptake (VO2 max) in the fitness tests at the beginning and the end of the program, on the same day as or very few days from the stage measure.

**Physical activity level** at the beginning and the end of the program was assessed using a self-report physical activity questionnaire (Freiburg questionnaire of physical activity, Frey et al. 1999), subdivided in everyday activity, sport activity and total activity. People reaching a total score of min. 30 points or min. 14 sport activity points are classified as doing enough physical activity, a total score of 15-29 as fulfilling the minimum, and below as being inactive.
Perception of the PHM was assessed by single items on a 5-point scale at the end of the program. Items included statements to evaluate if participants felt healthier, gained knowledge and liked using the PHM system.

4.4 Participants

We decided on an active recruitment approach, which has proved to be more successful than reactive approaches in other health promotion contexts (Prochaska et al. 1998). 140 inactive, overweight men and women with 2 or more metabolic syndrome risk factors were recruited through an in-house mailing sent by the worksite health promotion department and randomized into the basic (BG, n=55) and the premium group (PG, n=85). 107 took the fitness test in the start phase, 88 completed all questionnaires (baseline and 3 month questionnaire) in the pilot test (n basic group (nb)=33, n premium group (np)=55). Their age ranged from 25 to 60, averaging at 45.4 years. The remainder of this paper focuses on the participants who completed both questionnaires.

5 RESULTS

Motivational readiness for change: As expected, the vast majority of participants in both groups was in precontemplation, contemplation or preparation at baseline (PG: 78.2%, BG: 97.0%), 21.8% of the PG and 3% of the BG surprisingly already on a higher stage. After three months, 65.5% of the PG and 81.9% of the BG had progressed at least one stage. At the end of the programme, 72.4% of the PG and 81.8% of the BG had reached at least the action stage, meaning they were physically active on a regular basis (Table 5). These results indicate a very positive effect of the PHM, but must be interpreted with caution. According to the definition of the stages, a progress from preparation to maintenance (active for more than six months) is not possible within three months. Apparently, some participants did not understand or not answer the questions correctly. The average overall functional capacity (VO2 max) increased (p=0.03; np=46, nb=26), the difference between PG (+ 4.4%) and BG (+2.8%) was not significant (p=0.66).

</tbody>
</table>

Table 5: Number of individuals in each stage of change and progress through the stages (np=55; nb=33; own illustration)

Physical activity level: Everyday, sport and total activity have increased significantly in both groups at the end of the program. 49.1% of the PG and 42.4% of the BG have reached the recommended minimal activity level of 15 total activity points (Figure 3). There is no significant difference between the test groups (p>0.2).

Perception: The PHM was well received by the participants. On average, the participants felt well taken care of, liked using the system, found it easy to use, and have gained knowledge about physical activity and health. They felt healthier and more active (Table 6). The statements “I feel healthier” and “I have become more active” are strongly correlated (p<0.01). Moreover, “I feel healthier” is weakly correlated with functional capacity (p<0.05). Surprisingly, neither of the two is significantly correlated with the increased scores of the physical activity questionnaire. There is no significant difference between the test groups (p>0.2).

6 DISCUSSION

6.1 Summary and contributions

In this paper we have presented the design and empirical test of an IT-based physical activity programme, the PHM. Apart from face-to-face contacts in the beginning and in the end of the program, supervision was mainly delivered internet-mediated. Our design decisions were motivated by the TTM. This approach has proved to be successful in the pilot test. The PHM increased participants’ activity, functional capacity and motivational readiness for change. The supervision via internet was perceived positively, and the participants had the feeling of being well taken care of. However, enhanced active supervision in the activity phase did not produce stronger effects.

Our research has successfully implemented the approach of theory-driven design as proposed by Briggs (Briggs 2006), applying a theory from psychology to the design of an information system. The results are first evidence that internet-mediated supervision can be successful in promoting physical activity and provides a starting point for investigating the role of face-to-face-contact and other forms of supervision in physical activity programs. The multi-method evaluation data allows a comparison of different measurement results and therefore better interpretation. A major advantage is that the PHM allows supervision of and situational reactions to user behavior, but at the same time, the computer-mediated delivery and supervisor support functions allow a fast and efficient supervision and administration. Therefore, practice will find the PHM and similar designs eligible and useful for large-scale corporate or public health programs, providing an alternative to conventional interventions requiring personal presence.

6.2 Limitations and outlook

The duration of our pilot test was only three months, which might be too short to induce long-term behavior change. We are currently conducting a follow-up survey to shed light on the long-term effects. We are aware that self-report measures as we applied among others can always be biased by the participants’ intended or unintended false answers. Where possible, we try to validate self-report
data with other measurement methods, e.g. stages of change and functional capacity. The fact that the premium group did not perform better than the basic group might be due to some limitations resulting from the implementation of the study. There might have been a sense of competition between the groups biasing the results. Technical problems at the beginning of the test did not allow the full delivery of all supervision services to all members of the PG in the first month. An analysis of the qualitative interviews we conducted with all participants at the end of the test will reveal insights into this. Another reason might be that the importance of enhanced supervision increases with the duration of the activity phase, and the effect would only be visible in a longer test.

Further research should therefore examine the effectiveness of IT-supported physical interventions over longer periods of time and test different service levels of supervision. In addition to theories on exercise behavior, it should further draw on knowledge from the computer-human-interaction and technology acceptance and refine the intervention design. It is also necessary to inquire on appropriate easy and reliable methods to accurately capture and supervise participants’ activity levels.

Abstract

Health information portals (HIP) are now common place. Governments and other health agencies are using HIPs extensively to reduce costs and distribute information more effectively. Generally, HIPs are not very technically sophisticated specifically in terms of options for improving searching. There are many ways in which searching and retrieving relevant information can be improved. This paper presents an exploratory study which investigated five HIPs. Each HIP offered a range of features and functionality to assist with searching. Our research explored the features and functionality of each HIP. Through usability evaluations we compared the response of users to each HIP and identified users’ preferences for improved searching. We found that HIPs with improved search functionality and other features that assisted searching were better received by the users. Users regarded these portals as easier to understand, easier to use, required fewer steps in retrieving information and were more likely to say they would return. Comments from users are provided to illustrate further the importance of providing effective functionality. The paper concludes with recommendations for Health Information Portal builders on what is needed to improve the user search experience.

Keywords: Health information portals, functionality, usability.

1 INTRODUCTION

Governments worldwide are grappling with increased demands for health information and pressures on health systems. Coupled with this is an explosion in the quantity of health information available particularly through the Internet. Many governments and health agencies are disseminating health information via the Internet. Reasons for doing so include mitigating against the problems of poor quality information and helping defray costs in information distribution. Research findings by Kennedy (2003) suggest a strong correlation between health outcomes and the level to which patients are informed, that is, when patients have more information relating to their health this leads to improved health outcomes. Despite the best efforts of the various agencies distributing information, health consumers frequently report that the Internet based health information they find is not useful and are not meeting user needs (Vermaas and Wijngaert 2005). Information relevance is most important to health consumers (HON 2006) yet finding appropriate, relevant and timely information is often difficult (Zeng et al. 2004). Information is often incomplete (HON 2006) and difficult to read (Sillence et al. 2004). Further, most health Websites and portals swamp users with information (Burstein et al. 2005). There are however, a variety of ways in which users can be assisted in overcoming the identified problems in searching and retrieving relevant information.

To date there has been limited research exploring users’ perceptions of HIPs and what encourages use, this research sought to fill this gap. The exploratory study reported in this paper investigated the features and functionality of five non commercial Health Information Portals (HIP). Through usability
evaluations in a laboratory setting we explored users’ responses to each of the HIPs, their expectations when searching for health information, in particular how they responded to their search experience and the extent to which this was influenced by the features and functionality of the HIP and their willingness to use the same source in the future. The research found that HIPs with improved search features/ functionality, were better received by the users. Users also rated these portals as easy to use and as a result, were more likely to return to them.

2 HEALTH INFORMATION PORTALS

This section discusses mechanisms for improving searching and information retrieval from health websites or HIPs and factors that determine success. For the purposes of this paper a HIP is defined as an internet based system which assists users find relevant internet based health information resources. A HIP would generally facilitate information retrieval from other websites through a range of features and functionality but not store or provide information specifically.

Health websites should enable health consumers to easily find relevant information. A number of features a health information website or portal might have to support searching were identified by Luo and Najdawi (2004): “a catalogue of health information” - a mechanism for organizing edited health information; a search engine; “a personalization system” described as allowing health consumers to customize the interface based on their preferences and; “a network of communities” where health consumers can exchange information with others (Luo and Najdawi 2004). Other technologically possible features include 1. Providing a level of information differentiation to improve searching such as information organized based on a specific disease, drugs, for children, personal stories. 2. Spellchecking, many medical terms are unfamiliar to health consumers and difficult to spell. 3. Parsing where users can enter a question or sentence and the search examines both the key word/s and the context. 4. An ontology and/or thesaurus helps users identify specific medical search terms and narrow searching.

Other factors that will determine how successful a HIP will be include the users’ ability to find relevant information (Josefsson 2006; Pew/Internet 2006). One study reported that 37% of users were unable to find relevant health information (Zeng et al. 2004). Through observations, Zeng et al (2004) found a major reason was “the consumers’ use of simple search strategies (browsing or short text queries) that did not characterize their information needs well.” Zeng et al (2004) conclude from their research that there are three ways searching can be improved; health consumers making queries more specific, improved search functionality and limiting information retrieved. Research by Pew/Internet (2006) found 25% of users were overwhelmed by the amount of information retrieved and 22% were frustrated by their inability to find relevant information. Easy to use websites are also critical to success (Klein 2007). The 2006 HON survey (2006) found ‘Easy to use’ was ranked highest as helpful for searching. Factors such as the quality of the navigation, how long it takes to retrieve information and how easy the text is to read on the screen all contribute to ease of use (HON 2006). Research also suggests that these elements will impact on the overall user experience, influencing whether or not users will return to a Website (Fisher et al. 2007).

There are many examples of health information portals. Non-commercial providers are the focus of this research as previous research has found health consumers trust these sites are more (HON Survey 2006). Non-commercial providers include hospitals, governments and patient/advocacy groups. The choice for the average health consumer is therefore vast. The question this poses is how does the health consumer choose between these sources? This is no trivial decision if the patient is facing a life threatening illness and information and answers in relation to treatment are critical (Josefsson 2006).

The purpose of the research reported in this paper was to examine the features and functionality offered by HIPs in relation to searching, the impact this has on the user’s experience and to identify what users want. Whilst the authors recognise the importance of information quality, quality is a complex issue and was outside the scope of this research. The questions we sought to answer were:
What different features / functionality are provided for users of HIPs to improve searching?
What searching features / functionality do users want?
What impact do different features / functionality have on users’ overall experience, including searching and their intention to return to a HIP?

3 RESEARCH APPROACH

Five generic non-commercial, HIPs were identified. Portals from Europe (Health on the Net), North America (Medline Plus and Mayo Clinic) and Australia (Better Health and HealthInsight) where the research was conducted, were identified. The sites were selected based on the following criteria:

- Government sponsored. The HON Survey (2006) identified that 79% of health consumers preferred a government agency to be responsible for online health information provision.
- The health information provided is generic that is not specific to a disease, age group etc. This was to ensure the relevance of the task to all users.
- HIPs were selected based on the level of features / functionality available. We looked for HIPs with a greater number of features / functionality to test their effectiveness. Note only two Australian HIPs met the criteria.

The Australian portals are the two key government sponsored portals, Medline Plus claims to be the largest medical library in the world (Medline Plus 2009), the Mayo clinic is the largest not for profit practice in the world (Mayo 2009) and HON describes itself as one of the most respected HIPs in the world (HON 2006). It should be noted that in 1999 (not in subsequent years) the HON survey (1999) asked users which Website most closely met their needs. The results found Medline Plus was rated as the highest, Mayo Health System (now Mayo Clinic) was listed number eight and HON number 10.

From previous work we identified a number of features/functionality that can assist users searching for information (Fisher et al. 2007). We examined the home page of each HIP for evidence of features/functionality. Users are most likely to use features/functionality visible from the home page. Table 1 details the features/functionality and the method used to assess each. All had a search engine.

<table>
<thead>
<tr>
<th>Feature/functionality</th>
<th>How the feature or functionality was determined</th>
</tr>
</thead>
<tbody>
<tr>
<td>Personalisation</td>
<td>Examined if the portal asked for information to help in retrieving information relevant to the user. Did the HIP start an initial dialog to identify user’s personal needs eg ask the gender of the user, age or information type?</td>
</tr>
<tr>
<td>Differentiated Information access</td>
<td>Analysed information differentiation offered. Were users given topics to search within? Could the user retrieve other types of information eg personal stories?</td>
</tr>
<tr>
<td>Spell check and “Sounds like” index</td>
<td>Spell checking and ‘sounds like’ indexing tested using misspelt words.</td>
</tr>
<tr>
<td>Parsing</td>
<td>The sentence “What are the side effects of Ventolin?” was used to search each HIP to test if returned results contained both the phrase ‘side effect’ and ‘Ventolin’</td>
</tr>
<tr>
<td>Ontology and Thesaurus</td>
<td>Checked for an ontology and/or thesaurus. For example was a list of possible search words or terms available for users to access?</td>
</tr>
<tr>
<td>Other features</td>
<td>Were newsletters, forums or individual feedback available?</td>
</tr>
</tbody>
</table>

Table 1 – Features and functionality for HIPs

Usability is “the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use” (Bevan 2001). The research examined users’ response to the five HIPs, through a usability evaluation - in particular aspects of the HIPs that related to searching and retrieving information. The usability instrument was based on an instrument developed and tested previously by one of the authors (Fisher et al. 2004). A full copy of the instrument can be found at http://www.sims.monash.edu.au/staff/jfisher/.

The instrument is based on key items identified in the literature as important in websites designed for information distribution. The key items are how easy information is to read including terminology and...
instructions on using the Website (Becker and Mottay 2001; Cox and Dale 2002; Kunst 2002). The quantity of information presented (Bruce 1999; Zeng et al. 2004). The design and presentation of the text (Becker and Mottay 2001; Sutcliffe 2002) and how easy it is to use including locating information and navigation (Nielsen 1999; Fu and Salvendy 2002; Hargittai 2003).

The usability evaluation involved 223 users. The instrument consisted of Likert scale type statements, questions requiring a response from 1 scored lowest to 5 highest, questions requiring a Yes/No response (scored Yes 2, No 1) and questions requiring a free text response. Numerous usability instruments exist however each evaluation conducted needs to be designed specifically for the goals of the research and adjusted to meet those goals (Dumas and Redish 1994, 185). The instrument contains questions and statements similar to those in other studies (Zhang et al 2000; Nel et al. 1999).

The users were students, studying Human Computer Interaction, as part of their studies and during a class they participated in the usability test. 223 users evaluated the portals resulting in 411 usable evaluations. 33% of participants were female and 67% male and 91% described themselves as very experienced with Internet searching. The use of students for usability evaluations such as this is in line with other studies (Nel et al. 1999; Zhang et al. 2000). Abdinnour-Helm et al. (2005) argue that students can be appropriate providing they are similar to Web users generally and are likely to perform the tasks being investigated. The majority of users (91%) were aged between 21 and 30 years. This age group are likely to have searched for health information (Fox 2006). The users were asked to ‘Think of a health issue that is important to you, a friend or a family member. Using each of the health websites, search for information on that topic’. Users were provided with examples of information they might search for (exercise, diet, medication, a specific health condition). Each user conducted a search on two HIPs; one was an Australian portal and one international portal. Once the search was completed users completed the questionnaire and reviewed the next HIP. Each user spent about 15 minutes searching each HIP.

The quantitative data were analysed using SPSS. A Factor Analysis was conducted to explore the relationship between the identified elements and to assess the degree to which factors were measuring the same or a similar concept (Bryman and Cramer 1992) and descriptive statistics to compare results for individual HIPs. The qualitative data was analysed for the research themes relating to searching, using a meta-matrix approach which is described by Miles and Huberman (1994, pg 93) as “essentially the 'crossing' of two lists, set up as rows and columns.”

4 RESULTS

Users were asked if they had searched for information on the internet, 10% said they had never used the internet to search for health information, 70% indicated they occasionally search, 18% search often. Users were also asked how they searched. Users could tick more than one option. Most users, 185 (97%) had used a search engine, 7% used an Australian Website and 2% used an international Website. Next each portal is described briefly and the features and functionality available.

4.1 Features and functionality

**Medline Plus** [http://medlineplus.gov/](http://medlineplus.gov/) is the National Library of Medicine (NLM) located in Bethesda, Maryland, USA. It describes itself as bringing “together authoritative information from NLM, the National Institutes of Health (NIH), and other government agencies and health-related organizations.” Table 2 presents an analysis of features and functionality of Medline Plus.

Table 7 User views of features and functionality

4.2 Usability evaluation results

The usability evaluations explored more items than those presented in this paper. The results are confined to reporting on aspects influencing the users’ search experience. This includes factors such as ease of use, information quantity, terminology, design and presentation of text, navigation and information on searching. Each user evaluated two HIPs and all users evaluated one of the Australian HIPs. 76 users evaluated Medline, 66 evaluated Mayo Clinic, HON was evaluated by 65 users, 82 users evaluated Better Health and 122 evaluated HealthInsite. The HIPs were randomly assigned hence the difference in the number of users who evaluated each of the different portals.

4.2.1 Quantitative user responses to individual Health Information Portals

To understand the relationship between the different elements a factor analysis on nine of the variables was undertaken. Tables 8 and 9 present the questions/statements put to users and the results.

Table 9 Factor Analysis Extraction Method: Principal Component Analysis.

The Kaiser-Meyer-Olkin value, measuring sampling adequacy was .783. This should be greater than .6 for a satisfactory factor analysis (Pallant 2001). Bartlett’s test of sphericity was .000. The factor analysis indicated 69% of the variance can be explained by three components: Factor 1 relates to how easily users were able to find relevant information, Factor 2 relates to the presentation of the text and Factor 3 is the language used.

Questions requiring a Yes/No response were asked of the users. Table 10 presents the results, both the percentage of the Yes / No responses and the average response is provided. Bold indicates a Yes result higher than the overall average (questions 1-3) or No (questions 4 and 5) lower than the average.

*Table 12 Qualitative comments from users*

5 DISCUSSION

Fox and Rainie (2002) report that 53% of 18-29 year olds had searched the internet for health information. By 2006 this had grown to 77% (Fox 2006). We found 90% of our 18-30 year old users, have searched for health information, 97% using a search engine not a HIP. This is an internet savvy generation and the Internet is an important source of health information for this demographic. Our research demonstrates a link between the features users want, the features available on the portals we explored and the usability evaluation results. The two areas we examined and found impact on the user’s search experience are discussed next.

Features and functionality available to improve searching: Of the five HIPs analysed we found Medline Plus had the most extensive range of features and functionality. Providing an ontology or thesaurus to help users refine their search was the feature users wanted most followed by spell checking and differentiated information access. Only Medline Plus included an ontology and thesaurus. All, except HealthInsite had spellchecking however, only two assisted searching through parsing (HON and Medline Plus). All offered some form of differentiated information access. Only one HIP (HealthInsite) offered a personalised search but this was not available from the home page.

Users qualitative responses highlight further the importance of features to assist searching. It was evident in the responses users gave when asked about the best and worst features; many mentioned how useful the ‘dictionary’ was or a list of search terms or topics organised alphabetically. Users commented on the lack of spell checking, terminology and what they needed to improve their search. A number of users mentioned that the information was too broad suggesting that because some of the portals did not have well differentiated information that they could not refine their searches adequately enough. Even if a portal only provided an alphabetical search users commented that it was useful.

HIP design: The quality of the design includes how easy a HIP is to use and search, the way information is displayed and how frustrated users were in using the HIP. Tables 10 and 11 detailed users’ responses to a range of questions and statements relating to design. Medline Plus was ahead of the overall average on all items. Mayo Clinic was ahead on ten, HON, seven, HealthInsite five and Better Health, two. Users’ responses suggest a strong link between the quality of the HIP design, the features and functionality to assist searching and the overall reaction a user had to the HIP. The more features and functionality the HIP had the better the user experience. Medline Plus was the portal most users preferred, fewer users were frustrated and almost all said they were able to find information on the topic. Users also found it was the easiest to use, the search function was the most useful, the text display was regarded as the best and users said they were able to retrieve relevant information most easily from this HIP. Mayo Clinic was rated second by the users on most items; it also provides a high level of information differentiation and spell checking but does not offer an ontology or thesaurus. By
contrast the most poorly rated portal was Better Health, it provided minimum assistance to users for searching in terms of features and functionality. It had some information differentiated but this was limited to the information organised around a small number of topics. Better Health rated most poorly in terms of users’ ability to find information and to find enough information, 65% of users were frustrated at some point. Users indicated they did not like Better Health, they did not have enough information to complete the task, could not find relevant information and there were too many steps needed to retrieve information.

The number of negative comments users made can be an indication of dissatisfaction. User frustration was evident when presented with poor search results and lack of information. The number of users who said there was a ‘worst feature’ have been counted and expressed as a percentage of the total number of comments made for that portal. Note not all users provided a best or worst feature. There were very few negative comments from users on Medline Plus. 42 (68%) users commented on the worst feature eight users actually said there were no ‘worst features’. This portal attracted the fewest negative comments on the question of worst feature. A number of users mentioned specifically that the Mayo Clinic had a variety of ways of searching. In particular users mentioned the alphabetical search and how easy it was to search for a particular health issue. 77% (52 users) commented on the worst feature and of these none said there was no worst feature. Many of the users commented negatively on the quality of the search function of the HON Portal and many generally did not find it easy to use. 89% (58 users) made a comment on the worst feature, none said there was no worst feature. Fourteen users commented on the poor quality of the search function. 65% (72) users of the Better Health site commented on the worst feature, of those five said there was no worst feature. Most of the negative comments from users focused on the poor quality of the search function and the overall usability of the portal. For HealthInsite, 90% (110) of users comment on the worst feature. Only one user said there was no worst feature.

6 LIMITATIONS AND CONCLUSION

We acknowledge the fact that, most of the users were under the age of 30 and maybe less concerned about health matters than older users. It would therefore be useful to compare these results with users over 30. However, little previous research has reported on the extent to which people under 30 have searched for health information. It is not surprising that within our group more than 97% had searched for health information using a search engine. As it is likely this demographic will turn to the internet first for health information they are an important group to consider when designing a HIP. More statistical testing is needed to provide a deeper understanding of the impacts of the factors.

7 IMPROVING THE USER SEARCH EXPERIENCE

A key indicator of success is whether a user would use the HIP again. Most users (87%) would use Medline Plus again, 75% would use Mayo Clinic, 65% HON, 70% HealthInsite and 52% Better Health. One factor, the search experience, is likely to have influenced a user’s preparedness to return this includes finding information, finding information easily, the number of steps it takes to retrieve information and finding enough information. Medline Plus was ahead of all the other HIPs on all these items. Better Health however was last on three of the four (users found HON slightly less easy to use than Better Health). From this research it suggests Medline Plus offers users a better search experience, Medline Plus also provides the widest range of features and functionality to assist users in their search.

If HIP designers want to ensure users are satisfied with their search experience and will return consideration has to be given to improving the search experience. An analysis of the data helped us to identify features/functionality that should be included in a HIP. Table 13 describes those features/functionality and are in priority order.
<table>
<thead>
<tr>
<th>Feature/functionality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ontology and Thesaurus</td>
<td>Provide easy to access list of medical words and search terms and alternative words.</td>
</tr>
<tr>
<td>Differentiated Information access</td>
<td>Include a wide range of topics and then sub categories and provide alternative ways to access information. Users may not know the exact term or phase they are searching for therefore an alphabetical list of health topics is a useful feature one users like and want.</td>
</tr>
<tr>
<td>Spell check and &quot;Sounds like index&quot;</td>
<td>Many users cannot spell medical terms. Spell checking is essential. HIPs must avoid returning nothing at all if the term is misspelt.</td>
</tr>
<tr>
<td>Parsing</td>
<td>Providing a quality parsing facility where the search takes into account phrases rather than one word in a user’s question. This assists users with making queries more specific. Users should be able to ask questions as part of a search.</td>
</tr>
<tr>
<td>Other features</td>
<td>Include pictures particularly to help explain what is presented, provide the ability to search within results, support multiple languages, newsletters and discussion boards can be useful.</td>
</tr>
<tr>
<td>Personalisation</td>
<td>Personalisation can be used to limit the quantity of information retrieved and ensure a higher degree of relevance of information to individual users. This makes for better searching outcomes and reduces the quantity of retrieved information.</td>
</tr>
</tbody>
</table>

**Table 13 Recommended features and functionality for a HIP**

If the designers and sponsors of health information portals want to attract a wider audience, in particular those under 30, and draw health consumers away from search engines such as Google then attention has to be paid to the elements that improve users’ search experience. As argued by Kunst et al (2002) the Internet has “the potential to facilitate but also to jeopardise health care provision”. How HIPs are designed particularly how easily users can search and find relevant information is critical. Including key features and functionality such as an ontology or thesaurus, differentiated information access and spell checking are important for ensuring good search results and a good search experience. Until the design of HIPs incorporate what is needed to improve the search experience health consumers will continue to be dissatisfied with their searching results and the benefits if HIPs will not be fully realised.

DATA STAKEHOLDERS INTERACTING WITH PATIENT DATA

De la Harpe, Retha, Cape Peninsula University of Technology, 80 Roeland str., Cape Town, South Africa, delaharper@cput.ac.za

ABSTRACT

How data stakeholders interact with data is considered in this paper by incorporating a socio-technical perspective. A data interaction enactment model is proposed to better understand how a logical structure is enacted when data stakeholders interact with data. The proposed model expands a technologies-in-practice view to also provide for the embodied structures of data objects. This extended technology-in-practice view provides designers with an approach that focuses on the interaction between data stakeholders and data objects. Although the proposed model is a generic model it is applied in the healthcare context for this study. An interpretive approach was used for a private healthcare centre as the case to investigate how healthcare professionals interact with patient records. The findings indicate the design of patient records based on the perceived anticipated use may not sufficiently provide for their actual use where different stakeholders need to interact with the patient records. An understanding of the relationships between designers, data stakeholders, the patient record structure enacted during interaction and its physical components is important. This may be one of the reasons why patient records are still mostly paper-based in spite of efforts to develop and adopt electronic patient record systems.

1 INTRODUCTION

Organizations find it difficult to determine the value of their data, an important organization resource today and the abundance of data and increased sharing of it within and between organizations have amplified the problem (Bertolazzi & Scannapieco, 2001, Loshin, 2003). A practice related study has confirmed this problem (Eckerson, 2002). The objective for this study is to determine how data stakeholders interact with data by considering how they respond to each other during the period of interaction. This paper specifically deals with the interaction between the persons using data and the technology on which it is stored and which facilitates its processing. The focus of this paper is on a patient record representing the patient who is in need of a healthcare service.

This research is in the information systems field and the interpretive approach used provide for its socio-technical nature. The problem this paper addresses is that the perceived anticipated use of data objects is an inadequate means for designing data objects ultimately leading to data that does not sufficiently support the needs of the intended users. In order to address this perceived misalignment between designed anticipated versus actual use it is necessary to better understand the interaction between the designers, users and their perceived observations of real-world objects and data objects as the resulting presentations. The data object is the result of the interaction between the designer and user based on their perceived observation of the real-world object and the anticipated use of the data object. It is necessary to understand exactly what happens when the user interacts with a data object. A data interaction enactment model is proposed to extend Orlikowski’s (2000) technology-in-practice model. This is an attempt to address the concerns of Hanseth et al. (2004) that her model does not sufficiently address how technology-in-practice is shaped by the technological artefact as well as the relationship between the two and her responding suggestion to better understand the problem of agency by also considering the status of the object. Data stakeholders are regarded as social actors and data objects as conceptual artefacts because it is not yet clear how these objects are instantiated from their design templates in practice every time data stakeholders interact with data.
The objectives of the paper is twofold, firstly to propose a data interaction enactment model based on the research findings of other similar studies that can be used as a theoretical lens to analyse the interaction of data stakeholders with data objects; and secondly to apply the proposed model to a healthcare case. The purpose of the empirical part of this paper is to illustrate how the proposed model can be used in practice. Its validation is at this stage outside the scope of the paper since a more extensive empirical study is required.

The layout of the paper is according to the two objectives and the first part represents the logic that guided the conceptualising of the thoughts, constructs, reasons and structures of the different concepts of the proposed model presented in Figure 1. The focus of the paper is on the enacted structure indicated by the circle in Figure 1. The literature review did not reveal any appropriate model that could be used and the literature findings were instead conceptualised as the proposed model. In the first part of this paper the different views of data is discussed in terms of data stakeholder as the person using it and the data object as the logical unit for a patient’s data. Next the different views of technology in information systems are discussed with a specific focus on structure, agency and inscriptions to provide for the socio-technical nature of the study. This part is rather lengthy to give justice to the complexities around how humans interact with technology. It is concluded with a proposed model of how data objects are enacted during interaction. This model incorporates technologies-in-practice as the data object is constructed during interaction of data with the anticipated use inscribed during its design and the actual use inscribed in the actual data. The next part considers a healthcare case and in the discussion the proposed model is applied. In conclusion the usefulness of this model to investigate how data stakeholders interact with data objects is discussed.

2 INTERACTION IN SOCIAL AND TECHNICAL WORLDS

Persons using data have an interest in how it is defined and how they can use it. A data stakeholder is a person who has an interest in data and examples of data stakeholders are management using data for decision-making; a salesperson; a doctor, etc. Although stakeholders are usually humans, it is possible that a stakeholder is another organization, a department, a hospital, etc. The term data stakeholder is used as a generic term to describe any party interested in data regardless of the context. An external party is an outside person or organization that shares organizational data with an organization. All the data stakeholders interact with data in the roles of data producer, consumer or custodian (Strong et al. 1997). In the healthcare context data stakeholders are healthcare professionals and other persons and parties who need to interact with patient records.

A data object can be regarded as a logical record that is constituted of one or more physical records/parts. Data objects -data representations of real-world objects -are generic templates of the different organizational objects obtaining their values from data sources when instantiated through how they are used. Data objects are identified and defined during systems development by systems developers as they perceive the real-world object as well as the needs of the users (data consumers) of the data objects. The representation of real-world objects, such as for example a patient, is not limited to its representation as part of an information system, but also includes all data generated during the interactions of the organization with the real-world object, e.g., the patient. Not only is the healthcare organization interested in the best match of the data object with its corresponding real-world object, but it is also interested in the history of that data object, i.e., snap shots of all its states. This history is complete when it includes copies of all the different states as well as copies of all the interactions that lead to the changes in the states. Wand and Wang (1996) suggested the following states when considering the mapping of a real-world object, in this case the patient, to its IS data representation (patient record): proper, incomplete and ambiguous representations and meaningless state. These states will influence how the records are used in practice in terms of how well they were designed.

The healthcare sector is typically divided into a public and private sector and in some cases a mixture of the two. Although, for example, the primary goal of medical practices, hospitals and clinics is to provide a healthcare service to their communities, they also have to operate as businesses. Patient data
is used by healthcare professionals when providing a healthcare service for their patients whilst it is also used to manage the different healthcare enterprises.

The focus of this study is on patient data which to a large extent is still paper-based. There are different types of patient records but for the purpose of this study a patient health record is considered. An electronic health record (EHR) includes the patient’s health profile, behavioural and environmental data over time to represent different episodes of care by various providers (WHO, 2006). Fitzpatrick (2000) emphasises that a health record does not only contain data about a patient and the care of patient but should rather be regarded as an integral part of the practical “doing” of healthcare and as a record “at work”. She further argues that it is a working record evolving around a complex collection of related forms, papers, documents and records embedded in the social, spatial context of a healthcare enterprise.

For the purpose of this study technology as an infrastructure is regarded as pervasive and present, but data objects as technological components need to be specifically considered. Although data objects are non-human objects, they are socially constructed by humans, namely, designers and data stakeholders and it is necessary to consider the position of data objects in terms of the technical and social worlds.

In much of information systems (IS) research the focus is unavoidably on the interaction between social and technical systems. An improved understanding of the phenomena that emerges when these systems interact will therefore enrich IS research (Rose et al., 2004). The human-artefact relation is viewed by Widjaja and Balbo (2006) through a macro-level lens as human and artefacts are both social products as well as social makers in shaping and remaking each other. Technology is social in its origins as well as in its implications in that it does not influence human agency by imposing a single and mechanical functionality but by “inviting specific courses of action” (Kallinikos, 2002). Technology is not used within a vacuum but always involves social actors where technology shapes its users and at the same time responds to how it is used. Hosein (2002) responded to the concern of technology being “pushed into the background” by suggesting that researchers should, when relevant, attempt to understand the technological within their research.

While the IS researcher is neither in the social nor in the technical worlds, but rather where these two worlds overlap, it is possible to move beyond the properties of each world and to consider the relationship between them. It is then necessary to study how the human, from the social world, interacts with the technical components of the technical world when and how these two worlds become one. The definition of IS already provides for this boundary crossing between the two worlds.

2.1 Information Technology

Technology can be regarded as practical or useful, rather being an end in itself. It includes all the tools, techniques, materials, and sources of power that humans have developed to achieve their goals (Rose & Scheepers, 2001). Technology is not only objects or technical artefacts, but also ideas (object-oriented paradigm), practice (testing), etc., and is socially constructed and should not be investigated according to the laws of natural sciences (McMaster et al., 1998). Information technology (IT) is the acquisition and processing of data to support human processes and can be regarded as a material resource that supports information practices and such information practices in turn support a wider set of social practices (Rose & Scheepers, 2001). Information technology is the product of human agency and will reflect the structures of the social system that designs and manages it as well as interpretations of its anticipated use. Information systems (IS) can be regarded as a social system of information practice that is supported by information technologies (a material resource) and representation the essence of IS according to Weber (2004).

When the emphasis is on the interpretation of technology use then this could lead to a detachment of the IT artefact (Widjaja & Balbo, 2006). They base their arguments on the practical knowledge in dissecting and constructing artefacts of human-computer interaction research (HCI) as opposed to the socio-technical research that views human-artefact relations with both human and artefact as social
products and social makers in shaping and remaking each other. Monteiro and Hanseth (1996) argued that it is necessary to move beyond the “IT enables/constrains” position and they base their arguments on the departure point of IT being the crucial factor, simultaneously enabling and amplifying the trends for restructuring organisations. They felt the necessity to focus more on the interplay between IT and organisations by reaching a deeper understanding of this interwoven relationship as to how IT shapes, enables and constrains organisational changes. It is necessary to explain why a group of diverse people, e.g., data stakeholders, reach a single accepted agreement, based on an interest resulting in an inscription into material form.

Technology artifacts are made up of multiple components and are not fixed or independent with their stability being conditional. Interrogating interests and actions provide moments within a discourse where the actors may take form. This may particularly be true for objections, resistance to interpretation or obdurancy. Kallinikos (2002) suggests that “an essential part of the conditions underlying human agency are given expression and shaped through the very organization of cognition-based artifacts and the procedural standardization of their construction, interpretation, and utilization”. He bases this understanding of the relationship between humans and their artifacts on the humans’ ability to objectify and organize their experiences by means of various systems of notation and symbolic codification. A person may initially be constrained by a technological artifact such as, e.g., a mobile phone, but with repeated use may become more comfortable using it as the device’s properties become more familiar. Although the user as an agent interprets the artifact’s enabling capabilities each time it is used resulting in an improved understanding of how it can be used, the shaping effect of the technological artifact on the human cannot be denied. The human initiated interaction with the technological artifact and during this agency process displays intentions and has the ability to interpret whilst the technological artifact’s “machine agency” has the capacity to make a difference.

2.2 Structures

The view of technology as structure with the ability to enable and/or constrain human actions was contradictory to Giddens concept of structure as “traces of the mind” and with no material existence. This created a debate about the agency ability of technological artifacts as well as different interpretations of structures (Akrich, 1992; De Vaujany, 2005; Hosein, 2002; Kallinikos, 2002; Orlikowski, 1992, 2000, 2005; Orlikowski & Iacono, 2001; Rose, 1999; Rose et al., 2004, 2005; Widjaja & Balbo, 2006). Agency for both humans and technological artifacts plus the concept of structures as these apply to this study are discussed next.

Technology-in-practice is proposed by Orlikowski (2000) to bring her original structurational perspective of technology in line with Gidden’s view of structure as being only constituted when users interact with technology. Such a structure is enacted by humans only for the duration of that interaction, thus only fragments of the mind. Hanseth et al. (2004) argue that such an approach still does not address how the technology-in-practice is shaped by the technological artifact as well as the relationship between the two. Orlikowski (2005) responded to this criticism by agreeing that “by privileging either the technology or the social, we lose sight of their intermingling”. She suggests that further research should help with a better understanding of the problem of agency and by specifically looking at the status of the object. Instead of referring to material agency they prefer to use the term “material performativity” as opposed to “human agency” and these terms may be more useful to recognize the power of both without equating them. Both terms are implicated in the other since human agency could be materially performed whilst material performances are always enacted by human agency.

When humans interact with technology, a technologies-in-practice structure is enacted for the duration of the interaction. Humans use facilities, norms and interpretive schemes in response to the technology’s enabling/constraining properties to make sense of how to use the technology. This is
done by enacting a temporary structure based on rules and resources. This however does not provide for details about the relationship between the technologies-in-practice and actual technological artifact.

Action and structure cannot be separated and structure is both the means and the constraint for action (De Vaujany, 2005). Rose et al. (2004) refer to structure as “…to the common enduring pattern in social interactions and linguistic and semiotic discourse in which those interactions primarily take place”. They use Wand and Weber’s (1995) three structure types, namely: physical as the technological implementation of the computer system; deep as reflecting the meaning or underlining rule set of how the computer system represents the real-world system; and surface as the way the system represents itself in the form of interface, inputs and outputs to the user. The deep and surface structures form the basis of the linguistic perspective.

They concluded their paper with the statement that by “understanding how the deep and surface structures of social practice and discourse are consciously and unconsciously embedded in material computer systems, by the actions of designers, and subsequently interpreted by other stakeholders and reincorporated in the production and reproduction of linguistic and social structures continues to be one of the most challenging areas of inquiry in the discipline” (Rose et al., 2004). They further quoted Mol (2002) who refers to the practices in which an object is manipulated as not a single passive thing in the middle “waiting to be seen from the point of view of seemingly endless series of perspectives. Instead objects come into being – and disappear – with the practice in which they are manipulated”.

Burton-Jones and Grant (2008) adopt positivist assumptions for their study to investigate how IS can be used effectively and build their theory on representation theory. They propose constructs such as fit-in-use and transparent interactions, amongst others, as constructs in their model for effective system usage. They consider structures as the basis as to how IS provides its representations (deep structures) via surface and physical structures.

Inscriptions are discussed next to indicate how designers inscribe their understanding of how data stakeholders will interact with data and how data stakeholders inscribe their actual use of data objects in practice.

2.3 Inscriptions

Inscriptions are attempts to inscribe pattern of use or behavior in for example artifacts, work routines, legal documents, standards, procedures and other institutional or organizational arrangements (Monteiro & Hanseth, 1996). They further state that inscriptions may have different forms and it may increase understanding of how these artifacts, etc., are used when investigating how and where “patterns of use” are inscribed and the first step would be to study how the users’ interests are translated and inscribed. Callon (1986) describes inscription as a “process of creating technical artifacts that would ensure the protection of the actor’s interest”. It is important to note that an artifact never begins as a blank slate and in fact the inscriptions of IT artifacts represent the design, construction and use of different stakeholders, all with their own interests, values and assumptions in variety of communities of designers, users, investors, etc.(Faraj et al., 2004). The technology artifact can be modified through use with patterns of use inscribed and such inscriptions can then be viewed as properties of the artifact.

Inscriptions as the “way technical artifacts embody patterns of use” do not imply that actions are “inscribed, grafted or hard-wired into an artifact”, but rather that artifacts are “interpreted and appropriated flexibly”. During software development the “programs of action” for the users are inscribed in the data object based on the perception of how the data object will be used and this then anticipates how the data stakeholders interact with the data object in their different roles. Assumptions about the required competencies and roles of the data stakeholders are made and these roles and competencies are delegated to the components of the socio-technical network. Technology, having programs of actions inscribed, is an actor imposing its inscribed program of action on the data stakeholders. It can for example “resist” responding in the way expected by the data stakeholder such
as when it does not allow a value to be entered based on its validation criteria. Data stakeholders may also use data objects in unanticipated ways by, for example, bypassing validation criteria (enter 1111111 for a telephone number) or finding creative ways to enter data values in other fields such as entering a comment in an address field, etc.

The designer inscribing the perceived anticipated use for technology and as a caution Kallinikos (2002) warns that this should never become the arbiter of technological malleability. He further states that the spectrum of embodied intentions that characterize a particular technology cannot represent all possible embodied intentions that the user can enact when interacting with technology. In fact it may be important for the designers to consider the assumed user versus the actual user, real-world object versus its representation as a data object. Orlikowski (2000) states that the use of technology is situated, but not totally open to any and all possibilities. There will always be boundary conditions when using technology artifacts because they have physical properties that may limit their use. This does not imply predictable responses of human action (Widjaja & Balbo, 2006). Data stakeholders inscribe their understanding of how data can be used during their daily activities. The problem could then be that these understandings may not be recorded and that the understanding is reflected by the outcome of the action that is then inscribed, e.g., by how they produce or consume data to compensate for quality problems. Understanding is the outcome of the internalization process where different data inputs are combined with the data stakeholders own knowledge that (s)he has gained through experience as to how a similar situation was handled before. The inscriptions are not only based on the data stakeholders’ own competencies and assumptions, but may be influenced by factors of the environment in which the data stakeholder operates, as well as by other actors of the network. Data stakeholders may influence each other by convincing each other of their interests and how that may benefit them. All of these actions may be inscribed as patterns of use in the data object.

Next the design and use of data objects to provide for the data stakeholders technologies-in-practice is discussed.

2.4 Design and use of patient records as data objects

The designer, in this case the software developer, inscribes the beliefs, social and economic relations, previous patterns of use, legal limit and assumptions of what the artifact is about when defining the data object (Akrich, 1992) quoted in Faraj et al. (2004). Once the data object is created with its inscriptions its structure becomes material and these “embodies” structures represent various social rules (Orlikowski, 2000). Data in its different forms, e.g. records, database tables, reports, emails, etc., can be regarded as artifacts and as an artifact it has an embodied structure (refer to the physical structure) that includes the patterns, rules and resources that are embedded in the data object during its design as it may be used by data stakeholders (Widjaja & Balbo, 2006). Design is also regarded as the social construction of the data object’s embodied structure that emerges from their perceived understanding of the real-world object and through communication with the data stakeholders. The embodied structure could also contain inscriptions providing for data quality such as “rules” that are coded as software programs doing data validation or the use of triggers on databases. The design output (technology artifact) of the data object is referred to as a data object template and has inscriptions of the data object’s anticipated use. It is important to note that a data object does not refer to a single artifact as Jensen (2004) refers to an electronic patient record as “a multiplicity of things which forms a whole only sometimes or for some purpose”.

It is important to note that an embodied structure, i.e., the data object as an artifact, is a passive object that at the most has the potential to enable or constrain action but only when it is used in practice. By itself the data object cannot initiate any action or displays agency and an embodied structure can therefore be regarded as potential structuring elements emerging through the recurrent use of the data objects by humans. This in-use structure that is constituted during the process of agency, when data stakeholders interact with data though the data object structure, refers to the enacted structure of data objects. The same data object may be enacted differently by different data stakeholders and therefore
the appropriation of the data object can be viewed as “a weave of embodiment in-design and enactment in-use” (Widjaja & Balbo, 2006).

Data objects represent not only its physical structure, the template(s) defined by software developers during design, but when a data object is instantiated for each customer it is populated with the data representing the details of that customer. This is when data stakeholders capture or modify data. One data object template is instantiated by several data object instantiations when populated with data values to represent, for example, different customers and this multiplicity aspect requires a different view of structures and inscriptions as opposed to other technological artifacts. The result of this is that there are multiple instances of the data object, no longer necessarily being processed together but each could be enacted separately during its use. The data values can also be regarded as inscriptions because such values are captured or modified according to the data stakeholders’ perceived understanding of the data values during interaction with the data object.

The logical data object is constituted from the different physical parts during the process of agency and is, in that form, only available during the duration of that process.

The above discussion is illustrated next by considering patient records as data objects.

2.5 Patient records in practice

Patient records are used in healthcare for coordination and cooperation of a large collection of healthcare stakeholders as large and complex networks (Berg & Bowker, 1997; Hanseth & Monteiro, 1997; Fitzpatrick, 2000). Healthcare records, in this case patient records, are configured according to the needs and practices of the organisations they serve. The patient health record evolves into different views that are both independent and interdependent as the details about the patient’s care are recorded. In a medical practice the patient record is used by individuals rather than large groups as in hospitals.
Government regulations and Industry standards (e.g., code systems) are incorporated in how these records are used. The nature of what and how data is captured and used in patient records reflects the highly subjective judgments of their users, e.g., medical doctors, nurses, etc.

There is an interaction between the patient and the healthcare professional at the different points of healthcare therefore representing a network between the patient, healthcare professional and the corresponding data object of the patient. This interaction results in the exchange of data and information between the different data stakeholders.

The healthcare professional interacts with both the patient and patient record, contributing values to the patient data record based on his/her perception of the patient’s condition. This means that the medical practitioner is engaging with the patient’s data, integrating data from both the patient and patient data object, internalising these facts together with his/her observations, perceptions and professional knowledge. Data obtained from the patient are the facts provided by the patient and observation of the patient’s condition. Data from the patient data object are the facts previously recorded and stored, i.e., inscribed. This information is internalised and communicated by the medical practitioner to the patient and captured and stored, i.e. inscribed, in the patient data object in the form of clinical data. The patient receives the information which has to be processed and internalised by the patient in order to understand its meaning. Once the consultation is over the link between the patient and medical practitioner network is broken with the healthcare practitioner, patient and patient data object becoming inactive nodes of the network in terms of caring for that patient.

The logical patient record refers to the enacted structure temporarily constructed by the healthcare professional when interacting with both the patient and physical patient record at the point of care. The outcome of this interaction is inscribed in the actual patient record as the data recorded by the healthcare practitioner to represent the observations, diagnosis, treatment and other details. The physical patient record can be the patient file, notes, results, etc. One example is the prescription with the medication details that the patient takes to the pharmacy for dispensing of the medicine. All these physical components constitute the patient record even though it is possible that the individual parts may be physically in different places. This combination of components represents the real-world object – the patient. The temporary structure, the logical record, contains only the data necessary for the interaction between the healthcare professional and the patient’s data. This can be constrained by what data is available as the result of insufficient design where the anticipated use was not sufficiently perceived and or translated. It is also possible that the healthcare professional does not record all the interpreted data, such as diagnosis, observations, treatment, etc., resulting in incomplete inscription of data values. As a shared data object this means that other healthcare data stakeholders may have insufficient data to treat the patient and this can be regarded as a data quality problem.

Designers have a smaller role in the case of paper-based patient records because the structure and layout of the record evolves through its use rather than being designed first in terms of its anticipated use. Paper-based records usually provides for some structure combined with free text and are typically already in the format required for the type of document, e.g., X-rays, ultra-sound pictures, EEG, etc. The situation is different for electronic patient records because the systems supporting electronic patient records require a proper investigation, planning and design in terms of its anticipated use before such records can be used successfully. This is a complex task and research dealing with issues around electronic patient records should not only concentrate on identifying obstacles and barriers but also on exactly how such a record will be used in practice. In the case of electronic patient records the patient record has a pre-defined template to provide for all the possible data required to constitute the required patient record. This template can and probably will have more than one template components to provide for all the different parts of a patient record. This requires the designer sufficiently to understand the anticipated use of different healthcare data stakeholders to integrate it with the mapping of the real-world object. These templates guide the healthcare practitioner during the interaction to capture and use the data according to the specifications.
Even though patient records should not be regarded as passive repositories of data, it is true that the record is only active during the interaction between the healthcare practitioners and patient and then only for the duration of the interaction. Thereafter it is passive and cannot contribute anything to the patient’s care unless it is used by a healthcare practitioner. It is possible that the arrival of another part of the patient record, e.g., lab results, could result in the patient record becoming active again, but then only if a human attends to the arrival of such data. The patient record cannot alert the healthcare practitioner to something that may be unnoticed by the healthcare professional when it could in fact be significant for the patient’s care, e.g., unrelated observations on different parts that could in fact point to a specific condition or development. The patient data is as good as it is interpreted and used by the healthcare professionals.

Although the different parts of the patient’s record can be used independently, the significance of the interdependencies on each other has to rely on the healthcare professional’s ability to notice these interdependencies – the more experienced they are, the better they are equipped to interpret the patient’s data sufficiently to provide effective care. The data at this stage does not actively contribute to these interdependencies because it does not have the ability to initiate an action unless a procedure has been incorporated to process the interdependencies of data from time to time.

3 HEALTHCARE CASE

HealthCenter is a healthcare enterprise located in Cape Town, one of the fifteen such centres planned to operate in the private healthcare sector in South Africa by the end of 2008. They believe that an informed society is a healthy society and aim their services at accessibility and convenience. It provides a number of healthcare services under the same roof that cover the whole spectrum from sickness to wellness and primarily targets upper class citizens. Their patients either belong to a medical aid or can afford to pay for their healthcare services. The sub-acute hospital bridges the gap between hospital services and home-care for those patients who still require medical care on their way to recovery and who can no longer be treated in hospitals.

In the sub-acute and rehabilitation hospital a separate patient record is used where additional information is captured. This information supports the care period during the time that the patient has been admitted to this hospital until the patient is discharged. Most of these forms were designed by the current sister in charge based on her previous experiences at other hospitals. The main components of the ward patient record, also kept in a patient folder, are: discharge planning ward round; the FIMS (functional independence mobility score) form; admission form; medical admission record; nursing progress report; referral letter; medication administration chart; and vital signs chart.

3.1 Research methodology

This is an interpretive study in the information systems field with a relativist ontological stance and a subjectivist understanding of the research objects’ behaviour. A literature study was conducted to establish the different issues, themes etc. of the research topics. An exploratory case study was conducted with the group of data stakeholders and data objects as the units of analysis. Empirical data was collected through unstructured interviews where probing questions were asked and documentation and forms studied. Representatives of the following stakeholder groups were consulted: patient; management (centre manager, patient care manager and financial manager); administration (reception); healthcare professionals (doctors, nurses); and developers. Patient records were considered as the data objects. The approach was not to unpack all the possible uses of the different stakeholders but to rather understand how the different groups interact with patient records. The

1 Pseudonym used for the healthcare case
empirical data was analysed using the proposed data interaction enactment model as the theoretical lens as well as by identifying common themes and categorising data. Questions were derived from the proposed model and translated into suitable questions that were used during the interviews. Responses and observations were recorded and organised according to identified themes. The findings were further interpreted by establishing the meaning of the findings based on hermeneutics. The size limitation of this paper restricts the reporting of the case study in extensive detail and only the parts relevant to the interaction between data stakeholders and data objects are discussed. The data interaction enactment model is part of a more comprehensive research framework that also consider details about the influence of the context, profiling of the data stakeholders and the approaches they use during the interaction, roles, available resources and attributes. These details were considered but are not reported in this paper due to size limitations.

3.2 Analysis

HealthCenter’s patient data is still mostly paper-based and although electronic options could be made available the practice doctors and nurses in the sub-acute hospital the healthcare professionals still prefer paper records. This is in spite of patient folders that are often miss-placed. The business side of HealthCenter uses an electronic IS with effective appointment booking, medical aid claims, financial and other systems that support their business processes. Management has access to summary reports that they can use for decision-making but need easier access to be able to manipulate data for improved decision-making. The doctors indicated that their relationships with their patients are more important and their knowledge of their patients or family dynamics (not captured in patient records) may influence their diagnosis and treatment plans. The case notes based on the consultations are used differently by different doctors, e.g., for one doctor comprehensive and detailed notes are very important whereas another doctor feels that a template could deal with most of the standard observations. Data stakeholders adapted their use of patient records by inventing communication mechanisms, e.g., adding a red dot to folders of patients with outstanding accounts; blue message slip with phone messages to folders for a doctor’s attention; and using pink A4 paper sheets for female patients. There is limited sharing of patient data and this is even the case between the different care facilities of HealthCenter and doctors use referral letters to refer patients to other doctors or facilities. A new record, for example, is created for a patient admitted to the sub-acute hospital where all the patient details are again captured even though the patient is an existing patient of HealthCenter with a patient file at the doctors’ practices. There is still much duplication and disparate data sources at the different facilities.

When a patient is admitted in the sub-acute and rehabilitation hospital the nurse’s observations become important to manage the care of the patient. The nurse is the primary care giver and has direct contact with patients over a period of time. Patient records are stored and updated and then kept for a period of five years. Only the following patient details are captured on the computer: medical aid; payment; and medical condition.

The difference between patient records used by doctors and nurses reflects the purpose for which these records are used. The doctor interacts with the patient and/or patient record only for a short period during the visit in order to observe the patient’s condition and/or progress. The doctor may then decide to intervene by describing or changing medication, treatment; request for tests, e.g., blood, x-rays, etc. Nurses interact with both the patient and patient record over a longer period while the nurse cares for the patient. Nurses are therefore in a better position to become more familiar with the patient and the data that reflects their observations during the care period, in terms of the patient record, should be a more realistic representation of the patient. Typically, nurses data is not captured electronically and the value “hidden” in the data could become lost in the treatment unless the nurse and doctor specifically respond to observations recorded that may be relevant to the patient’s condition and treatment.

Following are the findings derived from the empirical data collected from Healthcenter:
• Different data instances of the same patient are located at different healthcare centres resulting in a lot of duplication and disparate sources of patient data.
• Patient data is important to all data stakeholders and although business data stakeholders interact with patient data to support an effective healthcare service from a business perspective, healthcare professionals still have the final say over how they will interact with patient data which at this stage is still secondary to their person-to-person interactions with their patients.
• Patient data used by healthcare professionals is still mostly paper-based and they are not specifically concerned about data quality except to provide for a comprehensive medical history for each patient in order to provide an appropriate healthcare service according to the legal requirements of their profession. Sharing of patient records is currently limited with referral letters the only mechanism to share patient data.
• Data inscriptions depend on how the data stakeholders interpret the use of patient data and although standard formats are used, e.g., patient observation cards, the actual values may be recorded and/or captured differently.
• Data is designed and used for two separate purposes, namely, business and healthcare. The data stakeholders are interested in using patient data for their purpose and may not recognise the benefit that they can derive from a design and use of patient data for a single purpose that supports both healthcare and business activities.

3.3 Discussion

When designing patient records, paper-based or electronic, designers need to consider how data stakeholders interact with patient data. This cannot simply consist of a list of the perceived user requirements but rather should be based on a sufficient understanding of the complexities associated with how the data stakeholders interact with data. The user interfaces to aid data stakeholders with interacting with patient records should be flexible enough to provide for a range of activities; for the different levels of expertise of the different data stakeholders; for the different purposes and ways that healthcare professionals interact with patients; to accommodate new, different requirements or enhancements. It is essential for designers and developers to understand how the different logical patient records are enacted for the different healthcare purposes according to the different healthcare professionals’ needs. Only then can the different patient record components be designed to support the different enacted logical patient records in practice. At this stage it seems as if most effort is spent on designing for anticipated use by defining the physical patient record (template) rather than focusing on the different enacted structures (logical patient record) to better provide for the different uses in practice.

The importance of the HealthCenter findings indicates that patient data is designed for two different purposes, namely to operate HealthCenter as a business and to provide a healthcare service but not for different uses in practice. Data stakeholders are only interested in using data for their own purpose and may not recognise the benefit they can derive from a design that can support more diverse activities. Design for use in practice should take into account the complexities of human interacting with technological artefacts by providing how different stakeholders interact with data at different times, at different locations and for different purposes. This cannot simply consist of a list of the perceived user requirements but rather should be based on sufficient understanding of the complexities associated with how data stakeholders interact with data. User interfaces, templates, records, reports, are all mechanisms designed for data stakeholders to interact with data and these should be flexible enough to provide for a range of activities; different level of expertise; and different purposes.

The socio-technical nature of IS should specifically be considered when designing for actual use based on representing the real-world in a way that effective facilitate actual use in practice – specifically its human-agency and Orlikowski’s (2005) machine-performativity as well as how data objects are enacted as “moments-of-interest” (Hosein, 2002). Patient records are shared between different data stakeholders, but in different ways as large and complex networks (Berg & Bowker, 1997; Hanseth &
Monteiro, 1997; Fitzpatrick, 2000). This is confirmed by the empirical study that emphasized the complexities around the interaction between data stakeholders and data objects where the actual use differs from the anticipated use. The reason why this is still the case could be the lack of understanding of how logical data objects are enacted as logical data objects and how these differ from the design templates (physical data objects). The empirical results of the healthcare case confirmed that a patient record currently still constitutes of many different physical components that are stored in different places and the concept of a logical record is not clear since users enact the required temporary logical structure with those components that they can locate with different levels of success and frustration. This enacted structure is also only available during the moment of interaction and needs to be enacted from scratch each time it is needed. Since these are still mostly paper-based careful consideration is required to provide for the same facility in any electronic patient record systems.

There is an important difference between the physical and logical structures of a record. Different temporary logical records are enacted to support different needs, i.e., it is necessary to provide for flexible logical records to enact the logical structures from the different physical parts as and when needed. In order for HealthCenter to compete as a business in an ever-changing global environment, they need to consider external factors that have an impact on the environment in which they operate. Better utilisation of their patient data will enable HealthCenter to protect themselves against legal actions and to improve their Healthcare service delivery. HealthCenter will be in a better position to interact with their partners, both internal and external, by recognising the importance of sharing patient data and this can be best achieved when their systems and patient record designs provide for their stakeholders to operate in a global world.

4 CONCLUSION

The purpose if this paper was to consider the complexities associated with humans using technology and to propose a model to consider how data stakeholders interact with data objects. This model illustrates the temporary enactment of the logical data object during the interaction with data objects. The problem seems to be the difference between the design for anticipated use and the actual use of these data objects. Data stakeholders inscribe their understanding of how the data object is used and these understandings are then inscribed into the actual data objects. The proposed data interaction enactment model can be used to investigate how logical patient records are enacted during interaction by considering which components are required to constitute the logical patient record for the different purposes. The proposed model indicates the extension of the technologies-in-practice model to provide for the embodied structures. The usefulness of the proposed data interaction enactment model still needs to be validated in practice to establish if this extended view sufficiently provide for improved design of the patient record components. Only once the data interaction enactment model is operationalized will it be possible to evaluate its usefulness as a practical model to support better design for actual use in practice.

The model built by Burton-Jones and Grange (2008) for effective usage provides for several constructs to consider for effective system usage, e.g., fit-in-use, transparent interaction, etc. Although their model also considers the three structures of Wand and Weber (1995), they focus more on to what extend the structures in terms of representing the users’ world, support effective usage as opposed to the data interaction enactment model that may provide more insights on the actual interaction between users and data as part of an IS. On the other hand it may be necessary to specifically consider representation theory for the proposed model to focus more on the representation aspect of the model, i.e., how the designer inscribe the perceived observations of the real-world object and anticipated use as the data object template and how that is instantiated to represent the real-world object (refer to the parts outside the circle in Figure 1). In this paper the focus is on the enacted structure indicated by the circle in Figure 1. It may be possible to combine some aspects of both models in which case further
research is required. Both models are at a formative stage and need to be operationalized and validated.

At this stage the contribution is more theoretical where the data interaction enactment model provides an explanation of the difference between a temporary enacted structure (logical data object) versus an embodied structure (data object template). The conceptual model was derived from the different explanations and descriptions to present a generic representation of the concepts on an abstract level. It is an attempt to visually represent the thoughts, constraints, events, reasons, behaviour or structures of the specific concepts. The interpretive research approach used contributes towards the improved understanding of the interaction between social actors and technological artefacts as the latter are designed to represent real-world objects.

The findings confirmed the notion that patient records are complex and that a consideration of both social and technical considerations are necessary, especially when these overlap when data stakeholders interact with data objects. Designers should focus more on the use of patient records in practice rather than only on their anticipated use. The contribution of this paper is more conceptual although the empirical results confirmed the issues identified by the literature review. Further research is required to translate these findings into practice design recommendations.

Abstract

This interpretive grounded theory study describes and analyses major power issues in a Scandinavian inter-organisational IS project which spanned four organisations, two suppliers, one national organisation and a research organisation. The paper explores different dimensions of power that emerged during the project – sources of power, power as resistance, reasons for the power struggle, and power as exercised. We conclude that, while power issues in ISD projects are by no means a new phenomenon, these power issues were exacerbated in this IOIS project due to the project governance structures necessary to coordinate several organisations.

Keywords: Power, inter-organisational IS project, Glaserian grounded theory

1 INTRODUCTION

It has been argued that the nature of IS development is always conflictual and political, and that researchers, instead of defining better methodologies and accepting manageralist agendas of IS development, should carefully analyse this conflictual and political context (Howcroft & Wilson 2003, Silva 2007). Silva (2007) has highlighted a lack of research on the politics of IS projects, and the challenges inherent in the belief that politics are ‘dark’ or illegitimate and somehow unsuitable for study. It has also been argued that academics should focus on dominance, power, marginality, and exclusions that take place both in IS development, adoption, and use (Beck 2002). Silva (2007) has argued in favour of an interpretivist approach for studying power and politics in IS, and this research fits into that category.

Conflicts and power struggle between users and IS professionals, and between users and managers, have been studied extensively over the years. In those studies, managers’ power over users has often also been criticised (Alvarez 2002, Hirschheim & Newman 1991, Howcroft & Wilson 2003, Kirsch & Beath 1996, Markus & Bjørn-Andersen 1987, Sarkkinen & Karsten 2005, Symon 1998, Yeh & Tsai 2001).
In the twenty-first century, inter-organisational projects have become much more common as a consequence of globalisation and standardisation in information systems. So far, inter-organisational information systems (IOIS), and especially their implementation with several stakeholders, have received only minor attention in the IS research (Evaristo, Scudder, Desouza & Sato 2004, Salmivalli 2008). Because there is even a larger number of stakeholders involved in inter-organisational IS projects, there is an even greater potential for conflicts (e.g. Kumar & van Diesel 1996, Levina 2005). In contrast to traditional problems in power between developers and users, our research considers the power issues between many more actors and parties in an IOIS project.

This paper discusses the power issues that arose in a public sector Scandinavian IOIS development and implementation project.

The research problem addressed by the paper is as follows:

What were the major power issues in a Scandinavian public sector IOIS project?

The paper is organised as follows. In the next section we present a summary of the relevant literature to this study. The third section outlines the research methodology. The fourth section gives some of the complex project case background of the study. The fifth section presents the findings of our grounded theory analysis. The sixth section discusses the implications of our findings, then we conclude our study with a brief summary of our contributions.

2 THEORETICAL FRAMEWORK

It is acknowledged that power is a very ambiguous and intangible concept and therefore exact definitions of it are difficult to give. Power is a multidimensional concept, and many definitions, interpretations and theories about it abound (Bourdieu 1998, Foucault 1980, Giddens 1984, Hardy & Leiba-O’Sullivan 1998, Jasperson, Cart, Saunders, Butler, Croes & Zheng 2002, Markus & Bjørn-Andersen 1987).

Many influential social theorists - such as Foucault, Giddens and Bourdieu - have conceptualised power. According to Foucault (e.g. 1980), power must be analysed something which circulates, or rather as something which functions in the form of a chain. Foucault was interested to study power in its external visage, which means that power installs itself and produces its effects. According to him, power is inescapable. In Giddens (1984) structuration theory, power has two different perspectives: the perspective of an action of the actor and the perspective of the structural aspect. Power is, then, the ability to make changes to behaviour, and control or dominate from an institutional perspective. Bourdieu (1998), on the other hand, is interested in power from the perspective of individual strategies. Bourdieu’s practice theory discusses sources of power (economic, cultural/ knowledge, social) as a particular kind of relational resource. Agents can influence their own and other agents actions in a particular context using these resources.

These social theories have been widely utilized in IS. Foucauldian analyses of power have been quite popular during recent years (e.g. Doolin 1999, Sayer & Harvey 1997, Wynn, Whitley, Myers & DeGross 2002). These studies analyse disciplinary power in different IS contexts. Many studies using structuration theory have argued that IT conditions and shapes human action, but also that human action conditions and shapes IT (see e.g. Majchrzak, Rice, King, Malhotra & Ba 2000, Orlikowski & Robey 1991). Levina (2005), among others, has adopted Bourdieu’s practice theory and focused on what people do and how their actions shape, and are shaped by, diverse sources of power resources.

Silva (2007) suggests that none of the three epistemologies used commonly by IS researchers – phenomenology, critical theory and structuration theory – are sufficient to engage with the ‘dark side’ of power and politics in organisations, as opposed to researching only the ‘legitimate’ face of power.

Jasperson et al. (2002) have pointed out that researchers have had problems defining and measuring the theoretical construct of power in IS area. They have identified common themes in power
conceptualisations: 1) authority 2) centralisation, decision rights, participation in decision making 3) influence 4) politics and 5) power. According to Silva (2007) authority is always contested, as formal rules are open to interpretation and that is the source of politics.

A very well known and extensive categorization of power is provided by Hardy and Leiba-O’Sullivan (1998). The first dimension shows that power is wielded by using various resources to affect the outcome of decision-making processes. In the second dimension, power is wielded by supervising access to those processes. In the third dimension power is wielded through legitimation, where power is embedded in the fabric of the system. The first two dimensions lean on the assumption that power is introduced only in the face of conflict (and opposition), whereas the third dimension acknowledges that power can be used to ensure that conflict never arises. The fourth dimension (‘limits of power’) enables the investigation of aspects of power which do not normally appear in the mainstream literature of power – for instance, while some actors may receive advantages from power relations, they can not control or escape them.

To Hardy and Leiba-O’Sullivan, power is integral to empowerment. To managers and mainstream management researchers, power is legitimate and functional. Power can be thus shared. In this case, empowerment can be as a tool to motivate employees to achieve organisational goals. For critical theorists, on the other hand, power is domination, and empowerment provides the means to combat the sources of domination.

Table 1. Empowerment and the Dimensions of Power by Hardy and Leiba-O’Sullivan, p. 462.

As stated in the introduction, many studies (e.g. Kirsch & Beath 1996, Sarkkinen & Karsten 2005, Symon 1998, Yeh & Tsai 2001) have shown conflicts between different user groups and between IS professionals and user groups as widespread. It has been argued that user involvement has been used only as a buzzword or a weapon for achieving management goals (e.g., Hirschheim & Newman 1991, Howcroft & Wilson 2003, Kirsch & Beath 1996, Symon 1998). Gärtner & Wagner (1996) have analyzed the political frameworks of IS design and participation, and state that agenda setting related to the IS design and participation is important, as well as the legitimation of certain agendas over the others. Conflicts between different actors - workers, managers, consultants, unions and IS professionals - are evident in this process.

Markus (1983) has highlighted that the strength of resistance in an IS project is likely to be affected by the organisational position of the person to whom one loses power. According to Markus (1983) the
explanations of resistance are important because, however informal or implicit, they guide the behaviour and influence the actions taken by managers.

In distributed and multi-party IS projects, there is even a larger number of stakeholders involved, and empirical studies have revealed that there is a great potential for conflicts in this context, and that power relations between the multitude of stakeholders (e.g. IS professionals, users, graphical designers, strategists, different participating organisations) should all be acknowledged (e.g. Kumar & van Diesel 1996, Levina 2005).

It should be pointed out that, because this is a grounded theory study, although we reviewed the literature before embarking on analysis, we didn’t use labels from the theoretical framework for to code the data. Glaser (1992) directs researchers to avoid forcing the data down preconceived theoretical avenues. The idea is that the emergent theory of the study determines the relevance or otherwise of the literature review. Thus we proceeded with an ‘open mind rather than an empty head’ (Dey 1999). Once the theory has emerged, it is then the duty of the grounded theorist to engage their emergent theory with the existing literature. The next section considers our methodology.

3 METHODOLOGY

This study is an interpretative study using Glaserian grounded theory (Glaser 1978, Glaser 1998) for data analysis and theory building. Grounded theory method is very suitable for research areas where there is little existing theory. In this case, grounded theory method was very useful because there is little existing theory in inter-organisational IS (IOIS) projects and especially their implementation area.

This research studied 8 organisational project teams and 2 inter-organisational project teams, in a large, three years long IOIS development and implementation project. The IOIS project studied, ViWo, was a Scandinavian public sector organisation collaboration. This research tracked the whole IS project and it had a unique approach – no framing questions were used, the focus was entirely on the experience of the project member.

Data collected in the project ranged from in depth interviews (250 pages of transcripts), to observations of project meetings (20), diaries (80 pages of notes), 48 memorandums of project and steering group meetings, and e-mails (over 700) containing what project members sent to each other during these years and other secondary data (the data of previous project) were also analysed.

Over the three year timeframe of the project, 36 different people were involved. Some people were involved only once or twice in project meetings. There were 20 active project members in the project, 14 of whom were willing to be interviewed. Among the interviewees were managers from the steering group, representatives of suppliers, members of the research organisation (Rhoo) associated with the project, and users active in the project. The interviews lasted from 45 minutes to two and a half hours. The open nature of the interviews enabled the interviewees to explain their deep feelings about the project that would not have surfaced otherwise. The interviewers told their own story about the project and its progress. It is said that through narrative stories we are able to get close to people’s experiences (Clandinin & Connely 1994).

In this study ‘Glaserian’ grounded theory technique was used as the method of analysis. Since 1990, grounded theory has evolved into two distinct versions (Urquhart 2001, 2007, Urquhart & Fernández 2006). This occurred on the publication of Strauss and Corbin’s (1990) book which is a distinct departure from the classic “discovering of theory from data” in the seminal book of Glaser and Strauss (1967) which introduced grounded theory. The 1990 book helped popularise grounded theory and is widely used; however, it has also been described as rather formulaic and overburdened with rules Kendall (1999). From our perspective then, the Glaserian version has the twin advantages of being closer to the original, classic version of grounded theory, and of being much more flexible.
Glaser recommends that the researcher takes a very open approach in order to ensure that concepts genuinely arise from the data as opposed to preconceived questions, categories and hypotheses (1992). We allowed the data to suggest categories to us, rather than using preconceived categories. It is also recommended by grounded theorist that researchers collect the data over many phases of research - when the same concepts occur over and over again, the saturation of concepts can be considered reliable. This was our experience that the concepts recurred over different phases. Glaser also (1992, 1998) recommends the collection of rich, versatile data in the form of different interviews, observations, and diaries, and our data collection followed this directive.

We followed the Glaserian (and classic grounded theory) coding stages – open coding, selective coding and theoretical coding. According to Glaser (1978), the open coding is the most important building block of GTM. At the open coding stage, the interview data, field notes and e-mails were analysed line by line, and the project memorandums were analysed paragraph by paragraph. Urquhart (2001, 2007) has pointed out that line by line coding is recommended by both Strauss and Glaser and is demonstrably fruitful. However, as the project memorandums were secondary data, it was appropriate to code at a paragraph or page level (Urquhart 2007). The coding process was done by one researcher (first author of this article) and then discussed with second author of this paper. After discussions, some code names were changed and open codes reallocated to different categories.

During selective coding and through an iterative process, we discovered our emergent categories. We then considered the relationships between categories during theoretical coding, and analytic memos (Glaser 1992) assisted with this process. Glaser (1978) emphasis that the bedrock of theory generation is the writing of theoretical memos. One of our emergent categories was power, and it is this concept that we concentrate on in this paper. In this study we can indicate what are the main strengths of Glaserian grounded theory method. A detailed and systematic analysis of data allows the discovery of new concepts.

4 PROJECT BACKGROUND

Here we give some of the complex background of the IOIS project, to help with interpretation of the findings.

4.1 History of the project

ViWo was preceded by a pilot project called PreViWo. PreViWo was implemented in three steps (specification, interface pilot and planning) in the years 2002-2003. The aim of the PreViWo project was defined as “to specify and implement a pilot IS to support a process, its actors and task performed by them” (Project card, March 8, 2002). Table 2 contains the actors in the pilot project. The pilot project was influential in framing the organisation of the larger project we studied (ViWo), and it could also be seen that the history of the pilot project influenced the perceptions of the participants. Alpha was the leading organisation for the pilot project as the organisation who applied and received funding for the project.

4.2 Main players – ViWo project

The goal of the IS project was that an Inter Organisational IS (IOIS), named ViWo, would be designed and taken into use by several organisations of the same type. The project aimed to carry out a pilot test of the IS in these organisations before establishing the system at the national level. The development of ViWo involved electronification of a work process to facilitate office work, consolidate information across organisations, and manage key activities.

In the ViWo project, Nofco was no longer in charge of the project - a project management organisation, Rhoo, was brought in. They also managed some research objectives around the project. The key user organisations now consisted of Alpha, the original lead user organisation, plus user organisations Beta, Gamma and Delta who came from Nofco and Opti. Nofco now consisted of 21 organisations, and it would be these organisations that would eventually use ViWo. The organisations collaborated with the relevant Ministry, suppliers and consultants.

| Nofco             | Consortium of 21 user organisations (Virtual organisation)  
                   • The basic function of Nofco was to promote and develop locally, regionally, and nationally the utilisation of IT and to enhance inter-organisational collaboration in multiple research-related issues and administrative practices |
| Alpha, Beta, Gamma, Delta | Lead user organisations in the project  
                   • Alpha was also the fund holder for the project |
| Rhoo              | Organisation responsible for project management and research objectives                                                                           |
| Socca             | Software company that supplies the software solutions for the project                                                                               |
| Cumma             |  
                   • Part of the national research network that develop research and IT based services for the needs of research and education, and the supporting IT administration  
                   • Acted as an expert advisor. Withdrew from the project before it ended                                                                          |

Table 3. Organisations involved in ViWo

Cumma, eventually, withdrew from the project: “We withdrew from so many occasions that we realized that we could not continue in this way. This was probably because we received a role that was more demanding than the one we pursued in the initial discussions and negotiations…”(Jack, Supplier Cumma)

4.3 Organisational project members in ViWo

The table below names members of each organisation and their roles in the project. As can be seen below, there were a large number of people involved, and some had experience of the previous project.

Table 4. Project group organisations and their members related to ViWo

A difficult question was who would be the ViWo project manager. ViWo was perceived to be a demanding project, and an experienced manager would be needed. Matthew, the Project Leader of Rhoo, suggested to Lucy and her colleagues from Beta and Gamma that Rhoo could take the responsibility of leading the project, Ruut being the project manager. This suggestion was approved, and so the project manager changed: in PreViWo it was Sheila from Nofco but in ViWo it was Ruut from Rhoo. Ruut had extensive experience in practical software development. It was envisaged that, in addition to Matthew and Ruut, Rhoo could provide a three person quality assurance group for ViWo development. When it came to the choice of software vendors, Matthew’s argument was that Socca would deliver a useful system even in the situation of unclear client requirements.

5 THE FINDINGS

Power was one core category which emerged through the grounded theory analysis, and this section discusses the category in detail. We identified Sources of Power, Power as Resistance, Reasons for the

Proceedings ECIS 2009
**Power Struggle** and **Power as Exercised** as important selective codes of the category. Table 5 presents the open codes and selective codes that make up the category.

Table 5. Construction of Power Category

5.1 **Sources of power**

This selective code illustrates the different sources of power in the project. For instance, Ruut (Project Manager, Rhoo) prohibited some project members attending the project meetings by using her legitimate power. She was pulling strings by not inviting all former people (Nofco, Consortium of User Organisations) to the project meetings. Some members guessed that she did it that was able to avoid competition between her and the previous project manager of PreViWo. She also sent an email to Simon (Rhoo) that his presence in project meetings is not necessary. Simon was amazed and asked if some other project management presence was necessary, if his presence was not. It was speculated that for some reason they did not get on well with each other.

Expert power was also in evidence and conflicted at times with the project managers legitimate power. For instance, there was a ‘tug-of-war’ between the suppliers and the project manager around various issues. The discussions were “little bit hostile” (Thomas, Rhoo). Supplier Cumma felt that disagreements were frequent and faults were dealt with by “tattling” to the project manager. So Supplier Cumma sought background support for their work from other project members on the basis of their expert power. At that time, Cumma had a good reputation and there was discussion among the project management people that it was not easy to disagree with Cumma because of the skill and know-how owned by the company. Later, however, the confidence in Cumma started to wane.

Thomas (Rhoo) pondered how the steering group should regard the matter, since nothing was happening. Thomas thought that the roles of “generals” and “officers” were not defined and consequently attempts were made “to transfer war leadership onto wrong shoulders” Thomas thought that because legitimate power were not defined in project it caused that people ‘took’ power and there were not abilities to manage it. This caused ‘anarchistic’ behaviour in his opinion.

In addition to legitimate and expertise power there was political power used in the project, as shown in how the project was represented as a success to those outside the project. At the end stage of the project, Nofco announced that a journal article had been published on the ViWo project. The announcement incorporated a message requesting receivers to notify their international partners of the publication of the article. At that stage, this raised criticism among the project members, because they thought that Nofco had wrongly collected merit from work that it had neither planned nor implemented alone. The issue came up among the employees of the other supplier as well as among the project management. Thus, the representative of the other supplier, Walter, posed the question: “…what was it that Cumma had planned and Nofco implemented? And noted that Socca’s name had not been mentioned at all in that connection … “ (Walter, Supplier Socca, Email June 30, 2005).
5.2 Power as resistance

In the experiences of project members, the notion of ‘power as resistance’ also emerged. There were situations where project members combated or at least wanted to combat domination by other project members.

Some members wanted for example to take control of decision-making in the project. “Who decides and on what? It would be good to know so that the matters do not need to hashed over unnecessarily at meetings...” (Walter Supplier Socca). Control of decision-making was a central problem in the project which caused resistance. The decision-making process was seen as “yeh-naw discussion” (Thomas, Rhoo) and as a “competition” (Ruut, Project Manager, Rhoo). There were tensions between the new and old project members. Both project management and supplier Cumma felt that it was often necessary to return to decisions due to questions or critique presented by Nofco (Consortium of User Organisations). Ruut (Project Manager, Rhoo) complained that it was difficult to see whose rules should be followed, although decisions were made at project meetings. Both Suppliers and Project Management felt that the representatives of Nofco (Consortium of User Organisations) inhibited decision-making. Jack’s (Supplier Cumma) quotation reveals that problem was that “too often problems that emerged from practical work or were brought up on discussions were ignored by pointing out that the process had already been defined...” Sheila (Nofco,), for her part, saw that really big problem was that suppliers were given the power to decide on matters in the project group.

*Tensions between old and new* were evident because of the previous project. Ruut, Project manager felt that she was an “outsider” when Sarah and Sheila (Members of Nofco) felt that maintaining an artificial separation between these two IS projects caused problems for organisational memory. “We assumed then that since Cumma was chosen as the second supplier, it would ensure the contiuance...but the old information had not been passed on, that gatekeeper’s task did not continue...” (Sheila) Sheila was, for example, surprised that Socca had begun to design a user interface even though one was already available that had been done in PreViWo.

There were also situations, where some people were aware of controversial issues, but were unable to use power effectively to influence outcomes or unable to get it to the decision making arena. In many cases project members just agreed to accept proposals (*seeming* acceptance), despite disagreeing with the decision.

Unclear plans caused *insecurity* among the project members. It was difficult to plan project schedules and estimate future workloads. So the members of Nofco demanded that some kind of long term plans should be made. "In other words, matters have some up kind of unexpectedly, or is that typical in IT projects and IS projects that it is so? I have pondered even from the standpoint of my own work that is it so... (related to) project planning and project management and these types of things..." (Sheila)

5.3 Reasons for the power struggle

When interviewing project members about their experiences, the topic ‘reasons for the power struggle’ also emerged. There were various open codes which made up the selective code of reasons for the power struggle; *previous project, positions in project, jargon, time pressure, and unclear responsibilities.*

The *previous project* affected the power struggle in many ways, for example leading questions could be asked by those who had knowledge of the previous project to those who did not. Ruut the project manager felt for example that it was difficult to see whose rules should be followed: “Naturally the previous project has caused pressures especially because the former people are there. I have sometimes sensed an air of competition concerning who is in charge and whose rules are followed...” (Ruut).
The previous project (PreViWo) managers were not invited to take charge of the ViWo project and the suppliers were replaced. Matthew (Rhoo) pointed out that discontent with PreViWo (schedule and specifications problems) had resulted in an effort to change actors in the new project.

It also became evident that the representative of the supplier (Cumma) who had been involved as an expert in (PreViWo) did not support the use of the material in the further project: “John described the specifications in his colourful style as suitable to be thrown into a waste basket…” (Matthew)

The positions in the project were very different to the PreViWo project. The quality of the specifications and the poor success of PreViWo were the reasons for the adoption of a different pattern of organisation in the new project. The project manager from Nofco was changed in summer 2003 because of project management issues. The suppliers were replaced in early 2004 because of the poor quality of the specifications.

Interestingly, Nofco’s members felt that too much power was given to suppliers to decide on matters. Suppliers, on the other hand, said that Nofco’s representatives and project management ignored many problems by saying that the process had already been defined.

The use of jargon was a problem in the project. John (Supplier Cumma) thought that users should take more part in decision-making, but the problem was, according to users, that it was difficult to understand technical matters. Lisa (User Representative, Alpha) felt that it was difficult to form opinions because she didn’t understand what was discussed. “If someone mentions the word interface once more, I’ll jump out the window…! Let’s speak about matter without technology…” (Lisa). Eventually, the users demanded that the project manager and supplier use language which they could understand.

Time pressure was also something which contributed to the power struggle. Project members had very different perceptions about the time pressure in the project. One project member pondered on how it was possible that people felt that there was no time to have a lunch or even to go to the bathroom. But she encountered a different attitude from other project members “Amazing that we wait at a meeting for an hour while someone (user representative) feeds her dog”.

Unclear responsibilities become also apparent in an e-mail message sent to the researcher by Cumma’s representative: “Interesting definition of policy, that because it is related to a [technical matter], it belongs to Cumma! In my opinion the application form belongs to Socca, but Cumma has to take part in ensuring the implementation of the form by specifying necessary interfaces…” (Peter, e-mail Aug. 31, 2004).

5.4 Power as exercised

How power was actually exercised in the project was very interesting. We found three open codes for the selective code power as exercised.

Final authority: The other project leader, Lucy (Alpha) said that she make a lot of decisions trusting to others views, using intuition and feelings, because she thought that she was layman in these things. She said that, for example, that when project manager pointed out something in a plausible way, she gave the necessary final authority. Final authority did not always rest with the same person. A good example was the situation where the project manager and Sheila (Nofco’s representative) battled about the appearance of the display, and where project manager finally climbed down. Some decisions were achieved asking project manager to use her final authority.

Veto power: Nofco had the ability to veto decisions, albeit informally. It was often necessary to revisit to decisions due to questions or critique from user organisations. Ruut (Project Manager, Rhoo) complained that it was difficult to see whose rules should be followed, although decisions were made at project meetings. Both Suppliers and Project Management felt that the representatives of Nofco (Consortium of User Organisations) inhibited decision-making.
“Forged” power. This was a positive experience as a result of organising and of social relationships. Things were done at short notice at the request of the project manager because she wielded this type of power. The members of Nofco felt that this was how the project manager got people to do things she wanted.

6 DISCUSSION

We have shown in the previous section the complex power issues that arose in a Scandinavian IOIS project. We illustrated different selective codes of power that occurred – sources of power, power as resistance, reasons for the power struggle, and power as exercised. While sources of power were easy to identify, it was also easy to see how resistance occurred. Reasons for the power struggle seemed to revolve around both the history of the project and unclear responsibilities. Power as exercised in the project came down to who could actually have the final authority in the project organisation structure, but this final authority was often contested and switched between people. Resistance was indeed more likely if the individual was a peer of the individual trying to impose the decision (Markus 1983).

The governance of the project was particularly challenging because of the number of organisations and structures involved. This is a potential problem for all IOIS projects, as of course governance does need to be defined between organisations in such projects. In this particular instance that the project structure, as set out, was a very complex one, with undefined governance and responsibilities. In particular, the authority of Nofco, the user consortium and its relationship to the lead organisations was poorly defined. What makes it even more complicated is that the background of the project was very ambiguous and unclear to many participants. The complex project structure led to all sorts of unforeseen problems. Silva (2007) argues that authority is always contested, as formal rules are open to interpretations and that is the source of politics.

In this case, all participants (users, suppliers, project management personnel and representatives of Nofco) had power in certain situations, but were also resisting the power of somebody else in other situations. In many cases it seemed that this situation was reciprocal, each actor in turn having power and resisting domination. For example, the users used their power to change topics of discussion, suppliers required users to make decisions, and Nofco criticised the project manager for giving suppliers too much power in decisions. There were also some situations, where some people were aware of controversial issues, but were unable to use power effectively to influence outcomes or unable to get it to decision making arena. The users were not necessarily the resource weak group in the project. Users could “talk back”, and in some instances even prevent the decision making and the progress of the project. Both project management and suppliers were affected by this, but could not use their power effectively to change the situation. In all, the ‘limits of power’ from the critical viewpoint was palpable in the case.

Hardy and Leiba-O’Sullivan (1998) enable us to see that aspect of power, which does not normally appear in the mainstream literature of power - ‘limits of power’. Limits of power were clearly seen in the case. Jasperson et al. (2002) and Markus and Bjørn-Andersen (1987) also emphasise that power which inheres in an official position. Our study reveals that in some situations it is easy to use power over others in some position, but on the other hand, it is also shown that it is possible to counter that power.

We can note that in IOIS projects, when there are any number of organisations and structures involved, it is more likely that there will be ‘competition’ and ‘tug-of-war’ situations, and that legitimate power is used as ‘justice’.

Our study also illustrated how unclear roles influenced the exercise of political power. According to Silva (2007), the study of power poses challenges because of the twofold nature of power: 1) power that arises from positions of authority or 2) its informal dimension, i.e. politics. Most of the challenges in this study came from the informal dimension, which then came up against a veto in the formal authority structures.

Proceedings ECIS 2009
7 CONCLUSION

Our research raises many important issues related to research on power in the IS field. We agree with Silva (2007) that we need research on power that emphasises the interpretations of meanings, intentions and actions which are suitable for making sense of such a complex phenomenon. In contrast to traditional problems and power struggle between developers and users or managers and users, our research shows that in a multiparty IS project it is extremely difficult to say who ‘has’ power and who is in need of ‘empowerment’. We have also made a methodological contribution, we feel, by our detailed consideration of day to day issues of power, using grounded theory analysis.

In contrast to traditional problems and power struggle between IS professionals and users or managers and users, this research shows that in an inter-organisational IS project it is difficult to say who ‘has’ power and who ‘lacks’ power. In all, power is clearly a complicated matter and there is no clear cut way of defining “whose power over whom” is to be analysed, in IS setting or elsewhere.

We would also contend that, with the advent of globalisation, there are an increasing amount of IOIS projects in existence, and that there is a need to research power issues in such projects. The potential for conflicts in such projects are greater than in organisational projects, because of the need to set up agreements and governance structures between parties involved in such projects. We urge IS researchers to explore how particular governance structures might either constrain or enable conflicts in such projects.

Abstract

This paper investigates how innovation of ICT based services takes place within existing infrastructures, including the whole network of technology, vendors and customers. Our research question is, how can an information infrastructure provide generative mechanisms for innovation of ICT based services?

Building on a critical realist approach, our empirical evidence was a case study within an international airline, aiming to diversify its services. From our analysis we propose that there are two self-reinforcement mechanisms in information infrastructures. First, we identified the innovation reinforcement mechanism, resulting in new services. Second, there is the service reinforcement mechanism, resulting in more users and profits.

The practical implication of our framework is to show that although ICT-based innovation cannot be planned and managed in detail, the innovation mechanism may help organisations to facilitate the innovation process in a structured way.

Keywords: Innovation, information infrastructure, generative mechanism, case study
1 INTRODUCTION

During the past decade innovation of ICT based services has transformed several industries, such as financial services, telecom and IT, and media. Other sectors are following, for example the music industry and e-government. Innovation is not easy; it is hard to plan and manage (Tidd and Hull 2003), it is socio-technical and non-linear (Janszen 2000) and should be done mindfully (Swanson and Ramiller 2004). As Christensen has shown, innovation is also paradoxical; the innovative company faces the danger of becoming a victim of its own success, as it develops a mindset that hinders new innovations (Christensen 1997).

This paper explores innovation from the perspective of information infrastructures. As defined by Hanseth an information infrastructure is “a shared, evolving, open, standardized, and heterogeneous installed base” (Hanseth 2002) (p. 2). The key term in this concept is the installed base, which denotes the number of components and users in the information infrastructure. For example, the installed base of iPod consists of the iPod players, the central music database and the millions of users. The key attribute of a successful information infrastructure is the self-reinforcing mechanism, illustrated with Gindley’s figure below. An installed base attracts complimentary products. This makes the information infrastructure more attractive to users, and generates more use, which in turn increases the size of the installed base.

![Figure 1. Grindley’s standards reinforcement mechanism. (From Hanseth, 2002).](image-url)

Compared to the traditional concept of information systems, the notion of information infrastructure offers two important advantages. First, it changes the object of study from a single application within a company to the world of large socio-technical networks. Second, it offers a new perspective on how such solutions are developed. While the stand-alone system can be designed and implemented, the information infrastructure is seldom designed from scratch; rather it is growing more organically from an existing base.

In the context of innovation this creates a certain paradox with information infrastructure; on one hand they are usually not made from scratch, on the other hand a number of information infrastructures are spectacular innovations. Well known examples are Internet based supply chain networks, FaceBook and eBay. This calls for more research on how successful infrastructures are developed in more detail.

This paper investigates how innovation of ICT based services takes place within existing infrastructures, including the whole network of technology, vendors and customers. One point of departure is that information infrastructures usually represent large investments in IT architecture. Thus, one ambition is to understand the self-reinforcement mechanisms in more detail, in particular the role of the IT architecture.

The research question is:
• How can an information infrastructure provide generative mechanisms for innovation?

This paper proceeds by a review of some central contributions on information infrastructure and innovation. Then, in section 3, the research approach is briefly presented, while section 4 presents the case study. Findings are discussed in section 5 and conclusions offered in section 6.

2 A BRIEF REVIEW ON INNOVATION IN INFRASTRUCTURES

Star and Ruhleder (1996) asserted that “infrastructure is a fundamentally relational concept. It becomes infrastructure in relation to organized practices” (p. 4). They defined information infrastructure in the following terms: It is embedded into other structures, transparent in use, has reach and scope beyond a single event, is learned as part of a membership, it links with conventions of practice, embodies standards to be able to plug into other structures, is built on an installed base and, finally, it becomes visible upon breakdowns (Star and Ruhleder 1996).

Thus, innovation in information infrastructures presents a double set of challenges.

First, ICT based service innovation is in itself a complex process. The service innovation process differs from the innovation of products: Services are usually developed in close interaction with the customers, and they are more often innovated in networks rather than labs. (Tidd and Hull 2003; Abramovic and Bancel-Charenso 2004). ICT based service innovation often redefines the roles of the service provider and the users. An illustrative and very successful example is the Internet bank. The real innovation of Internet banking is not the web software, but the redefinition of roles: The bank organization provides the technological infrastructure, the technology is available 24/7, and the customers are doing the transactions themselves. The actual innovation is the interplay between the providing organization, the new technology and the users.

Second, research on information infrastructures has shown that the development trajectories of information infrastructures are hard to predict and control (Ciborra 2000; Hanseth 2007). Extensive case research showed that many of the key approaches from strategic IT management, such as top-down planning, management control and strategic alignment, do not work as intended in the context of corporate information infrastructures. Rather, the authors assert that top-down approaches rather will increase the managerial problems of large information infrastructures, and instead they point to such concepts as cultivation and care in order to foster innovation and growth. Taking these ideas further Hanseth and Lytinen pointed out that large-scale information infrastructures have a complexity that goes beyond traditional systems design. They proposed a full theory on the design of information infrastructures, focusing on how to foster the growth of an installed base, building on networks economics and complexity theory (Hanseth and Lytinen 2008).

The five principles are (p.11):

• Design initially for usefulness
• Draw upon existing installed bases
• Expand installed base by persuasive tactics
• Make it simple
• Modularize by building separately key functions of each infrastructure, use layering, and gateways

These key design principles exploit the dynamics of self-reinforcing mechanisms of growing information infrastructures. In addition, we need to consider another feature of information infrastructure innovation, namely innovation as a collective process.

Fifteen years ago van de Ven described innovation as a collective process, including not only the entrepreneur, but also includes a variety of industrial and public actors (Van de Ven 1993). The insight that innovations today more seldom take place within a single organisation has triggered a strong interest in different forms of co-operative innovation processes (Bessant and Tidd 2007). Andersson et
al. found that architectural knowledge is crucial in inter-organisational innovation, in four dimensions: technology capability awareness, use context sensitivity, business model understanding and boundary-spanning competence (Andersson et al. 2008). Other researchers have investigated the innovative capabilities of distributed and heterogeneous networks, and showed that innovations in this context may be regarded as a series of cognitive and social translations (Yoo et al. 2008). Cognitive translations include the creation of ideas into actionable artifacts, while social translations take place at the borders of different knowledge communities, where involved actors negotiate and mutually adapt a solution. While the cognitive translation process is relatively linear, the social translation process is much less predictable.

Summing-up this very brief overview: We know that the innovation process in information infrastructures is complex and non-linear, that it is essential that it exploits the dynamics of self-reinforcement of the installed base and that it is a collective endeavour which is both cognitive and social. What we know less about, is the causal structure of innovation in information infrastructures, and how this is linked to the growth of the installed base. Thus, what we are looking for is a recursive structure of mechanisms, which links innovation and growth in more detail.

3 METHOD

3.1 Research approach

The general approach for this study was a critical realist case study. The basic assumption of critical realism is the existence of a real world independent of our knowledge of it. Reality is conceived as being stratified in three domains. The real domain consists of objects, both physical and social, with capacities for behaviour called mechanisms. These mechanisms may (or may not) trigger events in the domain of the actual. In the third layer these events may be (or not) observed, in the empirical domain. Thus, structures are not deterministic; they enable and constrain events (Archer 1995; Sayer 2000).

Critical realism combines a realist ontology with an interpretive epistemology (Sayer 2000); although a real world exists, our knowledge of it is socially constructed and fallible. This does not imply an epistemological relativism; since a real world does exist critical realism holds that some theories approximate reality better than others. This process of approximization is seen as a key part of scientific enquiry. It follows from this that critical realism does not aim to uncover general laws, but to understand and explain the underlying structure and mechanisms. This is done through retroduction; we take an empirical observation and hypothesize a mechanism that might explain that particular outcome. These mechanisms are associated with the nature of the object of study, not to the regularities of events (Sayer 2000).

Our object of study is an information infrastructure. Following DeLanda we envisage an information infrastructure as an assemblage, i.e.”wholes characterized by relations of exteriorities” (p.10). The basic attributes of assemblages are (DeLanda 2006):

- An assemblage consists of various types of components, which in themselves may be assemblages. An assemblage allows for interactions between components that are emergent, i.e. mechanisms whose behaviour cannot be explained by the properties of the component.
- A component is self-subsistent and may be unplugged from one assemblage and plugged into another without losing its identity.
- A given component may play a mixture of material and expressive roles by exercising different sets of capabilities. Assemblages may increase their homogeneity by sharpening its boundaries (territorialization) or destabilizing it (determinitorialization).

In an information infrastructure context we should conceive these structures as semi-stable. They are the result of relatively stable patterns of behaviour over time, but at the same time they are changing...
continuously, as the result of growth and change. For example, the behaviour of a user community will have some stable patterns (in spite of people joining or quitting), but it may also change its patterns of behaviour in interaction with a new service, at the higher level of assemblage.

3.2 Data collection

The case company, Norwegian, was chosen for two reasons. First, it was a young and successful company, with a reputation for innovation. Second, the company was expanding its initial successful infrastructure of booking services into new ICT-based services, thus constituting a fruitful case to study innovation in infrastructures.

Data collection at Norwegian was conducted during a period of six months in 2008. Ten managers and specialists were interviewed, each circa 2 hours, some of them twice. In addition a large volume of technical documentation (business plans, project plans, contracts, technical architecture documents) was analysed. To ensure internal validity the preliminary findings were discussed with informants, and paper drafts were sent key informants for comments.

3.3 Data analysis

The inspiration for the data analysis was the following passage from de Landa (2006):

“To give a complete explanation of a social process at a given scale, we need to elucidate not only micro-macro mechanisms, those behind the emergence of the whole, but also the macro-micro mechanisms through which the whole provides its component parts with constraints and resources, placing limitations on what they can do while enabling novel performances” (p.34).

The practical search for these mechanisms was conducted in the following three steps (Pettigrew 1985). First, a time line was established, and important events were identified. Then a comprehensive analysis of organizational design and culture, technical development and business strategies was done, focusing particularly on the interplay between these dimensions. Third, to ensure internal validity the preliminary findings were discussed with informants, and paper drafts were sent to key informants for comments.

4 THE CASE STUDY

Norwegian is an international airline carrier based in Norway. Its strong growth started in 2002, when it established a national network, helped by the government deregulation of the airline industry. Today the company has 1.300 employees, 85 destinations in Europe and carried 9.1 mill passengers in 2008. More than 85 % of ticket sales are accomplished on the web (Norwegian.no). The company has pioneered the Scandinavian low price airline market, and has been quite innovative. Some important events were:

2002 : Introducing low cost airline in Norway, with print-out tickets with bar-code identification
2004 : Introducing the low-price calendar (this was internationally patented)
2005 : Dialogue with 85% of customers is electronic
2007 : Bank Norwegian is introduced
2008 : Call Norwegian (mobile telephone operator) is introduced

In 2007 the company decided to enter the banking market with Bank Norwegian. Said the CEO Bjørn Kjos at the start: “Today we have one of the most visited web pages in Norway, with 2-3 million visitors each month. We aim at coupling this traffic towards bank services.” (E24, 4th May 2007). The initiative has been quite successful; in fact so successful that Norwegian will offer a mobile service Call Norwegian, based on the same thinking.
If we look closer at the company parts of the success may be explained by a particular IT architecture. It is illustrated and simplified in figure 2. The key elements are the web page for each service, the databases and “the bus.” Each service constitutes an information infrastructure, with a number of registered customers. For the airline this is currently ca. 1 million, for the bank around 80,000, while the mobile company was starting up in the autumn 2008. In this paper the focus is on the development of Call Norwegian, as an extension to the established infrastructure.

![Figure 2: Infrastructure at Norwegian](image)

The architecture allows the company to innovate on an existing infrastructure, in much the same way as Virgin and Amazon (Cai et al. 2008) have done. The traffic on the airline website may be routed to other services at very low marketing costs. Accordingly, extended infrastructure services, such as bank system and mobile system (from external providers) may be linked to the “bus” at low costs and in time windows of opportunity. It is essential that all communication with the customers is electronic, as a combination of web pages and e-mail. Of course, this lowers transaction costs, but more importantly, it makes it much easier to enroll new customers into the infrastructure.

### 4.1 Call Norwegian

The idea of a mobile company came in 2005, after the initial success of Norwegian. Where do ideas come from?

Said the Director of business development:

“We had established a very flexible IT architecture, and we realized at the time that it would be possible to innovate new services on this. First we were just brainstorming rather freely; how could a combination of brand and technology generate new business? A GSM operator seemed to have some similarities with airline booking. Later, after the establishment of Bank Norwegian and the reward system in 2007, the idea had matured. We now focused much more on achieving synergies with the airline by providing an integrated set of mobile services for the traveler. We believe that the mobile phone will become more important as a terminal than the PC”
After a board decision in January 2008 a project was established. The main ambition of the project was to establish a number of mobile services:

- A mobile portal, with booking, payment and check-in services, plus content from many providers
- Broadband mobile access at airports and during flights
- GSM mobile services

In March a detailed Request for Information was sent to various telecom vendors, and a series of meetings were held in April. The business model was completed in May, and the contracts with the key vendors signed in August. The project was then organised with 5 sub-projects, illustrated in table 2. Norwegian organised the project as close as possible to the future operations. The project was run by Norwegian Portal Director, acting as CIO in Call, using hired expert consultants in the planning and development phase.

Table 2: The Call Norwegian project

The Director of Business Development commented:

“When we started the project the solutions were only sketched out as architectural ideas and financial opportunities. We learned a lot from the meetings with potential vendors and content providers in the spring 2008, exploring a space of possibilities.”

Said the Portal Director:

“We focused on how to make money on new services, analysing which services we should provide ourselves, which we should buy and how they should be integrated. At the same time we are very concerned about our architecture; it as an important ambition to maintain it as ‘clean’ as possible. We don’t really go for cutting-edge solutions. Rather, we combine known and stable components in new ways.”

The technical solution is illustrated in figure 3. The central element is the Call Norwegian Business Bus and interfaces, and all communication goes via the bus, as web services. This also includes communication with the Airline bus (CRM base) and the Norwegian Bank Bus (reward services). Most new services were bought, but a few was developed in-house, such as the purchasing and handling of wireless access at the airports.

The bus serves as a backbone for the various transaction systems such as billing, finance, GSM services, and Norwegian’s shared CRM system. It also connects these systems to the sales and service channels, in particular mobile, web and email communications. Technically, the bus is a piece of .net software. It enables the company to expand the number of sales nodes (above) and the service nodes (below). In technical terms we might describe the function of the bus as bridging two different standards; the standards of World Wide Web with the standards of telecom and billing systems. This service oriented architecture allows the company to establish new nodes, and get rid of unneeded ones, in a very short time span, because the services are bought or leased, not developed.
Figure 3: Call Norwegian infrastructure (Courtesy of H.-P. Aanby)

Seen as information infrastructure we may describe it as a heterogeneous network, consisting of a large number of actors, connected to the business bus.

- Users will access the services via the mobile portal. One minor (but exciting) innovation is using the mobile phone to check-in and boarding, by providing a link to a ticket barcode, which may be read electronically right from the mobile screen.
- The providers of services include TeleBilling, who provided billing, Avinor who provided airport broadband, Network Norway, who provided GSM services, and Norwegian, who provided travel and profile services.
- A large number of content providers, who will provide news and travel information. A potential new service is location and context based information to travelers.

The complexity of integrating these very specialized services may appear large, but the bus structure and web services simplify the technical solutions. More interesting, in the context of information infrastructure innovation, which socio-technical mechanisms are active in the extending this infrastructure?

5 MECHANISMS FOR INNOVATING IN THE INFRASTRUCTURE

5.1 Returning to the research question: How can an information infrastructure provide generative mechanisms for innovation?

Following DeLanda’s call of investigation of both macro-micro and micro-macro mechanism; what we are looking for is a recursive structure of mechanisms. This structure should explain how the information infrastructure is generating innovation, and also how the innovations are modifying the information infrastructure. Further, these mechanisms should be “external”, in the sense that their capabilities are not decided from the components’ internal properties. For example, an IT architecture may have certain properties, such as being layered. This property is quite important, but it is not a mechanism. A mechanism emerges from the relationship between the IT architecture and some other
component, where the IT architecture plays a role in a larger context. For example, the IT architecture may allow someone to produce a new service. This does not (in itself) change the layer structure of the IT architecture, rather its ability to play different roles in different settings is more related to its interfaces.

5.2 Macro-micro mechanism

Several of the interviewees used the expression of space of possibilities, as the starting point for innovation. What constitutes this space? The respondents gave different answers. Some emphasized the business opportunity by logic of analogy; that a successful service (such as airline booking) is similar to the business of a mobile operator. Another informant pointed to the modularization and layers of the IT architecture, while a third informant emphasized the role of external partners in idea generation.

When examined more closely, the space of possibilities more fundamentally has to do with patterns of assembling different components into new services. The point is that these new services emerge through new combinations of components in ways that generate a self reinforcing mechanism. This mechanism was also identified (although at a business level, not service level) by (Davenport and Short 1990).

We may illustrate this process in figure 4.

![Figure 4. The innovation reinforcement mechanism](image)

The established information infrastructure (of Airline and Bank) offered a space of possibilities, constituted of the following elements:

- A large user group (ca 1 million individual customers), represented in the central CRM system
- An IT architecture, where components may be reused
- A (limited) number of key persons with a thorough knowledge of the dynamics of the information infrastructure, including a strong technical knowledge of the IT architecture.

The next step was to combine these elements into ideas, and from there to assemble the components into new services. More than 30 different companies from telecom and IT were involved in these talks. The Portal Director described the process in these terms:

“Based on the overall architecture we decided which components to build, reuse, buy or outsource. We involved various actors, such as IT, Sales, Marketing, expert consultants and
external vendors. Contracts with vendors were signed and integration specifications made. The design and development process was iterative, producing design sketches, arranging workshops, evaluating new builds, optimizing and testing.”

In this description we recognize the findings of Andersson et al. (2008), that inter-organisational innovation requires a demanding set of architectural knowledge. For example, the operator of the billing services had to a) understand the inner workings of both Norwegian’s corporate bus architecture and the Telebilling system and b) be able to implement a solution which connects these two resources.

5.3 Micro-macro mechanism

At the end of this process, illustrated with the upward arrow, we find the micro-macro mechanism. As the information infrastructure has generated a new service, this will extend the information infrastructure. Technically, this will in the form of a new bus with web service interfaces, a set of new databases and a new set of terminal devices. The information infrastructure will further include the vendors and operations, and the thousands of new customers.

The extended information infrastructure will increase the space of possibilities. To get the full picture we may extend the figure with another feedback loop, the self-reinforcing mechanism of services.

Figure 5: The double set of self-reinforcing mechanisms of information infrastructures

As illustrated in figure 5 the information infrastructure has two self-reinforcing mechanisms. First, there is the innovation reinforcement mechanism, which was described above. At macro (infrastructure) level the result of the mechanism is a new service which extends the information infrastructure. The Second mechanism is the service reinforcement mechanism, which is built on Grindle’s standard’s model, described in the Introduction. The result of this mechanism is more users to the information infrastructure.

The result is also a financial profit, which may be used to invest in more innovation. This closes the double loop. The innovation loop provides new services in the information infrastructure, which in turn (in the service loop) creates more profits. And so on.
5.4 Implications

The practical implications of self-reinforcing service mechanism have been described by other researchers, in the form of guidelines for information infrastructure design (Hanseth and Lyttinen 2008). The practical implications of the self-reinforcing innovation mechanism are more elusive, but two suggestions may serve as an inspiration for further research.

First, a successful information infrastructure constitutes a considerable resource for ICT-based service innovation. The innovation mechanism and the Call Norwegian case, illustrate how these resources may be assembled into new innovations. One should however not interpret this as a friction-free process, because the whole information infrastructure may be set under pressure as it expands, both in terms of IT architectural and social complexity. Using DeLanda’s (2006) terms, we might characterize it as a struggle between territorialisation (increased homogeneity) and deterritorialisation (destabilising).

Second, as described by Yoo et al. the innovation process in networks is both cognitive, social and non-linear (Yoo et al. 2008). In line with other information infrastructure research our findings illustrates that ICT-based service innovation cannot be planned and managed in detail. But the innovation mechanism may help organisations to facilitate the innovation process in a structured way.

6 CONCLUSION

This paper investigated innovation in information infrastructures, through a case study. Building on a critical realist approach, our empirical evidence was a case study within an international airline, aiming to diversify its services. From our analysis we propose that there are two self-reinforcement mechanisms in information infrastructures.

First, we identified the innovation reinforcement mechanism, resulting in a new service. This consists of the following steps: A space of possibilities in the information infrastructure architecture and operations creates new ideas for services. Together with external partners these may be developed into innovations, which will be included in the information infrastructure as new services. The new services and components in turn increase the space of possibilities.

Second, there is the service reinforcement mechanism, resulting in more users and profits. The information infrastructure provides a number of cheap and easy-to-use services. This attracts more partners with their add-on services, which reinforces the value of the information infrastructure, and attracts more users. This growth generates a profit which may be used to invest in new innovations.

The proposed mechanisms were derived from the information infrastructure literature and the case study. Further research should look at innovation in other information infrastructures, both to test the validity of the suggested mechanisms and to discover others.

7 ACKNOWLEDGEMENTS

The author thanks the Norwegian company for allowing me to conduct the case study, and the informants for spending their time. In particular I thank Hans-Petter Aanby and Håvard Haug Hansen. I also thank Ole Hanseth and Sturla Bakke for commenting on earlier drafts, and I acknowledge the useful comments of the anonymous ECIS reviewers and AE.

Abstract

The management of supply chains is a very comprehensive task. Predictability and response to incidents in process executions are challenging. With Supply Chain Event Management (SCEM), researchers propose an approach for overcoming these problems through proactive monitoring and notification of crucial process activities across the supply chain. The identification and definition of such crucial activities and information needs are necessary to handle possible abnormalities although they are challenging task which have not been solved in SCEM research so far. Hence, we propose a modeling approach which allows the conceptual specification of an adequate information exchange along the supply chain. With our approach we focus on the specification of relevant logistical objects, the definition of possible events, and the design of notifications for decision makers in the supply chain.

Keywords: conceptual modeling, supply chain event management, SCEM.
1 MOTIVATIONS

Divisions of labor and distributed value chain activities require a good management of logistic networks as a strategic competitive advantage (Steven & Krüger 2001). The role of Supply Chain Management (SCM) increases. Interorganizational integration of processes, logistics, and information supply becomes necessary in order to efficiently cooperate (Bechtel & Jayaram 1997; Holten & Schulz 2001). The provisioning of information and information systems throughout the supply chain is a key point within SCM (Barrat 2004; Bechtel 1997; Knolmayer & Mertens & Zeier 2000; Göpfert 2002).

Characteristic information systems for SCM such as Advanced Planning and Scheduling Systems are mainly used for the planning and implementation of logistic processes but offer only limited functionality for the monitoring and management of the operative execution of logistic activities. On the contrary, Supply Chain Event Management (SCEM) allows the short-term planning, management and controlling of information regarding the operative logistic processes. It is a proactive concept that allows diverging high process complexity. Therewith, it helps overcoming a bad predictability or forecast reliability within the different steps of a value chain. It fosters the interorganizational visibility of critical objects throughout the supply chain (Nissen 2002; Wieser & Lauterbach 2001). Proactive and automated monitoring and management of supply chain critical objects (e.g. palettes, customer orders) help identifying failures and disruptions in material, product, and information flows. Hence, countermeasures can be induced earlier and more systematic (Wiener 2007). An increased reactivity from various parties or stakeholders of the supply chain to possible disruptions or events can increase an effective information supply and an accomplishment of superior business objectives (Klaus 2004; Steven & Krüger 2004).

An adequate and prompt supply of information is a prerequisite for the realization and execution of SCEM. Hence, the conception and implementation of appropriate information systems is a basic condition. Nevertheless, the identification of critical objects or steps in the supply chain, the specification of information needs to cover possible incidents in process executions and the adequate provisioning of responsible decision makers with necessary information to handle such incidents as well as the implementation of an appropriate information technology are challenging tasks in SCEM (Liu & Kumar & van der Aalst 2007; Nissen 2002; Steven & Krüger 2004). Although there is much research on the overall concept of SCEM and related information technology challenges, a methodical support for identification and definition of such crucial activities and information needs of persons responsible to handle possible disruptions is neglected up to now. Conceptual models serve as an instrument for structuring and documentation of such complex problems and encourage a common understanding between different stakeholders, e.g. managers, domain experts, and technical experts (Rosemann, 1996; Kottemann & Konsynski 1984; Karimi 1988). Therefore, the exploitation of such a modeling approach for the management of supply chain events—that is for the identification and specification of incidences and for the preparation of necessary notification based on information needs as well as their implementation in information systems—seems reasonable. The article proposes an approach for the conceptual modeling of interorganizational events within the supply chain.

2 RESEARCH METHOD

In literature, the usage of conceptual models for the documentation and construction of real world events is broadly accepted (Rosemann 1996). Hence, using such models and modeling methods for an interorganizational supply chain information management seems to be reasonable. Information systems engineering is a process of change in order to achieve certain goals in information systems design (Hirschheim & Klein & Lyytinen 1995). With this article, we will present certain representation forms of the object systems that are necessary for the systematic and exact conceptual modeling of SCEM in the context of interorganizational needs.
The research process (cf. Figure 1) started with the awareness of a practical problem (Takeda & Veerkamp & Tomiyama & Yoshikawa 1990). We were faced with the question of how to specify a management system for supply chain events on a conceptual level. The aim of such a research process was to provide a conceptual modeling approach guiding the development of a SCEM information system from functional specification to technical implementation. The practical need for such a method became apparent during discussions with various retailers about their experience with Collaborative Planning Forecasting and Replenishment (CPFR) and Efficient Consumer Response (ECR) and their problems with data exchange between different stakeholders (Winkelmann & Beverungen & Janiesch & Becker 2008). It became obvious that there were many obstacles in sharing all information between the stakeholders within the supply chain. It was not possible to individually define notifications and information allocations for each member of the supply chain. Hence, a conceptual approach turned out to facilitate a consensus between the different stakeholders about the information sharing within the supply chain. To solve the identified problem we were looking for a method that:

(R1) supports the conceptual modeling of event-driven information flows according to business processes, information needs and restrictions in the supply chain (Requirement 1),

(R2) facilitates the technical implementation of an SCEM information system in accordance to address different stakeholders (e.g. domain and technical experts) (Requirement 2).

Having this in mind, a literature review was performed in order to consider available research on conceptual modeling techniques for SCEM. Based on the requirements R1 and R2 we were able to identify existing modeling methods which are possibly capable of fulfilling these requirements. However, within a detailed analysis of the approaches based on the comparison process of (Song & Osterweil 1994) we came to the conclusion that none of the existing approaches fully met our requirements. Hence, we decided to develop a new methodological approach.

Figure 1. Research Procedure

Having this in mind, a literature review was performed in order to consider available research on conceptual modeling techniques for SCEM. Based on the requirements R1 and R2 we were able to identify existing modeling methods which are possibly capable of fulfilling these requirements. However, within a detailed analysis of the approaches based on the comparison process of (Song & Osterweil 1994) we came to the conclusion that none of the existing approaches fully met our requirements. Hence, we decided to develop a new methodological approach.
The construction process of the approach is similar to the procedures proposed by Greiffenberg (2004) and Gupta & Prakash (2001). Based on previous discussions, interviews and literature reviews, we derived language concepts that were necessary for supporting our requirements R1 and R2. Afterwards, the resulting concepts were supplemented with attributes and, thus, relations between the concepts were defined in order to establish the conceptual modeling approach. All elements of the conceptual modeling language have then been consolidated in common specification.

For the evaluation of the artifact, we implemented the model in order to visualize and apply its implications. For a practical assessment and a better method refinement, we evaluated the approach with the help of a case study in retail. Based on our requirements we generated the following propositions for the evaluation:

(P1) The application of our modeling approach improves supply chain spanning information exchange in the context of SCEM. (Proposition 1)

(P2) The application of the approach facilitates the implementation of an information system for the management of events in the supply chain. (Proposition 2)

(P3) The approach is capable of modeling the appropriate information needs of the persons responsible to handle occurring events of fault. (Proposition 3)

(P4) The approach allows a linkage to existing process modeling languages in order to specify process events and information that should be promptly processed at occurrence of such events. (Proposition 4)

The results from interviews, literature reviews, method implementation, and case study research were then compared to the propositions. We were able to derive new requirements on the approach, to identify deficiencies, and refine the concept by omitting and modifying language constructs.

Our way of conducting research is based on the design science paradigm (Hevner & March 2004). We aim at developing a domain neutral IT artifact, namely a modeling approach for the management of supply chain events. The research method is built on works of Takeda & Veerkamp & Tomiyama & Yoshikawa (1990), Rossi & Ramesh & Lyytinen & Tolvanen (2004) and Greiffenberg (2004), in which a practical problem is the focus of the construction process.

3 STATE-OF-THE-ART IN SUPPLY CHAIN EVENT MANAGEMENT

The term Supply Chain Event Management (SCEM) is widely used ambiguous. On the one hand, this term is characterized as an overall concept, which abstracts from specific technical aspects. On the other hand, the term SCEM is considered as a specific technical implementation of application systems (Alvarenga & Schoenthaler 2003). In the following, we abstract from technical details and rather focus on the conceptual perspective of SCEM. Thereby, the core aspects of SCEM and especially the major tasks of the conceptual design are taken into account to derive requirements for a conceptual modeling language.

From a conceptual point of view, SCEM is primarily subdivided into the core aspects monitoring, notification, simulation, controlling, and measuring (cf. Figure 2), which are representing the core functionalities of this approach (Knickle & Kemmeter 2002). The basic aspect of SCEM is the monitoring (1) of logistic objects within supply chains in respect of occurring events. A logistical object represents a logical or physical item (e.g. a customer’s order or a container), an activity within a logistic process as well as a whole logistic process. In order to monitor such objects, they serve as reference points for possible events. An event is an indicator for differences between actual and planned conditions of a parameter, which is monitored for a logistical reference object (Wieser & Lauterbach 2001; Alvarenga & Schoenthaler 2003). Possibly, the occurrence of events has effect on the planning and execution of other (up- and downsteam) logistic processes. To handle critical effects on relating processes, the automatic notification (2) of corresponding decision makers is necessary. Hence, providing relevant information to persons responsible is an essential prerequisite in order to
take countermeasures to resolve variations while process execution. Based on provided information, simulations (3) are used to verify and benchmark handling alternatives to resolve variations and resulting effects to other processes along the supply chain. Subsequently, a selected alternative of handling is implemented in logistic processes and the supply chain is adjusted (control (4)). To ensure planned conditions while process execution, measuring (5) functionalities allow continuous observations and analysis of actual and planned conditions along the whole supply chain.

Due to the core concepts of SCEM, the major tasks of the conceptual design are the definition of supply chain processes, the identification of relevant logistical reference objects and the definition of related events, as well as the design of status notifications with relevant information (again cf. Figure 2). Further, countermeasures are defined by developing business rules (Nissen 2002; Steven & Krüger 2004).

The initial point of the conceptual design of a SCEM solution is the coverage and definition of supply chain processes. These processes are perceived as a logical order of logistical activities and described hierarchical in different levels of abstraction (Steven & Krüger 2004). According to methodical facilitation of describing supply chain processes in supply chain management, methods and languages of business process modeling are also used for the definition of supply chain processes. Modeling languages like value chain diagrams or simplified process chains are mostly proposed for the description and modeling of such processes (Arndt 2008; Kruppe 2007). These approaches have in common, that they are mostly used to describe processes on a high level of abstraction. In contrast to this, detailed descriptions of supply chain processes are necessary for the identification and specification of relevant logistical reference objects and related events (Steven 2004). In the field of business process modeling, Event-driven Process Chains (EPC) (Scheer 2000), Petri Nets (Petri 1962) or the Business Process Modeling Notation (BPMN) (White, & Miers 2008) are established universal modeling approaches, which take these requirements into account. Using these modeling approaches supply chain processes can be described in detail as well as hierarchically structured on different levels of abstraction. In addition to these universal modeling approaches, with the Supply Chain Operations Reference (SCOR) (SCC 2008) a specific method for designing and modeling of supply chains is given. Therefore, the SCOR serves as a reference model for supply chains and provides predefined building blocks of supply chain processes. Additionally, supply chain related ratios are provided by the SCOR for monitoring and measuring purposes.

Especially, the identification of relevant logistical reference objects, the definition of events, and the design of status notifications are commonly referred as challenging tasks in SCEM (Nissen 2002; Liu & Kumar & van der Aalst 2007). In the literature, these tasks are often discussed from a more general point of view, conceptual or technical aspects are mostly neglected (Steven & Krüger 2004; Nissen 2002). To define events, monitoring relevant ratios have to be specified in relation to a logistical
reference object as well as planned conditions and critical notification levels. The design of status notifications comprehends the definition of organizational units (addressees), which have to be informed in case of incidents in process execution as well as the identification of necessary information needs to cover such interruptions. Methodical assistance of these tasks is only provided for specific aspects, e.g. the definition of events. For the modeling of events Liu & Kumar & van der Aalst (2007) propose the use of time-related Petri Nets. In this approach, only the formal definition of critical notification levels is addressed. Other aspects of SCEM are neglected.

To sum up, the need of a methodical support of the conceptual design and implementation of information systems in the context of SCEM is identified. Especially, a comprehensive view of the definition of events, the identification of logistical reference objects as well as the design of status notifications and the identification of information needs is necessary. In order to overcome the identified methodical shortcomings, we propose a modeling approach which allows the conceptual specification of an adequate information exchange along the supply chain and facilitates the technical implementation of information systems to benefit the realization of SCEM.

4 CONSTRUCTION AND APPLICATION OF THE MODELING APPROACH

4.1 Language Construction

To describe the events and the triggered notifications we have developed a modeling language by applying meta-modeling as a design technique (Strahlinger 1996). The Entity-Relationship Model (ERM) (Chen 1976) is a widely established approach for the conceptual representation of modeling languages (Becker & Seidel & Pfeiffer & Janiesch 2006). As a result of the development process, we constructed a modeling language whose conceptual specification is shown in Figure 3. Additionally, the implemented language constructs, relations, and the proposed modeling process are illustrated in Figure 4. The constructs are classified into different modeling contexts according to the different components and tasks of SCEM. For a better understanding, from now on, constructs are highlighted italic with capital initial letters; the steps of the modeling process are numbered in round brackets.

Figure 3. Conceptual Specification of Modeling Approach

First of all, Events are set in relation to Logistical Reference Objects and Rules in order to trigger the particular Event. Moreover, Addressees of dedicated Information Objects are also related to Events.

Proceedings ECIS 2009
Therefore, the relevant Logistical Reference Objects (1) are defined. After that, certain Ratios (2) are defined and combined with a Rule Expression to specify the triggering Rules (3). Those Rule Expressions are certain arithmetic combinations of Basic Ratios or Calculated Ratios that are assigned to specific Rules. For each assignment specific values are defined. For example, a rule applies if the stock of a product is lower than a specified threshold. Based on this, the actual Events (4) are modeled by relating them to Logistical Reference Objects and Rules. At this point, Logical Operators may combine those Rules to a combined and hence more complex expression. The Addressees (5) are defined and arranged in a hierarchical manner. They possibly receive Information Objects (6) which are modeled afterwards. Addressees are related to Status Notifications depending on the Context of Usage. It can be interpreted as some kind of filter that specifies under which contextual conditions the Addressees receive the relevant Information Objects. In the end, those contextual conditions are related to Status Notifications (7) in order to notify Addressees about certain Events. For example, an addressee may receive an information object A in case of an event X and receive an information object B in case of another event Y. Thus, sensitive information objects can be filtered and each addressee only receives the information objects with depending attributes, such as additional amount that has to be ordered.

To integrate the different modeling contexts, the concepts of the modeling language are specified context-spanning and hence can be re-used in suitable contexts. This concept prevents from illustration conflicts of occurrences of the same object and from modeling redundant issues. This integration of contexts allows a comprehensive view on the different tasks of supply chain event definition.

**Figure 4. Representational Specification of Modeling Approach**

As mentioned before, the definition of logistical reference objects, events and status notifications are parts of the overall SCEM tasks (cf. Section 3). To provide a linkage of these tasks to the definition of supply chain processes, a methodical integration of our approach with supply chain processes is necessary. Thus, defined events can be linked to specific states in supply chain processes in order to provide a detailed view and to monitor crucial states. For example, to monitor the order status in a particular process, a defined event can be related to the different states. E.g. an event to monitor extraordinary deliveries is related to process states. In case of e.g. abnormal amounts or quantities the defined event is triggered and the contracting as well as the order management will receive status notifications (cf. Figure 5).
4.2 Exemplified Application based on a Retail Example

For the purpose of application, the constructed modeling language is implemented using a meta-modeling tool. Figure 6 displays a screenshot of the (meta-) modeling software containing the corresponding model. A general introduction to the tool support is given in Becker & Janiesch & Seidel & Brelage (2005) and Delfmann & Janiesch & Knackstedt & Rieke & Seidel (2006). The exemplary case evaluation deals with two (unplanned) events. Both events are regular incidents at wholesalers. The first event is the result of a stock monitoring. In this example, the stock falls below a certain limit. With the help of our approach, we are able to specify an automatic preparation of a further delivery to the customer and an additional order at the pre-supplier of the wholesaler. The second event is triggered by the arrival of a delivery, whose billing amount differs from the declared amount. The same event is activated if the scheduled delivery date is not met, the quantity delivered is not as ordered, or the delivery has happened without any preceding order.

The logistical reference objects (1) relevant for this example are defined in a specific context (e.g. Commodities, Customers, Suppliers). As a next step, relevant information objects (6) are to be defined. Relevant information objects in this context are Preliminary Order Forms (Customer), Order Forms (Supplier), and Packaging Notes (Supplier). To monitor events, specific ratios are to be defined (2). For example, a particular ratio Stock representing a customer's stock is required. To determine whether an incoming delivery is a planned or an unplanned delivery other ratios are needed. E.g.
quantity, billing amount, and scheduled delivery dates have to be checked. For this purpose the definition of calculated ratios (e.g. Billing Amount as result of the quantity multiplied by the price of a single item plus a possible flat rate) are necessary. Moreover, the check criteria are defined by rules (3). For example, the billing amount has to be matched against the expected billing amount as declared. Based on the matching results, the rules trigger respective events. By combining logistical reference objects with those rules, the related events (4) have to be defined (e.g. Extraordinary Delivery). To this event definition four rules are assigned by combining them with a logical AND-operator (and negating by a NOT-operator). The rules are evaluated in a cascading manner. To handle possible event occurrences, organizational units, namely addresses, have to be defined (5). The addresses will receive individual notifications and information about abnormality in process execution. Defining such notifications (7), relevant information objects are related to particular addresses in order to handle a specific situation (event).

Figure 6. Exemplified Application of Modeling Approach

5 CONCLUSION, LIMITATIONS AND OUTLOOK

The concept of supply chain event management is a further development of existing supply chain management concepts. It does not deal with goods themselves but with the handling of incidents (events) concerning the flow of goods. SCEM allows the notification of people and organizations across organizational boundaries to provide a prompt response on defined events. For example, SCEM can help reducing the bullwhip effect because information cannot only be forwarded to the next stage in the supply chain but information can also be forwarded to pre-suppliers or pre-pre-suppliers. So far, the discussion on SCEM has been focused on a managerial or a process level. However, a conceptual approach for the identification and definition of information needs across a supply chain to handle
possible occurring incidents is not provided in the literature up to now. With our conceptual approach we propose a concept for the identification of suitable logistical reference objects and for the definition of relevant events with regard to this reference objects. It is possible to design status notification based on reference objects and events.

As our exemplified application indicates, our initial approach supports the conceptual modeling of event-driven information flows according to the needs and restrictions in supply chain communication. Furthermore, it facilitates the technical implementation in accordance to address different stakeholders (e.g. domain experts and technical experts) in the development process and to effect a common understanding of the treated object. The application of our conceptual approach based on a tool implementation is a first evaluation step on our research agenda (cf. Table 1).

Table 1. Approval of the proposed approach

However, with respect to the intended objective different assumptions are made during the development process of the conceptual modeling method. Consequently, different limitations are attended with the proposed modeling method and have to be taken into account for further applications. First of all, the approach is limited to a conceptual perspective on SCEM, excluding specific implementation aspects. In this way, the managerial, functional, and technical perspective of SCEM is addressed in common. Nevertheless, interrelations to the organizational and structural implementation and management of supply chains are not covered by the proposed approach. I.e. in our approach linkage between supply chain processes and events are only defined in a logical way. A methodical integration with process modeling languages is still outstanding. As a result of this, effects of changes in supply chain arrangements and process could not be taken into consideration of the specification of SCEM. Reverse, the derivation of further details for development and improvement of existing supply chain structures is not methodically supported up to now. Furthermore, the proposed approach is focused on the field of supply chain management. With respect to unstructured domains like creative industries or research and development, the processes in supply chains are commonly structured. Hence, the application of our approach is focused on structured processes with clearly identifiable decision making entities, clearly delineated areas of authority, classifiable and predictable (planned or unplanned) events and event variations and predictable responses to such events. Unpredictable events should not be taken into consideration. An ex-ante definition of all possible but not predictable events seems to be not appropriate and would lead beyond the intention of the SCEM approach. Even though, results of such events can still be regarded.

Further research will focus on the evaluation of the provided modeling approach and on aspects of the before mentioned limitations. In the short-term, the approach will be applied in different domains and different application scenarios. In particular, the capability of our approach to cover the requisite aspects of SCEM to improve the event-driven information flows and handling of incidents across supply chains is evaluated. In a next step, possibilities and requirements for the connection with or
integration into supply chain tools are reviewed. Middle-term research will address the methodical integration with common process modeling languages. Furthermore, consequence of changes in supply chain structures and processes to the definition of SCEM will be addressed by identifying interdependencies and developing response mechanisms. As a long-term research field, the approach would be enhanced by a methodical support for the improvement of existing supply chain arrangements, e.g. the identification of potential risks in supply chain execution.

Abstract

Value-based IT portfolio management requires the consideration of intertemporal interdependencies that may exist among IT projects. Therefore, several papers suggest adopting the real options approach in order to include intertemporal interdependencies within the valuation of IT projects. However, this paper shows that the standard Black-Scholes model, which is often used for valuating real options, is not appropriate to correctly account for project-specific private risks due to its restrictive assumptions. Since this can have major impacts on the value of IT projects, we develop an approach – based on the Black-Scholes model – to consider private risks properly within project valuation. A comparison of the results of the standard Black-Scholes model used today and our approach finally reveals that the neglect of private risks results in a systematic underestimation of both risk and return of IT projects, which may lead to wrong investment decisions.

Keywords: Value-based IT portfolio management, intertemporal interdependencies, real options, Black-Scholes model, private risks
1 INTRODUCTION

Since firms with superior IT governance have at least 20 percent higher profits than firms with poor governance (Weill & Ross 2004), it is not surprising that in practice much effort is put towards implementing IT governance structures (IT Governance Institute 2008). Amongst others, companies seek to implement methods to plan and manage IT investments aligned with their business objectives. Since a lot of firms primarily seek to maximize shareholder value, they need to determine the value proposition of each IT investment considering its risk and return (IT Governance Institute 2008). But it is not sufficient to valuate each IT investment separately, because firms usually conduct several IT investments simultaneously or consecutively, which may cause the existence of interdependencies among these investments. Due to the fact that those interdependencies affect the value of a single investment, firms should rather implement methods to valuate the overall IT portfolio and make sure that interdependencies are considered correctly.

But as of today, only about half the firms are capable of measuring risk and return of their IT investments (IT Governance Institute 2008) and much less they are capable of accounting for interdependencies among multiple investments within a value-based IT portfolio management (ITPM). But interdependencies and conflicts among IT projects in particular are one of the primary reasons for budget over-spending, which affects about one third of all IT investments according to a study of CA Inc. (2007). Interdependencies also play a decisive role when investments in IT infrastructure (e.g. operating systems or core banking systems) are considered, which account for 31% of all IT investments (CIO Insight 2004). IT infrastructure investments are typically characterized by high cash out-flows and – if at all – only low direct cash in-flows. If firms valuate these investments without considering interdependencies, it is likely that they will be rejected from an economic perspective. Given that business objectives may require IT infrastructure investments (base projects) that provide an option to launch future value added projects (follow-up projects), the profits of the follow-up projects can be attributed to the base projects to some extent. Such intertemporal interdependencies are often modelled as real options. Research literature suggests adapting approaches from financial theory to the valuation of real options, but does not thoroughly verify the applicability of these approaches.

Therefore, this paper contributes to valuating IT base projects that contain intertemporal interdependencies with an advanced real options approach. After a discussion about the applicability of the Black-Scholes model (BSM) to the valuation of real options, we conclude that strict assumptions of the BSM prevent its application to a correct valuation of base projects, since project-specific risks (e.g. quality risks) that influence the value of possible follow-up projects cannot be considered. Hence, we extend the BSM in a way that it will be capable of valuating base projects correctly. Furthermore, we will show that the BSM – as it is used today for valuating base projects – underestimates the return of any base project as well as the associated risk due to the disregard of project-specific risks.

This paper is organized as follows: In chapter 2 we provide an overview of existing ITPM approaches. Thereby, we analyze how intertemporal interdependencies are considered today and question the applicability of the BSM to the valuation of IT projects that contain intertemporal interdependencies. In chapter 3, a model extending the BSM by a correct consideration of project-specific risks is proposed. The article concludes in chapter 4 with a recapitulation of the achieved results. Thereby, the limitations of the model as well as perspectives for further research are discussed. A real-world example will serve as running-example throughout the paper and underpin the relevance of our findings.
LITERATURE SURVEY AND RESEARCH QUESTION

IT governance, which is defined as „structure of relationships and processes to direct and control the enterprise in order to achieve the enterprise’s goals by adding value while balancing risk versus return over IT and its processes“ (IT Governance Institute 2008), postulates value-based approaches to manage IT investments. This is in accordance with the definition of ITPM by Kaplan (2005), who refers to ITPM as a „method for governing IT investments across the organization, and managing them for value“. According to these definitions firms have to valuate their IT investments as well as their overall IT portfolio under a risk-return perspective. Since existing interdependencies among IT investments can affect the value proposition of the investments (Santhanam & Kyparisis 1996), firms also have to consider them. These interdependencies can be categorized as follows:

- **Intratemporal interdependencies:**
  These interdependencies occur due to resource conflicts or structural bottlenecks (e. g. use of same processes or IT functionalities) in case that multiple IT projects are conducted at the same time.

- **Intertemporal interdependencies:**
  These interdependencies occur if IT projects serve as basis for potential follow-up projects.

As a result, value-based ITPM approaches require firms to focus on a risk-return perspective of their IT investments on the one hand, but also to consider inter- and intratemporal interdependencies among IT investments on the other hand.

2.1 Value-based ITPM: Status quo

Since value-based ITPM requires the quantification of both risk and return of IT investments, those approaches are also referred to as quantitative ITPM approaches. Verhoef (2005) for example uses the Net Present Value to valuate IT projects. He includes risk by introducing the “weighted average cost of IT” as discount factor, but he does not consider any interdependencies among IT investments, which makes this approach insufficient for a value-based ITPM due to the requirements mentioned above.

Santhanam & Kyparisis (1996), Butler et al. (1999), and Asundi & Kazman (2001) include intratemporal interdependencies among IT projects in their approaches. They use modern portfolio theory by Markowitz to aggregate IT projects to IT portfolios and intratemporal interdependencies are represented by correlations among IT projects. But these approaches still neglect intertemporal interdependencies, which leads to poor or incorrect valuations especially for infrastructure projects that are characterized by low or even none direct cash in-flows.

Bardhan & Bagchi & Sougstad (2004) in contrast focus on intertemporal interdependencies among IT projects. They assume that a firm has the right – but not the obligation – to conduct possible follow-up projects after the completion of a base project. This right is modelled as a real option.

2.2 Real Option Approaches for IT portfolio management

There exist many other approaches for IT portfolio management using real options theory. E. g. Benaroch (2002) suggests a real options approach called option based risk management (OBRIM) to mitigate risks of IT projects, which is empirically validated by Benaroch et al. (2006) and Hilhorst et al. (2008). But this approach is “not concerned with determining the monetary value that embedded options add to an investment” (Benaroch et al., 2006). Thus it is insufficient according to the requirements and concerns of this paper.

On the contrary, Taudes & Feurstein & Mild (2000), Benaroch & Kauffman (1999) and Fichman & Keil & Tiwana (2005) suggest the application of real options analysis (ROA) to the valuation of IT
projects analogical to the approach of Bardhan & Bagchi & Sougstad (2004) and fulfil consequently the requirements of a value-based ITPM. All these approaches use the standard BSM or binomial trees to valuate existing real options.

But the application of valuation models like the BSM, which is adapted from financial options to real options theory, is heavily criticized due to its restrictive assumptions (Emery et al. 1978, Schwartz & Zozaya-Gorostiza 2003). Thus, the differences between financial and real options must be regarded properly, otherwise the application of the BSM to the valuation of intertemporal interdependencies can lead to skewed results. We therefore discuss the applicability of the BSM to the valuation of intertemporal interdependencies in the next chapter.

2.3 Applicability of the Black-Scholes model to the valuation of intertemporal interdependencies

The BSM is based on a riskless valuation of the option, whereby systematic risks are eliminated through a replicating portfolio consisting of the underlying and the option (Hull 2003). In order to be able to build this replicating portfolio and to continually hedge it during the runtime of the option, liquidity of the involved assets is a key requirement. But since real options usually cannot be traded and thus are illiquid (especially in the case of IT projects), the replicating portfolio cannot be built, which raises critics about the applicability of the BSM to the valuation of real options.\[1\]

Sick (2001) picks up this criticism and argues that the replicating portfolio does not necessarily have to consist of the option and its underlying per se. In fact, any liquid assets can be used for constructing the replicating portfolio, as long as they possess the same systematic risk. Therefore, trading real options is not necessary for a correct application of the BSM. Hence, the BSM can be used for the valuation of real options in case that the systematic risks can be replicated by tradable assets, which accordingly requires a complete market.

Therefore, the application of the BSM implies that the underlying investments contain only systematic risks (market risks). This issue is also raised by Copeland & Antikarov (2003), who argue that with both financial and real options, risk - the uncertainty of the underlying - is assumed to be exogenous. This represents one major weakness of today’s application of the BSM to the valuation of real options, since there are also unsystematic risks inherent in every IT investment, which are referred to as “private risks” by Smith & Nau (1995). Those private risks or project-specific risks, like for instance deficient software quality, incorrect interpreted specifications, or problems with new technologies or frameworks, account for the major source of all risks concerning IT investments.

These risks cannot be considered within the replicating portfolio, since there are no liquid assets that perfectly replicate the private risks of the base project due to their uniqueness. As a result, the BSM cannot account for private risks and therefore neglects a major source of risks in the valuation of IT investments (Smith & Nau 1995).

In order to address this weakness, Smith & Nau (1995) suggest changing the assumption of a complete market into a partially complete market, which still provides liquid assets to account for market risks. Thus, the BSM can still be applied to the valuation of real options and does consider market risks, but private risks must be incorporated otherwise.

Irrespective of these facts, several articles apply the BSM to the valuation of real options without paying attention to its applicability and thus disregard the differences between financial and real options. Mason & Merton (1985) argue that although the underlying is not traded, firms rather seek to determine what the project cash flows would be worth if they were traded. A similar qualitative

\[1\] For a thorough explanation of the BSM see Hull (2003).
discussion, which eventually equates real options theory with financial options theory, can also be found in Benaroch & Kauffman (1999) and Taudes & Feurstein & Mild (2000).

In these articles the expected value of the cash in-flows (of the follow-up project in our case) usually serves as underlying of the option, since there is no observable market value (Schwartz & Zozaya-Gorostiza 2003). This expected underlying value contains the potential impacts of market and private risks. It can be determined by specifying scenarios and valuating them through a decision tree analysis. Possible deviations from the expected underlying value, which are caused by market risks as well as private risks, are oftentimes considered solely within the volatility of the BSM (cp. Bardhan & Bagchi & Sougstad 2004). But – as we have discussed above – this is not valid since only market risks can be hedged in a replicating portfolio of liquid assets. Taudes & Feurstein & Mild (2000) and Benaroch & Kauffman (1999) do not pick up the different risk types as a central theme in their articles. If we assume benevolently that the authors consider only market risks within the volatility of the BSM, their application would be consistent to the assumptions of the standard BSM. However, in this case they would completely disregard private risks in their valuation, which leads to skewed results because a significant part of IT project risks are neglected.

2.4 Research Question

Because of the major weakness of the standard BSM regarding the consideration of private risks, we will answer the question, how intertemporal interdependencies can be correctly valuated using the BSM within the scope of a value-based ITPM. Therefore, it is necessary to extend the BSM by a correct consideration of the impacts of private risks of the underlying (follow-up project) on the risk-return position of a base project.

But before answering this research question using our approach, we introduce a real world example to illustrate the relevance of this question. This example is taken from an IT Portfolio of a German retail bank, which invests a high binary million amount per year into IT projects. For reasons of confidence we changed the data proportional to the original values. The example will be continued throughout the paper.

A multi-channel retail bank wants to enhance its market position (relative market share) in distributing consumer credits. To reach this strategic objective, they want to increase the level of automation of their credit processes and enable a risk-adjusted pricing of consumer credits. Therefore, existing credit processes have to be redesigned, which requires the adaption of the IT landscape. First of all, their core banking backend-systems has to be changed. The costs for this infrastructure project are estimated at 2 million Euros. Furthermore, the investment into the backend-system does not generate any direct cash in-flows, which leads to the fact that it should be rejected from an economic perspective if the project is considered independently. But the bank decided to base their investment decision not solely on the NPV of this infrastructure project. The company rather considers this project to serve as a base project that provides the launch of future value adding project opportunities, which can be realized once the backend-systems are implemented successfully. Thereby, the company identifies a follow-up project that integrates the new credit-pricing into the existing retail frontends (i.e. in-store, online, and call-center) as a lucrative opportunity and decides to include this possible follow-up project within their investment decision. In contrast to the base project, the bank anticipates high cash in-flows from the follow-up project due to the involved launch of new credit products as well as savings on human resources due to the automation of credit processes. In order to integrate this possible follow-up project into the investment decision, the company wants to use the real options approach to evaluate the base project with the follow-up project being an option to expand.
3 CONSIDERATION OF PRIVATE RISKS WITHIN THE VALUATION OF INTERTEMPORAL INTERDEPENDENCIES

To illustrate our model and the impact of private risks on the risk-return position of a base project, we firstly have to introduce some notations and assumptions.

3.1 Notations and Assumptions

A firm has to decide, whether it invests in an IT project (base project) at time $t = 0$ with a runtime of $T$ periods. This base project creates the technical requirements for a possible follow-up project. In case of conducting the base project, the firm can decide in $t = T$ whether it invests in the follow-up project or not. This can be interpreted as an intertemporal interdependency and thus be modelled as a real option (option to expand) on the follow-up project. Because the focus of this paper is the correct valuation of the real option using the BSM, we state the following simplistic assumption:

(A1) The direct cash flows and thus the isolated Net Present Value ($NPV$) of the base project (without considering the impacts of the follow-up project) are known and fixed.

In order to valuate the real option under a risk-return perspective we have to consider the risks concerning the follow-up project. During the runtime of the base project two major types of risk exist which cause uncertainty regarding the cash in-flows of the follow-up project. The first type of risk can be described as market risks, which – as we mentioned earlier – can be considered by the volatility of the standard BSM. Examples for market risks are uncertainties regarding economic conditions like the prime rate or the demand since they are subject to fluctuations. The second type of risk – private risks – cannot be considered in the standard BSM as discussed above. It results from uncertainties regarding the implementation quality of the base project. Some examples of those uncertainties are:

- Uncertainty regarding the requirements of the base project: At the beginning of the base project it is not conceivable whether the functional or technical specifications describe the requirements unambiguously. Missing functionalities due to missing or incomplete functional specifications will limit the amount of possible subsequent applications.
- Uncertainty regarding the replacement of legacy systems: If (poor documented) legacy systems have to be replaced, unpredictable side effects can occur and reduce the scope of available functionalities.
- Uncertainty regarding the product quality: Irrespective of the uncertainties mentioned before, the implementation itself can be inaccurate. If too many critical mistakes are made during the implementation, it is likely that the scope of available functionalities is reduced.

These uncertainties can be responsible for providing an insufficient amount of functionalities at time $t = T$. The fact that the cash in-flows of the follow-up project (underlying of the real option) depend on the implementation quality of the base project leads to our second assumption:

(A2) At time $t = 0$, there is a known functional connection between the achieved implementation quality of the base project at time $t = T$ and the cash in-flows of the follow-up project. The present value of the cash in-flows of the follow-up project at time $t = 0$ is represented by the non-negative random variable $\tilde{S}_0$ with its known corresponding density function $f(s)$.\footnote{$\tilde{S}_0$ can also be a discrete random variable with probability mass function $f(s)$.}
Function $f(s)$ represents the potential impacts of the private risks on the present value of the cash inflows of the follow-up project.

Since the follow-up project will be conducted by an IT services provider and is already contractually fixed in $t = 0$, the cash out-flows of the follow-up project can be considered as independent of market and private risks, which leads to the following assumption:

\[(A3)\] The present value of the cash out-flows $X_0$ of the follow-up project is known and fixed at time $t = 0$.

This paper focuses on the correct consideration of private risks during the runtime of the base project, which affect the cash in-flows of a follow-up project. Therefore we abstract away from the existence of risks during the runtime of the follow-up project with the following assumption.

\[(A4)\] The present value of the cash in-flows of the follow-up project is known and fixed at time $t = T$ (depending on the implementation quality of the base project).

On the basis of these assumptions we will discuss the impacts of private risks on the risk–return position of the real option and consequently on the base project in the next chapter. Therefore, we compare the results of the standard ROA with our approach.3

3.2 Impacts of private risks on the risk-return position of the base project

According to standard ROA, the extended net present value ($ENPV$) denotes the return of the base project. It consists of the isolated net present value of the base project ($NPV$) and the value of the option ($C_0$) to extend the base project with a follow-up project (Trigeorgis 1996). In order to calculate $C_0$ the value of the underlying is required. But since the underlying is not traded on a market, the expected value of the underlying ($E(\tilde{S}_0)$) is often being used instead (Schwartz & Zozaya-Gorostiza 2003). Bardhan & Bagchi & Sougstad (2004) therefore approximate $E(\tilde{S}_0)$ by conducting a scenario analysis. According to the BSM function $c(s)$, which is described in appendix A-2, the value of the option ($C_0$) then equals $c[E(\tilde{S}_0)]$ according to our notation. As a result, the return of the base project calculated with the standard BSM can be obtained through the following equation:

\[
ENPV = NPV + C_0 = NPV + c[E(\tilde{S}_0)]
\]

According to this approach the value of the option depends on the risk, but it still can be calculated deterministically, because all risks are hedged by the replicating portfolio. But note that equation (1) is only valid in case of a complete market, where only market risks exist, which can be replicated by traded securities, and private risks do not. But in a partially complete market private risks have to be considered separately.

Bardhan & Bagchi & Sougstad (2004), for instance, consider private risks within their scenario analysis for the calculation of $E(\tilde{S}_0)$. They include the deviation of the underlying value within the volatility of the BSM. But unfortunately, this approach cannot account for private risks since only market risks can be considered within the BSM (cp. chapter 2). Other approaches neglect the impacts of private risks completely (e. g. Benaroch & Kauffman 1999), which leads to wrong investment decisions if a value-based valuation takes place.

---

3 The notation used in this paper is summarized in appendix A-1.
4 Even though the standard ROA does not explicitly account for $\tilde{S}_0$, we denote the expected value of the underlying as $E(\tilde{S}_0)$ according to our notation, as it provides an intuitive description as well as a better comparison of the two approaches.
In order to correctly account for private risks, we first consider the present value of the cash in-flows of the follow-up project being a non-negative random variable \( S_0 \) due to its uncertainty according to \((A2)\). Since the corresponding and known density function \( f(s) \) denotes the different realizations of \( S_0 \) \( (s^*) \), we can picture all possible impacts of the private risks on the cash in-flows of the follow-up project.

In a next step we need to find out how this uncertainty of the underlying affects the option value. Therefore, we need to focus on the functional connection (in our case the BSM function \( c(s) \)) between the underlying and the option value. As the BSM function cannot handle private risks, an option value has to be generated for every possible realization \( s^* \). Since every option value \( c(s^*) \) has the same cumulated probability as its corresponding underlying value \( s^* \), we obtain \( \int_0^{c(s^*)} g(c)dc = \int_0^{s^*} f(s)ds \) for all \( s^* > 0 \), and thus we can sufficiently approximate the density function \( g(c) \) of the option value \( C_0 \), which is also a random variable. According to this transformation we now know the different impacts of the private risks on the option value. Finally, we have to add the option value \( C_0 \) to the net present value of the base project \( (NPV) \) to get the extended net present value of the base project \( (E\tilde{NPV}) \), which is consequently represented by a random variable:

\[
E\tilde{NPV} = NPV + \tilde{C}_0 = NPV + c(\tilde{S}_0)
\]

At the time when the decision about the base project is made \( (t = 0) \) we only know the approximated density function \( g(c) \) of the option value and thus the probability for every possible option value, but we do not know the actual realization in \( t = T \). In order to account for this uncertainty caused by private risks, we will use the expected option value \( E(C_0) \) to calculate the expected extended net present value of the base project \( (E\tilde{NPV}) \), since it includes all possible realizations of the option value that are caused by private risks. By doing so, \( E(\tilde{NPV}) \) represents the return of the investment decision and can be obtained by the following equation:

\[
E(\tilde{NPV}) = NPV + E(C_0) = NPV + E[c(\tilde{S}_0)]
\]

In order to compare the return of the base project obtained by our approach (equation (3)) with the standard BSM (equation (1)), we need to go into a more detailed analysis of the BSM function. In case of call options the first and second derivative (i.e. the greeks “delta” and “gamma”) of the BSM function are positive (Hull 2003), thus we know that the BSM function is strictly monotonically increasing and strictly convex. Therefore, Jensen’s inequality, as is denoted in equation (4), becomes valid:

\[
E(c(\tilde{S}_0)) \geq c[E(\tilde{S}_0)]
\]

Since the BSM function is strictly convex, Jensen’s inequality can be rewritten in our case as \( E(c(\tilde{S}_0)) > c[E(\tilde{S}_0)] \), which implies:

\[
E(\tilde{NPV}) = NPV + E[c(\tilde{S}_0)] > NPV + c[E(\tilde{S}_0)] = ENPV.
\]

This leads to our first result:

(R1): The expected value of the real option and therefore the return of the base project are underestimated if the standard BSM (equation (1)) is used to valuate intertemporal interdependencies.
The return of the option derived by both, the standard BSM (equation (1)) and our approach (equation (3)), are pictured in Figure 1. It further shows the density function of the underlying $f(s)$ and the density function of the real option $g(c)$, as well as their functional connection through the BSM function $c(s)$.

![Graph showing the connection between $f(s)$, $g(c)$, and $c(s)$](image)

Figure 1 – Impacts of the private risks on the option value

Figure 1 also visualizes the consequence of Jensen’s inequality: The density function $g(c)$ results from a compression of $f(s)$, which is stronger for small values than it is for larger ones due the convexity of the BSM function $c(s)$ (The skewness of $g(c)$ is greater than the skewness of $f(s)$). This leads to the fact that the cumulated probability for $E(\tilde{C}_0)$ is greater than the cumulated probability for $E(\tilde{S}_0)$. But since the cumulated probability for $s^* = E(\tilde{S}_0)$ equals the cumulated probability for $c(s^*) = c[E(\tilde{S}_0)]$, $E(\tilde{C}_0)$ must be greater than $c[E(\tilde{S}_0)]$.

The bank decides to evaluate the possible follow-up project (option to expand) with the BSM, which created some challenges due to the collection of the data. Although the costs of the follow-up project, the risk-free rate, and the runtime of the base project could be estimated easily, the estimation of the discounted cash in-flows of the follow-up project (underlying of the option) seemed to be a major challenge, because they are based on the sale of new credit products. In order to address the uncertain success of the project, a scenario analysis (consisting of a worst-case, most-likely, and best-case scenario) was conducted (cp. Table 2) that should cover possible outcomes. By doing so, the bank derived an expected value of the discounted cash in-flows in the amount of 5.7 million Euros. Furthermore, the estimation of the volatility of the discounted cash in-flows were another major challenge: Since the volatility can only account for market risks, the bank used the volatility of a credit derivative index, because it was believed that this volatility represents all relevant risks of the credit markets.

An overview of the estimated values of the parameters needed for the BSM is provided below:
Expected Present Value of Cash In-flows ($E(S_0)$) & Costs ($X_0$) & Risk-free rate ($r$) & Runtime ($T$) & Volatility ($s$) \\
5.7 mio. Euros & 4 mio. Euros & 5% & 1 year & 40%

Table 1. BSM Parameters

According to the standard BSM the option value obtained by the bank was 2.05 million Euros ($C[E(S_0)]$). Since the option value outweighs the negative NPV, the consideration of the intertemporal interdependency resulted in a positive value for the investment decision.

(a) $ENPV = -2$ mio. Euros + 2.05 mio. Euros = 0.05 mio. Euros

In the following, this result will be compared to the result the bank would have achieved if they had considered private risks correctly. According to our approach, the different scenarios represent the private risks, and thus an option value has to be determined for each scenario. Based on the resulting realizations of the option values the expected value of the real option has to be derived by summerizing the realizations weighted with their adherent probabilities.

<table>
<thead>
<tr>
<th>Scenario:</th>
<th>Present Value of Cash in-flows</th>
<th>Expected Present Value of the cash in-flows</th>
<th>Option value</th>
<th>Expected value of the option</th>
</tr>
</thead>
<tbody>
<tr>
<td>most-likely</td>
<td>6 mio. Euros</td>
<td>5.70 mio. Euros</td>
<td>2.31 mio. Euros</td>
<td></td>
</tr>
<tr>
<td>worst-case</td>
<td>3 mio. Euros</td>
<td>5.70 mio. Euros</td>
<td>0.23 mio. Euros</td>
<td></td>
</tr>
</tbody>
</table>

Table 2. Scenario Analysis and Option Valuation

As we can see from Table 2, the expected option value calculated with our approach equals 2.26 million Euros. This leads to the following equation:

(a') $E(ENPV) = -2$ mio. Euros + 2.26 mio. Euros = 0.26 mio. Euros

Illustrated by this real world example we can state, that considering private risks correctly can lead to a fundamental increase of the return of the base project (in this case by approx. 420 %).

The standard ROA approach also suggests that the value of the option ($C_0 = c[E(S_0)]$) is riskless, which means the resulting value of the base project ($ENPV$) is a fix return on the investment. Thus, no consideration of further risks concerning the investment decision is required. Our approach enables the consideration of private risks, which are the major source for uncertainty regarding IT projects. Hence, we modeled the value of the option as a random variable ($\tilde{C}_0 = c(\tilde{S}_0)$), which means the value of the base project is also a random variable ($\tilde{ENPV}$) with its expected value $E(\tilde{ENPV})$. This expected value represents the return on the base project. But the possible deviations of $\tilde{ENPV}$ and so the private risk must be included in the investment decision about the base project. This leads to our second result:

5 The number for the volatility was adapted from Wigan (2006).
3.3 Consequences for the investment decision

Because of the uncertainty of the value of the base project resulting from private risks, the return or expected extended net present value is not sufficient for a risk-return integrated valuation within the scope of a value-based ITPM. Hence, it is necessary to balance risk versus return of the investment decision in order to get a thorough result. Therefore, the deviation of the project value resulting from our approach has to be opposed to the higher return in comparison to the standard BSM to get a risk adjusted value of the base project. The impact of this uncertainty on the risk adjusted value (value proposition), which results from private risks, heavily depends on the risk attitude of the decision maker.

If the decision maker is risk neutral or risk seeking, our approach leads to a higher value proposition for the base project compared to the standard ROA. This results from the increase of the return on the investment, which is shown in equation (4). However, if companies put efforts towards identifying and considering risks, they are aware of risk. Through this risk awareness and the consequent risk management such companies can be assumed to be risk averse. In this case, the consideration of the private risks within a risk-return integrated base project valuation will lower the return on the investment. In this case, the value of the base project can be lower than using the standard ROA, depending on the degree of risk aversion – which symbolizes the perception of the weight of private risks – and the specific utility function that the decision maker chooses in order to integrate risk and return.

Using the standard BSM, the bank based its investment decision on one deterministic value for the ENPV (cf. equation (a)) and thus neglected the existence of private risks. Based on this positive ENPV the bank decided to conduct the project.

But, according to our approach, the Bank should have considered private risks separately and carefully balanced their decision dependent on their risk attitude. As the bank also suffers from the subprime crisis, the company is currently risk averse. Therefore, a monetary valuation of the private risks regarding the degree of risk aversion would have been required. Based on such a risk valuation, the bank could have also rejected the base project, if the private risks had been assigned according to the degree of risk aversion with a monetary value greater than 0.26 million Euros. This would have led to the fact that the risk adjusted value of the base project is negative – although a higher return was realized compared to the result of the standard BSM.

Finally, we can state that the valuation of the intertemporal interdependencies with the BSM, as it is done today, can lead to false estimations and therefore to wrong investment decisions due to the neglect of the impacts of private risks on the risk-return position of the investment.

4 CONCLUSION

In this paper we propose an approach to consider intertemporal interdependencies within a value-based IT portfolio management. Therefore we analyzed current approaches of valuating intertemporal interdependencies among IT projects. Since intertemporal interdependencies are usually modelled as real options and valuated with the BSM, which is adapted from financial options theory, we examined the applicability of the BSM to real options. Through this examination we revealed that the BSM is only able to consider market risks, but not to consider existing private risks of IT projects. Since private risks mostly preponderate in case of IT projects, we developed an approach based on the BSM that allows the consideration of private risks and thus provides a correct valuation of intertemporal
interdependencies. The main findings in this paper are that today’s real option approaches based on the BSM underestimate the risk as well as the return of IT projects systematically. Hence, the application of the standard BSM can lead to false investment decisions.

4.1 Limitations

But there are still limitations that come along with the introduced model.

E.g. the assumption of fixed cash in-flows of the follow-up project at time $t = T$ (A4) leads to a neglect of any risks that can occur during the follow-up project. As software is usually developed in sequent releases which contain intertemporal dependent projects and in order to provide a thorough assessment of all risks involved in the IT portfolio, the consideration of follow-up project risks would further increase the results of this approach.

Another limitation comes along with assumption (A2), where we assume, that the cash inflows of the follow-up project depend only on the implementation quality of the base project at time $t = T$. But there may exist different other aspects which influence the cash inflows of a follow-up project. These aspects cannot be considered within our approach.

Furthermore, we are not able to calculate a concrete risk adjusted value of the base project, since we do not model the risk attitude and the risk itself by a specific risk measure.

4.2 Further Research

In order to overcome these limitations further research is required. To cope with the last mentioned limitation, we want to extend this paper by developing and introducing a decision model. Therefore, private risks need to be quantified by an adequate risk measure in a first step. Since firms usually focus on downside risks, the lower partial moment (LPM) can serve as an adequate risk measure. Otherwise, if firms also want to take the upside chances of a base project into account, a symmetric risk measure like the standard deviation can be chosen. Once a risk measure is selected, a preference function will be introduced that accounts for the investor’s risk preference. Founded preference functions for different risk measures can be found in decision theory literature.

Since firms not only conduct projects consecutively but also parallel at the same time, further research is needed to additionally consider intratemporal interdependencies among projects. The approach suggested by Santhanam & Kyparisis (1996) can serve as a fundament for this extension.

Further research is also needed regarding the consideration of multiple real options within an IT project and their impact on its risk and return. Smit and Trigeorgis (2006) already propose an approach to manage a portfolio of real options, on which our further analysis can be based. On the one hand, compound options, i.e. options on options, which occur if a follow-up project again serves as basis for another follow-up project, can be considered. On the other hand, the impacts of either deferral options or abandonment options on the risk-return position of IT projects deserve a more detailed analysis.

Abstract

Investments in information technology (IT) do not always result in the expected tangible payoffs, and the factors which influence the effect of IT investments on organizational performance are not well understood. Stock market reaction is one approach to appraising IT investments. In this paper we propose a conceptual model describing the factors that impact IT investments based on market reaction findings of major event studies on IT implementation announcements. This preliminary model may serve as a starting point to better understand the complex issue of stock movements related to IT investments.

1 INTRODUCTION

In light of the apparent importance of IT to organizational performance, combined with the lack of clarity as to what makes IT investments successful (Oz, 2005), it is not surprising that much research has been dedicated to identifying and understanding the factors that lead to improved payoffs from IT. IT productivity has implications not only for the firm and its stakeholders, but also for the economy at large. Much current research is dedicated to the impact of IT on global competitiveness and development, particularly in emerging and developing countries (Roztocki & Weistroffer, 2008b).

In addition to the more traditional approaches to investigate IT productivity, such as case studies, surveys, and research databases, event studies are also increasingly being used (Roztocki & Weistroffer, 2008a; Roztocki & Weistroffer, 2009). According to the efficient market theory (Fama, 1970; Fama, 1991), which provides the foundation for the event studies methodology, all available information to investors is reflected in the stock prices. When unanticipated news reach the financial markets, investors assess their relevance and potential effects on particular firms, industries, and economic regions. Stock prices of a company will move up when the news are perceived to be favorable, and bad news, i.e. news indicating the possibility of diminishing future cash flows for a company, will result in decreasing stock prices. In the event studies approach, the reaction of stock markets to reported events is used to explore the perceived relevance and implications of these events (McWilliams & Siegel, 1997).

Event studies are now widely-used in business research areas such as accounting, finance, and strategic management. More recently event studies have become quite popular in IT research to identify specific factors which impact the outcomes of IT investments. Most of these studies, however, have taken an oversimplified approach, looking at particular factors in isolation – the interaction among the influential factors has hardly been considered at all (Oh et al., 2006). Frequently, this simplistic approach may lead to a perceived absence of market reaction to IT investments in a large sample of announcements, as the interaction of various factors can have a nullifying effect. Despite the fact that interaction among factors seems apparent and has been observed by several authors (Hayes et al., 2001; Oh et al., 2006), according to our knowledge, no attempts have been made to construct a model to explain the interaction among multiple factors.
In this paper we try to close or at least narrow this gap and propose a model which encompasses a variety of factors and possible interactions between these factors. The proposed model is based on a systematic literature review and backed by experiences from conducting our own event studies.

2 METHODOLOGY AND DATA COLLECTION

Our conceptual model is constructed from a systematic review of previous event studies investigating stock price reactions to IT investments. To identify appropriate published studies, we checked several literature databases, such as ABI/Inform (Proquest), Business Source Premier (EBSCO), JASTOR, and Science Direct. To find papers relevant to our proposed model, search queries including keywords such as “event study”, “stock market reaction”, “market value”, “announcement”, “information technology” and “information system” were used. This literature review was first conducted in spring 2007, with several up-dates, the last one in fall 2008.

The selection of research papers describing relevant event studies was topic driven and not particularly focused on specific publication outlets. However, to be included for the construction of our model, an article needed to satisfy the following three criteria: First, the article needed to be published in an academic, peer-reviewed journal, or in refereed proceedings of a major IT conference. Second, the article needed to use an event studies approach as the primary research method. Third, the topic of investigation presented in the paper had to be some kind of investment in IT, where investment in IT is defined as any large, non-routine expense for implementing new technology or aimed at making better use out of existing technology. This definition basically follows that proposed by Bacon (1992), though we broaden it slightly beyond hardware and software to also include human resources. Thus, implementing a new enterprise information system qualifies, but so does creating a new executive position dedicated to the administration and management of existing technology.

After assembling the appropriate papers, we conducted a systematic review of the reported studies, following the steps suggested by Rosenthal and DiMatteo (2001). Consequently, each paper was examined for independent, dependent, and control variables, and the reported results across the different studies were compared and analyzed for possible explanations when the outcomes differed or seemed to contradict each other.

Overall, our final sample includes at total of twenty-three studies.

3 REVIEW OF EVENT STUDIES ON IT INVESTMENTS

3.1 General Overview of the Event Studies

Twenty-two of the twenty-three papers included in our sample were published in the time period 2001-2008; one paper was published in 1993. The twenty-three papers in our sample represent a combined authorship of forty-eight authors, most (thirty-four) affiliated with US universities; the remaining fourteen authors were from Australia (three), Canada (two), China (two), Netherlands (three), South Korea (one) and Taiwan (three). The main focus of the investigations was stocks of US based companies.

The majority (nine) of the twenty-three papers investigated the stock market reaction to IT investments in general, while most of the others focused on investment in a particular technology, such as e-commerce initiatives (six), enterprise resource planning (ERP) systems (two), enterprise application integration (EAI) applications (one), supply chain managements systems (one) and customer-related systems (one). One paper examined both integration solutions (ERP and EAI) and two investigated IT related investments in human resources, specifically the creation of a CIO position. Table 1 summarizes the event studies in chronological order.

Table 1. Summary of Event Studies Reviewed
3.2 Variables Used in the Studies

Following the meta-analysis approach of Rosenthal and DiMatteo (2001) we examined the independent and dependent variables in the studies of our sample. Almost all studies used changes in stock price as dependent variable. One study used changes of systematic and unsystematic company risk as consequence of investments in IT (Dewan & Ren, 2007). Additionally, a few studies used changes in trading volume as dependent variable. We also identified the control variables reported in the studies. Overall, the independent and control variables used in the studies fall into five major categories: company characteristics, type of IT investments, vendor characteristics, economic conditions, and characteristics of the announcements. Tables 2 and 3 summarize the independent and control variables.

### 3.3 Comparison of Reported Stock Market Reactions

Typically, the stock market reaction to IT investments is assessed by calculating abnormal returns (AR) around the time of the announcement (Roztocki & Weistroffer, 2008c). The day of the announcement is denoted as day 0. The period around the announcement day is called event window and may include several days before and/or after. The most commonly used event window includes one day before (day -1), the day of announcement (day 0), and the day after the announcement (day 1). The AR for the days included in the event window are added up to get the cumulative abnormal returns (CAR). Frequently, the AR are standardized and the stock market reaction for particular event windows is measured by cumulative standardized abnormal returns (CSAR). (The formula for
calculating the CSAR can be found in, for example, Roztocki & Weistroffer (2008c). Table 4 shows the stock market reactions reported by the studies included in our sample.

Table 4. Stock Market Reaction

4 SUMMARY OF FINDINGS

A comparison across different studies suggests that there are a large number of factors, which may influence stock market reaction with varying contributions. Company size and timing of the investments appear to be highly influential, whereas industry type seems to have a more moderate effect. As stated earlier, the variables examined in the reviewed event studies can be grouped into five major categories: company characteristics, type of IT investments, vendor characteristics, economic conditions, and announcement characteristics. The market reactions observed in the twenty-three studies reviewed are summarized in Table 5.

Table 5. Observed Market Reaction

4.1 Company Characteristics

Several event studies looked at a number of different company characteristics as potentially influential factors to explain stock market reaction. The industry of the investing company was most often used as a variable, with the idea that companies in certain industries, such as finance, will benefit more from IT investments. This assumption was derived from the fact that banking is an information intensive industry. Most event studies, however, fail to provide evidence that industry is an influential factor.

Firm size effect was also examined by several studies. Overall, it appears that the magnitude of stock reactions diminish with company size. This makes sense, as the same size investment will have larger impact on a small firm than a large firm, i.e. the size of the investment relative to the size of the company or its capital assets is important.

4.2 Type of IT Investments

Type of IT investments investigated includes those with innovative content, transformative IT investments (as opposed to investments for operational efficiency only), investments in specific types of IT such as ERP or e-commerce, and asset specific focused investments. Only innovative IT investments and investments of strategic significance (transformative IT investments) resulted in positive stock market reactions. Innovative and transformative IT investments may result in competitive advantages for the investing company, and seem to be rewarded by the stock market.
4.3 Vendor Characteristics

Large, established vendors seem to instill trust, and investments in IT from large vendors are more likely to result in positive market reactions. In other words, it seems that stock market investors believe that large vendors are more likely to possess the technical expertise and resources to make IT investments successful.

4.4 Economic Conditions

Investments in IT in times of bull market conditions are more likely to result in positive stock market reactions than investments during bear market conditions. It appears that stock market investors are more doubtful about investments in IT and their effects on financial performance during bear markets.

4.5 Announcement Characteristics

Relatively few event studies looked at the characteristics of the announcement itself. However, it may reasonably be expected that the way the investments are communicated to the investors is of some relevance. The study by Oh et al. (2006) compared the stock market reaction to announcements made by the investing companies and announcements made by the vendors, and found a significant difference in the reaction. Financial markets appear to respond more positively to announcements made by the investing company. Interestingly, a large number of companies (approximately 60 percent) as reported by Oh et al. (2006) do seem to prefer that the announcements are made by vendors or service providers.

In addition to the source of announcements, there may also be influential factors related to the wording used in the announcements themselves. For example, investors may interpret specific language used in the announcements as an indication of presence or absence of clear objectives, technical competence, or support by management. No published studies have investigated this aspect, to the knowledge of the authors.

5 PROPOSED MODEL

The results from the literature review also suggest that there may be complex interactions between the factors that impact abnormal stock price returns. For example, the study by Hayes et al. (2001) implies that there is an interaction between the financial health and the size of a company. The most positive reactions to ERP investments were observed for small, financially healthy companies. As a company’s size increases while the financial health remains strong, the magnitude of the stock market reaction diminishes. When the financial health of a company worsens, the stock price reaction seems to become more positive for large firms and become more negative for smaller firms.

While the study by Hayes et al. (2001) looked at the interaction of two factors related to company characteristics, a comparison across different studies provides evidence of more complex interaction between factors. For example, while most studies were unable to find positive stock price reactions to non-innovative, automate IT investments (Dos Santos et al., 1993), Roztocki and Weistroffer (2006) reported positive reaction to automate investments when a company is using activity-based costing (ABC).

5.1 General Model

Overall, the reviewed studies confirm that there are a large number of influential factors that may affect investments in IT, and that these factors seem to be subject to complex interactions. As stated earlier, the identified factors can be categorized into five major groups: company characteristics, IT investment type, vendor characteristics, economic conditions, and announcement characteristics, thus suggesting the general model as depicted in Figure 1.
5.2 Application of the model

For the purpose of illustrating the use of the model and complexity of multiple factors interacting, we look at innovation content for a possible investment type. For vendor characteristics we look at size and for economic conditions we use the conditions of the stock market (i.e. bear or bull market), as shown in Figure 2.

Regarding the innovation content of IT investments, the stock prices seem to react more favorably when the investments are innovative and move the company ahead of its competitors. Therefore we show a positive effect for IT investments for innovation. Regarding vendor characteristics, a positive stock market reaction is more likely for large established vendors than for smaller and less established ones. Therefore again, we show a positive effect in our model. Regarding economic conditions, a bull market seems to benefit a positive stock market reaction. While declining stock markets, i.e. bear
markets, are more likely to result in less favorable stock price reactions. Again these are shown as positive and negative effects respectively in our model.

Our model, at least to some extent, explains the inconclusive findings of previous productivity studies (Oz, 2005). It is for example possible, for exactly the same type of IT investment to obtain significantly positive or negative stock price reactions when not controlling for other influential factors. A significantly positive stock price reaction is likely for a sample including mostly smaller companies buying from large established leading vendors during bull markets. For the same type of IT investment, the stock market reaction could be significantly negative when the companies in the sample are buying from small, non-leading vendors during bear market conditions. In both situations, investments from smaller companies seem to result in heftier stock market reactions.

5.3 Possible Business Implications

The model and the observed effects as shown in Figure 2 may have some important implications for businesses that are considering new investments in IT. Companies, particularly large companies, should not expect a positive reaction by the stock market to new IT investments, unless it is clearly communicated that the IT investment will likely result in innovation and provide strategic value to the investing firm. Furthermore, IT investments realized through small, less established vendors, are perceived as particularly risky and likely to result in negative market reactions. Using large, established vendors seems to be a safer way to go, if negative market reactions are to be avoided. If possible, IT investments are better done during bull market conditions; thus if market conditions are unfavourable, it may be wise to hold off with any non-critical new investments. Finally, the investing company should take the initiative in communicating the news to its shareholder and make the initial announcement of the new IT investment itself, rather than let the vendor make the announcement.

6 CONCLUSIONS

6.1 Contribution

We believe that our systematic review of event studies related to IT investments and our model presented in this paper make a substantial contribution to the body of knowledge in that this is perhaps the first meta analysis of event studies in the field of IT investments and the first attempt to construct a model to explain the impact and interactions of various factors on market reaction to IT investments. This model and the results of our review of twenty-three papers should greatly benefit other scholars, as it may serve as a foundation for further research on IT productivity. Future research building on our model need not be limited to event studies, as the compiled list of potentially influential factors may impact other measures of IT productivity, besides stock market reaction, and thus serve as a foundation for other types of research as well. Furthermore, as mentioned earlier, our model may help explain some of the inconclusiveness and inconsistency in the results of earlier IT productivity studies.

We believe that our model is also useful to business executives, as stock performance is often seen by stakeholders as a crucial indicator of firm performance. It is difficult for executives to ignore unfavorable stock movements of their companies, as such movements may lead to loss of confidence by employees, customers, suppliers, creditors, etc. In this regard, our model may help managers better understand favorable or unfavorable conditions for making IT investments.

Moreover, since the ideas presented in this paper are based on a comprehensive literature review, the proposed model may also lead to increased and improved usage of event studies in IT research.

6.2 Limitations

Although event studies in the field of IT have become more common, as compared to other disciplines, the absolute number of such studies is still small, which constitutes our first limitation.
Basically, our conclusions are drawn from event studies published in twenty-three academic papers. It is likely that as more studies are conducted and published, more influential factors will emerge.

A second limitation is related to the methods of estimating the stock market reaction. There is variation in estimation periods and event windows used by the different studies. Therefore the comparison of the findings from different studies may be limited. In addition, there is always a chance that the particular data set is contaminated. For example, Dehning et al. (2003) reported finding two outliers in their earlier event studies. Some outliers may go undetected and lead to faulty conclusions.

A further limitation of this study is that our model was constructed mostly based on findings derived from US companies and stock data. It is possible that for international companies some factors could vary in importance and the model would need further refinement to accommodate country characteristic.

6.3 Future Research

The results presented in this paper are not final but provide a more complete picture and new ideas for possible research avenues. Overall, it seems that previous event studies in the field of IT call for substantial revalidation. Future research may validate and enhance or improve our model by looking at additional factors that influence market returns. It is quite possible that other economic factors, such as interest rates, inflation level, and exchange rates substantially influence the stock market reaction. Also, with respect to announcement characteristics, there may be influential factors related to the communication of the investments. For example, the wording used in the announcements themselves could impact the investors’ reactions to IT investment announcements. Thus, investors may interpret overly use of some words as a sign of lacking decisiveness, lacking technical competence, or lacking support by management.

Abstract

Consumers’ product evaluation, choice, and use are driven by both utilitarian and hedonic considerations. Digital games, that are typically considered to be a homogenous product category, are often claimed to be high on hedonic value. However, there is a multitude of digital games genres available. Differences in their appeal, gameplay, and purpose in practice indicate that digital games vary significantly in their proposed outcome.

In this research paper, we present results from an observational survey study in which digital games were investigated at subcategory level. We found differences in weights consumers place on hedonic and utilitarian value at the product subcategory level, and also observed differences between evaluations of experienced and inexperienced consumers. The results indicate that subcategories act as a more assuring source of information than the general product category of digital games. Furthermore, higher gaming experience may lead to more optimistic evaluation on subcategories.

Rather than grouping digital games into one category and treating them all as hedonic products, they should be discussed at their specific subcategory level, by researchers and practitioners, alike.

Keywords: digital games, hedonic value, utilitarian value, product categories
1 INTRODUCTION

Since the 1980’s, various studies in consumer goods and services (Dhar et al. 2000; Okada 2005); information systems (Davis 1989; Van der Heijden 2004), and digital games (Choi et al. 2004; Hsu et al. 2005) have shown that consumer choice and use of different products and services are driven by both utilitarian (UT) and hedonic (HED) considerations.

Hirschman and Holbrook’s (1982, p. 99) early outlook to hedonistic consumer behavior is that “hedonic consumption designates those facets of consumer behavior that relate to the multisensory, fantasy and emotive aspects of one’s experience with products”. In other words, hedonic or pleasure oriented consumption is expected to be motivated by the desire for sensual pleasure, fantasy and fun (Strahilevitz et al. 1998, p. 436). In contrast, utilitarian or goal oriented consumption is “more cognitively driven, instrumental, and goal oriented and accomplishes a functional or practical task” (Dhar et al. 2000 p. 61; Strahilevitz et al. 1998).

Earlier research has found major differences between the perceived value of utilitarian and hedonic software applications, also in the context of digital games (Davis 1989; Raessens et al. 2005). Digital games are most often assumed to be high on hedonic value (Batra et al. 1990; Chen 2007; Hirschman et al. 1982; Hsu et al. 2005; Voss et al. 2003), and the motives for using hedonic systems, such as digital games, are different than those for utilitarian systems, such as office information systems (Van der Heijden 2004).

Digital game production has grown to be a significant sector of software business (Crandall et al. 2006; Siwek 2007). Even though digital games are often treated as a product category among other, relatively heterogeneous consumer products (e.g. paper clips, beer, blue jeans) Batra et al., (1990), Voss et al., (2003), there are multitudes of different types of games, and the reasons to play them vary greatly: games can be played, for example, for educative purposes, or mainly just for fun. The great differences in the appeal and use of games in practice suggest that instead of studying games as one general category, we should be looking at the subcategories.

In this study, we will analyze the perceived hedonic and utilitarian value of digital games in different game subcategories. We will also explore the differences in these values between experienced and inexperienced players, as expressed in recommendations to others.

The structure of this paper is as follows: In section 2, we present our theoretical background. In section 3 we introduce the hypotheses and research model. We then describe our research method and the empirical study setting in section 4, and present the results of our study in section 5. Section 6 summarizes and concludes the paper.

2 THEORETICAL BACKGROUND

Our study builds on the Motivational theory (Deci 1975) to understand the motivation of players of digital games, and on the theories of consumer behavior (Ajzen et al. 1980, see e.g.; Bettman et al. 1980) to understand the effect of prior knowledge and experience on the perceived value of the games.

2.1 Motivation of Game Playing

One of the objectives of game developers is to optimize game experience by designing elements of gameplay that motivate the player to continue playing without too much anxiety or boredom (Chen 2007). Specifically, in digital games production, this concept of flow experience (Csikszentmihalyi 1975) is widely used to provide outcomes such as enjoyment, pleasure, and

Proceedings ECIS 2009
fun, and to maintain the flow at the desired level. The flow experience is a part of an individual’s motivation to play games and has been defined as “an extremely enjoyable experience, where an individual engages in an on-line game activity with total involvement, enjoyment, control, concentration and intrinsic interest.” (Hsu et al. 2004).

Therefore, the motivational theory by Deci, (1975) lays the basis for the understanding of how digital games are chosen and why they are played. From motivational perspective of consumption, hedonic goods entail intrinsic value, whereas utilitarian entail more extrinsic values. Intrinsic motivation has been defined as “the inherent tendency to seek out novelty and challenges, to extend and exercise one’s capacities, to explore, and to learn it is performing an activity for the satisfaction of the activity itself” (Ryan et al. 2000, p. 70). Extrinsic motivation, in turn, is expected to lead to performance of an activity, in order to attain some separable outcome (Ryan et al. 2000).

Different products and services often vary greatly in their proposed outcomes (Hirschman et al. 1982). For instance, many services intend to provide an outcome closer to hedonistic value (e.g. movies, concerts) rather than utilitarian value provided by many packaged goods (e.g. shoe laces, hammers). Different digital games are similar in their delivery format, but many times distinct in their proposed outcome, making the analysis of the game subcategories necessary.

A category exists “when two or more distinguishable objects or events are treated equivalently” (Mervis et al. 1981, p. 89). This equivalent treatment means different ways of labeling distinct objects or events with the same name, or performing the same action on different objects. Consumers have been found to rely on the categorizing process: Evaluation of a product depends on the particular category to which it is perceived to belong (Blackwell et al. 2006, p. 110). Given this, specific brands can be built around these consumer segments (Rust et al. 2004).

We define digital games as examples of social systems which have information technology embedded in them (Land 1992). In practice, digital games are software applications, the purpose of which is to entertain (Hsu et al. 2004) – or with some games, educate – the users.

There is a multitude of ways to categorize digital games: gameplay, technology platform, delivery channel, age limit, language, graphics, user type, purpose, producer, temporality, price, and character, to name a few (Mäyrä 2008; Rutter et al. 2006). In this study, we classify different subcategories of digital games by their proposed gameplay experience, which has been defined as “a complex dynamics of interaction between the player and a game in which the structure of game including characters, virtual space, rules and story elements are at central focus” (Ermi et al. 2005). Digital game sub-categories, such as, sports games, massively multiplayer online role playing games (MMORPGs), racing games, and so on, are commonly identified segments which can be benchmarked with competitive analysis and product positioning (Rust et al. 2004). Most importantly, the labels of these categories are also those used by the consumers who play the games.

2.2 Experience

The essence of consumer behavior has been described as a choice between different product and service alternatives (Ajzen et al. 1980). This is based on the assumption that behavioral changes related to choice are often dominated by cognitive processes and systematic use of available information, even if people often strive to simplify their decision making (Howard et al. 1969). Nevertheless, consumer decisions are context dependent and subject to, for instance, the influence of product type and category (Zeithaml et al. 2006). Additionally, individual differences drive consumers to manage their deliberative processes differently, depending on many factors and situations (Foxall 2005). Decision making involves many environmental factors that lie outside the control of the individual. Foxall (2005) maintains that social, business, cultural and
Economical factors affect the consumers’ stimuli and attention. When information is received, it is recorded either on the short or long term memory, and processed depending on the consumer’s prior experiences, beliefs, attitudes, goals and other evaluation criteria.

Consumers’ choice criteria are influenced by prior knowledge and experience (Bettman et al. 1980). People with little prior knowledge and experience tend to simplify their product evaluation process and decision making. While they acknowledge the benefits of additional product information, the perceived high cost of information processing discourages search for and processing of more information. In contrast, people with high levels of prior knowledge face low search costs; yet, they tend to shortcut the search process, as they rely on previously acquired information. People with some prior knowledge have both the ability and motivation to process new information available to them. Prior experience shapes the decision process through other heuristic effects, as well. For example, consumers with high levels of experience tend to engage in brand comparisons, while less experienced consumers rely more on product attribute information (Bettman and Park 1980). Most importantly, an experienced user has different, typically higher, enjoyment related expectations than inexperienced user (Atkinson et al. 1997).

Experienced consumers are expected to be more confident sources of recommendations than inexperienced consumers. Word-of-mouth (WOM) recommendation has been depicted to be an effective method to influence consumers in their choice process. According to Brown and Reingen (1987), WOM—type of recommendation can be divided into two distinct sources. Firstly, strong tie sources are those that are socially relevant to the consumer and known personally (e.g. friends and family). Strong ties have been shown to be important at the micro level of referral behavior. Secondly, weak tie secondary sources are those seldom contacted acquaintances, or those not known personally at all, that have been found to play a crucial role in the flow of WOM information across groups (Brown et al. 1987 p. 360). Most importantly, recent research evidence suggests that a simple response to a question “How likely is it that you would recommend this product to a friend or colleague?” would actually reveal how loyal a consumer is to a specific product or a brand (Reichheld 2006). Even though our focus is on the strong tie elements, we acknowledge that the weak tie effects of larger social communities have a great importance in individual’s behavior (Granovetter 1973).

In essence, digital games are experience goods, the quality of which can be determined only through consumption (Bryce et al. 2006; Zeithaml et al. 2006). Information in different forms (e.g. demonstration versions) and from different sources (e.g. reviews on websites and WOM) helps the consumers in obtaining critical pre-purchase product information (Klein 1998). Intentional or not, these different sources of information act as recommendations which influence consumers’ product evaluation process positively or negatively (Smith et al. 2005).

3 PROPOSED RESEARCH MODEL AND HYPOTHESES

In this study, we propose that different digital games vary by their perceived hedonic (HED) and utilitarian (UT) value. Following that, we propose that HED is a better predictor of recommendation than UT.

We formulate our hypotheses as followed:

Hypothesis 1 (H1) = Consumer’s prior experience significantly influences his/her perceived level of both HED and UT value of digital games at the product subcategory level.

We report this by creating a scatter plot of the summated variables and comparing statistical differences between single, summated, and latent factor variables.
Hypothesis 2 (H2) = Consumer’s perceived HED value of digital games predicts better strong-tie recommendation than the UT value.

We measure the effect of HED and UT latent factor variables on recommendation with a multiple linear regression model: Recommendation = constant + HED + UT. Specifically, we are interested in the proportion that HED and UT explain recommendation (see Figure 2.).

![Figure 2. Research model.](image)

4 RESEARCH METHOD

According to Voss et al. (2003), the hedonistic and utilitarian constructs can be reliably observed by using five variables in both latent constructs. We adapted these variables for our survey questionnaire (see Table 1). The questionnaire item labels were translated from English to Finnish. Due to the translation issues (e.g., synonyms and overlapping terms), only four of the suggested five terms were used. Due to these issues, two attributes (Enjoyable and Useful) could not be measured as variables within their respective original constructs as they are used to define HED and UT constructs. Thus, they were observed separately as two HED/UT (single) variables. We used semantic differential scaling from -3 to +3 in questionnaire items, however, the final results were transformed to scale from 1 to 7 for easier comparability with prior research.

Table 1. Utilitarian and hedonic variables used in questionnaire (adapted from Voss et al., 2003)

The questionnaire form was first commented and pre-tested by five colleagues and pilot users. A web server based application called Webropol (webropol.com) was used to create and conduct the survey. The respondents were students in a Finnish Business School, taking a course on “Personal Computing Skills” in September, 2008. The empirical set of data was processed using the SAS Enterprise Guide, version 4.1.

During the first two actual data collection sessions out of five in total, 71 respondents were asked to categorize the adjectives used in the questionnaire by their perceived meaning as utilitarian or
hedonic words. All used adjectives were correctly grouped under their respective, expected constructs.

After answering questions measuring background information, the subjects assessed digital games without any reference to any specific game brand or subcategory. For general digital games category, respondents were asked to answer to a question in which the level of HED (enjoyable) and UT (useful) was measured by using them as opposite terms.

Thereafter, respondents were asked to answer questions on 16 different digital game product categories (see Appendix 2). Users were asked to evaluate different categories such as, sports games or massively multiplayer on-line role playing games as a whole. Each questionnaire page with a product category started always with two to nine real digital game package cover pictures. The objective was to create better understanding of real-life products related to the evaluation of images rather than only by using text. All selected games were relatively well known and widely spread, and mostly published for consoles, handheld consoles and PC platforms.

After assessing the psychometric values for game categories, the respondents were asked about their experience during past twelve months in each category. The order of the variables was randomized, but they were in the same order at each product subcategory level. We deemed it unlikely that all respondents had either awareness or experience on every category. For better reliability, each psychometric questionnaire item also included an option to respond “I can not say”.

5 RESULTS

5.1 Descriptive statistics

There were 135 usable responses out of 136 in total (1 uncompleted form). Forty-eight percent of the respondents were female, and 52 % were male. The respondents were between 18-31 years, 20.4 years being the average age and 20 years the median. As many as 44 %of the respondents reported to be active game players, while the remaining 56 % had not played at all in the past 12 months. The average age of starting playing digital games was 7.6 years (Table 2.).

Table 2. Descriptive statistics on the respondents

There were only a few missing answers. Generally, with few exceptions, those who reported being experienced game players answered to all questions. There were only two categories which had relatively high amount of “I can not say” responses (professions and text based adventure). In all other categories, the number of "I can not say" -responses ranged from 3 to 28 inexperienced respondents.
5.2 Data analysis

To the general question about digital games HED/UT value level, respondents evaluated digital games to be more fun or entertaining than useful (in a scale of 1-5). Experienced respondents’ (n=59) average was 3.93, while it was 3.61 for the inexperienced (n=76). Furthermore, the difference between experienced and inexperienced respondents was statistically significant (t-value = 2.46, p < 0.05).

We first produced a correlation analysis and calculated the reliability score for both HED and UT variables in general digital game and subcategory levels. All the used variables fit well into their responding latent factor variables (Cronbach’s Alpha > 0.86). Then, we formed a single composite summated measure of both HED and UT by combining their respective variables (Hair et al. 1984).

To test our hypotheses, we first created a summated scatter plot that presents the perceived HED/UT value for each category and between experienced and inexperienced respondents (Figure 3) (for detailed statistical data, see Appendix 2 and 3).

Figure 1. HED / UT summated scatter plot
We then computed factor scores for both HED and UT in all subcategories by using principal component analysis without rotation. These latent variables were used to measure the effect of HED and UT on recommendation with a linear regression model.

The summated HED/UT scatter plot indicates that there is no game subcategory which would be high on only hedonic or on utilitarian value. The experienced respondents seem to be more coherent in their opinions, and there was less variation between the game subcategories for them than for the inexperienced respondents. The inexperienced assess mainly more HED/UT value for playing games generally, but at the product subcategory level their beliefs and attitudes become more negative, decreasing both HED and UT. In contrast, the experienced game players mainly assess the subcategories higher than the digital games in general. The results indicate that higher experience may lead to more optimistic evaluation.

The most notable difference (mean difference => 1.99 - 2.74) between experienced and inexperienced respondents in both HED and UT was in games which war and violence are the focus of the gameplay (FPS as first person shooters, war strategy and action adventure games). The greatest perceived hedonic value among experienced was assessed to party games with a significant difference to inexperienced game players. Singing, dancing and playing together is perceived as a hedonic act also in real-life and those not experienced are probably not interested in these acts in real-life, either.

The least difference in HED and UT was assessed to the general category of digital games and to exergames (games incorporating real physical exercise). Exergames is a new subcategory in which especially Nintendo (Wii) has been very active, promoting the console as a new way of experiencing digital games. It can also be stated, that this category is marketed to inexperienced consumers with a purpose of enlarging the market potential for game industry. These were followed by educative and platform games. Educative games are probably perceived to include beneficial outcomes for their players. In this research setting, the examples of platform games were well known game characters such as Mario and Sonic. The extensive brand building efforts by the brand owners and earlier experiences from the respondents’ childhood could have added to the positive image.

In four categories, there were not enough experienced respondents to make reliable comparisons. These were pet raising (targeted at children), professions (targeted at young girls), text based adventure and MMORPGs.

We then tested the interaction effect of HED/UT latent factor variables to recommendation (RECO) by using multiple linear regression model in all subcategories. Furthermore, the means procedure and t-tests were computed (see Appendix 3). Among the experienced respondents recommendation for all game categories was high (>4.2) as for inexperienced respondents it was relatively low (<3.0). In all subcategories differences were statistically significant (t-test between means, p<0.5). Generally, digital games were recommended based on their hedonic value, which is similar to the finding for the single variable (HED vs. UT) item. Further, the level of adjusted coefficient of determination, r², is notably higher in the subcategory level than in the general category of digital games. This indicates that HED and UT explain better RECO in subcategory level and respondents are more confident about their opinions.

The largest differences between experienced and inexperienced users can be found in games with war and violence (FPS, war strategy, action adventure). The highest recommendation would be given for party games among experienced and for educative and exergames among inexperienced consumers.
Our first hypothesis (H1) was supported. Experience significantly influences the perceived level of both hedonic and utilitarian values of digital games at the product subcategory level. The experienced have constantly higher perceived HED and UT for different subcategories.

For the second hypothesis (H2), we may conclude that even though recommendation can be explained by using hedonistic and utilitarian value, the main interacting variable varies between product categories. There is no general, systematic evidence that only HED would explain recommendation but that it depends on the subcategory. Hence, H2 was rejected.

6 SUMMARY AND CONCLUSIONS

In this study, we set out to investigate the hedonic and utilitarian values of digital games, as perceived by the consumers. Using Business School students as subjects, we conducted a survey to test our hypotheses.

Results of our empirical study demonstrate that, digital games, in all observed subcategories, provide more perceived hedonistic than utilitarian value. However, our analyses suggest that digital games are not only high on hedonic value, but that the level of perceived HED and UT depends on the user's gaming experience and the product subcategory. Hence, digital game evaluation and product positioning should be done at the product subcategory level, rather than generalizing all games being equal in their proposed outcome.

Secondly, we classified the respondents into experienced and inexperienced players. Experience was clearly found to be a differentiating factor for evaluation of the different outcomes of digital games. To accomplish these objectives we used psychometric measurement instruments, specifically hedonic and utilitarian values of information systems as an operational tool.

Statistically, HED and UT variables strongly correlate in all different kinds of data analysis and among different subcategories. This would suggest that perceived hedonic and utilitarian values are not separate constructs, but that, in the context of digital games, they are processed simultaneously in product evaluation situation.

The consumer’s perception about the digital game subcategory affects the beliefs about specific products within it. Digital games subcategories act as a more confident source of information for the consumers than the general category of digital games. Further, the results indicate that higher experience on games within a subcategory may lead to a more optimistic evaluation of HED and UT. This finding has clear implications for the practitioners in the digital game development business who intend to attract new players for their games.

There are some limitations in this study. First, the dualistic perspective in which complex sensory and emotional experiences are measured by using two quantitative constructs such as HED and UT within a survey may be misleading. HED and UT do not fully explain what is the true meaning of these games for the users and why certain game categories are preferred. Therefore, a more in-depth qualitative study by interviewing game players is needed to understand why these differences may occur. Another limitation is the use of students as our subjects. This sample did, however, work well to accomplish our objective of differentiating different types of game categories.

THE TWO CULTURES AND THE INTERNET REVOLUTION

Abstract

This document reinterprets C. P. Snow’s famous “Two Cultures” (the so-called “literary elite” and scientists) lecture of 1959, in light of advances in information systems in the past fifty years. While Snow referred to specific groups, his analysis is generalizable: cultural groups differentiate through lack of communication. Here Snow’s analysis and advice are applied to a different pair of “cultures” (IT purveyors and IT users) as an example of his general principles. At a time of great unease about terrorism in the face of apparently relentless technological advance—analogous to Snow’s speech at the height of the Cold War—and also during a time of (then) apparently dramatic technological advance, the lessons Snow derived can now apply usefully to today’s specific “two cultures” case.
1 MID-CENTURY ANGST

The year 2009 is the 50th anniversary of Sir Charles Percy Snow’s now-classic “Two Cultures” Rede Lecture at Cambridge University (Snow, 1959, 1971). This lecture seemed, at the time, to be a polemic intended to inflame and annoy and yet is now clearly typical of the mid-20th-century essay attempting to find order in the chaos created by conflicts between science and the arts (Boytinck, 1980; Davis, 1965; Glass, 1959; Halperin, 1983). This current 2009 essay seeks to find lessons in Snow’s lecture for practitioners of the “science” of information systems; position IS intellectually on a far broader canvas than is usual, and contribute to critical thought concerning what IS is really about. Using Snow as a springboard for insight, we come to the conclusion that users can and should play a bigger, more pivotal role in determining use and ultimately the value of information systems.

Here is the plan of the paper: to recast Snow’s “two-culture” hypothesis as a general principle by revisiting his original speech and then to apply that general principle to the current interaction of another “two cultures”: purveyors (ITP: developers, marketers, and researchers of information technology) and users (ITU: those who employ IT for business and daily life). It will focus on the following questions:

- What is the essential argument that Snow made about the “split into two polar groups,” in his words, of Western society, independent of the specific groups he identified?
- Which of Snow’s statements concerning the “gap” he pronounced as existing between the two cultures he cited in 1959 are true of today’s ITP and ITU “cultures”?
- Are the causes of today’s cultural gaps identical, similar, or analogous to those Snow decried in 1959? Are they in any sense predictable and/or controllable?
- Are the lessons Snow derived in 1959 applicable today to the “user-IT” gap?

There is a caveat. When Snow spoke about the “scientific revolution” in his speech, he certainly did not mean the Copernican revolution, the rise of the scientific method and the development of scientific thinking. It is the Industrial Revolution to which he is really referring. He said in his lecture that the Scientific Revolution “comes from the application of real science to industry, no longer hit and miss, no longer the ideas of odd ‘inventors’, but the real stuff.” Similarly, when we refer here to the “Internet Revolution” we are not necessarily referring to the immense change in focus that the Internet is bringing about, including virtual communities, globalization, and vastly distributed computing. Instead, we are thinking about the application of these ideas to everyday life. To rephrase Snow’s words for today: “The Internet Revolution comes from the application of real global, networked information to industry, no longer hit and miss, no longer the ideas of isolated ‘technologists’, but the real stuff.”

The middle of the twentieth century was a time of great re-thinking. Not only had a great war devastated much of the heart of modern civilization (east and west), but atomic threats to the survival of the human race were made palpable to the public through modern realistic media such as television. Most of what passed for history during the second half of the twentieth century was a working out of the great clashes of the first half: the end of empires and colonialization, the modernization of societies, the shifting of labor from the farm to the factory and the office, the movement of people from the countryside to cities, an explosion in literacy and democracy. In every sense, the 1950s were a time of thinking about and exploring the implications of the great dichotomies of the previous half century: freedom vs. totalitarianism, ignorance vs. knowledge, privilege vs. participation, fear vs. security, workers vs. the establishment, gender roles, and so on.

In this intellectual environment in 1959, the British novelist-scientist-politician Charles Percy Snow, not
yet Baron Snow of Leicester, delivered the annual Rede Lecture at Cambridge University. The series provides a forum for noted individuals to discuss the issues of the day. For Snow, delivering the Rede lecture was not only a personal triumph for the scientist-turned-author-turned-bureaucrat, but also a chance to deliver a personal statement very much in tune with the mid-century spirit of the times.

Snow’s career embodied many of the dichotomies that were the subtext for the mid-century angst expressed on both sides of the Atlantic and elsewhere. In addition, he brought together the disparate intellectual threads found in the range of speakers in the Rede Lectures. The son of a working-class Leicester family, he became a life peer; an outsider in an “old-school” British Establishment society. He created a new kind of literature documenting his own kind – the scientist-bureaucrat. He was appointed to position of parliamentary secretary to the first Minister of Technology in 1964 and served in this position two years (the ministry survived on its own only four more years, until 1970).

Snow was thus in a unique position to see all sides of technological progress, or lack thereof, from both the scientific as well as the high-level government viewpoint. Sir Charles delivered a lecture that was a synthesis of a number of discourses on the topic of “gaps” or “divides” and how to bridge them or narrow them. True to the mid-century ethos, he dwelt on these, among others, distinctions: the West vs. the East, science vs. the arts, pure science vs. applied science, literary intellectuals vs. scientific intellectuals, the wealthy countries vs. the poor countries, industry vs. art, the political left vs. the political right, among others.

Snow’s conviction in 1959, in the face of real danger of all-out nuclear warfare directed by governments that didn’t really understand the science, was that one very useful way to defuse the situation was through technology transfer. Not, of course, nuclear technology transfer, but scientific knowledge transfer. The mid-century nuclear angst passed with the fall of the Berlin Wall. It is questionable whether an analogous information wall’s falling (i.e., the advent of the Internet) relieves the early 21st-century information angst.

Snow made three major points in his lecture, one empirical and subject to test, one controversial and highly personal, and one universal and largely ignored. The empirical statement concerned what he termed “the two cultures”, namely that scientists and the “literary intellectuals” (i.e., British writers, critics and university professors) operated in completely separate, mutually non-communicating cultures (one major problem with Snow’s lecture is that he provided no consistent, acceptable, reliable definition of “culture”), each with its own language, rites, rituals, and values. This point was uncontroversial in its essence and not novel (for example, Matthew Arnold delivered a Rede lecture on the same topic in the 1880s). However, after the lecture, this point was misunderstood by many and used as a smokescreen for those wanting to avoid discussing the second, more controversial, point.

This second point was that the culture gap was a threat to civilization and that it was the job of education to repair this. The point became controversial because he chose to criticize the very social system that enabled the rise of Baron Snow by implicitly derided a seven-hundred-year-old educational system. Less controversial in America, Snow’s second point was welcomed with open arms by educationalists eager to reform a system always ready for reform. But in Britain, the debate focused instead on Snow’s literary “credentials” as a member of the literary intelligentsia (Leavis, 1963).

Point number three was that the cultural and educational gaps aid and abet a third gap, that between the rich and the poor worldwide, and that this gap would respond positively to technological knowledge transfer. Of course Snow didn’t invent this idea; the World Bank came into existence in 1944 for reconstruction of war-torn Europe. Snow’s idea, of a kind of technological Peace Corps (to use an American term from the 1960s), was well intentioned and useful, but generally ignored. It’s an idea that
needs to be reexamined.

In summary, Snow could point out in 1959 that the world was dangerously divided in multiple ways around the role of science amidst the threat of atomic annihilation, driven by economic inequalities. In 2009 the same is still true, but the pivot is information. If Snow’s thoughts could be brought up to date and put into information terms, what advice would he give now analogous to what he suggested in 1959? Each of the ideas in his speech is worthy of revisiting, but it is to his first two that we turn here, mapping his thoughts from “science” to “information.” Sections two through four of this essay refer to his first idea, that of the “two cultures” gap and its implications. Sections five and six address ways of reducing this gap.

A note is in order on the use of the term “culture.” Snow did not give it much thought in 1959. At times he seemed to be referring to “high” culture (i.e., literature and the fine arts) and at other times merely to group membership. As we will see later, “shared values” may serve better as a distinguishing characteristic, although Snow did not dwell on this concept in the Rede lecture, but of course a great deal of thinking has been directed towards this term in the past 50 years. Leidner and Kayworth (2006) have provided the seminal work here. They chose to conceptualize this troublesome idea of “culture” as “shared values”. They would fit Snow’s thoughts -- and our recasting of them in modern terms -- into their theory of IT-culture conflict as contribution conflict arising from mismatches between user group values and IT values. While this does not completely capture the very broad and inexact application of the term “culture” that Snow intended, it is useful for our discussion below.

2 TWO POLAR GROUPS

The Rede Lecture gave rise to the “Two Cultures Hypothesis.” The largest part of the speech presented evidence for a gap between two important groups in mid-century British intellectual life: scientists and the “literary elite.” Little of his speech was true science subject to hypothesis testing. To refer to his idea as a hypothesis stretches the metaphor. Nonetheless, let us assume that the gist of what he was referring to was true in 1959. What is the essential argument that Snow made about the “split into two polar groups,” in his words, of Western society?

C. P. Snow referred specifically to “literary elite” (sometimes he refers to them as “literary intellectuals” and other times merely as “intellectuals”) and “scientists.” It is clear that the literary intellectuals he referred to were writers, essayists, Oxbridge dons, and to some extent the journalists who make the intellectual basis available. By extension, he was referring to the British political and social elite with this term. Initially – and increasingly – Snow’s “literary intellectuals” became identified with “the arts” and numerous essays appeared to debate the “science vs. the arts controversy” (Boytinck, 1980).

By “scientist”, Snow meant practicing bench scientists, individuals who derive and test scientific hypotheses. Snow was not comfortable with including technologists and engineers in this group and it is doubtful that he would have had as much to say about applied scientists, social scientists, and computer scientists, either. On occasion he does put engineers and scientists together, but generally he makes a strong distinction between pure scientists and those who are applying scientific principles.

Why were and are these two groups important? One might, with the comfortable space of fifty intervening years, conclude that Snow’s polemic was personal. Perhaps the only real reason he felt the need to draw attention to the gap between these two groups was that as a novelist and a physicist Snow felt drawn to both camps. But if we follow O’Hear’s (n.d.) argument, these are two essential groups in a society such as ours as they represent ways of apprehending the world through either a value-tinged lens or a value-free
lens. O’Hear said

To put all this another way, science aims at an observer-independent account of the world, transcending human meaning, culture and ideology. Its success derives from its success in approximating to this aim, for it is in so far as we go beyond looking at the natural world in terms of its first meanings for us that we are able to penetrate further its causally essential core, and so become rather more adept at manipulating and directing it than those who remain at the level of first impassions. The lesson of post-Galilean science is that there is no reason to suppose that the effects and processes we identify in our first transactions with nature will turn out to be those which are fundamental from a causal point of view.

Hence, by working in complementary ways, science and the arts put the value basis of our living in stark relief. By transcending “human meaning”, science, in O’Hear’s words, shows us where values are active. Without science, everything is “impassioned”. Since we cannot reliably describe, define, and delimit the passions and come to understand everything, the literary elite need science.

Similarly, science also needs the literary elite. O’Hear says that “…an exclusive concentration on scientific modes of thought can affect the way in which judgments of value are made. In particular, it can lead to an importation of quantitative considerations, and a tendency to see social and moral problems in terms of hygiene and environmental manipulation.” There are two complementary ways of apprehending reality. This complementarity is a characteristic, too, of the ITU/ITP “gap”.

### 3 TODAY’S “TWO CULTURES” AND TODAY’S “GAPS”

Let us now shift the emphasis and focus from “Would Snow be right today?” to “Is there something happening today that is like what Snow was describing both in extent as well as impact? ITP and ITU communities share characteristics that separated Snow’s original “two cultures.” ITP and ITU speak different languages, have experienced different education; have paths that, if they ever intersect, cross only at a desktop computer; and generally appear ignorant of each other’s ideas and values.

The “gap” between these two groups is legendary. For much of the past fifty years, there has been a monumental struggle within business organizations concerning information tools and their purveyors. Beginning in the 1960s with the concept of “resistance” and moving through the “end user revolution” and “IT/business alignment” to today’s thoughts about “IT governance”, the struggle over who gets to control IT investment and deployment has endured through multiple generations of software, hardware and Microsoft products. It does not seem to go away, whatever the current manifestation of the presenting problem. The underlying “cultural” gap may be the ultimate cause. Complaints of “The system doesn’t work!” “The help desk is unresponsive”, “The IT guys are arrogant and speak in computerese”, and “IT is too expensive” come from the ITU side. “IT doesn’t sit at the ‘table’”, “We are seen as plumbers, not as contributors to strategy”, “I can’t get my budgets approved” and “It’s impossible to keep talented staff in this environment” come from the ITP side. This certainly indicates a gap. Is it the kind of gap that Snow referred to in 1959? Is it as important? Is the “ITP/ITU gap” the “two cultures gap” of 2009?

One way to approach this question is to think about which of Snow’s statements concerning the science/arts “gap” in 1959 are true today of ITP and ITU. Are ITU and ITP “cultures” in Snow’s sense? Do they have the kind of alienation Snow alluded to in 1959? Are the predictions the same? How can Snow’s hypotheses be understood in terms of today’s society and its information issues?

Clearly there are important differences. Science is a system of procedures and philosophies with a long
history and the goal of understanding the physical universe. The liberal arts represent the accumulated total of human experience and thought on moral issues. On the other hand, the activities and the body of thought of ITP go back at most about sixty years. This body of thought is generally limited to two major areas: business (or, more broadly, administration) and engineering (including software engineering and computer science). The comparison might seem stretched and nebulous. Unlike science, there is no real canon of IT practice; no ethical history; no historical struggle against, say, established teachings; and no systematic methodology comparable to the scientific method. Unlike the practitioners of the liberal arts, the users of IT (ITU) are not a group of intellectuals focusing on the fiber and core of civilization; they aren’t homogeneous and dedicated to increasing our understanding of issues unrelated to profit or proper administration; they don’t wield “power” in any arena and are, in many cases, totally powerless, at least to get their IT “working properly.”

Yet these differences do not dispel the comparison. Because IT is now critical to the survival of culture (which has come to depend on digital information and the World Wide Web to keep commerce and culture alive) and because IT users are in fact the drivers of that culture, Snow’s comparisons are particularly apt. Here are some from the original lecture, slightly modified to reflect the new groups:

[T]he intellectual life of the whole of western society is increasingly being split into two polar groups. When I say the intellectual life, I mean to include also a large part of our practical life…. Two polar groups: at one pole we have the [information users]…. at the other [information purveyors]…. Their attitudes are so different that, even on the level of emotion, they can’t find much common ground. On each side … some of [this prejudice] which is not entirely baseless. It is all destructive. Much of it rests on misinterpretations which are dangerous. [Emphasis mine]

What about the relationship between these two “cultures”? Surely IT users use IT in ways that the “intellectual elite” never “used” science in 1959? IT users depend on IT more directly and intensely than the intellectual elite of 1959 depended on science. Innovative IT users sometimes develop their own systems and applications using common packages such as spreadsheets or databases. And it is unlikely that the intellectual elite of 1959 developed scientific hypotheses which they then tested in experiments. Is this comparison strained, then?

Yes and no. The alienation Snow spoke of was related mostly to a lack of communication, the lack of a common language, differences in values, and a large “gap” in terms of attitudes and values. In Snow’s own words:

The two cultures were already dangerously separate sixty years ago….Thirty years ago the cultures had long ceased to speak to each other: but at least they managed a kind of frozen smile across the gulf. Now the politeness has gone…. It may well be that this process has gone too far to be reversible.... Closing the gap between our cultures is a necessity in the most abstract intellectual sense, as well as in the most practical. When those two senses have grown apart, then no society is going to be able to think with wisdom.

Today, this alienation takes on a more modern appearance if we stop thinking about science as an esoteric practice completely out of reach of the literary elite and instead view it more as a different way of understanding the world. Of course “the world” in Snow’s terms was restricted to the physical universe – and he focused strongly on physics as the exemplar of science. A C. P. Snow of 2009 would have to recognize social science and administrative science as legitimate scientific ventures, whose purpose is to understand in a systematic way a limited set of phenomena, some of which take place in the physical
universe, some of which take place within derived social – but still physical – domains and some of which involve virtual domains such as money and influence. Yet, within these domains, the goal is still understanding. But the goal of the literary elite is also understanding -- understanding the human heart, in its broadest (and least medical) sense: human endeavor, aspiration, love, morality, history and conflict. It was just a different way of understanding from that of science. In both cases, there is an “out there” that needs to be understood by people “in here.” Science and the arts are separated most fundamentally by their ways of apprehending the world. That this understanding is *supposed* to be objective for science and *can be* comfortably subjective for the arts is important for judging the aptness of our comparison of ITP and ITU as cultures.

What separates IT purveyors and IT users to generate a gap comparable to that between science and the arts? The answer must be that information is the “object” of the purveyors and the “subject” of the users. The purveyors value information as an object, one that must be handled systematically, carefully, and with great respect for its beauty and brittleness. Most IT users – especially business users -- value information because of what they do with it. The information describes the subject of their work lives so information is respected respect for what it means, not what it is. Information is, ironically, a work of art to the purveyors, and a means to an end to the users. Information *represents* power, confidence, and influence to the users. Information *is* none of this to the purveyors; it represents nothing, but is itself, the thing. And this difference is precisely the same as that dividing science and the arts.

Are the two IT groups “cultures” in the same sense in which Snow applied the term? Snow was not an anthropologist but he was using the term “culture” in its usual (dictionary) sense: a particular group of people and their ideas, which are passed along or transferred to successive generations. Both scientists and literary intellectuals do indeed have sets of ideas that they pass along, through education and the media to which they contribute and subscribe, to successive “generations”. Within their own ambit, both science as well as the literary and intellectual arts do ascribe ownership to sets of ideas (sometimes referred to as “schools”), provide titles, and enforce customs and regulations. It was this restricted sense of “culture” that made it easy for Snow to identify these two “cultures” and their alienation, since they did not share “a language” between them, but only shared a language within a group. He said, “[A]fter a few thousand Atlantic miles, one found Greenwich Village talking precisely the same language as Chelsea, and both having about as much communication with M.I.T. as though the scientists spoke nothing but Tibetan.” Thus knowledge and language served to divide cultures in Snow’s mind, although he also referred to shared values (scientists were, to Snow, what we would refer to today as “liberals”; the literary elite, “conservatives”) but treated differing values more as the result of differing cultures than the cause, unlike Leidner and Kayworth (2006).

In the way Snow used the term “culture”, it is difficult to label ITU a homogeneous “culture”. But clearly “users”, despite the enormous difference in their jobs, goals, and work processes, share similar attitudes and values, at least with respect to information. Perhaps this sharing stems from a common feeling of helplessness at the end of the phone line to the help desk. Or maybe these attitudes stem from accumulated negative emotions through years of experiencing unresponsiveness or even arrogance of the ITP. Regardless of the source, evidence of the cultural “values” of the ITU are mostly evidenced by resistance, coping strategies, and work-around activities (Jasperson, Carter and Zmud, 2005; Lapointe and Rivard, 2005; Beaudry and Pinsonneault, 2005). In general, their experiences are at best neutral. And these experiences and values are definitely “passed along” through on-the-job training, office “lore” and gossip. This is alluded to by Leidner and Kayworth (2006) in their listing of “IT values”. Their contention is that a mismatch between IT values and “group member values” (i.e., user values) results in “contribution conflict” a mutual misunderstanding of what IT is “about.”
ITP “culture” is easier to describe. Because IT education is generally highly circumscribed, the IT world view is relatively homogeneous, centered on the technology itself and the supporting platforms such as application environments, operating systems, physical equipment, protocols, etc. The ITP view of ITU is that ITU users are the uncontrollable variable at the other side of the “interface”. This is not to deny that there are sub disciplines in the ITP universe that focus on users. We have multiple theories of technology adoption, end-user system involvement, and human-computer interaction. The field of “management information systems” promotes the idea that information systems are essential in business and work towards bridging the IT-user “gap”. Yet there are few useful theories of the role of the user in system use. The literature of user involvement generally focuses on users as objects of study (during the early stages of system development) or as difficult-to-handle interfacing systems (looking at the diffusion or adoption of innovation and the “resistance” literature). There is almost no post-implementation literature looking at user innovation, user stewardship or ownership, or user responsibility. Just as scientists do not really worry daily about whether non-scientists will actually apply the principles upon which gunpowder functions as an explosive to build and operate lethal weapons, so, too, are members of the ITP largely unconcerned about what users actually do with information systems. The values of the ITP rarely extend to any aspect of the deployment of systems. And these values and experiences are also passed “along” through on-the-job training, office “lore” and gossip.

4 THE CAUSES OF THE “GAPS”

If we have two IT cultures with a relationship strongly analogous to those Snow described, can we also ascribe this relationship to causes similar to those Snow referred to? Snow strongly implicated specialized education as the major reason for the gap between his two 1959 “cultures”. ITU and ITP also have differing educations. Just how different are these educations? And is it the education that is the cause, or is it the effect? In 1959, Snow referred extensively to an educational difference as “specialization”. British university education in the 1950s was highly specialized. Even today, students enter these universities directly into narrow specializations in science, literature, and other fields. In America, most universities and even most institutes of technology require a one or two years of “liberal arts” education in any degree program. Few students enter a “major” in their first year of university training. Things are a bit different in technical schools, where training is specifically in the discipline.

However, one important difference between the “two cultures” of Snow’s 1959 and the “two cultures” of 2009 is that science education was then (and remains now) a purely academic discipline, whereas IT education in the US can be obtained in a variety of ways. Typically any bachelor’s or first university-level degree will have a large liberal arts component. For members of the ITP, understanding of the ITU will come from daily life, for the most part, rather than from academic training. Few offerings to members of the ITP contain any content oriented towards understanding the role, impact, function, responsibility, or worth of information and information technology in general society, even in liberal arts course. Courses that may be required of some members of the ITP may examine “social issues” or “ethics”, but unless the lessons are reinforced through positive and clear examples, they are hardly going to survive as important bridges after this training.

For members of the ITU, any vague understanding of the ITP can stem from modern life, with its myriad computer-based, -enabled, and –enhanced applications. There are the ubiquitous “computer literacy” courses offered at universities, colleges, community and seniors' centers, voluntary organizations, service clubs and prisons; all provide some introduction to one or more applications under the heading of “literacy”. Whether or not this kind of literacy is really anything like reading is controversial and is very much related to the “two cultures” challenge, if only because building the bridge across the gap from only
one side is dangerous engineering. Just having users understand “how computers work” is not sufficient to bridge the gap.

Secondly, beyond the lack of IT cross-training is a lack of shared positive experiences. A typical member of the ITU will experience information systems in two different ways: “I use an application and it’s great; there are no problems” or “What a piece of garbage!” In the first case, there is little reason to explore the other “culture” – rarely are members of the ITU asked to contribute in meaningful ways to subsequent releases of systems that already work well. In the second case, interaction between ITU and ITP people generally suffers from all the communication problems noted by Snow, exacerbated by the pressure of modern life to get things done fast using information-based, enabled, and –enhanced system. When systems don’t seem to work and when users have little recourse to getting them fixed, users manifest anger and resentment. Often individuals in the ITU try to become knowledgeable about IT either in self-defense, rarely out of interest. They become the office “computer guy” even when they aren’t in any way members of the ITP fraternity. This might create more positive experiences for others in the office, but it doesn’t build shared positive experiences.

A third cause of the gap, especially in the business arena, is the development of IT ghettos, areas of the organization into which members of the ITP are relegated and isolated from the rest of the organization. While most firms would deny this reality, the numbers clearly tell the true story. Few members of the ITP ever become CEOs (Chief Executive Officers) of any non-tech firm. Few CEOs of modern companies have any vocational background in IT. Although there is some disagreement over the statistics, fewer than half of CIOs (Chief Information Officers) or individuals having a CIO-like position have a meaningful role in determining corporate policy or strategy. “Having a seat at the table” is the cause célèbre of the IT trade magazines. This seating varies depending on the industry, with information-rich industries such as banking and entertainment promoting CIOs to “table” status but most primary and heavy industries relegating the CIOs to reporting through Chief Financial Officers. The concomitant loss of prestige and benefits to the members of the ITP because of the relatively low status of their primary advocates is harmful enough. But by denying positive and regular interaction with CIOs leaves CEOs impoverished and information-disempowered, at the mercy of Boards of Directors and vendors when it comes to making decisions about IT. Even worse than potentially negative economic outcomes is the lack of contact itself, which leads to disinterest, or at least further isolation. This can only hurt IT governance, as an example of one critical aspect of IT. There is no doubt that most governance schemes, such as ITIL, focus on procedures rather than governance. This may be because the organization itself cannot be trusted to “do the right thing” with IT, because of a history of poor communication focused on problems, a lack of a common language and values, and totally different world views. This is the legacy of “two cultures”, exactly paralleling Snow’s description from 1959. Snow’s reference to Tibetan is particularly apt, since (1) few people speak Tibetan, (2) Tibet is a long, long way from the West, and (3) Tibet no longer exists as a separate political entity. Each of these is a quality of the ITP, at least in business organizations.

The underlying causes can be addressed. It is possible for an IT person to interact meaningfully with users and it is possible for a user to argue for IT. However, it is unlikely to happen without a major shift in business values. For instance, for two decades, alignment has been either the top issue for CIOs or in second place. Aligning IT to corporate strategy is always on CIOs’ minds, it seems. This lack of alignment is, of course, simply a symptom of the “two cultures.” Generally, the emphasis is on “aligning IT to the firm” rather than the other way around. There is a large literature on this topic, too great to be reviewed here. There is, however, no literature on the opposite: aligning the firm to IT. And there is only a very small body of thinking about mutual alignment (Luftman, 2000, 2003, 2007). Keeping the alignment “problem” in mind, let’s turn, once again, to Snow’s lecture to see how these two cultures can be brought together, perhaps through lessons he pointed out half a century ago.
5 SNOW'S LESSONS

Snow’s diagnoses and prescriptions may have some value in 2009. In this section we will review several of them and see how the lessons can be applied. In essence they boiled down to providing more science education in the schools. But given how little difference such education has made in ameliorating the gap between his “two cultures” since 1959, one may legitimately wonder about the effects of such education on the ITU-ITP “gap”.

First, here’s what Snow prescribed in order to reduce or ameliorate the “two culture” gap of 1959:

[Twentieth-century science] has got to be assimilated along with, and as part and parcel of, the whole of our mental experience, and used as naturally as the rest. There is only one way out of all this: it is, of course, by rethinking our education. This [list], or something like [it], is the specification for the scientific revolution. First of all as many alpha plus scientists as the country can throw up. Second, a much larger stratum of alpha professionals -- these are the people who are going to do the supporting research, the high class design and development. Third, another stratum, educated to about the level of Part I of the Natural Sciences or Mechanical Sciences Tripos, or perhaps slightly below that. Some of these will do the secondary technical jobs, but some will take major responsibility, particularly in the human jobs. Fourthly politicians, administrators, an entire community, who know enough science to have a sense of what the scientists are talking about.

Snow advocated an increase in the number of scientists. But he also spoke strongly in favor of what might be called the “users-of-science community” -- politicians and administrators -- “an entire community” learning enough about science “to have a sense of what the scientists are talking about.” And by this, he did not mean understanding the basis of particle physics. He meant enough understanding of the importance of particle physics to be able to make critical judgments. That is what politicians, government officials, civil servants and business leaders do: they make decisions among courses of action. Snow, naturally enough as a scientist-politician (and a scientist-administrator, too, during WWII), knew that these decision makers were influential enough and had enough clout to move the rest of society. Snow proposed educational programs both for scientists and for the “literary elite.”

Was this effective? Unfortunately we have no way of knowing, because the intervening years were not kind to Snow’s ideas as scientific hypotheses. No one did the experiment. Instead, the enormous ramp up in technological and applied-science development has culminated in a technology-oriented society, at least in most of the West. This seems to have completely obviated the apparent need to understand science. America, for example, is a society that literally runs on technology. For example, the Internet is rapidly replacing the shopping mall as the price of fuel rises. America looks to technology for solutions to almost all social problems (for example, tethering of convicted criminals instead of imprisonment, high-tech medical care instead of nursing, e-learning instead of wide-spread education, for example). Yet decreasing numbers of Americans enter science and engineering programs each year.

Snow was also ambivalent about industry and technology:

And we know almost nothing about [the industrial society of electronics, atomic energy, automation. H]ighly educated members of the nonscientific culture couldn't cope with the simplest concepts of pure science: it is unexpected, but they would be even less happy with applied science…. Pure scientists and engineers often totally misunderstand each other….
It is simply that technology is rather easy. Or more exactly, technology is the branch of human experience that people can learn with predictable results.

Yet even this “easy” pursuit, which pure scientists misunderstand as much as highly educated members of the nonscientific culture, is unpopular with members of the ITU. Here in America, for example, the management of ITU “culture” is increasingly content to outsource its information needs to India and to populate their schools of engineering and science with students from India and China, countries that Snow ironically had much to say about in the third part of his lecture, concerning the developing world.

So perhaps “education” is not the answer. Instead, consider the underlying message of Snow’s argument in 1959. That message is that even a non-scientist who doesn’t understand science (in depth) should understand and be responsible for the implications of his or her use of science. That is, members of the “literary elite” (which correspond to our ITU today) should at least appreciate the importance of science in contributing to the basis of their own activities. This is responsibility.

To this end, Snow proposed a sort of scientific (and to an extent technological) “Peace Corps” to go to what we now call the “developing world” and bring it into the modern “scientific” era. His proposal was to bring the vehicle of science -- the scientific revolution -- to the rest of the world:

The West has got to help in this transformation [from half rich and half poor]. The scientific revolution on the world-scale needs, first and foremost, capital …including capital machinery. The second requirement is …trained scientists and engineers adaptable enough to devote themselves to a foreign country’s industrialization for at least ten years out of their lives. [T]he third essential of the scientific revolution … is an educational programme …With scientific teachers from this country and the United States, and … teachers of English, other poor countries could do the same in twenty.

In effect, Snow implied that while the individuals who might bring the “scientific revolution” (read here today “the Internet revolution”) to the developing world would be “scientists and engineers”, such a project would have necessitated the intellectual elite taking “stewardship” of science and technology. It is this stewardship idea to which we now turn.

“Stewardship” means the sense of responsibility that an individual has for the proper use and sustaining of a resource. We speak, informally, of being “stewards of the earth” when we refer to environmental responsibility. Similarly, it is possible to speak about “information” or “application” or even “system” stewardship in the same vein. Such IT-oriented stewardship builds a sense of responsibility and respect for information, information tools and, ultimately, information purveyors (i. e., members of the ITP) among the users (i. e., members of the ITU). Typically users expect the corporate IT unit to be responsible for designing, developing, distributing, and maintaining systems. For the most part, this responsibility rests well with members of the ITP. However, again typically, IT users also expect members of the ITP to be responsible for the use of the applications. The users certainly don’t feel this responsibility. For example, few firms have active programs to reward innovation in IT use. Even fewer firms consider IT users as potential initiators and managers of IT development projects even when the users are paying for these projects. It is doubtful whether firms have sufficient maturity to understand the concept of application stewardship, so ingrained is the idea that an information tool is something that only the ITP should be responsible for. Yet the use of such tools logically cannot be solely an ITP responsibility; it is also an ITU responsibility. Programs encouraging stewardship are important. Successful programs of stewardship remove both major causes of the “two cultures” gap and thus ameliorate the harmful implications that Snow dreaded fifty years ago. The “two cultures” must explore each other’s workplace reality. This is the
best reading of Snow's mid-twentieth-century advice for today's two IT cultures.

6 CONCLUSION

The gap described between ITP and ITU in 2009 is analogous to the “Two Cultures” gap of C. P. Snow's 1959. The pairs of cultures (ITP/ITU in 2009 and “scientists”/“literary elite” in 1959) differ, of course, but the causes of the gaps are similar. The effects of the gap are analogous, too, and probably just as threatening. For example, did the ability to create and track mortgage-backed securities enable the recent large-scale meltdown in worldwide financial markets? Information systems provide the ability not only to create a large range of unregulated derivatives of questionable provenance, but certainly to manage and make marketable these virtual “securities.” This is not the atomic Armageddon of Snow's subtext in 1959, but it could have analogous destructiveness if the economic system of the West (and Russia and China) comes tumbling down. One way forward may be to develop stewardship programs among users to increase user responsibility. Stewardship programs have an educational component as well as an experiential one. Not only will members of the ITU and ITP learn more about each other's “cultures”, but by having common and positive experiences, they will come to value each other's way of understanding the world. Each employs information in a unique, but complementary way.

OPPORTUNITIES AND CHALLENGES OF MOBILE PERSONALIZATION: AN EXPLORATORY STUDY

Ho, Shuk Ying, The Australian National University, Canberra, 0200, Australia, susanna.ho@anu.edu.au

Abstract

In the decade since the creation of wireless handheld devices, mobile commerce (m-commerce) has become a ubiquitous channel for accessing information and conducting business. Mobile users can now access information anytime and anywhere. Mobile advertising, retailing, and gambling are popular, and gradually the competition among mobile services providers turns fierce. Hence, some services providers adopt personalization technologies to customize content for their users. This paper explores the opportunities and challenges of the use of personalization technologies in m-commerce. Although the effectiveness of personalization on the web is well-examined, there is little work on personalization in mobile services. The debates regarding the effectiveness of personalization and technological limitations and privacy concerns motivate us to conduct focus groups with mobile users, and explore the opportunities and challenges of personalized mobile services. The focus groups findings illustrate that mobile users are very concerned about their privacy and spam. We then extract a list of personal information from the focus groups findings. This list of personal information is highly related to mobile users’ privacy concerns. We conduct an online survey to gain a better understanding of which piece of information mobile users are more willing to share with services providers and we perform a multi-dimensional scale analysis.

Keywords: Personalization, Mobile Commerce, Expectation, Focus Groups, Multi-Dimensional Scale Analysis
1 INTRODUCTION

1.1 Personalization in Mobile Commerce

In the decade since its creation, mobile commerce (m-commerce) has become a ubiquitous channel for accessing information and conducting business (Allen 2003; Tarasewich et al. 2002). M-commerce is the buying and selling of products and services through wireless handheld devices (Hong and Tam 2006). These devices range from small handsets, such as cell phones and personal digital assistants (PDA), to wireless laptop computers. Apart from retailing, there are applications on mobile advertising and mobile gambling. According to Wu and Wang (2005), only 16% of half a billion Internet users were global wireless Internet users in 2001; however, the percentage jumped up to 57% of 1.5 billion Internet users in 2007. A telecommunications analyst, Paul Budde, estimated that 300 million text messages are sent by 11.5 million mobile phones over the three Australian mobile networks each month. Undoubtedly, m-commerce is gaining significance.

The proliferation of wireless-based applications has turned these devices into an essential “touch point” of corporate services (Gopal and Tripathi 2006; Stafford and Gillenson 2003). With recent advances in wireless location technology, such as Global Positioning Systems (GPS), mobile operators can identify the location of a wireless device within several metres. Prior research asserts that with such a location awareness capability, this mobile channel provides firms with more valuable promotions and sales opportunities than the web channel does (Balasubramanian et al. 2002).

In leveraging the strengths of m-commerce, the question that lurks in the back of mobile operators’ minds is: what type of location-based content should be delivered? With increasing customer expectations, presumably, one-message-fits-all is not a strategic move. Customers prefer customized, or even personalized, services (Blom and Monk 2003). Tailoring the content in relation to users’ locations (and even their preferences, shopping goals and context) is necessary in order to realize business opportunities in m-commerce. Thus, personalization is the answer for mobile operators.

Personalization is to tailor content to the needs of individual consumers. The technology enabler, a personalization agent, is a collection of software modules that deploys tools to collect and analyze customers’ behavior and their purchase transactions. These modules, including data mining, collaborative technology, click stream analysis components, and pattern recognition, allow real-time detection of user behavior and manipulation of web content (Ardissono et al. 2002). The agent is a context-aware application designed to deliver targeted promotions to online users about the products they like and protect them from information overload. Providing responsive and high quality services is a key factor for firms to achieve a sustainable competitive advantage. The goal of personalization is to leverage the above technologies to provide the right content in the right format to the right person at the right time in the right location. That said, not only are firms now able to retrieve the profile of a user when the user accesses a service, they are also able to change the content and its format adaptively according to the timing and the context of interaction (Fan and Poole 2006).

On the web channel, web personalization is found to be a very useful approach to facilitate customers’ decision making (Tam and Ho 2006). If personalization is applied in m-commerce, many business opportunities are available. One popular application is mobile advertising. Mobile services providers use a short message service (SMS) to send messages to their subscribers. The message content can be an advertisement or a cash coupon. Consider the following scenario: mobile operators learn a user’s preferences with regular surveys, and cooperate with different business partners to offer trade

---

promotions. With GPS, mobile operators detect the location of a cell phone user. This user is fond of Chinese food (i.e. user’s preference). It is about lunch time (i.e. time and goal), and she is now near Chinatown (i.e. location). If the operators send her a mobile coupon (e.g. 10% discount in The Dragon Restaurant) in the form of SMS and she can enjoy the discount by simply showing this SMS to the waiter, then this can greatly increase the chance of her having lunch there.

Location-based services can be classified into various categories (Rao and Minakakis 2003). The first category is “where am I?” services. They relate to information about users’ locations and navigations. After detecting where service clients are, service providers can send information such as maps, driving directions and yellow-page listings to service clients. The “where am I?” services are also adopted by drivers. The second category is point-of-need information delivery. Service providers send product information and promotions to service clients. To personalize the information, the providers not only need to know the clients’ location, but also access their preference profiles. The example of The Dragon Restaurant belongs to this category. The third category is industrial/corporate applications, which are business-to-business oriented. Barcode scanners become the technology enablers for firms to track materials and product movements. Location-based services can be incorporated in the supply chain management and asset management, and location-specific task checklist and real time reports can be sent to workers. Table 1 presents a summary. The first and the second categories are the focus of this research.

Table 1. Summary of Three Categories of Location-Based Services

1.2 Motivations and Research Questions

Mobile services providers adopt personalization technologies with the intention to better communicate with their users and to generate more business opportunities. The impact of personalization in m-commerce is under-investigated. Generally speaking, we believe personalization can increase the value of an organization by focusing on customer intimacy, but at the same time, it leads to users’ concerns.

With the gaining popularity of wireless handheld devices, this paper examines the use of personalization technologies in m-commerce. We are going to address the following research questions:

1. What business opportunities are offered by personalization in m-commerce?
2. What are major challenges to personalized mobile services?

The paper is organized as follows: In Section 2, we review the literature of personalization. Section 3 outlines the methodology, and Section 4 presents the focus groups findings. With the insights brought by the focus groups, a survey was conducted. Section 5 presents the survey and the findings. Section 6 discusses the findings and the last section concludes the paper.

2 LITERATURE REVIEW

The use of personalization in web-based applications has been widely examined. Several authors have found evidence for the effective influence of personalization on users’ decision making (Kumar and
Benbasat 2006; Tam and Ho 2006), as well as for perception of e-services (Nysveen and Pedersen 2004). By providing individualized content, offers and services, personalization eliminates aimless surfing activities (Shahabi and Banaei-Kashani 2003), eases business-to-consumer interaction (Ardissono et al. 2002) and increases users’ satisfaction (Liang et al. 2007). Also, personalizing content empowers firms to deliver customer value and to achieve profitable growth. It is reported that online retailers using personalization technology have had significant revenue increases.

While much prior work examines web personalization, the current work focuses on personalization in m-commerce. Personalization in m-commerce refers to the process of adapting content with the dual objectives of serving users’ needs as well as maximizing business opportunities. In general, it can take three forms:

(1) User-driven personalization – A user specifies in advance the desired layout and content that match his/her interests and preferences. For example, an investor would like content on a financial portal tailored to his own investment portfolio. The goal is to provide tools and options for users to customize the available information and the presentation format.

(2) Transaction-driven personalization – Similar to the previous case, customized layout and content are generated by the online merchant. In the transaction-driven context, personalization is driven by previous transactions rather than specified by the user in advance (Al-Natour et al. 2006; McGinty and Smyth 2006; Wei et al. 2008). For example, page organization and information indexing of mobile sites is automatically adjusted for different users depending on their preferences as inferred from previous transactions.

(3) Context-driven personalization – In this case, a very adaptive mechanism is employed to customize content and layout for each individual user. The mechanism is sensitive to the context of the interaction and users’ location, and adapts to the context in real-time. Advances in click analysis and text mining have made it possible to understand the context and to infer the processing objective of the user in real time. For example, context-sensitive persuasion messages in the form of cash coupons are dynamically generated and sent to users via SMS to realize cross-selling and up-selling opportunities.

Figure 1 summarizes different types of personalization technologies. The size of the bubbles reflects the usage in B2C commerce. While transaction-driven personalization is common at the current moment, we expect widespread adoption of context-driven personalization in the future, as mobile services providers can harness the power of GPS technologies, and take users’ location and contexts into consideration.

But still, there remains skepticism on the prospects of personalization. Several personalization initiatives have failed without generating any benefits to the adopting firms. One main reason for such failures is inappropriate resource allocation. Chellappa and Sin (2005) claim that investments in online personalization services may be severely undermined if online users do not use these services due to privacy concerns. Nantel and Sekhavat (2008) suggested that the effects of SMS advertising depend...
very much on the languages used in SMS and the receivers. This motivates us to conduct focus groups with genuine mobile users to explore business opportunities and possible challenges.

3 METHODOLOGY

We conducted a number of focus groups to explore mobile users’ concerns and expectations of personalized mobile services. They were dual-moderator focus groups. That is, there were two moderators. One moderator ensured the session progressed smoothly, while another ensured that all the topics were covered. The reason for adopting this approach is that focus groups are likely to bring to light the collective views of mobile users and are effective in producing richer data because of interaction (Bryman 2001; Cooper and Schindler 2008 p. 177).

3.1 Participants and Research Design

We conducted six focus group sessions comprising 48 students from a university in Australia. We considered students to be appropriate participants, because they were typical mobile services users. The sessions were held in the university during the second week of October 2007. Sessions were recorded and transcribed to produce qualitative data for subsequent analysis. In this study, we followed the general guidelines of focus group research closely (Fern 2001). Each session comprised four to six students.

The participants we selected were all mobile phone users. There were 29 females and 19 males. Their average age was 21. On average, they had subscribed to mobile services for at least five years. Thus, they had reasonable knowledge of mobile services. A moderator who had performed a similar role in previous research ran the focus groups. The main role of the moderator was to facilitate useful and relevant discussions among group members. We encouraged participants to freely express their views since their identities would remain anonymous throughout the data collection and analysis processes. The questions were open-ended. The focus group questions included “What is mobile-commerce?”, “In your opinion, what are personalized mobile services?”, “Why do you use personalized mobile services?”, and “What possible reasons may discourage you to use personalized mobile services?”. For example, we asked students their perceptions of mobile services, whether they would use personalized mobile services, and their concerns. Each focus group lasted approximately 1.5 hours.

3.2 Data Coding and Analysis

After the data were recorded, they were transcribed immediately to allow for coding and analysis. The data analysis involved rigorous examination of extensive focus groups transcripts. We compared, conceptualized and categorized our data. Coding categories reflected the interpretations that focus group participants formed about m-commerce. We eventually arrived at ten fundamental attributes. The data suggested most participants we talked to were curious about and had high expectations for personalized mobile services, however, they expressed strong privacy and security concerns. The concepts and patterns observed were linked to the IS literature. We endeavored to provide a data-theory link (Klein and Myers 1999) and attempted to understand participants’ perceptions of personalized mobile services that are associated with the theory. In order to reduce researchers’ bias and also to validate that no important attributes had been missed in the result summaries, a colleague was asked to comment on the analysis of the data. This allowed the incorporation of two different perspectives for our results and minimized the potential that we might have overlooked something important. The role of this colleague was to “bring a different and possibly more objective eye to the evidence” (Eisenhardt 1989 p. 538). The information this colleague received did not include the field researcher’s list of attributes. We went through the focus group transcripts several times and moved back and forth between the data, IS literature and the concepts emerged.
4 FINDINGS

In the following, we will present the conceptualization and categorization of the data in our final round. There are ten major categories.

4.1 Technological Issues

This category focuses on the technological aspects of personalized mobile services. It covers performance of personalization and mobile interfaces.

4.1.1 Location-Related Functions

Most focus group participants suggested that the major use of personalization was to meet their instant needs. Personalized mobile services act as a recommender, and this aligns with personalization literature (e.g. Gretzel and Fesenmaier 2006). Weather report, stock prices, restaurant recommendation and movie listings are typical examples of instant services. For instance, one participant used the mobile devices to “check the weather forecast”. Another participant mentioned, “I got an SMS from restaurants, stock exchanges and other service providers. Sometimes reading them is quite interesting and it’s always good to get some valuable information for free.” However, the participant highlighted that, “I don’t want them to send me junk SMS everyday.” Mobile services are useful for impulse purchase as well. One participant said, “when you go to the starbucks in the US, and if you like the music playing there, you can download it to your mobile phone”. Participants also tended to focus on hedonic activities, such as “discount sales” and “social events”.

Traffic updates are considered to be very useful mobile services. For instance, one participant mentioned that “maybe personalized services can be location based in such a way that tells us where the nearest petrol station is and also list out the one that’s offering the best price”. Another said that “I use it for traffic updates back home in Malaysia and it is a very helpful service”. The main advantage of using location-based mobile services was “convenience”. One participant said, “If I get the level of personalization it’ll be good and it’ll save me a lot of time.”

4.1.2 Personality-Related Functions

Focus group participants gave suggestions on location-based mobile services. For instance, a few participants suggested personalized mobile services could take more variables on customers’ characteristics, in particular personality traits, into consideration. One said, “SMS advertising should be related to my character and it should be things that match my personality, but in order for them to know that, we must provide them with that information”. And another participant mentioned that “I know some other websites that take personalization to the next level and actually study your personality and base their advertisements on your past preferences”. This echoes the findings from the work by Moon (2002) who empirically showed that a match between users’ personality and personalization strategies improves the effectiveness of the strategies.

participants pointed out that emotions and moods are important variables for individuals to make decisions on purchases. One participant said, “Maybe if they sent me a listing of movies that is in some language I don’t understand. But ultimately, it depends on my mood if I want to watch it or not.” This indicates that users’ preferences and peripheral user parameters (e.g. spoken language) may not be the only factor to be considered in personalization, and users’ moods and emotions, which are fuzzier, are useful in personalization. However, some participants thought that it was not easy to detect individuals’ emotions and moods with mobile devices.
4.1.3 Technological Limitations

(a) Feasibility of Predicting What Users Want

Although there is a significant amount of “hype” about what sort of personalized mobile services will be useful, most participants were not optimistic about the feasibility of location-based personalization. Some participants did “not like to be categorized and put into a frame”. Some emphasized that individuals’ preferences were changing constantly, and thus, hard to predict. For instance, one participant said, “I think that personalization takes too much time and my preferences can change”, and another participant mentioned that “some people don’t exactly know what they want or what they want to do. So they cannot give accurate information”.

(b) Small Screens and Limited Display

One major limitation of wireless handheld devices was small screens. One participant said that “the screens are too small to surf the internet”. Another participant mentioned that “some websites are not designed to fit on the mobile screen even if it’s a PDA”. This aligns with the suggestions by a participant, who said that “I don’t like phone advertising mainly because it’s so small and I prefer pictures, color and motion. SMS is so boring. Advertising is creative and so should be the advertisements”. Although the screens are small, participants expected more information to be packed on the screen. For example, one participant expected a rating system. That is, there are “a green-light or a red-light to show the importance [of the recommendations]”, and this type of color code is expected to “be standardized among the service providers”. This dilemma aligns with an IS research stream which explores increasing the usability of small screens (e.g. Kumar et al. 2004; Lee and Benbasat 2004).

(c) Security Issues

The increasing attacks on mobile devices by malicious hackers heighten individuals’ awareness of security. Individuals are concerned about how data are stored at mobile devices and how data are transferred across the wireless channels. Participants were concerned about “identity theft”, which they considered to be “a major issue right now” and “viruses that [might] be downloaded into the mobile phone”. One participant questioned, “I would like to know that all the information that the service providers have about me, is it safe?”

Security concerns discouraged individuals from using mobile services in general. For instance, one participant said, “Occasionally when I want to share a picture I send an MMS or sometime use the Bluetooth transfer. But I keep it off most of the time because hackers are always on the look out. So I keep it off for security reasons.” Another participant mentioned that “I wouldn’t use services like gambling because I don’t know what the source of the message is. One participant said, “there is always an issue if these service providers sell your information to third parties. It is illegal but it still does happen on a very large scale. Sometimes employees from within the company who have access to all this information can sell it illegally.”

People have serious concerns about the security of mobile devices, because mobile devices play a central role in daily life. One participant said that, “if someone hacks into my mobile phone or if I lose my mobile phone, they get details about my entire life.”

4.2 Social Issues

4.2.1 Opt-Out Options

Participants showed a considerable amount of concern about how these personalized mobile services should be regulated. For instance, giving users an option to opt-out is important. One participant questioned, “Will I be able to de-activate the service?” Since mobile communication plays a
significant role in our daily lives, it is not easy for customers to switch off the phone to stay away from spam. Hence, participants highlighted that what users could do is to “just turn off the service not the phone”.

4.2.2 Privacy Concerns

Individuals are concerned about their privacy. Most participants did not want to be tracked, and considered that personalization technologies may “abuse” their personal data. This aligns with the findings from prior IS work (e.g. Awad and Krishnan 2006). Some participants suggested that “the thought of the service provider being able to track your exact location is kind of scary.” They preferred simpler services to make their lives private. One said, “I think I’d rather get an incomplete service and keep my life private.” Another mentioned that “I think services should be personalized to some degree but it should not go over the limit where privacy issues are violated. Maybe it should just stay as it is right now. Just give me the information and I will decide what I want at that time.” Some even questioned, “Wouldn’t that be a bit dodgy if they knew where you are at all times?” Another said, “If that got really specific and if it could actually predict exactly what I want and what I like, I think it’ll be kind of spooky”.

4.2.3 Spam

Users dislike spam. Some participants got annoyed “when getting five to six of the same messages”. Some participants indicated that they simply “ignore all those kinds of SMS advertisements”. One participant said, “I heard that they get your number and send start sending you spam.” Users can subscribe to personalized mobile services free of charge; however, if they find that there is spam, users cannot stop the spam unless they pay a fee to the services providers. Hence, users are worried about the “hidden charge”.

4.3 Economical Issues

Price is a major concern. The participants tended not to use “mobile services that cost extra money”. One participant thought that personalized mobile services might incur extra costs, and hence, “it’s a bit too expensive”. Other participants said that personalized mobile services are “cool but expensive”. Some participants said that “if the price wasn’t a major factor, I think it definitely draws attention”. Users are uncertain of the prices, and their worry about being over-charged is another reason for them to reject mobile services. One participant said, “the most important thing is I don’t know how much it costs to send the message.”

If the services are provided by the Internet and by mobile services, the services on the Internet are usually free of charge. Hence, the Internet is a major threat to personalized mobile services. One participant said that “I remember when the soccer world cup was on, you could get the highlights each day on the mobile phone and that cost $60 a month which is quite expensive. You can do the same thing online for free.” Participants tended to “subscribe to the advertisements on a website from a company”, rather than receive personalized mobile messages. Another participant said, “Well, Google maps is slower compared to the GPS. But if it is a cheaper way then I’ll use the cheaper way”.

4.4 Firm-Customer Relational Issues

Participants did not trust mobile services providers, and they thought that personalized content presented by mobile services provider is “not neutral”. They considered “profit-making” to be the major objective of mobile services providers. One participant said, “I don’t know if I can ever trust a service provider because at the end all that they want is profit. Maybe if all this was supervised by the government, then there would be some sense of security”. Most participants considered that mobile services providers might bias the information. One participant said, “I am mainly concerned if the
personalized information I receive is actually neutral and not biased by the advertiser”. Another said, “I think that some advertisers make things that you don’t like sound like things that you do like.” This aligns with the findings that perceived “honesty” of services is crucial (Priester and Petty 1995).

One participant pointed out some tricks played by mobile service providers. He said, “when I’m at home, I use the free SMS service from a website. But there are some dodgy ones that keep sending you advertisements once you sign up with them. And to stop the advertisements, you need to send them an SMS which costs you $10.” These tricks, undoubtedly, arouse the concerns of individuals. These interesting findings echo prior research (e.g. Komiak et al. 2005; Komiak and Benbasat 2006) who emphasized the role of trust in a personalization agent in B2C commerce.

Some participants suggested that a contract on how mobile service providers use customers’ data is important. This helps customers develop a trusting relationship with mobile service providers. For instance, one participant said, “Well, I guess there would be some contract which says that they wouldn’t use the information for any other purposes.” Another participant pointed out, “I think companies must sign a confidentiality contract with the customers so that customers can trust the service provider. And once the contract is signed, the customer can give all the information that the provider requires.” But a participant also suggested that customers had the responsibility to “read the terms and conditions when they sign up for a service.”

5 A SURVEY

The findings of the focus groups illustrated that individuals were concerned about their privacy. Some of them were unwilling to be profiled and tracked. This motivates us to conduct a survey to gain a better understanding of what personal data they are willing to share with mobile service providers in return for personalized mobile services.

A self-administered online survey was conducted. Apart from demographic questions, the questionnaire consisted of 26 questions referring to 26 personal information attributes. We extracted these 26 information attributes2 based on the focus group findings. Subjects were asked to assess seven aspects of information nature. For each piece of information, we provided the participants with seven statements, and asked them to evaluate each of the 26 attributes on a 7-point Likert scale (1 = strongly disagree; 7 = strongly agree). The seven statements were: (1) this information is necessary for mobile personalization; (2) this information can improve the personalization quality, (3) this information reflects the uniqueness of a customer, (4) it is necessary for mobile services providers to get an updated information from customers regularly; (5) sharing this information will increase mobile users’ risks, (6) sharing this information will infringe on customers’ privacy; and (7) customers are willing to share this information with mobile services providers. The time required to complete the whole questionnaire was 20 minutes.

We posted the survey in five online forums for three weeks. The participation was voluntary and anonymous. We received 81 responses. There were 46 females and 35 males. Their average age was 29. We calculated the average score for each aspect of each personal information attribute. With the average score, we conducted a multi-dimensional scale (MDS) plot (Figure 2).

---

2 The 26 attributes are name, nickname, age, gender, date of birth, monthly salary, current location, preferred spoken/written language, preferences for food, preferences for music, previous purchases, home address, home activities, working address, working time, professional field, countries you plan to travel to, hobby, identity document details, financial details, income, leisure time, best friend’s name, best friends’ dates of birth, family members’ names, and family members’ dates of birth.
We arrived at a 2-dimensional plot. By analyzing the attribute pattern, dimension 1 (i.e. x-axis) referred to the importance of the attributes. For instance, hobby (d) and previous purchases (h) were found to be important attributes for mobile personalization. Family members’ names (m), the best friend’s name (l) and working time (k) were found to be less important in the personalization process. The x-axis dimension gives insights to mobile services providers on what questions they should ask their customer to collect rich and useful information for personalization.

Dimension 2 (i.e. y-axis) referred to the inverse of risk and privacy concerns. Sharing users’ attributes, such as education background (c) and preference for food (v), with mobile services providers were found to be less “risky”. There was a higher concern if users were asked to share information such as current location (f) and family members’ names (m). The y-axis dimension tells mobile services providers that mobile customers may be hesitated to answer some questions from the providers.

The interesting part is the top-right quadrant. Attributes falling into this quadrant are useful for personalization, but users tend not to answer questions on these attributes because of privacy concerns. Mobile services providers can explore personalization methods, e.g. collaborative filtering or data mining, to draw an inference on these attributes, rather than to ask users directly.

6 DISCUSSION

While prior research has shown that personalization is effective in influencing users’ information processing in the Internet, our understanding of its effectiveness in m-commerce is far from conclusive. This research aims to bridge the gap between the potential growth of mobile personalization and the lack of understanding of mobile users’ expectations. No prior IS research, of which the investigators are aware, examines this issue. This research conducts focus groups with mobile users, and our results can also provide implications to firms on how to leverage mobile personalized services to improve their service quality, resulting in higher customer satisfaction.

First, it is a pioneering effort to examine the location dimension in personalization research. Personalization of IT services intends to provide the right content in the right format to the right person at the right time in the right location. Recent research on personalization has focused on content personalization (e.g. Tam and Ho 2006) and adaptive interfaces (e.g. Billsus et al. 2002). Little work has been done on the location dimension. Since the success of personalization in m-commerce hinges on an understanding of the context of interaction which is location sensitive, it is imperative to understand whether individuals are willing to share location-related information with mobile services providers and what potential location-based personalized services can be offered. Together these dimensions (user preferences, content, layout, and location) capture many of the functionalities of
personalization and user characteristics at a particular instant. This represents a formal characterization of the notion of personalization.

Second, while personalization has been shown to be effective in influencing user behavior, its use should be balanced by taking a proactive approach to protecting data privacy on the user side. Our findings provide a better picture of users’ privacy concerns. Prior IS work (e.g., Awad and Krishnan 2006; Chellappa and Sin 2005) confirmed that users are concerned about their privacy being compromised by the personalization process. However, there is little information which mobile users are willing or unwilling to share with the services providers. Our work fills the gap by identifying 26 pieces of information that mobile users are concerned about. We conducted a survey and asked mobile users to comment on these 26 pieces of information. With an MDS plot, we identified some patterns. Mobile services providers should ensure fair access to individuals’ personally identifiable information and should provide a mechanism for users to change inaccurate or unauthorized personal information conveniently and quickly. Acceptable criteria for “opt-in” and “opt-out” should be provided as consumer privacy options. Our MDS plots provide insights for mobile services providers on mobile users’ focus of the mechanism implementation.

7 CONCLUSION

The role of personalization in m-commerce is gaining significance. Conducting focus groups with mobile users allowed us to gain a deeper understanding of their expectations and concerns for personalized mobile services. On one hand, users look for accurate, high-quality personalized services. On the other hand, users are concerned about security, privacy and spam. Based on the focus groups results, we conducted a survey and asked mobile users which personal information they are willing to share with mobile services providers. Our results provide mobile services providers with valuable knowledge on how to strike a balance between effectively leveraging location-detection features and easing users’ privacy concerns.

Abstract

The aim of this research is to determine and evaluate whether differences in national culture impact on the buyer behaviour of Thai and British consumers when purchasing a mobile phone. Furthermore, the research was conducted in order to identify and compare key cultural attributes that influence mobile phone purchasing between Thai and British consumers. An empirical study was based on the concept of Hofstede’s dimension of Individualism /Collectivism and Power Distance and Schwartz’s values dimension of Power, Achievement, Hedonism and Self-Direction. The data was collected from 140 questionnaires using students at the University of Surrey. The findings indicated that there is a significant difference between Thai and British consumers in terms of mobile phone purchasing behaviour as far as Hofstede’s cultural dimensions and Schwartz’s cultural values are concerned. The findings also recommend that managers in mobile phone organizations should be concerned with the cultural dynamics of consumers as part of their ongoing re-segmentation, communication and promotion strategies within their overall marketing strategies. Additionally, the cultural factors will assist managers to guide the specifications required for the development of online customer decision support systems.

Keywords: Impact of Culture, Mobile Phone, Culture

1 INTRODUCTION AND BACKGROUND

Mobile phones have become an integral part of human daily life and personal communication across the globe. By the end of 2007, there were approximately 3.3 billion mobile phone users worldwide which is equivalent to a penetration rate of 49% of the last year (International Telecommunication Union, 2008). Thailand and the UK were chosen for this research for several reasons. According to the Ministry of Information and Communication Technology (2008), the mobile phone penetration rate in Thailand increased its growth rate to over 50% in 2006 in comparison to 35% in 2005. In the UK, Ofcom (2007) reported that the mobile phone market grew by 41.3% between 2003 and 2007. Within this competitive market, it is essential for mobile phone companies to better understand purchasing behaviour to enable them to acquire new customers and retain existing ones. Blackwell et al., (2001) demonstrated that culture has a profound influence on ‘how’ and ‘why’ consumers purchase a range of products and services. Furthermore, Foxall et al., (1994) stated that the consumer’s motivation of product and service choices as well as lifestyle could be shaped by cultural dimensions. As a consequence, culture can influence an individual’s interaction with a product and ultimately the purchase. The cross – cultural comparison of mobile phone purchasing behaviour between the Thai
and UK markets will provide an insight to the overall East and West cultural divide. Therefore, it is imperative that cultural attributes need to be taken into consideration for marketing managers when investigating mobile phone purchasing behaviour.

The objectives of this research were to: (i) Determine and evaluate whether differences in national culture impact on the buyer behaviour of Thai and British consumers when purchasing a mobile phone; (ii) Identify and compare key cultural attributes that influence mobile phone purchasing between Thai and British consumers; (iii) Develop a framework for determining the cultural information requirements of a customer decision support system that will assist a marketing manager when addressing a culture sensitive market place; and (iii) Evaluate the management implications of the above objectives. In the following sections a definition and brief review of culture is presented. Secondly, Hofstede's cultural dimensions and Schwartz’s cultural values are reviewed and their relevance to the research is presented herein.

2 MOBILE PHONES

Srivastava (2005) stated that the mobile phone has shifted from being a ‘technological object’ to a key ‘social object’ as communication with others is the main purpose for mobile phone purchasing. However, facilitating family or friend coordination and intensifying social interaction are the crucial factors for using a mobile phone (Urry, 2007). According to Castells et al. (2007, p.85), “obtaining a mobile phone is a milestone that indicates success, not only financially but also culturally in term of the integration within society”. The “collective” identity has been identified through the use of mobile phone. Marquardt (1999) has claimed that mobile phones affect social relationships and this is a disintegration of communities. Mobile phone usage has resulted in greater electronic interactions between friends and family at the expense of face to face interaction which have been dramatically reduced. Consequently, it could be proposed that mobile phones are changing individual cultural norms and values (Rauch, 2005).

3 LITERATURE REVIEW

3.1 The concept of culture

There are numerous definitions of culture but for the purpose of this paper, culture is identified as the “collective mental programming” of people in an environment (Hofstede, 1980). Hall (1976) stated that culture is not genetically inherited, and cannot exist on its own, but is always shared by members of a society and is identified as a societal level construct. However, it certainly has implications for individual behaviour (Hofstede, 2001). Hofstede (1997) has also stated that culture influences an individual’s behaviour through the manifestations of values, heroes, rituals and symbols. Hence, an individual’s behavior is a result of that individual’s cultural value system for a particular context which are changed and developed over time (Luna and Gupta, 2001).

3.2 Hofstede’s Cultural Dimensions and Schwartz’s Cultural Values

The description and analysis of Hofstede’s and Schwartz’s theory are provided in this section. Hofstede (2001) stated that the cultural values research conducted by Schwartz (1994) was more appropriate to use in a cross cultural research project. However, Smith et al., (2002) argue that Hofstede’s cultural dimension remains the significant framework to apply in international research. Therefore, a study that combined Hofstede’s dimension and Schwartz’s theory was used in order to be more valid.
3.2.1 Hofstede Cultural Dimensions

In this research, the “power distance” and “individualism” dimensions are considered. As these two dimensions have been found to be valid across several other studies (Blodgett et al., 2001; Gregory and Munch 1997). Hofstede (2001) found that “individualism” and “power distance” where the two main attributes that characterized the difference between Thai and UK cultures. “High power distance” cultures (Thai) tend to be “low on individualism”, whereas “low power distance” societies (UK) tend to be “high on individualism”.

<table>

</tr>
</tbody>
</table>

*Table 1. Hofstede Cultural Dimensions*

**Power Distance**

“Power Distance” is the extent to which people accept that power is distributed unequally, and is related to conservatism and maintaining status (Yeniyurt and Townsend, 2003). In high power distance societies, the individuals are associated with acceptance of one’s positioning society (Hofstede, 1984) and a social value exists where everyone has his or her own rightful place in the society (Morsini, 1998). On the contrary, the low power distance societies are much more concerned about society values independence and competition. The powerful members seek to look less powerful and they believed that there are an equal rights and opportunities for everyone (Greg et al., 1995). The research form Hofstede (1980) has illustrated that Thai societies are considered as a “high power distance” society which is relatively high in comparison to the UK society. On the other hand, the UK is implied as “low power distance”. Thus, relative to the UK; Thai culture is more acceptable of societal inequities.

**Individualism / Collectivism**

According to Hofstede (2001), “Individualism” refers to the society where the ties between individuals are very loose. In contrast, “collectivism” is defined as a society where individuals are integrated into strong and cohesive in-groups. In individualist cultures, people tend to be motivated by their own preferences, needs and rights in order to achieve their personal goals (Lee and Kacen, 2008). On the side of “collectivist culture”, societies have a significant attitude toward building long-term relationships and the role of trust. Members of societies are often motivated by duties and norms of societies (Usunier, 2000). Triandis (2004) also demonstrated that collectivist societies” are more concerned with ‘interpersonal relationship’ than an individualist culture. With reference to Hofstede’s work (1980), the UK scored high in individualism which is relatively high compared to Thai society. Thus, it can be implied that the UK societies can be defined as “Individualism”, whereas Thai societies are considered as “Collectivism” ones. Hence, it is possible that customer social values and reference groups have a greater degree of influence in Thai societies than the UK society when purchasing a mobile phone and this is a point that deserves further investigation.
3.2.2 Schwartz’s Cultural Values

Schwartz’s value theory is primarily concerned with the basic values of individual recognized across culture (Schwartz, 1992). There are ten key cultural values that were defined by the motivational goal it serves namely; Power, Achievement, Hedonism, Stimulation, Self-Direction, Universalism, Benevolence, Tradition, Conformity and Security. In accordance with Lee et al., (2002) and Ros et al., (1999), a more parsimonious of Schwartz’s cultural value are employed which fit in well with the social used mobile phone (See Table 2).

3.3 Limitations of Hofstede’s Cultural Dimensions and Schwartz’s Cultural Values

There are many researchers who have argued that Hofstede’s work may not be absolutely correct (Koveo and Tang, 2008; Smith et al., 2002 and Shenkar, 2001). First of all, Hofstede’s framework has become outdated as the data is forty years old. Kirkman et al., (2006) stated that Hofstede’s dimensions fails to capture the change of culture over time in which viewed culture as “static”. Indeed, Hofstede’s theory appears to perceive time as linear and ignores the profound influence of the substantial modernization such as travel, media and technology (Usunier and Lee, 2005). Also, Hofstede’s principle assigns to be “standard theory resistance when new work on culture distinction is substantiated (Kock et al., 2008). Additionally, Yoo et al., (2002) noted that Hofstede’s model lacks individual level analysis and maintain that Hofstede’s scores were calculated by total scores of the country thus, ignoring the individual difference within cultures. Finally, Hofsteded’s theory is assumed to be homogeneous and devoid of subcultures as the data was collected using only a single organization (David et al., 2008). However, as most of the dimensions are independent, Beckmann et al (2007) argued that Hofstede’s dimensions led to useful explanations of cross-cultural differences in consumer behaviour.

Schwartz’s Cultural Values

There are significant drawbacks associated with Schwartz’s cultural values that should be considered. The first limitation is caused by the obsolete information as the data was gathered fourteen years ago (Schwartz, 1999). Secondly, Schwartz’s cultural values scale focused on the research of an initial group set of basic human values (Schwartz 1994, 1999), which ignored the fact that individual actions are complex, reflexive and contingent on the context (Burroughs and Rindfleisch, 2002) which may create value conflicts. Nevertheless, from a psychology perspective, they have been shown to be valid and sufficient (Marcus and Baumgartner, 2004).

3.4 Buyer Behaviour Factors

Research conducted by Kimberly et al., (1995) using the Hofstede theory, indicated that cultural differences are seen as especially important for consumers’ choice of products and services. Roth (1995) discovered that the services that place emphasis on variety and hedonistic experiences can
generate value to an individualist society. Also, Strabub et al., (1997) found that high power distance and collectivist societies would reject the communication media which do not support the social pressures. According to Heine and Lehman (1997), self concept of independent corresponds to the cultural concept of individualism, whereby people express themselves as inherently separate and distinct. Conversely, the cultural concept of collectivism is related with the interdependent self concept which concerned on contextual, relational, and socially situated. Further, Lee and Kacen (2008) discovered that subjective cultures tend to influence the buying intention of consumers. The study from Choi and Geistfeld (2004) showed that functionality design, feature images and brand images are highly positive correlated with cultural characteristics of the users. Whilst, Page (2005) stated that promotional appeals have played an important role for international business practice.

4 HYPOTHESIZED MODEL

The main variables have been identified and are presented as a hypothesized model in Figure 1. The research has investigated the strong correlation between cultural attributes and buyer behaviour attributes.

![Hypothesized Model of the main variables of cultural attributes & buyer behaviour](image)

Figure 1. Hypothesized Model of the main variables of cultural attributes & buyer behaviour

5 RESEARCH METHODOLOGY

In order to achieve the objectives, the hypothesis formulation, data collection method, sampling method, sample size, the questionnaire design, pilot study, reliability and validity are presented below.

5.1 Hypothesis Formulation

Based on the research objectives and literature review, the hypotheses are stated below:

H a: There is no difference between Thai and British consumers when purchasing a mobile phone.

H b: There is no difference in Hofstede’s cultural dimension of Individualism /Collectivism between Thai and British consumers.

H c. There is no difference in Hofstede’s cultural dimension of power distance between Thai and British consumers.

H d: There is no difference between Thai and British consumers in term of Schwartz value.”(Power, Achievement, Hedonism and Self-direction)

H e. There is no relationship between Hofstede’s dimension and mobile phone choice criteria.

H f. There is no relationship between Schwartz value and mobile phone choice criteria.
### 5.2 Data Collection

A self-administered questionnaire was used to obtain the primary data and consisted of 11 questions divided into four sections. The objectives of the four sections were to: (i) collect demographic data and the mobile phone purchasing experience; (ii) identify whether Schwartz’s cultural values (Power, Achievement, Hedonism and Self-direction) had an impact on Thai and British consumers; (iii) examine to which extent values of “Individualism and Collectivism” and “Power Distance” influence Thai and British consumers; and (iii) identify the mobile phone buying decision factors and its relationship with cultural attributes.

A non-probability sampling method by using quota sampling was conducted in this research. The sampling units were both male and female students who had mobile phones. As students are the social economic groups and future business people, plus professional, therefore these students were representative for the population of British and Thai people. The sample frame for this research was the University of Surrey in UK. The questionnaires were measured on a five-point Likert Scale in accordance with cross cultural research conducted by Richardson and Smith (2007). In their research, the five-point Likert scales are adopted to examine the cultural constructs; high and low context, power distance and the media choice behaviour of two nationalities. Hence, the five point likert scale was suitable for this study. For the “Individualism/Collectivism” and “Power Distance” measurement, a score of less than 3 indicated that the respondent could be classified as “Individualist” and “High Power Distance”. Conversely, scores more than 3 illustrated that respondents could be classified as “Collectivism” and “Low Power Distance”.

### 5.3 Pilot Study

In order to determine the reliability of the research, a pilot study was undertaken to minimize the research error by testing the reliability of questionnaire. A pilot study was conducted for two weeks amongst 16 students at the University of Surrey. The variables used to develop the questionnaire are drawn from figure 1. The reliability of this research was measured using the Crobach alpha coefficient which indicates the level of inter-item consistency. The consistency alphas met the acceptable rate which was 0.723; thus, the scale used for this study is considered to be reliable. On the scale validity, the standard deviation (26.161) of the population was used to calculate the sample size by the formula: \( N = \frac{(z*SD)^2}{(E)^2} \) where \( N \) represents the minimum sample size, \( Z \) is the degree of confidence required, \( SD \) is the standard deviation of population and \( E \) represents the range of error around the sample estimate acceptable. Using the formula, the sample size was calculated using a 95% confidence interval which \( Z \) value equals 1.96, within plus or minus 5% of the population mean. Hence, the minimum sample size should be: \( N = (1.96 * 26.161)^2 / 86.6250*0.05)^2 = 140 \). Therefore, a minimum of 140 questionnaires should be issued in order to achieve reliability. The questionnaire was distributed to Thai students (70 sets) and for British (70 sets) students in the University of Surrey. After checking and collecting the final data, Independents- samples t test and Pearson Correlation Test were employed to further analyse the data.

### 6 ANALYSIS OF THE RESEARCH FINDINGS

The results of the first four hypotheses are shown in the following tables.

#### 6.1 Hypothesis Testing - Independent Sample-test

Proceedings ECIS 2009
Hypothesis Ha aimed to test whether differences in national culture impact on consumer buyer behaviour. The results indicated that “Buying Intention”, “Social Acceptance”, “Service”, “Brand Image”, “Promotion” and “Product Quality” show significant differences between Thai and British consumers (Sig.values <0.05). Thus, the null hypothesis is rejected; there is a significant difference between Thai and British consumers for these six variables. Table 3 shows that “Product Quality” and “Feature / Appearance Image” are the important elements for British consumers. However, the “Product Quality” “Promotion” and “Brand Image” are found as the important variables for the Thai consumers. Hypothesis Hb HC and Hd are aimed at testing whether any differences exist between Thai and British consumers in terms of Hofstede cultural dimensions and Schwartz’s cultural values.

<td>Status</td>
<td>3.69</td>
</tr>
</tbody>
</table>

Table 4. Independent Sample t –test of Hypothesis Hb and Hc

The findings of Hypothesis Hb indicated that there is a difference between Thai and British consumers for five questions “Being accepted”, “Reference Group Influence”, “Family / Friend Discuss”, and “Increases Interaction” (Sig.values<0.05). Referring to the mean values (Table 4); there are some results that go against the assumption of Hofstede that Thais tend to be a collectivist culture. The calculated mean in the questions “Reference Group Influence” (2.9) and “Group Opinion” (2.7) indicates that Thai consumers responded as an “individualist society”. Conversely, Hofstede predicted that the British consumer is a “high individualism” one. The calculated means shows that the question of “Increase Interaction” has high scores (3.69). As the full statement of the question is “mobile phone has increased the frequency of interactions with family and friends. Hence, it is logic to explain that mobile phones tend to activate the collectivist attribute. For the Hypothesis Hc, the Sig. values for the four questions “Impress other people”, “Successful”, “Present Arguments” and “Status” are less than 0.05. Thus, the null hypothesis is rejected; there is a significant difference in the mean scores between Thai and British consumers.

Hypothesis Hd

<td>0.002*</td>
</tr>
</tbody>
</table>
Table 5. Independent Sample t-test of Hypothesis of Hypothesis Hd

As shown in Table 5, in the three elements: “Power”, “Achievement” and “Self Direction”, the mean values of Thai respondents was greater than that of British ones. The Sig.-values of three variables: “Power”, “Achievement” and “Self –Direction” was less than 0.05. Therefore, the null hypothesis is rejected, implying a difference in Schwartz values in terms of Power, Achievement and Self-direction between Thai and British consumers. The results of hypotheses He and Hf are shown in the following tables.

6.2 Hypothesis Testing - Pearson Correlation Test

<table>
<thead>
<tr>
<th>Hypothesis He</th>

<tr>
<td>Promotion</td>
<td>0.633 Social Acceptance</td>
<td>0.306 Feature Image</td>
</tr>
</tbody>
</table>

Table 6. Pearson Correlation Test of Mobile Phone Buying Decision factors that were highly positive correlated with cultural attributes of Individualism and Power Distance * (R= Pearson Correlation )

With reference to Table 6, all three variables: “Social Acceptance”, “Buying Intention” and “Promotion” are strongly correlated with the cultural attributes of “Individualism”. As the correlation coefficient R = 0.733, 0.725 and 0.633. Furthermore, there is a strong correlation with the cultural elements of “Power distance” which was observed through the “Service” and “Social Acceptance”, the correlation coefficient was r = 0.936 and 0.602, these outcomes demonstrate a strong relationship between two continuous variables. Thus, Thai consumers are extremely influenced by their culture in these four purchase decision factors. For British consumers, the results (Table 6) show that there is a strong relationship between “Promotions” and the cultural dimension of “Individualism” in which the correlation (r) was scored at 0.694. Moreover; there is a medium relationship between the “Social Acceptance”, “Brand Image”, “Product Quality” and “Power Distance” cultural dimension. Hence, it can be assumed that British consumers are more likely to be influenced by their cultural element in these four criteria.

<table>
<thead>
<tr>
<th>Hypothesis Hf</th>
<th>Thai Respondents</th>
<th>British Respondents</th>

</tr>
<tr>
<td>Feature/Appearance Image</td>
<td>0.535</td>
<td>Buying Intention</td>
</tr>
<tr>
<td>Social Acceptance</td>
<td>0.51</td>
<td>Price</td>
</tr>
</tbody>
</table>
The findings have indicated that Thai’s have strong correlation scores amongst “Feature/Appearance Image –Hedonism” and “Social Acceptance –Power”. Thus, Schwartz’s cultural values of “Hedonism” and “Power” are more influenced in these two buying decision variables. For British consumers, the strong correlation exists where the correlation is between “Buying Intention- Self-Direction” and “Price –Hedonism”. Hence British consumer’s cultural values in the Schwarz dimension are highly influenced by “Buying intention” and “Price”.

In this section, Consumer decision factors and cultural impact framework developed for the marketing of mobile phones in Thailand and the UK

Two frameworks were developed for marketing mobile phones in Thailand and the UK in relation to consumer decision factors and cultural impacts of consumers of these two cultures. Figure 2 is a diagrammatic representation of the results and findings that illustrate the key consumer decision factors and cultural attributes that influence Thai consumers when purchasing mobile phones. This framework (figure 2) can assist marketing managers dealing with Thailand’s mobile phone market. The findings also indicate that the “collectivism” cultural dimension is strongly correlated with “social acceptance”, “promotion” and “buying intention” variables (this is indicated by the + + + symbol on the diagram). Also, the strong correlation with “power distance” cultural dimension was observed through the “service” and “social acceptance” criterion. Furthermore, a strong correlation exists between “hedonism-feature/appearance image” and “power –social acceptance”. Thus, “collectivism”, “power distance”, “power” and “hedonism” represents important cultural attributes. The most important dimension has been found to be “collectivism” as this cultural element influences three variables (social acceptance, promotion and buying intention). Similarity, the results indicate that “social acceptance” factor is mainly influenced by “collectivism”, “power distance” and “hedonism” cultural elements of Thai consumers. Hence, managers have to be aware of “collectivism”, “power distance”, “power” and “hedonism” cultural dimension when dealing with Thai consumers purchasing mobile phones, especially “social acceptance”, “promotion”, “service”, “buying intention” and “feature/appearance image factors.

Figure 3 is a diagrammatic representation of the results and findings for UK consumers and indicates that “individualism”, “hedonism” and “self-direction” are the major important cultural attributes that influence mobile phone purchasing. The framework (Figure 3) shows that a strong correlation exists

---

| Brand Image | 0.484 | Product Quality | 0.433 |

*Table 7. Pearson Correlation Test of Mobile phone factors that were highly positive correlated with cultural attributes (Schwartz’s Cultural Values) * (R= Pearson Correlation)*

---
amongst “individualism -promotion”, “hedonism- price”, “self-direction – buying intention” and this is indicated by the + + + symbol on the diagram. Marketers should therefore consider the “individualism /collectivism”, “hedonism” and “self-direction” cultural dimensions carefully because they have a high impact on British consumers. Further, marketers need to take “promotion”, “price” and “buying intention” factors into consideration for British consumers alongside their cultural attributes.

7 CONCLUSIONS

The primary purpose of this research was to determine and evaluate whether differences in national culture impact on the buyer behaviour of Thai and British consumers when purchasing a mobile phone. By addressing the Hofstede’s cultural dimensions and Schwartz’s cultural values with respect to mobile phone buying decision factors, the findings indicate that there is a significant difference between Thai and British consumers. From the findings, “promotion” is the important element for both Thai and British nationalities as the results showed high correlation with the cultural attributes of “collectivism” and “individualism”. For Thai consumers, it is important to note that “social acceptance” acts as the main buying decision factor alongside their cultural attributes. The most important cultural dimension has been found to be “collectivism” as this cultural element influences three variables (See Figure 2). In contrast, a strong correlation occurred between “buying Intention- self-direction” and “price – hedonism” with British consumers. Furthermore, “individualism” is found as the one of the cultural values that has a high degree of influence of mobile phone’s price criterion (See figure 3). This knowledge may then be exploited for the development of a culturally informed customer interface design.

The implications of the findings are valuable for mobile phone marketing managers to understand better the cultural attributes of consumer behaviour when purchasing mobile phones. From the findings, it shown that Thai consumers purchase a mobile phone which enables them to have social connection and relates them to their peer groups. Indeed, Thai consumers are likely to be sensitive to the influence of their group orientation and reference groups such as families and friends. Triandis, (2004) stated that the concern of interpersonal relationships tends to be in collectivist societies rather than in individualist ones. Hence, it is advisable that promotion and communication strategies should send ‘collective’ messages which are group-oriented based and appeal to families. Conversely, British customers have a greater degree of influence and are a more individualist oriented culture as opposed to the Thai culture. According to Roth (1995), services that place emphasis on variety and hedonistic experiences are suitable in a high individualist culture. Thus, it is recommended that mobile phone companies offer a variety of mobile phones that can be personalized to the individual customer. Additionally, the research has shown that not all Thai’s behave as “collectivism” and not all British consumers are characterized as “individualists”. The model developed by Hofstede’s (1984), viewed culture as static, however the contribution that study provides is that culture is dynamic and can be interchangeable over time. An individual’s behaviour could be influenced and dominated by the dynamics of culture, technology, and in particular mobile phones. Therefore, it is recommended that marketing managers address these cultural dynamics as part of their ongoing re-segmentation, communication and promotion strategies.

An understanding of the different cultural dimensions on buyer behaviours will assist managers in the management of customer decision support systems. The findings of the research have shown how culture can inform the design and functions of the information system in order to create a more effective customer decision support system. Hence, managers should be able to tailor online communications and the design of the system to target the customer more effectively, which in turn will lead to improved customer relationship management (CRM). An appreciation of the cultural factors will provide managers with insights into how to develop marketing information systems, especially the promotional and communication strategies. In addition the results of the study suggests that collective messages which are group-based should be targeted towards the Thai culture, whereas
the individualist oriented messages such as personalized messages are more appropriate to the UK culture. The research instrument and analytical tools employed in this research will help marketing managers to track culture changes in their chosen markets. Moreover, managers can use the frameworks developed in Figure 2 and Figure 3 to guide what information features should be included and emphasized in order to create an effective decision support system that takes culture into account and accommodates cultural differences within an international setting.

MODELLING USE CONTINUANCE IN VIRTUAL WORLDS:
THE CASE OF SECOND LIFE

Abstract

There are now many virtual worlds in existence, a number of which have built considerable user bases. However, there is little empirical evidence to suggest what factors underpin their continued usage and success. This study set about determining why users continue to use virtual worlds, using the example of the popular virtual world of Second Life. The study adopts continuance theory and extensions to the basic model to examine the effects of enjoyment, habit and absorption. The results (n=339) suggest that continuance intention is driven by perceived usefulness, habit, absorption and enjoyment, which together provide a comprehensive explanation for virtual world behaviour ($R^2=0.565$). Interestingly, satisfaction did not appear to play a direct strong role in determining intentions. The paper rounds off with conclusions and implications for future research and practice in this very new area of inquiry.

Keywords: virtual world; continuance; enjoyment; absorption; habit; Second Life.
1 INTRODUCTION

The notion of a ‘virtual world’ is a relatively novel phenomenon that emerged from the juxtaposition of recent advancements in computer graphics, online gaming and social networking technologies. A ‘virtual world’ may be defined as “an electronic environment that visually mimics complex physical spaces, where people can interact with each other and with virtual objects, and where people are represented by animated characters” (Bainbridge 2007, p. 472). Such ideas were, until relatively recently, restricted to rather crude graphical representations and enabled limited interactivity. However, virtual worlds have become very sophisticated and increasingly realistic – often integrating advanced 3-D rendering, in-world currencies, avatar and object customization and development, property ownership and permissions, text and voice communication, and social networking tools – and the number of virtual worlds has increased dramatically in the last five years. Gartner (2007) predict that 80 per cent of active Internet users will be members of at least one virtual world by 2012.

If we restrict our discussion to virtual worlds that are not purely massively multiplayer online games (Barnes & Mattsson 2008), i.e. they have a freeform element, then there were around 70 virtual worlds in existence or under development as of the third quarter of 2008 (KZero 2008a). 23 worlds aimed at the under 10s (the largest being Poptropica with 20 million users and Barbie Girls with 15 million), 14 aimed at the pre-teens (the largest being Habbo with 100 million users, Neopets with 45 million and Club Penguin with 19 million users), 14 aimed at the groups from 13 to 20 (including Stardoll with 21 million users, IMVU with 20 million users and Gaia with 15 million users), and 21 aimed at the over 20s (the largest being Second Life with 15 million users). Some of these are centred around a specific brand (e.g. Neopets, Stardolls, Disney Fairies, Virtual MTV, Barbie World, Fusion Fall (Cartoon Network), Hello Kitty, Club PonyPals and Lego Universe) while others are more general (e.g., Second Life, Multiverse, Active Worlds, There, Qwaq and Kaneva). Further, they vary considerably in their content focus (KZero 2008b), including content creation (Second Life, Active Worlds, HiFiHi and Multiverse), Socializing/chat (Utherverse, There and IMVU), fashion/lifestyle (Frenzoo, Stardoll and GoSupermodel), education (Whyville, Medikidz and Jumpstart), music and media (vMTV, Onverse and vSide) and sports (Football Superstars, Empire of Sports and Sportsblox).

The combined population of users of the virtual worlds discussed above is well in excess of 300 million. The virtual goods sector is estimated at more than $1.5 billion per annum (Wu 2007). Second Life, the best known and broadest virtual world platform, has grown rapidly from 2 million residents in January 2006 to nearly 15 million residents in August 2008 (Second Life 2008a). In August 2008, there were nearly 20 million transactions and more than US$338 million were spent in the year to June 2008 (Second Life 2008b). Residents owned 1.714 million square meters of land and the million or so residents that logged in July 2008 spent 34.7 million hours in Second Life, nearly nine times that of July 2006 (Second Life 2008c). Evidence suggests that there is a high level of continued usage of virtual worlds such as Second Life.

Academic research into virtual worlds is still at a very early stage. With the massive recent growth in virtual worlds and their users and the very high sustained level of usage of these virtual worlds, we were very interested to find out why this might me the case. Thus, the research question for this study was: “Why do users continue their usage of virtual worlds?” As a basis for the research, we use continuance theory and three related theories that are likely to drive continuance: habit (Limayem et al., 2007), absorption or ‘persistent flow’ (Csikszentmihalyi 1990, Schaufeli et al. 2002) and enjoyment (van der Heijden 2003). As the context for the investigation, we focus on the largest and best-known of the freeform adult virtual worlds, Second Life.

The structure of this paper is as follows. In the next section we examine the theoretical development of a model of continuance in virtual worlds. The third section describes the methodology used in the study. Section four presents the results of the study. In the final section, the paper rounds off with a discussion, limitations, implications for research and practice, and conclusions.
2 THEORY AND RESEARCH MODEL

In this section we pull together the various strands of theoretical literature that we use to create our research model. In particular, we examine the salient literature on the concepts of use continuance, enjoyment, habit and absorption. Each of these is now examined in turn.

2.1 Continuance theory

The roots of continuance theory, as applied to information systems research, are from the marketing literature. Expectation-confirmation theory (ECT) emerged from the consumer behaviour and services marketing literature and has proven broadly robust in a number of service contexts (Dabholkar et al. 2000, Oliver 1993). The general thrust of ECT is the assessment of post-purchase intentions, as influenced by initial expectations about a product or service, subsequent adoption and use (consumption) and the formation of perceptions about performance as influenced by the confirmation or not of initial expectations, the latter determining the level of satisfaction with a purchase and subsequent repurchase or use discontinuance. Bhattacherjee (2001) was the first to fully formalize the theory into an ex-post framework that could be applied to the domain of information systems, adapting the theory to be applied post-acceptance and to encapsulate perceived usefulness (Davis et al. 1989, Davis 1993) as a replacement construct for expectations. Perceived usefulness has consistently proven to be an important construct in longitudinal adoption to post-adoption behaviour (Davis et al. 1989, Karahanna et al. 1999). Thus Bhattacherjee’s (2001) model relates the constructs of perceived usefulness and satisfaction to the extent of confirmation of a user’s expectations about an IS, whereby expectations that are fulfilled drive greater satisfaction and perceived usefulness. High levels of perceived usefulness are also posited to lead to greater satisfaction with a system. In turn, the outcome variable of continuance intention is determined by the level of satisfaction with an IS and the perceived usefulness of the system.

Bhattacherjee’s model has been successfully applied to individual user contexts involving the Web, such as online banking, and the Internet more broadly (Bhattacherjee 2001, Limayem et al. 2007). Virtual worlds are also distributed systems reliant on Internet technology, and the focus of this study is on individual users; Bhattacherjee’s theory (which appears to have broader application and generalization in any case) is adopted as a suitable core for a model examining continuance behaviour in this context.

2.2 Enjoyment

The applications of virtual worlds for organizations are potentially very broad, including product branding, promotional events, product development and testing, collaboration, process rehearsal and simulation, employee recruitment, education and training, commerce, and communication. However, at the individual user or consumer level, which is the focus for this study, virtual worlds can be construed as hedonistic systems where users experience pleasure or fun when using the system. Such uses may include, for example, socializing, romantic encounters, shopping for desirable personal items, customizing one’s personal appearance, playing games, fantasy, the creation of an alter-ego (Hemp 2006) and other experiences that may for example contribute to building self-esteem, social bonding and self-actualization. To have a pleasurable experience, individuals often seek sensations on multiple sensory channels (van der Heijden 2003), and clearly virtual worlds are equipped to provide such multimedia experiences by design.

Unfortunately, the IS continuance theory described above is built primarily on the utilitarian paradigm of providing instrumental value to the user. The consumer behaviour literature has determined strong support for repurchase and use intentions driven by both utilitarian and hedonic value in products or services (Bauer et al. 2005). Recently, the extension of this hedonic value conceptualization, hereinafter referred to as enjoyment, to the user acceptance of hedonic information systems has been...
formalized and empirically tested by van der Heijden (2003). Early research in virtual worlds has also confirmed the relationship between enjoyment and behavioural intention (Wu et al. 2008). This study adopts this theoretical development and the related theoretical relationship between enjoyment and intention to continue using a hedonic information system (as clearly implied, although not longitudinally tested in van der Heijden’s study). Further, in the spirit of the expectation-confirmation theory, as discussed above, the inclusion of a hedonic construct (enjoyment) as well as a utilitarian one (perceived usefulness) has clear implications for the fulfilment of expectations. Here, we theorize that hedonic value expectations are manifested or not in the same way as utilitarian ones. Thus, a user will hold expectations about the hedonic value of a system, in other words its perceived enjoyment, which will be confirmed or not by the adoption and use of the system, thereby triggering an evaluative response in the form of satisfaction.

2.3 Habit

Previous research has found that use continuance in information systems and other contexts can be predicted by the extent to which a behaviour has become automatic because of prior learning – typically conceptualized as habit (Limayem et al. 2007). Research has variously examined habit as a moderator between intention and actual behaviour, as a direct effect on actual behaviour, and as an indirect effect on behaviour that primarily determines intentions. Our focus in this research is on use intentions rather than actual behaviour, and so naturally we focus on that latter of these formulations. Our focus on intentions is in line with a core body of previous IS literature (Legris et al. 2003), whilst the focus on indirect habit effects is a view that is held in a number of previous studies that have examined the effects of habit (and the much used proxy construct of experience) on behavioural intentions (Legris et al. 2003).

In addition to the effect of habit on intention to continue using an IS, we also posit that habit is significantly influenced by satisfaction. Limayem et al. (2007) in their comprehensive definition, application and analysis of the habit construct in continuance theory find very strong support for the linkage between satisfaction and habit. Further, they find that frequency of prior usage has a positive association with habit, an assertion that we also make for the purposes of model development.

The creation of habit requires a stable context conducive to its formation through repetition or practice (Orbell et al. 2001); we would hold that such a context exists when focusing on individuals’ behaviour with respect to a single system such as a virtual world. This position is in line with that of Limayem et al. (2007) in their study of habitual use of the Internet.

2.4 Absorption

Csikszentmihalyi (1990) examines experiences that are ends in themselves and are not tied to external considerations: within such experiences, an individual is caught up in the “flow” of an activity and subsequently absorbed into it (Wang & Calder 2006). This work emphasizes the role of pleasure and enjoyment in the flow experience. Indeed, Hoffman and Novak (1996) describe flow as an intrinsically enjoyable state, which others have found to be strongly related to feelings of pleasure and arousal (Csikzentmihalyi 1990, Wang et al. 2007). Further, flow theory suggests that users absorbed in a flow experience may tend to lose behavioural control and get locked into patterns of greater usage and habitual behaviour (Csikzentmihalyi 1990). Turning to the use context in this study, previous work on flow in the context of Internet use and online gaming has found a significant relationship between flow and use intentions (Hsu & Lu 2004).

Flow is purported to be a multidimensional construct that has variously been defined in terms of concepts such as concentration, control, challenge, attention focus, curiosity, enjoyment and intrinsic interest (Webster et al. 1993, Wang et al. 2007). However, the concept of flow has some issues worthy of note. As Schaufeli et al. (2002, p. 75) suggest: “… [flow is a] complex concept that includes many aspects and refers to rather particular, short-term ‘peak’ experiences instead of a more pervasive and
persistent state of mind, as is the case with engagement.” Since our aim is to measure more persistent states of mind that influence intentions to continue use of an information system it would seem logical to focus on the concept of engagement rather than traditional flow, or more particularly the dimension of engagement that represents persistent flow states – that of absorption. As Schaufeli et al. (2002) state in their application of the absorption construct to the work context:

... absorption is characterized by being fully concentrated and deeply engrossed in one’s work, whereby time passes quickly and one has difficulties with detaching oneself from work. Being fully absorbed in one’s work comes close to what has been called ‘flow’, a state of optimal experience that is characterized by focused attention, clear mind, mind and body unison, effortless concentration, complete control, loss of self-consciousness, distortion of time, and intrinsic enjoyment … (p. 75)

From a theory perspective, we posit that an individual’s intention to continue using a virtual world will be driven by the level of absorption, or persistent flow, experienced in the media environment. In turn, absorption will be determined both by the level of enjoyment experienced in the virtual world and the level of habitual behaviour that has been established.

The theoretical developments above were combined with the basic IS continuance model for the basis of this study. Together these theories provide an extension to the typically utilitarian approach of continuance theory, which may be limited in its application, to capture broader elements related to hedonistic use (enjoyment), automatic behaviour (habit) and persistent ‘flow’ (absorption), all of which are likely to impact on the use of virtual worlds. The full research model tested in the research is provided in Figure 1.

3 STUDY DESIGN AND METHOD

The sections below describe in detail the data collection process, the measurements used, and the type of data analysis executed.

3.1 Data Collection

We chose the context of Second Life since it is the largest virtual world for the adult age group and the most well-known of the freeform virtual world environments. Evidence also suggests that it is the virtual world platform with the broadest user base and range of applications (KZero 2008c).
Data collection involved the use of two traffic ‘bots’ in Second Life operating at busy traffic points. Each bot is essentially an avatar automated to deliver a survey advertisement and a URL in text form in-world. Each bot had an advertisement for the survey in its group name, above the avatar. Details of the survey were also provided in the profile of the avatar and respondents were requested to IM (instant message) the bot. Respondents initiate contact and are given details of the survey and the URL to begin the survey. The survey was provided using QuestionPro. To collect sufficient responses, each bot was placed at a high-traffic location selected from Second Life’s ‘popular locations’ list. The locations were chosen to be as generic as possible (to appeal to both genders, different ages and nationalities) and each focused on providing both free and paid-for digital content and on generating traffic through paid ‘camping’ activities (where individuals are paid small amounts of money for time spent ‘sitting’ at a particular location).

A monetary incentive (of L$250 or approx. $0.95) was provided to respondents for each completed survey. A non-conditional incentive was used, since there is evidence that this is likely to improve response rates in social science research over conditional incentives such as a prize draw (Church 1993). Further, evidence suggests that incentives do not necessarily bias sample composition or data quality (Brennan 1992) and are more likely to attract harder to reach groups, by providing motivation (Groves et al. 2000). There is no guidance on the recommended value of incentives for virtual world surveys, but we felt that L$250 was favourable compared to market research surveys delivered through Second Life by HippiePay and other companies. This is much smaller in monetary terms than the typical $10-$20 provided in other modes of social science research (Simmons & Wilmot 2004). The survey ran for approximately six months. After filtering for duplicates and invalid responses we had a total of 339 survey responses.

3.2 Measurement

All of the constructs and scale items used in the research were adopted from previously validated sources. The core of the model and measures for confirmation, perceived usefulness, satisfaction, continuance intention, habit and frequency of prior usage are adapted or adopted from Bhattacherjee (2001) and Limayem et al. (2007). The semantic differential measure for enjoyment employed in the instrument is that of van der Heijden (2003). Finally, the measure for absorption is taken from the engagement inventory of Schaufeli et al. (2002).

3.3 Data Analysis

Data analysis was performed using a variance maximization approach to structural equation modelling (SEM) and associated statistics for validity and reliability. More specifically, we used the partial least squares (PLS) technique with reflective indicators in Smart-PLS 2.0 (Ringle et al. 2005). The PLS technique has become increasingly popular in information systems research, marketing and in management research more generally in the last decade or so, influenced by its flexibility; indeed, PLS does not have the same distributional assumptions of normality for data, is able to handle small- to medium-sized samples (Chin 1998).

4 RESULTS

4.1 Respondent Characteristics

Of the 339 responses, approximately three-fifths were male (58.4%). The median age was 25-34 years, with only a third of the sample being 35 years or over. The average use experience was between one and three months, with around two-thirds using the virtual world for less than six months. However,
actual usage was high amongst the sample, with a median usage of between 4 and 10 hours per week, over five or six sessions per week.

4.2 Tests for Validity and Reliability of the Measures

Table 1 examines convergent validity – the extent to which theoretical scale items are empirically related. The loadings of the measures on their respective constructs in the model range from 0.756 to 0.946, with all being significant at the 0.1% level. Further, all of the constructs fulfill the recommended levels with reference to composite reliability (CR) and average variance extracted (AVE); as shown in Table 1, all items were higher than the cut-off of 0.50 recommended by Fornell and Larcker (1981). All the values of AVE are considered acceptable, ranging from 0.672 to 0.865. Similarly, the values of composite reliability are very good, ranging from 0.892 to 0.962, well above the reliability values of 0.70 and 0.80 that are typically advised for building strong measurement constructs (Nunnally 1978, Straub & Carlson 1989).

Table 2 examines discriminant validity – the extent to which question items measure the construct intended or other related constructs. A standard test for discriminant validity was used whereby the square root of average variance extracted for each construct is compared with the correlations between it and other constructs; discriminant validity is demonstrated if the square root is higher than the correlations. Table 2 clearly indicates that each construct shares greater variance with its own measurement items that with other constructs with different measurement items, with a good margin.
of difference, the closest margin being 0.122. To further confirm the discriminant validity of the scale items used in testing the research model we utilized the cross-loading method of Chin (1998); the method prescribes a requirement for measurement items to load higher on a construct than the scale items for other constructs and for no cross-loading to occur. Item loadings in the relevant construct columns were all higher than the loadings of items designed to measure other constructs; similarly, when glancing across the rows the item loadings are considerably higher for their corresponding constructs than for others.

Table 2. Correlations between constructs (diagonal elements are square roots of the average variance extracted).

Overall, these tests for validity and reliability provide us with a high degree of confidence in the scale items used in testing our research model.

4.3 Test of the Research Model

Figure 2 presents the results of PLS path modelling (Centroid Weighting Scheme) in Smart-PLS (Ringle et al. 2005). The shaded items are those that have been added to Bhattacharjee’s (2001) basic continuance model. A power analysis in G*Power 3.0 (Faul et al. 2007) shows that the sample (n=339) is sufficient for explaining even small population effects ($f^2 \geq 0.044; \alpha=0.05; \beta=0.2$) in our model, with a power of 1.000 for moderate population effects ($f^2=0.15$).

![Figure 2. Results of PLS analysis.](image-url)
The data supports all relationships in the model except two – the linkages between perceived usefulness and satisfaction and between satisfaction and continuance intention. Interestingly, these are core relationships in the basic continuance model. Not surprisingly, confirmation strongly influences and contributes to explaining perceived usefulness ($p<0.001$, $R^2=0.481$). Confirmation also strongly relates to enjoyment, with modest explanatory power ($p<0.001$, $R^2=0.207$), whilst confirmation and enjoyment together strongly influence satisfaction ($p<0.001$ and $p<0.01$ respectively) and explain a rather substantial 45.7 percent of variance.

Habit in our model appears to be significantly determined by satisfaction and the frequency of prior usage behaviour (both $p<0.001$ in our model); these two variables together explain a healthy 33.1 percent of variance in habit. Absorption has strong relationships with habit ($p<0.001$) and enjoyment ($p<0.01$), which together contribute to explaining a very considerable level of variance (50.4 percent).

Overall, the research model explains a very considerable level of variance in continuance intention – 56.5 percent. Four determinants contribute to explaining behavioural intention, specifically, in order of the strength of their relationships: perceived usefulness ($p<0.001$), habit ($p<0.001$), absorption ($p<0.01$) and enjoyment ($p<0.05$). In sum, users build their behavioural intentions to continue to use the virtual world of Second Life based on utilitarian assessment of value (perceived usefulness), hedonistic assessment of value (enjoyment), chronic disposition (habit) and via the persistent “flow” of the virtual world experience within which users are absorbed.

**DISCUSSION AND CONCLUSIONS**

This study has tested an extended continuance model in the context of virtual worlds, or more specifically, in the context of the virtual world of Second Life. The tested research model combines the ex post continuance intention model of Bhattacherjee (2001) with additional constructs for habit (Limayem et al. 2007), enjoyment (van der Heijden 2003) and absorption (Schaufeli et al. 2002), that are each posited to play an important role in continued virtual world usage. Using a sample of 339 respondents collected in Second Life we find strong support for the validity and reliability of all constructs. Furthermore, the model is tested using PLS and four of the determinants of continuance intention are clearly supported in the model (perceived usefulness, habit, absorption and enjoyment), along with all of the extended relationships proposed. However, although aspects of the expectation-confirmation theory are supported, including the extension to include hedonic value (enjoyment), the traditional link from utilitarian value (perceived usefulness) to satisfaction is not supported by the data. Similarly, the link from satisfaction to continuance intention is also not supported – only a linkage that is mediated by habit. This would appear to suggest that the standard continuance model is not supported in this context, and that a construct such as enjoyment (which bears some similarity to satisfaction) may be more suitable as a measure of the confirmed value derived from virtual world adoption and use than that of satisfaction per se. Users of the virtual world do not continue their use based directly on whether they are ‘satisfied’, but rather on an assessment of hedonic value and of utilitarian value, and based on established patterns of automatic behaviour and the chronic disposition to be absorbed in system use. Indeed satisfaction is mediated by habit in its path to continuance intention. Satisfaction appears to be a term more suited to non-hedonic product or service evaluation and is rather telling of the context from which it is derived – services marketing. Users of virtual worlds may be too bound up in the experience and the use of the system to be able to detach themselves and make an objective assessment of how satisfied they are or not with the virtual world within which they are habitually absorbed and use this as the basis for further usage decisions.

The nature of virtual worlds is clearly quite different to other product or service contexts within which ECT marketing theory is generally applied. The closest group of products/services would appear to be online gaming; although virtual worlds such as Second Life are not strictly games there is striking similarity to other hedonic systems such as online games and this is a domain that is likely to help in informing practice. Users of virtual worlds clearly place an emphasis on hedonic and utilitarian value derived, and these are areas within which developers can contribute to the success of virtual worlds.
Other aspects, such as habit and absorption, are dispositions of the individual and are not directly controllable; however, they can be manipulated indirectly through the design of the virtual world. Enjoyable experiences that leave users wanting more contribute to building habitual behaviour. Similarly, enjoyable experiences in realistic virtual worlds and compelling human-computer interaction can help to build persistent flow experiences and a chronic disposition where individuals find it hard to discontinue use of system – perhaps even an addictive behaviour, as has been shown for computer gaming environments.

Utilitarian value, as represented by perceived usefulness in our study, can be enhanced by creating additional instrumental value for users. Such value is created by providing additional functionality and content to virtual worlds that is clearly of benefit to residents and that will ultimately be used. This could include, for example: tools for communication, collaboration and social networking; tools for entrepreneurial or commercial endeavours; utilities for customization and creation of objects and other content; tools for the development of simulated environments; systems for establishing and managing a presence in a virtual world and in relation to the operator of the world; educational and training-oriented systems; other productivity tools; and content that appeals to the typical goals of individuals using the virtual world.

Hedonic value, as discussed by van der Heijden (2003, p. 696), can be enhanced by “the inclusion of hedonic content, animated images, a focus on colours, sounds, and aesthetically appealing visual layouts.” Within the context of Second Life this means creating ever more realistic and visually appealing 3-D rendered environments, with strong visual appeal and integration of quality audio; Second Life has continued to work in this space, including, for example, more realistic representations of sky and water – originally trailed through the WindLight test version but now built into the standard client. The key is providing emotional content including images, objects and sounds that stimulate the user, provoke a response and assist in creating an absorptive experience. The provision of emotional content should be dynamic and changing, rather than static, creating a compelling reason for users to return to the virtual world and contributing to the creation of a persistent absorptive effect on the user.

Our research is limited to the extent that we have focused solely on the virtual world of Second Life. Other virtual worlds differ according to aspects such as the payment model, gaming model, sectoral customer focus and technical design. Notwithstanding, the constructs used in our model would appear generic and robust enough to be applicable in a wide variety of combinations of these virtual worlds. It is possible that the expectation-confirmation model may reveal different results – in particular a link from perceived usefulness to satisfaction to continuance intention in different virtual worlds. Given the nature of Second Life, this is perhaps unlikely and we might expect Second Life to behave more as a barometer for other virtual worlds, many of which are only beginning to establish a presence and build a customer base. Future research should aim to test the model in further virtual world environments in order to confirm this assumption.

A further limitation of our research model is the absence of demographic and other factors, such as age, gender, geographical location, experience with Second Life, use intensity, personality and so on. Although demographic and use data were captured in the study, there was not appropriate scope in this paper to examine their direct or moderating effects in a research model. For example, we are likely to have a heterogeneous sample of a global nature; capturing and analyzing information on the sample may help to understand the behaviour of different groups of global consumers. New PLS techniques such as finite mixture analysis (FIMIX) may prove to be very useful in this regard, providing a means of respondent group segmentation and analysis (Ringle et al., in press). Further, since virtual worlds have elements of hedonic and utilitarian value and can be used for many purposes (including social and work purposes, for example) it would be useful to delve deeper into the specific purposes of usage and whether these have an impact on continuance behaviour in future studies.

This paper represents an early attempt to understand behaviour in virtual worlds from an information systems perspective. There is much to learn in this new environment and IS theory needs to develop further to assess virtual world behaviour. Virtual worlds different to standard domains of theoretical
application in technology acceptance of IS which, although they may exhibit intrinsic elements, tend to be largely extrinsic in use motivation, such as individual use of organizational systems, e-commerce systems and the Internet, mobile technology, and so on. Hedonic systems and related theory are underrepresented in the overall IS acceptance literature, which is unfortunate given the hedonistic nature of the system under investigation here. Virtual worlds appear too complex to be the focus of one discipline alone. This is an issue of concern for future research, which should look towards a multidisciplinary approach towards understanding hedonistic IS such as virtual worlds; in such an approach disciplines such as psychology, human-computer interaction and consumer behaviour are likely to play important roles.

Abstract

Web 2.0 is now an important internet application because of the integration of social interaction and web technologies. Previous information system studies usually specified their research context as a utilitarian system or hedonic system and the results were concluded within one specific system type. Web 2.0 application provides a flexible environment for different kinds of user motivations that can be used for utilitarian or hedonic purpose. This study extended the Technology Acceptance Model (TAM) by introducing a moderating factor into the model, in order to study users’ behavioral intentions in a Web 2.0 environment. We designed two task types of user motivation and conducted our experiment on two Web 2.0 websites. According to the PLS (Partial Least Squares) analysis, this study demonstrated that utilitarian and hedonic purposes had a moderating effect on the relationship between perceived belief and user attitude as well as the relationship between perceived information quality and perceived belief in the Web 2.0 application. The relationship between perceived usefulness and attitude was stronger in the utilitarian user motivation; whereas the relationship between perceived ease of use and attitude was stronger when the user had hedonic motivation to use the Web 2.0 application. We also found that perceived information quality had significant impact on the perceived usefulness and perceived ease of use.

Keywords: moderating effect, utilitarian/hedonic user motivation, perceived web quality, technology acceptance model (TAM), web 2.0 application
1 INTRODUCTION

With the rapid development of internet technology, numerous web applications have become available to internet users over the past decade. Web 2.0 is one innovative web application that provides an environment for human social interaction as well as information sharing. Based on the core spirit of Web 2.0: ‘participation’, many kinds of applications such as blogs (i.e. Weblogs), folksonomies, wikis, etc., have emerged to satisfy various user needs. The user studies related to Web 2.0 application have grown quickly during these years. However, most of them only choose one specific type of Web 2.0 applications and seldom discuss the user motivation influences while they use the Web 2.0 application (Hsu & Lin 2008). For this reason, this study chooses two types of Web 2.0 applications and designs two types of user motivations to examine the user behavior in Web 2.0 applications.

The Technology Acceptance Model (TAM) is widely recognized within the information system (IS) research field as a useful model for exploring user attitude and intention toward an information system. Many studies have included other factors into TAM (such as: subjective norm, output quality, intrinsic/extrinsic motivation, etc.) to provide different perspectives as well as to enhance the explanatory power of user behaviour (Davis et al. 1992, Jarvenpaa & Todd 1997, Venkatesh 2000, Venkatesh & Davis 2000, Shang et al. 2005). Other studies have explored the effect of the moderating factor on user acceptance of information system (e.g. experience, voluntariness, etc.) (Castañeda et al. 2007, Jarvenpaa & Todd 1997). The user motivations studies in the IS field usually viewed user motivations as determinants of user perceived belief, and divided user motivations into intrinsic and extrinsic motivation. In many studies, the TAM model was applied to the internet environment in order to examine the user acceptance of internet applications (Jarvenpaa & Todd 1997, Moon & Kim 2001, Shang et al. 2005). Related researches also considered other important factors in internet application, to enhance the explanatory power related to user behavior (Jarvenpaa & Todd 1997, Dishaw & Strong 1999, Venkatesh & Davis 2000, Shang et al. 2005, Hsu & Lin 2008). For example, the user’s perception of web quality is now recognized as a factor that influences the user’s perceived belief regarding the internet application (Lin & Lu 2000, Liu & Arnett 2000, Moon & Kim 2001, Cao et al. 2005, Éthier et al. 2006). In the internet environment, a user might use one web application for utilitarian or hedonic purpose and these goals might moderate the user’s acceptance of these applications (Childers et al. 2001). Web 2.0 applications have a special characteristic that can be used for utilitarian or hedonic motivation, providing the possible extension to explore user motivation from a different perspective. Our research model, based on TAM, will include the perceived web quality factor to explore the moderating influence of utilitarian/hedonic user motivations in Web 2.0 application.

In this paper, we propose a model that combines the perceived web quality factor with the TAM model to examine the moderating effect of utilitarian/hedonic user motivations on the user acceptance of Web 2.0 application. We designed four experimental tasks based on two user motivations (i.e., utilitarian and
hedonic motivation) and two web 2.0 applications (i.e., video share and blog websites) for participants to collect self-report questionnaire data. This study used SmartPLS 2.0 to analyze the experimental data and provided some implications for the development of the Web 2.0 application.

2 RESEARCH MODEL AND HYPOTHESES

The moderating role of utilitarian/hedonic user motivations in the context of the Web 2.0 application has never been studied thus far. Our model, based on TAM, assumes that utilitarian/hedonic user motivations will moderate the relationship between users’ perceived belief and attitude, as well as the relationship between users’ perceived web quality and perceived belief. Figure 1 shows our proposed model. The following parts will describe the hypotheses.

![Figure 1. Theoretical Model](image)

### 2.1 Technology Acceptance Model (TAM)

The Technology Acceptance Model (TAM) proposed by Davis (1989) attempted to explain and predict user acceptance of IS and posited that user acceptance can be determined by user behavioral intention. The intention is determined by user attitude and the user’s perceived usefulness regarding the IS. User attitude is determined by two salient beliefs: perceived usefulness (PU) and perceived ease of use (PEOU). Furthermore, perceived ease of use is a determinant of perceived usefulness. These relationships in TAM have been examined in many related studies (Davis 1989, Venkatesh & Davis 1996, Venkatesh & Davis 2000). TAM is now widely used to predict the acceptance of new technology applications, such as new information systems, new web applications, and mobile services, etc (Lin & Lu 2000, Cao et al. 2005, Ahn et al. 2007, Hsu & Lin 2008). Many scholars extended the TAM model by introducing more variables to enhance the explanatory power of TAM (Dishaw & Strong 1999, Venkatesh & Davis 2000, Shang et al. 2005, Ahn et al. 2007). The purpose of this study is to extend...
TAM model by including perceived web quality as the determinants of perceived belief, and examine
the moderating role of utilitarian/hedonic user motivations, and consequently, we only revalidated the
original relationships in TAM model in the Web 2.0 application. These hypotheses are:

H1: Perceived ease of use has a positive effect on perceived usefulness in the Web 2.0 applications.

H2: Perceived ease of use has a positive effect on user attitude in the Web 2.0 applications.

H3: Perceived usefulness has a positive effect on user attitude in the Web 2.0 applications.

H4: User attitude has a positive effect on user behavioral intention in the Web 2.0 applications.

H5: Perceived usefulness has a positive effect on user behavioral intention in the Web 2.0 applications.

2.2 Perceived web quality

Delone and Mclean (1992) proposed a model using information and system quality to evaluate the
success of an information system. Information quality captures the users’ perceived value of the output
produced by a system and can be measured by information accuracy, relevance, timeliness, and
completeness etc (Negash et al. 2003, Éthier et al. 2006). System quality is a measure of the
functionality of a system including: usability, availability, reliability, and response time, etc (Delone &
Mclean 1992, Negash et al. 2003, Cao et al. 2005). A service quality component was added to enhance
customer service settings in later studies (Kettinger & Lee 1994, Pitt & Watson & Kavan 1995).
Service quality measures how well the delivered service matched the customer expectations (Cao et al.
2005, Ahn et al. 2007). In recent years, many researches have explored the perceived web quality
impact on user acceptance in the context of web applications (Cao et al. 2005, Éthier et al. 2006, Ahn et
al. 2007). Most of them categorized perceived web quality into: information, system, and service
quality; they showed that perceived web quality had a positive impact on perceived belief (Lin & Lu
focuses on the moderating effect of utilitarian/hedonic user motivations on user behavior by conducting
four experiments. We will not examine the service quality component of perceived web quality. The
perceived web quality impact on user perceived belief will be examined with the following hypotheses:

H6a: Perceived information quality has a positive effect on perceived usefulness (PU) in regard to Web
2.0 applications.

H6b: Perceived information quality has a positive effect on perceived ease of use (PEOU) in regard to
Web 2.0 applications.

H7a: Perceived system quality has a positive effect on perceived usefulness (PU) in regard to Web 2.0
applications.

H7b: Perceived system quality has a positive effect on perceived ease of use (PEOU) in regard to Web
2.0 applications.
2.3 Utilitarian/Hedonic user motivations

Many traditional information system studies are under the research context of utilitarian system type. Some scholars have argued that the results of IS user behavior studies might differ when the system types are different. Van der Heijden (2004), for instance, validated the technology acceptance model from the hedonic system perspective. The distinction of hedonic/utilitarian systems is derived from the utilitarian and hedonic products concept of consumer behavior literature (Hirschman & Holbrook 1982, Holbrook & Hirschman 1982, Van der Heijden 2004). The consumer behavior studies showed that the utilitarian or hedonic nature of the product determined the intention to consume (Babin et al. 1994). Some studies in the marketing field also find that the utilitarian or hedonic shopping purposes influence consumer shopping behavior (Chitturi et al. 2008, Kim & Shim 2002).

In the IS field, much research has explored the impact of user motivations on user behavioral intention by defining user motivations as intrinsic or extrinsic (Davis et al. 1992, Venkatesh 2000). Beyond the traditional IS research, user motivations are also discussed in the context of internet application. Some studies defined two types (i.e., specific task and general task) of motivation to observe user search behavior (Kim & Allen 2002, Kim 2008). Other studies examined the user online shopping behavior and included the utilitarian/hedonic motivation factors of consumer consumption behavior that are widely used in the marketing field (Childers et al. 2001). Our study adopted the utilitarian/hedonic perspective that the Web 2.0 application could satisfy users with both utilitarian and hedonic purposes; therefore, this study designed the experimental tasks from just such a perspective. We assumed that the determining strength of perceived usefulness (PU) and perceived ease of use (PEOU) on user attitude would be different when the user had a different motivation. We also proposed that the strength of the relationship between perceived web quality and perceived belief will differ according to the utilitarian/hedonic user motivations. The moderating effect of user motivations on user attitude will be examined with the following hypotheses:

H8: The relationship between perceived ease of use and perceived usefulness is stronger in hedonic motivation than in utilitarian motivation.

H9: The relationship between perceived ease of use and user attitude is stronger in hedonic motivation than in utilitarian motivation.

H10: The relationship between perceived usefulness and user attitude is stronger in utilitarian motivation than in hedonic motivation.

H11a: The relationship between perceived information quality and perceived usefulness is stronger in utilitarian motivation than in hedonic motivation.

H11b: The relationship between perceived information quality and perceived ease of use is stronger in hedonic motivation than in utilitarian motivation.
H12a: The relationship between perceived system quality and perceived usefulness is stronger in utilitarian motivation than in hedonic motivation.

H12b: The relationship between perceived system quality and perceived ease of use is stronger in hedonic motivation than in utilitarian motivation.

3 RESEARCH METHOD

3.1 Research variables

There are three kinds of research variables in this study: (1) TAM related factors, (2) perceived web quality, and (3) utilitarian/hedonic user motivations. The TAM related measures (i.e., user behavioral intention, attitude, perceived usefulness, and perceived ease of use) were adapted from the original TAM and the updated TAM model, TAM2 (Davis 1989, Venkatesh 2000). The measure items of perceived web quality (i.e., information quality and system quality) were derived from prior studies that had been widely validated in related studies (Cao et al. 2005, Éthier et al. 2006, Ahn et al. 2007). The wordings of these measure items were slightly modified to fit the Web 2.0 application environment. A seven-point Likert type scale was adopted with anchors ranging from strongly disagree (1) to strongly agree (7). As for the utilitarian/hedonic user motivation, it was the control variable that we assigned with different types of experimental tasks to the participants of this research.

3.2 Experiment design

To examine the moderating role of user motivation, this study designed two types of experimental tasks: (1) utilitarian user motivation, and (2) hedonic user motivation. This study defines the utilitarian task as finding the information that the participants want to know related to their work tasks or school courses. On the other hand, the hedonic task is defined as finding the information in which the participants are interested in their own life, for example hobbies, leisure activities, etc. The participants were asked to define two subjects regarding the experimental task type that they are assigned and search information that they wanted to obtain in the Web 2.0 application. This study chose two Web 2.0 websites for the experimental environment setting. The first is a worldwide video share website (called Website A in the following parts), which allows users to easily upload and share video clips across the internet through websites, mobile devices, blogs, and email. The second is a famous blog website (called Website B in the following parts), which provides an easy way for general internet users to publish material of any topic that they choose to share or discuss. This blog website also provides functions to share photos, pictures, and videos etc. With the combination of the two user motivations and the two Web 2.0 websites, four types of experimental tasks emerge. The experiments were conducted in computer laboratories with twenty minutes allowed for each task. The participants were
randomly divided into four groups and were asked to complete the online questionnaire immediately after finishing their experimental tasks.

3.3 Data collection

Data were gathered from students registered in eight business courses in the business school at a university in Taiwan. Of the 408 questionnaires collected, 366 completed and valid surveys were received. According to the four types of experimental task, 102 valid responses were obtained from the utilitarian task experiment and 92 valid responses were collected from the hedonic task experiment in Website A. 88 valid responses were obtained from the utilitarian task experiment and 84 valid responses were collected from the hedonic task experiment in Website B. Among the usable respondents, 71.6% were part-time students who had weekday jobs and 49.7% were male. 48.1% of the participants were between 18 and 25 years of age. Participants in this research frequently used internet applications with which they connected to the internet on average more than three hours each day. 76.8% of the participants had more than six years of internet experience.

4 DATA ANALYSIS AND RESULTS

Partial least squares (PLS) was applied to test our research model using SmartPLS 2.0. PLS is appropriate for exploratory research because it is more prediction-oriented than other structural equation modelling tools (Éthier et al. 2006). Data analysis proceeded in two stages (Anderson & Gerbing 1988). First, the measurement model was evaluated using confirmatory factor analysis (CFA) to validate the reliability and validity of the constructs. Next, the structural model was estimated using hypotheses testing to test the significance of the path coefficients. Our research model was evaluated with three groups of sample data: (1) the sub-sample of the utilitarian experimental task, (2) the sub-sample of the hedonic experimental task, and (3) the full sample.

4.1 Measurement model

The adequacy of our measurement model was evaluated on the criteria of composite reliability, convergent validity, and discriminant validity. Table 1 shows the analysis results of our measurement model. The composite reliability values ranged from .909 to .970, well above the suggested criteria of .7 (Fornell & Larcker 1981), indicating a commonly acceptable level for confirmatory research. Convergent validity was assessed by the average variance extracted (AVE) for each construct, which should exceed the variance due to measurement error for that construct. The AVE of each construct ranged from .590 to .924, exceeding the acceptable value of 0.5 (Fornell & Larcker 1981). Discriminant validity examines the uniqueness degree of item measures in defining a construct (Gefen 2003). The satisfactory discriminant validity is achieved when the square root of AVE for each construct exceeds all correlations between that and other constructs (Fornell & Larcker 1981). As shown in Table 1, our
evaluation of discriminant validity was acceptable. The analysis result in this stage showed that the measurements in our study were reliable and valid.

Table 1. Reliabilities, Convergent validity, and Discriminant Validity

Notes: a: PIQ is “perceived information quality”; PSQ is “perceived system quality”; PU is “perceived usefulness”; PEOU is “perceived ease of use”. b: CR is “composite reliability”. c: Diagonal elements in the “correlation of constructs” matrix are the square root of the average variance extracted.

4.2 Structural model

To test the hypotheses, the bootstrapping technique was used to produce the t-value and test the significance of the path coefficients. The results of hypotheses testing are presented in Table 2.

- TAM related hypotheses were all confirmed (H1, H2, H3, H4, and H5). With the exception of the positive relationship between perceived usefulness and user intention (H5) could not be found in utilitarian user motivation.
The positive relationship between perceived information quality and the user perceived belief were all supported (H6a and H6b).

H7a was not supported, which meant that the perceived system quality did not have a positive effect on perceived usefulness. On the other hand, H7b was supported, which meant that the perceived system quality had a positive effect on perceived ease of use.

H8, H9, and H10 proposed that the relationship strength between perceived belief and user attitude will different when users has different motivations. They were all supported. The relationships between perceived ease of use and perceived usefulness and user attitude were stronger in hedonic motivation (.538, .220) than in utilitarian motivation (.290, .164). However, the relationship between perceived usefulness and user attitude was stronger in utilitarian motivation (.682) than in hedonic motivation (.559).

H11a and H11b examined the relationship strength between perceived information quality and perceived belief. Only H11a was supported: the perceived information quality had a stronger relationship with perceived usefulness in utilitarian motivation (.509) than in hedonic motivation (.287). H11b was not supported: the relationship between perceived information quality and perceived ease of use had no obvious difference (.395 versus .332).

H12a and H12b examined the relationship strength between perceived system quality and perceived belief. They were all rejected. According to the original hypothesis, H7a was rejected: the perceived system quality had no significant effect on perceived ease of use. H12a was supposed not to be supported.

Proceedings ECIS 2009
5 DISCUSSION AND CONCLUSION

The purpose of our study was to extend the TAM model by including the perceived web quality component and examine the moderating impact of user motivations on user behavior in the Web 2.0 application. We demonstrated that perceived web quality (i.e., information quality and system quality) affected the perceived belief (i.e., PEOU and PU) of users, with the exception that perceived system quality did not have significant impact on perceived usefulness, which meant that users care about information quality more than system quality. It provides a practical implication for service providers. When designing applications, service providers should think about how to well organize, store, and share user provided information to strengthen attraction to their provided services.

The results showed that utilitarian and hedonic motivations had a moderating impact on the relationship between perceived belief and user attitude as well as on the relationship between perceived information quality and perceived belief in the Web 2.0 application. An interesting finding was that the relationship between perceived usefulness and user attitude was stronger in the utilitarian user motivation. On the contrary, the relationships between perceived ease of use and user attitude and behavioral intention were stronger when the user had hedonic motivation. From the practical perspective, the developers and designers of Web 2.0 application should clearly define what type of values they want to provide to their users. For example, if service providers want to attract more utilitarian-oriented users or provide their users with more utilitarian-oriented values, they should devote greater efforts to determining which design of their services can strengthen the users’ perception of the usefulness of those services. Furthermore, the user motivation only affected the relationship between perceived information quality and perceived usefulness, which was stronger in utilitarian user motivation. Therefore, the service providers should endeavor to ensure the information quality of their services, especially when they aim to provide utilitarian value to their users.

TAM related hypotheses were all supported, with the exception of the H5, which meant that perceived usefulness did not have a direct relationship with user intention in utilitarian motivation. The result showed that the path coefficient between user attitude and user intention was greater in utilitarian motivation (.650 versus .590). It might imply that the relationship between perceived usefulness and user intention in utilitarian motivation is indirect and also mediated by user attitude. This phenomenon still needs further exploration in future research.

This study has some limitations that provide some opportunities for future research. First, Web 2.0 applications are not limited to these two types we chose for conducting experiment. Further research needs to include more kinds of Web 2.0 applications to reach a more general research conclusion. Second, though most participants had weekday jobs, still 28.4% of the sample was full-time university students. The data collection in future research has to recruit participants from various backgrounds to avoid sampling bias.

Abstract

Ratings are important for building up trust among different parties. Since the arrival of the internet era in the 1990s, countless online rating systems have emerged. For example, Amazon.com established a rating system for books and other products in 1995. Today online rating can be found everywhere, be it e-commerce sites, social networks, and information or recommendation platforms. In most cases, users provide the input to these systems which is then aggregated and directed to appropriate recipients. The increasing relevance of these rating systems forms a new distinct research field with a growing need for research on the design, effects, and validity of rating systems. Hence, we contribute to the body of knowledge by conducting a thorough analysis of the state of the art of online rating systems. We especially focus on the functional design options by analyzing 102 different systems with the help of a criteria catalog of 237 criteria. In this paper, we discuss an excerpt of our findings and present a morphological box that categorizes functional design options for online rating systems.

Keywords: E-Commerce, Reputation, Web 2.0, User Participation.
1 INTRODUCTION

Ratings are important to people, especially for building up trust among business partners. The traditional offline rating systems have always been and still are word of mouth and gossip (Cheung & Luo & Sia & Chen 2007, Dellarocas 2001). Nevertheless, since the internet era begun in the 1990s, new online rating systems emerged. As some of the first, Armstrong and Hagel III (1995) dealt with these systems and they found out that customers fall back on advices and recommendations of other customers when executing online transactions. Moreover, they discovered that online rating systems can even be a means to improve customer retention (Armstrong & Hagel III 1995). Being one of the rather progressive in this field, Amazon.com has enabled its users to rate books and other products since 1995. Many other online stores have also included rating systems on their websites and even pure rating web-portals have emerged; e.g. Epinions.com was launched in 1999 which – according to the Alexa Rating – is the most popular web-portal for reviews on products and services today. All this contributes to make electronic shopping a social experience because of an intensive sharing of recommendations and reviews (Vossen & Hagemann 2007).

The advantage of online – in contrast to offline – ratings is scalability and formalization (Bolton & Katok & Ockenfels 2004, Dellarocas 2003). Scalability means that ratings can be gathered from and communicated to a multitude of parties, independent from time and place (Resnick & Kuwabara & Zeckhauser & Friedman 2000). Users can access a huge number of ratings provided by other users in an easy and cost-efficient manner (Cheung et al. 2007). According to Töpfer, Silbermann and William (2008) especially the fast diffusion of up-to-date rating information is a main advantage (Conte & Paolucci 2002, Töpfer et al. 2008). Through unification of gathering, aggregation and presentation ratings become more comprehensible and their acceptance increases (Resnick & Zeckhauser 2001).

In fact, the main field of application of online rating systems is e-commerce which has gained increasing importance over the last two decades (Kapell 2007, Sebralla 2008). Nevertheless, one key problem of online transactions is the lack of trust among business partners. Users of online shops often have problems in estimating the quality and reliability of offers and their counterparts (Ward & Lee 1999). To address this issue, rating and reputation systems have become an integral part of many e-commerce sites and are especially supposed to facilitate the identification of trustworthy business partners. For instance, each transaction at Ebay.com is expected to be rated by the involved users in order to build up their rating profiles which are accessible to any other registered user. Analyses have shown that there is an impact of the seller’s rating profile on the likeliness of a successful transaction as well as the achieved selling price (Armstrong & Hagel III 1995, Sebralla 2008).

Nevertheless, rating systems can also be found apart from e-commerce, e.g. in social networks that people use to manage their connections to other people. A typical example of a social network used for business purposes is LinkedIn, where users can write recommendations for colleagues, business partners or professional service providers. Similar to a traditional job reference, recommendations refer to their work and are listed in their profiles. Even more rating systems are found on non-business network sites like MySpace.com, Facebook.com or Skyrock.com where people are able to rate e.g. user profiles or videos.

The increasing relevance and spread of rating systems forms a new distinct research field. According to Peters and Reitzenstein (2008), there is an increasing need to do research on the forms, effects and validity of rating systems. For instance, relevant questions are how to aggregate rating input and represent valid rating results as well as the effects on (business) partner selection or trust building. So far, there is a lack of studies on the functional design of differing rating systems although it is the design of rating systems that determines the effect of their results to a large extent. In this paper, we will analyze the state of the art of existing rating systems and derive a consolidated set of design options which are discussed in respect to their influence on the entire rating system.
The remainder of this paper is structured as follows. The next section will provide a brief theoretical background on online rating systems. Thereafter, we will present the research method we applied for our state-of-the-art analysis. Then, we will describe excerpts from our results which we will subsequently discuss in order to provide a consolidated morphological box of design options. We will conclude with explaining the limitations of our study and providing an outlook on further research.

2 THEORETICAL BACKGROUND

The basic idea of online rating systems is to let users rate entities by means of web applications and hence to collect, aggregate and distribute reviews on entities (Resnick et al. 2000). The aggregated ratings about a given party or entity can be used to derive a score, e.g. a trust or reputation score, which is communicated to other parties. These scores can assist these parties in deciding whether or not to transact with certain other parties in future (Josang & Roslan & Boyd 2007). Typically, rating systems have a central authority that collects ratings and disseminates the rating results/scores.

The terms rating, review and reputation are closely linked. “Reputation is what is generally said or believed about a person’s or thing’s character or standing.” (Josang et al. 2007) It can be considered as a collective measure that is based on the reviews or ratings from members in a community. Web applications that gather reviews or ratings in order to compute and communicate reputation scores are called rating systems or reputation systems which we regard as synonyms throughout this paper. However, recommender systems must not be confused with reputation or rating systems. Recommender systems generate individualized recommendations to guide users in a personalized way by applying collaborative filtering or similar (Burke 2002); e.g. Amazon.com’s “Customers Who Bought This Item Also Bought” application. Rating systems can rather be described as collaborative sanctioning systems because they are based on the assumption that all users in a community should judge the performance or quality of an entity (e.g. transaction partner, product, information or multimedia contents). The aim is to sanction poor entities and to give an incentive for improvement (Josang et al. 2007).

A rating itself can be understood as a certain believe to which degree the rated entity is useful for a given objective (Miceli & Castelfranchi 2000). The criteria for this rating are usually determined by the objective whereas the entity determines the values that are assigned to each criteria (Schuler 2004). The appraisal usually happens subjectively and depends on the skills and experiences of the party that rates the entity. Obviously, a rating is only a single opinion which also refers to a specific situation and time (Sabater-Mir & Paolucci 2007). Furthermore, as an empirical analysis showed, users tend to rate positively and avoid negative statements (Resnick & Zeckhauser 2001).

The use of online rating systems requires an adequate design of the underlying mechanisms. According to Chen, Hogg and Wozny (2004), one of the main decisions refers to the gathering of information. Operators of such systems must determine which users are allowed to rate which entities. Especially, deliberate manipulations by single users must be avoided (Dellarocas 2003). To respect user privacy, users should have to opt-in before being subject of ratings (Ziegler 2008).

3 RESEARCH METHOD

Our main research objective was the analysis of the diverse functional designs of online rating systems leading to a consolidated set of design options. The visual design was not in scope of our analysis. Our research process included the following six steps:

- Selection of websites to be analyzed
- Identification of rating systems that are part of the online service
- Iterative design of the criteria catalog
- Appraisal of the online services according to the criteria
- Analysis of the appraisal data
- Consolidation of criteria into a morphological box of design options.
Selection of websites to be analyzed

Our initial literature review did not reveal any reference study that has analyzed rating systems in respect to their functional design. Consequently, we needed to decide on an appropriate sample of websites to be analyzed. The selection of the sample was supposed to be transparent and objective with enough rating mechanisms needed for a thorough analysis.

To meet these requirements, we selected the Top50 websites of the Alexa Traffic Ranking (April 2008; see Table 1). This popular ranking is basically derived from users that have added the Alexa Toolbar to their Browser. Although the traffic ranking is only an approximation, it provides a suitable means for the identification of the most popular websites. Due to adult contents and contents limited to languages apart from German or English, we excluded thirteen websites from the initial sample.

Identification of rating systems that are part of the online service

Having selected the sample, the next step was to identify the rating systems on these websites. We had to consider that the Alexa Top50 includes portals like e.g. Yahoo.com which offer a huge range of separate online services. To avoid accessing every single page of such portals, we restricted our search to services that were linked on the home pages. Some services provided further sub-services which we also only included into our search when linked at the service home page. Where possible, we did at least one rating at each system and analyzed several ranked entities. Altogether, we identified 102 rating systems by searching the online services.

Iterative design of the criteria catalog

In order to gather the characteristics of each rating system systematically and to allow for comparisons, we iteratively elaborated a list of 237 criteria. The criteria are mainly related to functional aspects of rating systems but also cover the environment in which they are embedded. Lacking an existing list of criteria for this particular purpose, we started to derive relevant criteria by a literature review. We continuously extended the criteria catalog in the course of analyzing the broad range of existing online rating systems. We designed each criterion in a binary manner, i.e. a system either possesses the characteristic or it does not.
Appraisal of the online presences according to the criteria

We applied the list of criteria to each rating system and assigned the matching values. In some cases it was not possible to determine if a system possesses a certain characteristic. Therefore, we also assigned ‘not applicable’, and ‘not testable’. A criteria is ‘not applicable’ if its prerequisites are not met, i.e. it is not possible to edit a review comment when the system just allows to rate an item. ‘Not testable’ was assigned when we could not determine the value without doubt, e.g. because of missing documentation.

Analysis of the appraisal data and consolidation of the criteria

Due to page restrictions we can only present exemplary excerpts of our appraisal results in the following section. We already ordered these excerpts according to the key dimensions of the morphological box we will present in section 5. The morphological box (Zwicky 1969) was developed through a critical discussion of the long list of criteria and cross consistency assessments by all authors in order to aggregate and structure the appraisal results (Bailey 1994).

4 ANALYSIS OF THE STATE-OF-THE-ART

The following presentation of our analysis results is structured along six key dimensions of the functional design of rating systems. The first dimension is the service provider who operates the rating system. Secondly, we identified which kinds of entities are rated. Furthermore, we had a closer look on how the rating is entered and aggregated. Finally, we analyzed the representation of the ratings as well as the incentives provided for reviewers in order to evaluate entities.

4.1 Service Providers

In our sample, the range of service providers that use rating systems is very broad. For example, we analyzed producers, retailers, review sites and broadcasters. The service provider diversity goes along with their diverging objectives. Consequently, rating systems can fulfill different functions. For our sample we were able to identify six different functions of rating systems as visualized in Table 2.

Table 2. Functions of Rating Systems

77 of our 102 investigated rating systems focused on the central entity of the service, i.e. it is possible to rate the entity that the website was actually intended for. Moreover, 12 of these 77 systems strongly depend on the rating systems to fulfill the intended website service. For example, Pixnay.bebo.com is a social community that is limited to people rating each other’s pictures.

4.2 Entity

The entity can be seen as the central element of each rating system as it determines most of the design parameters. Concerning entity types we distinguished between subjects, abstract subjects and objects (see Figure 1). Subjects are active actors, in general other users. Objects are e.g. goods or pieces of information. The concept of an abstract subject means that an object or event is rated but the aggregation is assigned to a subject. For instance, at Ebay.com buyers rate a seller through transactions made and ratings are linked to the user profile of the buyer although actually an event (transaction process) was rated. The information behind this kind of ratings is limited to the specific situation and therefore not directly transferable to other contexts and situations.
Some rating systems allow the rating of different entity types. For example, some city guide portals allow the rating of subjects (companies) and objects (points of interest). Most systems (78) offer the assessment of objects only. Ratings about products or services prevail. The object usually does not belong to the website owner (this is only the case for 11 systems) but is provided by users (29) or external third parties (48).

### 4.3 Gathering of Ratings

The gathering of ratings should be designed in a way that it allows users to enter ratings as easily as possible. However, 84 of the analyzed systems required an enrolment for the online service. About two third of these systems (62) asked for a valid email-address. At 11 systems, users had to additionally qualify for ratings, e.g. through membership (2) or through a specific member status (3; e.g. reaching a certain score at Answers.yahoo.com). In other cases (6) the accomplishment of a certain transaction is a pre-requisite for rating, e.g. at Ebay.com.

In 16 cases, the user (7 cases) or some other stakeholder is able to restrict the rating of entities. For example, at Pixnay.bebo.com a registered user is able to decide whether other users are allowed to rate his/her picture or not.

The rating entry forms of the service providers vary. Some are very detailed and therefore require a lot of input from the user. Furthermore, some allow a meta-rating such “X out of Y users found the rating very helpful”. However, most turn out to be very simple with just one or few rating options.

### 4.4 Aggregation of Ratings

93 out of 102 systems consolidate single ratings to one holistic score (see Table 3). This can be problematic as a consolidation reduces the rating information (e.g. it blurs the differences between positive and negative ratings). Some services such as ‘Karma’ at Orkut.com allow the entering of single values such as trusty, cool and sexy without consolidating the assessments. Furthermore, 8 systems display the number of ratings for each value (e.g. 17 positive, 3 neutral, and 23 negative ratings).
Table 3. Aggregation of Entities

78 rating systems compute the aggregated score as an average rating value (see Table 3). The other quarter of rating systems uses a cumulative approach such as counting of votes (12), cumulating based on scale values (5) or cumulating with subtraction of negative ratings (4) as well as relative values (1). Some websites such as Propeller.com or Epinions.com use further information for the calculation of the scores. At Propeller.com, the score is also based on comments and the number of users that have read the article. The exact calculation is not explicitly described to avoid manipulations. At Epinions.com, a score is additionally based on the number and the age of ratings.

4.5 Representation of Ratings

The representation determines the explanatory power of ratings (Sabater-Mir & Paolucci 2007) and relies on the data input (Dellarocas & Wood 2008). 89 systems work with ratings that are visible for all users (see Table 4). Of those 13 remaining, 4 are only visible for registered users and 9 rating systems require a qualification prior to accessing the ratings. In most cases (85), the total number of ratings is quoted on the profile page of the rated entity (e.g. in the user profile, product details, etc.). However, 28 rating systems use ratings for enriching search results on individual entities. 28 systems display the number of ratings for each scale values such as 17 users rated “very good”, 24 users rated “good”, etc.
The providers of 32 systems state that they approve each rating (see Table 5). E.g. Expedia.com claims to take up to 10 days for checking each evaluation. Our tests indicated that 12 out of these 32 systems did not approve the ratings but allowed an immediate visibility of our judgments. 69 systems allowed an immediate visibility of ratings without any editorial approval.

Some services provide a sorting or selection mechanisms. A good example is the filter mechanism of IMDb.org that provides extensive options for selecting movie ratings of specific rater groups (see Figure 2).

![Figure 2](image)

**Figure 2. Selection of ratings at IMDb.org**

### 4.6 Incentive Schemes

Incentive schemes can be used for encouraging users to rate specific entities. The reason behind this is the fact that a rating provides value for the consumer rather than for the evaluator. The visibility of login names or real names as an incentive to excel evaluators is only used by 51 systems (see Table 5). 26 systems allow a linkage to the individual profile page of the evaluator. 22 systems enable an aggregation of ratings within the own profile. Furthermore, a rating of evaluators and specific labels are used by a fraction of services. Only two online services, Epinions.com and Orbitz.com, offer monetary compensation for rating efforts. Refunding at Epinions.com is based on the number of users that read the rating. Orbitz.com offers coupons to each reviewer.

### 5 DISCUSSION OF RESEARCH RESULTS

Our analysis – based on 237 criteria applied to 102 different rating systems – shows a wide variety of characteristics among rating systems. In our sample, a quarter of all systems are used as a means to gather and provide user information for specific entities e.g. a certain type of car. The support of sales activities and product comparison are common areas of use. There are some elements that are similar in nearly all rating systems. However, it is not possible to identify a best practice approach that is suitable for every situation. Every type of entity and business model has its own requirements on rating systems.

Hence, we will discuss the key parameters and parameter values we derived from our findings. We included these key parameters into a morphological box (Zwicky 1969). They were determined
through a critical discussion of all identified criteria as well as cross consistency assessments by all authors (Bailey 1994). The goal was to aggregate and structure the results of our analysis.

**Figure 3. Conceptualization of Design Options**

The searched online services are of either commercial or non-commercial interest. It turned out that 100% of all analyzed rating systems have a commercial background. A further analysis of non-commercial services may add to our framework, although we believe that their rating systems will deal with the same entities and objectives.

The rated entities turned out to be either subjects such as individual people, abstract subjects or objects. In most cases (77%) the rated entities had been objects such as hotels, products or services. Rating systems for objects are usually not restricted to certain brands. Only at YahooShopping.com we found that it is possible to rate some shoe brand, while it is not possible to rate other brands.

Furthermore, providers use rating systems not only for their specific service but also in other service areas or even across various providers. However, there is no standardized mechanism for exchanging rating information between platforms. With the emergence of Open Social (OpenSocial.org) at the end of 2007, which is a standardized API for social applications across multiple websites, we expect the interaction among different platforms will increase within the next years.

Linking the permission for rating to certain prerequisites can improve the rating quality (Dellarocas 2000). In most cases, the user group is restricted (82%). Hence, it is possible to automatically validate whether a user is authorized to conduct a rating or not. However, there are also some rating systems which do not require a user registration. The decision whether to provide an user-restricted or unrestricted rating system very much depends on the acceptance of people, the general business model behind the website and the importance of the rating. If, for instance, the user has to be registered in order to use services anyway, a restricted rating system is preferable. But if the rating system is the main part of the service (e.g. Pixnay.com’s picture rating), a unrestricted rating system might limit the acceptance of such a platform. In some contexts it may even be sensible to set up further prerequisites before a rating is admitted. For example, at Ebay.com people have to conduct a purchase first before they are able to rate the seller of the product. Qualification can also be useful in areas of high interest but low general knowledge. Hence, a qualification mechanism is sensible for websites that need specific expert knowledge or for social networks where only friends are allowed to rate other friends.
We found that most ratings are direct ratings that express an opinion directly (‘I like Mandy’, ‘This hotel receives 5/5 stars’, etc.). For the provider, this sort of rating is very easy to aggregate and calculate. However, there are academic discussions and studies about problems with fraud (Gregg & Scott 2006). In addition, a bilateral direct rating may lead to revenge ratings. Even at Ebay.com, the old bilateral direct rating system, which was restricted to transactions, turned out to be very problematic and has been changed to a more or less unilateral rating system recently. In few cases we also found some relative rating systems on the internet where ratings are made based on the comparison with other entities (Dellarocas 2003). Unfortunately, such an approach is only possible in social applications with a high degree of cross linking (Botsch & Luckner 2008). In general, relative rating systems can help overcome some (but not all) fraud issues since a rating is only possible in comparison to other subjects or objects. Nevertheless, this kind of rating systems is not applicable to all services. For instance, relative ratings may not be helpful in situations where the entity cannot be compared to other objects (e.g. other services) or the evaluator only knows a limited number of comparable entities (e.g. comparing a hotel to other hotels in this region).

Providers of rating systems tend to aggregate individual ratings in order to receive an overall score although they risk losing relevant individual information. For example, an average mark does not give any information about the number of positive and negative ratings. Hence, it is sensible to display ratings for each score value (e.g. for positive, neutral, and negative ratings, see Google.com/products as an example). Since many ratings systems calculate scores out of single ratings, the method for this calculation is one of the key design options.

Most aggregation approaches for ratings have proven to be very simple. Usually, all ratings counted equally. Simple Systems compute an average of all ratings or a total score as the sum of positive scores minus the sum of negative scores. Advanced methods compute a weighted average of the ratings, where the rating weight can be determined by different factors, e.g. trustworthiness of the rating participant, age of the rating or distance between rating and current score. Furthermore, even more sophisticated statistical methods can be applied. In almost any case (98%), the aggregated score is only based on individual user ratings but there are also other factors that might influence ratings (e.g. at Epinions.com).

Retrieving ratings or scores is usually open to everybody that accesses the according online service. The high number of generally visible ratings indicates the importance of ratings for individual business models. E.g. e-commerce websites heavily rely on user ratings in order to offer additional value to potential buyers.

The need for incentives to attract ratings largely depends on the general activity and involvement of users on the platform and hence the business model itself. For example, pure rating platforms like Pixnay.com do not need any form of incentive for rating at all. In contrast, platforms that sell services that have to be used before rating them (e.g. hotel stays, craftsmen services, etc.) will need incentives in order to persuade users to return again to their websites for rating.

The social aspect of profile building and reputation is a basic incentive that is very popular among online services. These services either use the real name of a person or a pseudonym. In case of using the real name there will be a connection to the real world. Depending on the service, this can be an advantage (e.g. the user can prove that he is an expert in his profession) or a disadvantage (users fear a loss of privacy). Advanced incentives can be of monetary or other beneficial nature. For example, Epinions.com offers money for reviews. Some services offer indirect incentives such as the opportunity to participate in a raffle as a reward for entity rating. Hence, they provide additional value to the user with relatively low effort.
6 LIMITATIONS AND FUTURE RESEARCH

Our analysis is based on a large sample of websites and their rating systems. However, due to language barriers we were only able to analyze German and English websites. Furthermore, we only considered the most popular ones. There may be a possibility that there will be other rating systems in other cultural regions (e.g. Asia) that would additionally contribute to our body of knowledge. At the end, our criteria catalog was made out of 237 criteria and we believe it to be fairly comprehensive. Nevertheless, the analysis of additional rating systems might add even further criteria.

Unfortunately, we were only able to test the rating algorithms from the user perspective and could not look behind the curtains. However, we are convinced that our observations are quite accurate. Future research should also include less popular websites in order to understand differences between rating systems on high traffic websites and low traffic websites.

Today, most rating systems are on objects rather than subjects. We believe that the emergence of social networks and social applications will change the focus of rating systems towards users. Social networks may offer new rating systems within the next years and will raise additional questions regarding data privacy, self-determination, etc. Furthermore, new APIs such as Open Social may change the way of interaction among websites and hence the design of cross-platform rating systems. We believe our recent “snapshot” of the state-of-the-art of rating systems to be a valuable contribution to these and further emerging questions that have to be addressed by future research.

CONTROLLING COMPUTER-BASED MULTITASKING THROUGH PROVISIONING SYSTEMS IN CO-LOCATED LEARNING SETTINGS

Truman, Gregory, Information Systems Area, IE Business School, Maria de Molina 12, 4 Derecha, 28004 Madrid, Spain, gregory.truman@ie.edu

Abstract

Computer-based multitasking behavior has become commonplace, however its efficacy in co-located settings is disputed. An important question therefore is how computer-based multitasking can be controlled when traditional organizational control mechanisms are infeasible or unavailable. We conceptualize and operationalize computer-based multitasking in terms of on-task and off-task uses. Our research objective is to examine a provisioning system’s effectiveness with respect to restraining off-task uses while leaving on-task uses unaffected in a co-located learning setting. We conclude that provisioning systems alone are not sufficient to effectively control computer-based multitasking—to restrain off-task use, so it may be advisable to augment provisioning systems with behavioural modification and reform efforts.

Keywords: Multitasking, provisioning systems, co-located learning, technology-mediated learning, e-learning, agency theory, longitudinal, field study
1 INTRODUCTION

Technological advances related to information and communication technologies are transforming learning processes in various contexts (Hiltz and Turoff 2005, Alavi and Gallupe 2003, Alavi 1994, Young 2005, Arbaugh 2000). Of assorted nature, these transformations have generated interest among information systems, management education, education and education psychology researchers (Balkovich, Lerman, and Parmelee 1985), and have created a field of inquiry called technology-mediated learning (TML). In this paper, we follow Leidner and Jarvenpaas’ (1995) characterization of TML as learning experiences that are modified in some way through use of information and communication technologies.

TML learning is facilitated by applications such as email, chat, blogs, virtual whiteboard, video-conferencing, document management, assessment facilities, and the Internet in general among others (Tu 2000, Navarro and Shoemaker 2000, Ross and Schulz 1999). These applications may be combined into one system or “package” (Arbaugh 2000, Hiltz and Wellman 1997), which we refer to here as technology-mediated learning applications (TMLAPP). TMLAPP running on contemporary computing platforms are expressly designed to facilitate computer-based multitasking. As a result, computer-based multitasking behaviour has attained a commonplace nature in both virtual and co-located learning settings.

In this paper, we are specifically interested in examining computer-based multitasking in co-located learning settings. We argue that the co-located setting is critical to study, because it is this setting that appears to heighten contention over both the appropriateness and efficacy of computer-based multitasking behaviour (Gomolski 2006, Wallis et al. 2006, Chudoba et al. 2005, Wasson 2004, Shellenbarger 2003, Hwang 2002). While the reasons for this are likely manifold and not entirely understood, one can reasonably claim that co-located settings produce behavioural norms with respect to participants’ attention and effort. In co-located learning settings, where people organize with the intention of performing some learning task, behavioural norms produce expectations that each participant will give undivided attention and effort. Since computer-based multitasking in co-located learning settings is palpable, and may suggest—although is not definitive of—diversion of attention and effort, contention over multitasking appropriateness and efficacy heightens. For instance, approaching the issue from an anthropological perspective, Wasson (2004) concludes that multitasking behaviour may require or effect change in standards of politeness to the extent that it becomes culturally embedded.

2 LITERATURE REVIEW

Currently, there is no consensus regarding the efficacy of engaging in computer-based multitasking in co-located settings. Some suggest that a potential of bringing TMLAPP into co-located settings, especially ones of large numbers of participants, is to establish back-channel conversations, where participants’ attention and effort may be stimulated through enhanced content sent over back-channels. On the other hand, some question whether it is possible to concurrently multitask and pay attention to others in effective ways (Gomolski, 2006). Due to its very nature, multitasking behaviour may create distraction effects for other participants. In fact, in some co-located contexts computing devices or Internet access are altogether banned (Guernsey, 2003).

Consequently, an important question is—how can computer-based multitasking be controlled such that the attending advantages are maximized and disadvantages minimized? In this paper, we conceptualize and operationalize use behaviour in terms of on-task and off-task uses vis-à-vis the use context. Our research objective is to examine the effects and effectiveness of employing a
provisioning system (PS) for the intended purpose of restraining off-task uses. We utilize agency theory to frame our hypotheses and we use longitudinal data from a quasi-experimental field study to operationalize objective measures on actual use in a co-located setting.

2.1 Controlling use through provisioning systems

In this study and for purpose of subsequent discourse, we assume that at least one co-located participant assumes the role of facilitator, who is responsible for organizing and coordinating participants’ activity directed to task completion. Additionally, we define participants on-task (off-task) use behaviours as those that are (are not) related to the task at hand. Ideally participants will remain on-task however anecdotes and commonplace experience suggest that they will engage in off-task uses as well. While computing devices may be banned altogether, this is often not desirable or feasible for a variety of reasons. As an alternative and in an effort to restrain off-task uses, a facilitator may employ a dynamic provisioning system (PS) to limit participants’ access to certain applications and devices. For example a facilitator may allow access to shared file servers and printers within the local network, while disallowing network-based applications such as email and chat. By selectively allowing some applications and devices while eliminating others, the practical value of computing devices in co-located contexts is presumably enhanced by balancing on-task uses against off-task ones.

In practice, the options of prohibiting computing device use altogether or allowing unimpeded use represent end-points on a continuum of various provisioning levels, each allowing access to some applications and devices to varying degrees. The assorted provisioning levels that are made available are determined by the PS’s design, which may be customized for the user entity. Generally speaking a PS enables the facilitator to specify infrastructure or application service provisioning. The PS that we examine here offered provisioning options for email, shared (local) file servers, local printing, an Intranet application and the Internet. Each service could be denied or allowed, although the five provisioning options were not entirely independent of one another. For purpose of subsequent discourse, we use the term ‘access setting’ to refer to the applications and devices that are provisioned during co-located sessions. We qualify an unrestricted (restricted) access setting as less (more) impeded—allowing participants access to relatively more (fewer) applications and devices.

3 THEORETICAL FRAMEWORK

We argue that a generalized co-located context involving at least one facilitator and participant may create conditions that satisfy agency theory assumptions (Eisenhardt 1989, Eisenhardt 1985, Ouchi 1979). We predicate this argument on others’ general assertions that agency theory is applicable to a broad range of organizational design issues with respect to control mechanisms (Eisenhardt 1985, Ouchi 1979). More specifically Eisenhardt (1989) states that "The agency structure is applicable to a variety of settings, ranging from macro-level issues […] to micro-level dyad phenomena such as blame, impression management, lying, and other expressions of self-interest. (italics ours, p.58)", and concludes that researchers may "...use agency theory in their study of [a] broad range of principal-agent issues facing firms. (p.72)"

Broadly characterized, agency theory may be applied to any dyad relationship that involves cooperative behaviour between its members. Commonly members assume roles that exist in superior-subordinate, supervisor-worker or leader-apprentice arrangement with respect to one another. In addition the relationship typically involves the principal in delegation of a task to an agent, and in subsequent control over agent’s task performance and/or outcomes. A frequent assumption about the principal-agent relationship is that the principal and agents’ objectives or interests with respect to performance or outcomes will differ, diverge or depart. Consequently the principal’s primary problem lies in extracting the agent’s cooperative behaviour so that behavior serves the principal’s objectives.
In reviewing agency theory's contributions to organization theory, Eisenhardt (1989) identifies similarities and differences between two research lines—positivist agency theory and principal-agent research. Both lines share assumptions about people, organizations and information. For instance, agency theory assumes that human behaviour and decision-making is driven by self-interest. Second, there exists at least partial goal conflict between principals and agents. Third, there exists information asymmetry between the principal and agent such that the principal cannot fully monitor the agent's behaviour and actions. Intentionally absent any mathematical rigor, our application of agency theory falls into the realm of positivist agency theory, where researchers are generally focused on identifying situations where the principal and agent have conflicting goals, and on describing control or governance mechanisms that restrict the agent's self-serving or opportunistic behavior. Positivist research broadly identifies two control or governance mechanisms for curbing opportunistic behaviour — outcome-based contracts and information systems (Eisenhardt 1989).

We argue that a co-located learning setting may create a situation where the goals of the facilitator (principal) and of the participants (agents) begin to conflict or diverge. For example, we assume that the facilitator has interest in engaging, soliciting input from, or imparting information to participants. Said differently, the facilitator wants the participants' attention and effort focused on the learning task in order to facilitate the learning process and to yield successful learning outcomes. While participants may fully comply with the facilitator's wishes, their behaviour may succumb to self-serving interest as they direct attention and effort to other work or personal tasks or leisure activity. To the extent that participants' engage in self-serving behaviour, co-located facilitator's and participants' goals begin to diverge or conflict.

The facilitator is able to monitor some of the participants' behaviour. However, from a practical perspective, the facilitator's monitoring capacity is constrained by assorted factors such as the number of participants, the nature of participants self-serving behavior, the facilitator's cognitive abilities, and the participants' physical arrangement among others. In short, there is in general information asymmetry between facilitators and participants with respect to participants' attention and effort and, consequently, to facilitator's and participants' goal alignment. Therefore when participants can engage in self-serving behaviour with minimal concern or regard for detection, they are likely to do so.

With the introduction of computing devices into co-located learning settings, participants' ability to pursue self-serving behaviours is significantly expanded because much work and personal tasks and leisure activity is computer-mediated. For instance, a participant may check the value of personal stock holdings, compose a letter to a relative, or check the latest standings of local professional sports teams. To the extent that participants' self-serving behavior increases, agency theory predicts that goal conflict between facilitator and participants increases.

The facilitator's ability to monitor participants' behaviour is further compromised by introduction of computing devices. Assume a simulated learning task where participants take on the role of institutional investors at a financial brokerage firm and the task of revising company-wide investment guidelines. A participant may use the computing device to look up on-line information about investment instrument prices or holdings in order to provide input to the task. This use behaviour is on-task. In contrast that same participant may look up current information about his own investments. This use behaviour is off-task. From the facilitator's perspective, the participant's computing device use is virtually indiscernible with respect to on-task or off-task usage, unless the facilitator has view of the participant's computing device screen which is seldom the case. In short, because the difference between a participant's on-task and off-task uses is effectually indiscernible for the facilitator, information asymmetry effectively increases thereby exacerbating the monitoring problem.

In summary, from an organization design perspective, control or governance mechanisms ameliorate information asymmetry between the co-located facilitator (principal) and participants (agents) and thereby bring about goal alignment between them. Governance mechanisms take on at least two forms according to the positivist's research realm—outcome-based contracting and information systems (Eisenhardt 1989). The specific choice between these is generally guided by efficiency.
considerations—i.e., which control mechanism is the least costly to implement. In co-located learning settings, neither outcome-based contracting nor information systems is a feasible alternative from a practical perspective.

Where these control or governance mechanisms are impractical, an alternative way to bring about goal alignment is through socialization (or clan) structures (Ouchi 1979). While socialization structures are many and varied in practice, on a conceptual level we envision socialization processes that correspond to Ouchi's (1979) description of "…a highly formalized and lengthy period of socialization during which [participants] are subjected not only to skill training but also to value training or indoctrination. (italics ours, p.837)."

Absent any outcome-based contracting, information systems or socialization structures for attaining goal alignment between principal and agent, a co-located learning setting may offer the option of utilizing provisioning systems (PS) that can effect control through "brute-force." For instance, under the assumption that the facilitator wants to discourage participants’ off-task behaviour, the facilitator can dynamically provision devices and applications so as to restrict access to select ones. By restricting use of some devices and applications for some duration of the learning task, the facilitator will effectively reduce the potential for participants' off-task behaviour. In short, the facilitator can provision a restricted access setting, which should lead to reduced off-task use levels among participants. We submit the following hypothesis.

**Hypothesis 1:** Off-task use behaviors are lower under a restricted access setting when compared to an unrestricted access setting.

By provisioning a restricted access setting, the facilitator is restricting specific devices and applications from participants’ use. While this should have the intended effect of reducing off-task use, the devices and applications are no longer available for on-task use either. Since devices and applications can be used for both purposes, one may argue that on-task use behaviour will also be reduced. However, dynamic provisioning should allow the facilitator to provision an unrestricted access setting on opportune occasion, thereby providing access to devices and applications when their use is efficacious to the learning task's objectives and activities at hand. Therefore as another goal of facilitators is presumably to leave participants’ on-task behaviour unimpeded or unaffected, we argue that the impact on participants' on-task uses should be negligible assuming that the facilitator dynamically provisions an unrestricted access setting on opportune occasions. We submit the following hypothesis.

**Hypothesis 2:** On-task use behaviors are not significantly different between an unrestricted access setting and a restricted access setting.

### 4 RESEARCH METHODOLOGY

#### 4.1 Research setting

The research design is a longitudinal quasi-experimental field study that involves subjects who enrolled in a required freshmen course at a business college in the Northeastern United States. The setting is a two-semester integrated course that presents a multidisciplinary perspective by interweaving topics and concepts from different academic disciplines (or functional areas) into one course, which we refer to here as Business Introduction. The pedagogical approach of this course is heavily applied, and much of the curricula was designed and delivered under the assumption that each participant would have a dedicated laptop computer during co-located sessions. Business Introduction is offered in seven sections, and each section is capped at 60 participants. Two faculty members teach each section. In January 2006, the course received an Excellence in Education Award from the U.S. Association for Small Business and Entrepreneurship (USASBE) for its innovative and entrepreneurial pedagogical approach.
4.2 Research design

For this study, subjects came from four Business Introduction sections, which were instructed by two lecture teams. Each team instructed one section in unrestricted access and another in restricted access to avoid confounding effects between lecture team and access restrictions. Unrestricted access allowed use of all applications including course management application, shared file servers and printers, the email system and the Internet. Restricted access prohibited network applications such as Internet browsing, email and chat, except on occasions where the facilitators deemed them to be pedagogically relevant. This exception normally involved allowing Internet access for some learning sessions. In addition, lecture teams alternated between sections to control for order effects and eliminate the second section advantage of receiving the lecture after it had been delivered to the first section.

The lecture teams shared teaching materials. Their efforts to ensure uniform course requirements across sections resulted in a relatively standardized curriculum. However, curriculum delivery was not scripted and was subject to idiosyncratic lecturing styles and the emergent nature of discussion periods. Facilitators were generally non-directive in controlling participants' computer use however. The subjects were free to use their laptop without limitations under unrestricted access setting and with email, chat and Internet access limitations in the restricted access setting.

4.3 Sampling

Taught by two facilitators, each of seven sections capped enrolment at 60 participants. We solicited four sections for participation, and 122 subjects volunteered to participate. This represents a 51% (=122/240) participation rate. From these 122 subjects, we obtained 95 monitoring log files and 89 surveys of which 72 overlapped. Four subjects switched sections after term onset, so we have primary data on 68 subjects.

Although the subjects were not informed about the specific research questions, they were made aware that participation involved unobtrusive monitoring of their computer use during Business Introduction sessions (primary data), filling out a survey (primary data), and releasing course performance data (secondary data). Monitoring occurred only during the first term. While subjects were not randomly assigned to sections, the access setting was designated for each section well after the participant registration period, so no self-selection bias with respect to "getting into" an unrestricted section could have occurred.

4.4 External Validity—Monitoring Awareness

To the extent that monitoring affected subjects’ behaviour, external validity is undermined thereby yielding no generalizable conclusions. Thus, we took several measures to reduce subjects’ monitoring awareness. First, recruitment during a May-June timeframe provided a three to four month lag between consent and onset of monitoring to mitigate awareness effect over use behaviour. The research project was never raised by the facilitators, and subjects were not reminded of their participation until asked to fill out the survey at monitoring conclusion. Finally, the monitoring program was installed and uninstalled through an unobtrusive SMS (server-side) procedure, and it was configured to run in stealth mode—the monitoring program icon never appeared on the desktop, task bar or task list. Log files were copied from the learners’ computers’ hard drives by an undetectable server-side custom program called the “harvest” program. Thus, no subject was ever alerted to the monitoring program.

Responses from a relevant survey item strongly suggest that most subjects did not change their use behaviour in response to being monitored. Eighty-four percent of subjects disagreed with the statement “I changed how I used my computer because I know that I was being monitored.” Fifty-seven percent
strongly disagreed with the statement. In addition, a consensus opinion emerged from the four facilitators, three of whom had previously taught Business Introduction, that subjects' did not alter their use behaviour due to monitoring awareness. Altogether then—the lag between monitoring consent and onset, the monitoring and harvest programs being undetectable, and other efforts to keep the research project at low profile helped to mitigate subjects’ awareness of being monitored.

4.5 Variables and Measures

Subjects’ use was monitored only during co-located sessions, and use activity is logged to the local drive so all use is recorded independent of any network connection. Periodically, the log file was copied from each subject's local hard drive to a file server by a custom-designed server-side program called the “harvest” program. The “harvest” program required that the subject establish a network connection, but that connection could occur at any time. The precise timing of log file “harvesting” was jointly determined through the random occurrence of subject network login and time of last harvest, and generally occurred about every seven to ten days. The harvest program operated inconspicuously.

Sample use logs are shown in Tables 1 and 2. Fields include application name, window title and keystrokes among others. Each time a subject set the window focus, a log record was created. The window focus start and end times are recorded as AppGotFocus and AppLostFocus, respectively. Divided into active and inactive parts, elapsed time is the difference between focus times. Active time generally reflects the amount of time that the subject operated any input device, which in this context includes the keyboard and mouse. Inactive time generally reflects idle time with respect to input device manipulation.

Each sample highlights use that is either predominantly on-task or off-task. Table 1 illustrates mostly on-task use where the subject is taking notes on a problem-solving exercise involving breakeven analysis. Table 2 shows mostly off-task use where the same subject at a different time is in an instant message dialog. (See Keystrokes column.) If the record represents on-task (off-task) use, then the on-task column is coded as ‘1’ (‘0’) and the off-task column is coded as ‘0’ (‘1’). Some records are coded ‘0’ in both columns, because they represent neither on-task nor off-task use, or they are indeterminate with respect to use behaviour. In no case was a record coded as ‘1’ in both columns, because no use can be simultaneously characterized as on-task and off-task. The coding process was partly subjective and not entirely error free, so the data were reviewed by two independent coders. Agreement level was 82% (89,260 out of 109,057), and the records in non-agreement were removed for subsequent analyses.

Four measures each for on-task and off-task uses are computed from the data—focus change, keystroke, active time and inactive time. Focus change is a count on the number of records, and represents the number of times that a subject sets focus to an application (window). Keystroke is the sum on the key counter column, and represents the number of keystrokes made by the subject. The key counter values include nonprintable character key depressions, such as shift, control, alt and function keys among others, despite these being absent in the keystrokes columns. Active (inactive) time is the sum of the active (inactive) time column, and represents the amount of active (inactive) time in seconds. All use measures are ratio scaled.

Aggregate results are shown by on-task, off-task and neither use activities in Table 3, which presents nominal and proportional figures. These results indicate that about two-thirds (one-third) of all use activity is off-task (on-task). Records coded as neither account for a small percentage, and these are removed from subsequent analyses. We also eliminate inactive time due to a critical interpretability problem.

4.6 Data Analysis

Our hypotheses require that we test for differences between groups on a set of ratio-scaled measures.

Table 2: Mostly off-task use
More specifically, the independent variable has two levels—restricted and unrestricted. For each hypothesis, the dependent variable has three measures—focus change, keystrokes and active time. When one must test for significant differences between two groups on two or more dependent variables, one may use Hotelling's T-square statistic.

Table 3: Use Measures

5 RESULTS

The results in Table 3 show that about two-thirds of all use is off-task and about one-third is on-task. Thus, a majority of use behaviour is off-task although a sizeable amount is on-task. When given tools to be more effective in a co-located learning setting, subjects appear to gravitate toward off-task use behaviours. This is unfortunate from a facilitator’s perspective.

Table 4: Use Measures by Use Behaviour, Access Setting

The Hotelling's T square test results are shown in Table 4. The results indicate that off-task use was significantly different between restricted and unrestricted access settings on the three use measures at p<.05. Off-task levels were higher in the unrestricted access setting, which is consistent with expectations. Levels of focus change (p<.01) and keystrokes (p<.05) in the unrestricted group were almost twice that of the restricted group. The unrestricted group had a greater level of off-task active time (p<.05) compared to the restricted group as well. Hypothesis 1 is supported. On-task use was not significantly different between unrestricted and restricted groups on the three use measures. This is also consistent with expectations, assuming that the facilitator dynamically provisions services as needed. Hypothesis 2 is also supported.

6 DISCUSSION, CONCLUSION AND LIMITATIONS

The collective findings are largely consistent with expectations, but it is important to remain mindful that overall use is characterized by a preponderance of off-task use. Viewing the data differently (see Table 5), we see that in restricted access off-task use is significantly higher than on-task use at p<.01 across the three measures. This highly significant finding stems from the large difference on focus change (p<.01), where the off-task level is almost three times the on-task level. Thus, despite the PS's infrastructure and application restrictions, participants continue to find ways to engage in off-task uses. Additionally, for participants who were provisioned all infrastructure and application services
(unrestricted), their use was overwhelmingly off-task as indicated by $p<.01$ significance levels for the overall Hotelling’s T square test and for each use measure.

Table 5: Use Measures by Access Setting, Use Behaviour

Our findings support the view that PS are effective at reducing off-task use while leaving on-task use unimpeded. Stated differently, PS may offer one means to balance the advantages and disadvantages of computer-based multitasking. Nevertheless, a preponderance of computer-based multitasking was off-task despite restriction of certain devices and applications to reduce off-task use. A main explanation for this breach lies in participants’ use of local applications, which lay outside the PS’s “reach.” Another explanation lies with some users devising clever ways to circumvent the PS control, although this was relatively uncommon. In either case, the findings suggest that PS are only partially effective as an organizational control mechanism for bringing about goal alignment between facilitator as principal and participants as agents in a co-located learning setting. Consequently, additional ways to control computer-based multitasking are needed.

Considering established theories, we contend that socialization structures as described in Ouchi’s (1979) theoretical work may be necessary to restrain off-task use. Extending from Ouchi’s (1979) description of them as "...a highly formalized and lengthy period of socialization during which [participants] are subjected not only to skill training but also to value training or indoctrination. (p.837),” we imagine value training and indoctrination could manifest in formal procedures to bring about behavioural modification and reform with the objective of restraining off-task uses. We envision formal procedures that would inform about appropriate computer-based multitasking uses, where notions of appropriateness encourage participants to stay on-task and resist off-task uses. These formal procedures would be executed at the onset of the learning process in order to establish behavioural norms at the beginning, and be delivered on a repeated and frequent basis for continual reminder until conclusion of the learning sessions. The formal procedures would include punitive measures, which would be clearly communicated and reliably enforced in case of violation.

An additional option may be the use of a “public” display that is large and viewable by all participants, where the “public” display could show any participant’s personal screen. While simultaneously showing all participants’ personal screens on the public display is not practical, skilful design and implementation of contemporary infrastructure and applications can allow the facilitator to selectively put one participant’s personal screen on “public” display. A viewing of a personal screen by all participants would likely be effective at discouraging off-task use, assuming that procedures were fully disclosed to participants beforehand. On a theoretical level, this is akin to using an information system such that the principal (facilitator) is informed about the agent’s (participant’s) actions (computer-based multitasking behaviour) in an effort to bring about goal alignment (reduce off-task use).

We conclude that participants’ computer-based multitasking is characterized by greater levels of off-task use when compared to on-task use by a significant margin. We also conclude that provisioning systems alone are not sufficient to effectively control computer-based multitasking—i.e., to restrain off-task use, so it may be advisable to augment provisioning systems with behavioural modification and reform efforts.

One obvious limitation relates to generalizability of these results. The data were collected from co-located settings of a college-level classroom setting. The roles of instructors as principals and students...
as agents, and the attendant role dynamics, may not adequately overlap or correspond to those of co-located facilitators and participants in ordinary business co-located settings. Thus, the findings may not generalize to this situation.

Another limitation relates to an implicit assumption in our hypotheses development that off-task and on-task use behaviours are independent of one another. It may be that some dependency exists in that as off-task use increases then on-task uses may decrease or vice versa. This may occur under circumstances where a user has no slack cognitive resource, so that any increase in off-task use will result in a decrease in on-task use. While this may be true in some instances, we argue that it is more likely that slack cognitive resources are available in co-located contexts, thereby allowing off-task and on-task uses to increase or decrease independent of the other.

MANAGEMENT COLLUSION: KEEPING THE LID ON THE CAN OF WORMS

This paper suggests that issues surrounding non-compliance should not be dismissed as resistance but instead should be further studied by managers and developers, leading to accommodation of differing views. The technological frames of reference strand of social shaping of technology theory is used to overlay the issues arising from a case study looking at non-compliance with information systems. This procedure highlights underlying antecedent organizational conditions which are likely to underpin non-compliant behaviour. These antecedent conditions include acceptance, control and proceduralisation. Examination shows that change in these areas is within the remit of managers and yet noncompliance continues and is accepted by managers. This raises the question not of why or how these behaviours exist, but why they continue to exist in the light of their unmasking and exposure. This paper suggests that non-compliance should not be dismissed as resistance but should addressed by managers and developers leading to a skeleton or framework for understanding problems and developing organisationally aligned solutions.

Keywords: Social Shaping, Technological Frames, Resistance, Workaround.

1 INTRODUCTION

The purpose of this paper is to examine complicity and collusion by managers who fail to address issues underlying non-compliance to information systems. Several terms in this paper are deliberately selected to differ from the usual terms used and the term non-compliance is used instead of the more usual term resistance, with all associated negative connotations. In addition terms such as complicity and collusion are used to describe managerial knowledge of non-compliance along with their inaction in addressing such behaviours, where these are identified as managerially controllable. Collusion implies secret understanding with negative intent and complicity implies tacit conspiracy in underhand matters. This paper builds on work identifying categories of non-compliance with information systems (Ferneley and Sobreperez, 2006; Ferneley, Sobreperez and Wilson, 2005). The author now ties in the technological frames of reference aspect of social shaping of technology (Bijker, 1995; Orlikowski & Gash 1994) and applies these to the case study data to identify relevant social groups. This paper applies, across case study sites, the notion of technological frame incongruence across identified relevant social groups, and uses indicators for non-compliance to construct contrasting technological frames. In this way, this paper applies the lens of technological frames theory to the findings of the original case study (Ferneley & Sobreperez 2006) and uses the identified groups of conditions underpinning non-compliant behaviour to create the structure of the technological frames. This action outlines clearly that relevant groups of employees who interact with information have widely disparate views of the nature and purpose of the information they use, and that this can stifle congruence or commensuration of attitudes to information systems.

In addition, the application of technological frames helps to identify areas where management, supervisors and developers take different standpoints and dismiss or minimise non-compliant behaviours and their subsequent negative impact on data integrity, accuracy of reporting, and organisational culture. An organisational ideal is the seeking of technological frame congruence (Orlikowski and Gash, 1994) and the comparison of stances across different dimensions helps to identify the differing attitudes, beliefs and viewpoints of the relevant social groups. In this way areas in which these differing standpoints have contributed to conditions which are precursors for non-compliant behaviour are highlighted. This action may assist in the categorising, across other contexts, those behaviours which are harmless, hindering or, vitally, essential to the completion of tasks, processes or roles within an organisation (Davis and Hufnagel, 2007; Ferneley and Sobreperez, 2006). Further, this action of categorising could become important in the identification of behaviours to
ignore and behaviours requiring action in individual organisations. Non-compliant behaviours capable of mitigation by management action are continuous in their manifestation and the action of classification could assist managers in the seeking of curative or alleviating systems

2 THEORETICAL AND RESEARCH BACKGROUND

Where users show opposition to information systems, this has traditionally been seen as recalcitrant, negative behaviour, labelled as resistance, to be minimised and overcome as much as possible throughout an organisation (Franz and Robey, 1984; Lyytinen and Hirschheim, 1987a). More recently, other researchers have pointed out that resistance can be seen as a positive force and may highlight the shortcomings of systems or of organisational arrangements (Hirschheim and Newman, 1988; Levine, 1997; Markus, 1983; Mumford, Land and Hawgood, 1978). This seems to be especially true where an organisation has distinct hierarchy and operators are distanced from those who specify, develop and implement systems (Lapointe and Rivard, 2005; Marakas and Hornik, 1996; Martinko, Henry and Zmud, 1996; Prasad and Prasad, 2000). Resistance studies are generally seen as control versus resistance, management versus workers, repressive power and subsequent response, overlooking the ambiguity and complexity often found (Thomas and Davies, 2005) and assuming polarity of management and workforce.

Some attempts have been made to create environments in which resistance is minimised and this has resulted in the development of Technology Acceptance Models (TAM) (Davis, 1993; Ventakesh and Davis, 2000) which predict the impact of external variables on the internal attitudes and behaviour of people in new technology situations. However, widespread use of these has failed to significantly affect this area, or account for social influence in the adoption and utilization of new information systems (Malhotra and Galletta, 1999); developers and managers continue to view any non-compliance as resistance, with associated negative connotations, to be overcome for business reasons.

The literature has largely been managerialist in outlook focussing on the behaviour of workforce and theories of resistance from the exclusive point of view of managers (Jermier, Knights and Nord, 1994; Lyytinen, 1987b; Markus, 1983). This has involved taking a view from the outside and above, looking at the workforce as different and separate from those who manage them, who make decisions governing their use of information systems, and who determine implementation and control of new information systems (Boje, 1995).

Managerialist ideology became popular with the rise of corporate capitalism over family-owned businesses and assumptions are that managers are different kinds of people from ordinary working people, that they have skills, knowledge and attitudes that differentiate them in a superior way (Chandler, 1977). It is argued that managers are infused with a paternalistic and ‘know-best’ attitude through virtue of their position, they have a ‘responsibility’ to the organisation greater than that of lower workforce members and are agents and functionalists of the survival and growth in profitability of the organisation (Alvesson, Mats and Willmott, 1996; Boje, 1995; Hoskin and Maeve, 1993a; Hoskin and Maeve, 1993b).

The flattening of hierarchies occurring with harmonisation and removal of layers of middle managers purports to drive down decision-making and to ‘empower’ lower levels but rarely are these other than operational decisions (Appelbaum, Hebert and Leroux, 1999; Harley, 1999). Thus the unitarist approach favoured by the rise of the Human Relations school of management thought is contrasted with the pluralist ‘us and them’ idea of managers versus workforce implying tensions, conflict, and resistance to systematic and continuous workforce subjugation. Shoshana Zuboff (1988) considered the use of computer technology as a radical discontinuity in industrial history. She observed that more data is now available on the minutiae of work based tasks than ever before, and one of her findings was that power lies with access to that data. She construed that this could constitute a fundamental organisational change and would have far reaching effects for employment, social relations and power relationships providing managers did not block the development of intellectual skill of workers to
protect their own authority. She concluded that technology could be either restricting or unleashing depending on the choices made within the organisation and that these choices might threaten the fundamental distinction between managers and the managed. Thus true empowerment of the workforce at operational level becomes a threat to the power and authority of managers.

The issue of differing groups of people holding differing views of technology is introduced by the Technological Frames of Reference (Orlikowski and Gash, 1994) strand of Social Shaping of Technology Theory. The essence of this theory is that groups of people interact with technology in different ways and are identified by shared tacit knowledge, assumptions and understanding. Groups are identified as having similar purposes and objectives of technology and similar understanding of data use, data quality and ultimate information utility.

Orlikowski and Gash (1994) suggest an ideal of frame congruence, where differing groups of people are aligned on the structure and content of their frames and thus share expectations and assumptions around key technological aspects. The existence of incongruent technological frames implies differences in the view of division of labour, autonomy of employees, and status and position of individuals are consciously or implicitly built into information systems by systems planners and designers (Hirschheim and Klein, 1989).

Should incongruence be identified, the implication is that in order to move towards congruence, one or several relevant social groups will need to amend or change their frames of reference in order to resolve incongruence. Clearly these amendments and attitude changes will be expected of the user or operator and not by the designer, consultant, manager, executive champion or financer of the project Davidson (2006). The very idea of communicating and cooperating with users and seriously considering their views and outlooks undermines the status, power and privilege of managers and developers. The groups involved in IT often have different priorities and goals (Dunlop and Kling, 1991), and added to this are social and hierarchical differentials over issues such as salaries, employment benefits and social status, and this creates the potential for conflict and controversy.

In the light of the case study, there are clear issues of resistance to or non-compliance with Information Systems and underlying antecedent conditions for these acts of non-compliance are identified as issues surrounding proceduralisation, acceptance and control (Sobreperez, 2008). This paper highlights the fact that the adjustment of these determinants to minimise non compliance is within the remit of managers and explores reasons for continuation of situations where these are overlooked or ignored.

There is much literature on the tendency of managers to support the status quo and supporting analysis of the reasons why they do this (Buchholz, 1978; Hambrick, Geletkanycz and Fredrickson, 1993; Hambrick and Mason, 1984). Top executives are not necessarily open minded about change and it is often in their interests to maintain an existing state of affairs where their position, reputation and importance are understood, accepted and believed (Jost, Banaji and Nosek, 2004). Propositions expounded in Hambrick, Geletkanycz and Fredrickson’s (1993) paper are that: the longer an executive has worked in the organisation or in the industry; the greater the organisations current performance; and the more they are allowed discretion in their decision making, the greater will be their commitment to the status quo.

The upper echelons share psychological factors such as beliefs, knowledge assumptions and values (Hambrick and Mason, 1984) and these can be seen to coincide with factors that underpin relevant social groups (Orlikowski and Gash, 1984). The upper echelons theory concludes that decisions made by managers are the outcomes of these behavioural factors rather than any attempt to optimise organisational efficiency or effectiveness.
3 RESEARCH APPROACH

The GarmentCo Case study was selected as an example of a production-based conveyor system where operators follow what appear to be rigid step-by-step instructions to complete orders within a pre-arranged workflow construct. This provided the opportunity for detailed study of actual practices taking place, variations from procedures and the situations in which these occurred. In addition there was the opportunity to study the call-centre approach of the office where orders were taken.

In contrast, the fire service case study site was selected due to the unique nature of the organisation and the extraordinary context of incidents. In this case study, each incident was different in a way that cannot be true for office or production based systems. The fundamental stage of the firefighter’s work is dynamic risk assessment due to the diversity in site, progress, and danger of each incident.

Although there are two case studies, it may be argued that there are multiple incidents of issues at two domains. The GarmentCo study includes several stages in the composition of outfits and also covers the ordering and despatch sections. The fire service includes reference to many divergent incidents where few factors are repeated.

GarmentCo hires out men’s formal clothes for weddings and other formal functions through high street retailers. Outfits are distributed by company vehicles or other couriers to the retail branch through which they were ordered and after the event, they are returned through the retail branch and company vehicle to one of the main processing warehouses. There they are checked, brushed, dry cleaned or laundered as appropriate, and returned to stock to be available for the next order. The workspace shop floor at the Lancashire depot is arranged into six zones. Each zone is used to process and store a particular type of clothing and each garment is bar-coded either with an iron-on or card label attached to the garment. An automatic conveyancing system known as Gartner is used to transport an order around the shopfloor where the appropriate garments and other items are added. Each zone has at least one operative selecting (picking) garments, scanning the barcode and attaching them to the appropriate order. On collecting a ticket the user types in their user number to one of the ‘Picking’ terminals and scans the barcode on the ticket. This assigns the order to the operator and the ticket contains the garments that need to be ‘picked’ from that area. The garment is attached to the hanger and the order is placed onto the conveyor system. This ticket follows the conveyor system around the factory, in order, through all of the areas from ‘Picking’ to ‘Dispatch’. The Gartner Transfer File communicates with the system tells the order where to drop off, and comes into action at every scan point on the conveyor system. An employee will assign themselves to the order by keying in their user number at the station and scanning the order ticket. This will update the system to show that the user has ‘picked’ the required garment and when.

The regional Fire Service case study is concerned with the mobilisation of fire engines to incidents and the reporting of said incidents. As incidents are reported to the Fire Service a centralised control office records initial incident details including incident location, who has reported the incident, Fire Service personnel and fire engines that are dispatched immediately and subsequently, the route or routes taken by fire engines, dispatch and arrival times and a log of all communications with the deployed Fire Service teams. After the incident a detailed electronic report is completed categorizing and reporting on the incident, the report is semi-structured and any level of Officer can be assigned the responsibility of completing the report. Structured attributes of the information system include cause of fire, location within the address, degree and speed of fire spread, number of casualties, other emergency services involved, specific equipment used and arrival and departure times. Free format responses include incident handling strategies and lessons learnt. These reports are collated and summarized by a centralised office that then presents the abstracted results to management who allocate human and physical resources from this data. In addition the summarized data is reported to central government who allocate funding and make policy decisions based on the data.

Data collection methods at GarmentCo included non-participant observation of work practices in the warehouse and telephone office, supplemented by semi structured interviews with warehouse staff and...
managers of finance, stock and personnel functions. At the Fire Service, data was collected through focus group interviews with groups or watches of firemen supplemented by interviews with senior fire officers and administrative staff at local and national statistics offices.

4 DATA ANALYSIS

Data was analysed using inductive coding and grounded theory principles of categorising and clustering data (Strauss and Corbin, 1994; Wolcott, 1982). The aim was to allow a conceptual framework to emerge during the course of study as the data was gathered, facilitating an open minded approach to analysis, although it is ‘impossible to embark upon research without some idea of what one is looking for and foolish not to make that quest explicit’ (Lincoln and Guba, 1985). Interview and focus group transcripts were read several times by two researchers and a coding framework was developed through discussion and verification of terms.

Following the development of the initial framework the analysis was conducted by firstly identifying key terms and concepts within the case studies, these terms were then restated to ensure that they remained as descriptive and literal as possible. Terms were cross validated to ensure the meaning was maintained and appropriate para-phrasing was used. An iterative clustering process was then performed with different clustering permutations being trialled. Clusters were then named (or coded) and combined to derived ‘meta-clusters’. Comparisons were made at cluster boundaries to test the cluster coherence and mini-theories (or ‘memos’) were generated for each cluster. At the highest, most abstract, level the core category is a summary of the concept of workaround rationale. The central theme of the conceptual framework is therefore ‘workarounds are manifestations of employee deviation from the intended use of technology’. This fits with the definition ‘intentionally using computing in ways for which it was not designed, or avoiding its use and relying on alternative means’ (Gasser, 1986, P216) from the earliest paper that specifically mentions workarounds.

The initial first level categorisation scheme was applied both at the time of data collection and by retrospective analysis on the completed transcripts and supporting field notes. Because qualitative data analysis is an open and iterative process applying the initial coding scheme to the case studies resulted in the emergence or induction of a richer coding set as the initial codes were ‘extended’, ‘filled in’, ‘bridged’ and ‘surfaced’ (Eisenhardt, 1989).

The case study data was analysed in two stages, within-case analysis and cross-case analysis (Miles and Huberman, 1994). Within-case analysis was performed to allow unique patterns to emerge and to gain a richer understanding of each case study. Individual acts of resistance or workaround were analysed identifying the conditions stimulating deviation from the prescribed or intended process, the objects affected by the behaviour and the associated threats. Cross-case analysis was undertaken using analytical induction to identify both common themes and unique patterns or behaviours. Abstracting from the individual cases focussed on the causes, pre-existing conditions or antecedents that generated the resultant behaviours. Segments of interview text were coded allowing an analysis of interview segments on a particular theme. The specific interest was in finding evidence of rationale for the various manifestations of workaround activity. Applying clustering techniques across the case studies identified sets of common sub-clusters.

The following set of tables display quotes from members of relevant social groups and are set against the three identified antecedents.

DISCUSSION

Resistant Behaviours The empirical case studies conclude that at the top level there are three pre-
conditions or antecedents for non-compliant behaviour with regard to information systems (Ferneley
and Sobreperez, 2006; Ferneley et al., 2005). These are identified for the purposes of this study as
enforced proceduralisation, lack of acceptance and unwillingness to control. Under enforced
proceduralisation, systems are overly procedural and employees must perform jobs in a certain
sequence so that the system can record them. This sequence is numerical and therefore chronological
despite situations such as at GarmentCo when greater efficiencies can be gained by batch processing
(selecting several of the same garment at once) or by pre-emptive processing (taking jobs out of
sequence) because it is known that similar non-standard items are required. At the Fire and Rescue
Service, the enforced proceduralisation was in the sequence of the FDR1 form and the lists of possible
responses available for selection in answer to questions. Under lack of acceptance, user failure to
identify to the system was widespread across both case studies. There seemed to be two reasons for
this: firstly the time taken to log in and out again using low specification desk top machinery and a
less than contemporary network technology was seen to be wasted and secondly any attribution was
viewed with suspicion and seen as surveillance. Employees were happy not to be personally
accountable for the recording of events as this was a way to sidestep any possible retribution for
errors, omissions or incorrect usage. The third antecedent is termed unwillingness to control, this
nomenclature is intended to convey that managers do not attempt to eliminate or minimise the non-
compliant behaviours outlined under proceduralisation and acceptance. The issue of collusion is
highlighted by the contradictory and opposing views of information systems usage and utility.

Management Collusion. Across both case studies, some interviews with managers revealed
awareness of resistant behaviours but no indication of actions intended to address them. Other
interviews did not even acknowledge that such behaviours occurred and managers were much more
likely to state the official organisational view despite evidence to the contrary. It is clearly within the
control of managers to write user guides and policies, to train users to use technology in a particular
way, to ensure access to support, to establish particular controls and to ensure that those who enter
data have understanding of where their input is used, by whom and for what purpose. It was clear that
users of information were happy to continue to use information they suspected or knew to be incorrect
which leads us to the question why this might be the case. Burawoy (1979) uses the metaphor of the
fig leaf to explain how the exploitative nature of the capitalist labour process uses consent to mask the
true relationship between those who sell their labour and those who profit from it. He describes a
mask that sometimes slips but generally does a good job of obscuring exploitation. In this way
collusion becomes the tacit agreement of both (or all) parties that they must work together and reach
agreement on aspects of their working life.

Managers appear to collude in several ways. Firstly, Managers deny or refute any occurrences of non-
compliant behaviours, this is illustrated by the manager’s comment

_The system is highly routine and cannot be overridden_

And the opposing view of operators

_We sometimes break down orders to find matches we can pick together_

Secondly Managers contradict or oppose evidence of non-compliant behaviours, note the comment
below from telesales office supervisor

_All telesales operators have to fill in a sheet monitoring time spent away from the telephone.
Telesales staff are monitored in everything they do_
And the opposing view from a telesales operator

*There’s loads of things we can do to get a skive ....... Sorting post, chasing parcels, dealing with input errors are all unmonitored.*

There are many examples of direct contradictions in the data collected, operator level staff giving one account of what happens and supervisory or management staff giving other, opposing views. The reasons for this may be complex but several seem to be apparent. Firstly, commitment to the status quo as mentioned earlier may well be a strong influence; secondly many senior managers throughout organisations are of an age where information systems were not taught in schools. They will tend to have learned anything they know about information systems on the job and in an applied way and may be unaware of steps that need to be taken to re-configure systems. Similarly in many organisations there are no direct lines of communication between departments and no systems for requesting modifications. Managers are likely to be wary of displaying their lack of technological knowhow by pointing out modifications that are very simple or too complex to implement.

We do not need to believe that managers consciously deceive workers or that all workers are exploited to see that some collusion is necessary simply to perform daily activities. Surveillance and monitoring are coercive and division of labour between managers who conceive work tasks and workers who execute them form constituents of the class division. However this view does not take into account the liberal view that if we believe that managers are custodians of the interests of all then we must see control by the few in the name of the many (Sewell, 2008). In the functionalist view (Durkheim, 1911) any kind of workplace ‘deviancy’ is a dysfunctional response that deviates from the normal and rational and consideration of this issue and the roles of managers directs the questioner to ask not how it arises but why it remains (Hacking, 1983). Information is only a small part of organisational decision processes, data are not merely an intellectual commodity but a political resource, whose redistribution through new information systems affects the interests of particular groups (Keen, 1981). There are few studies of resistance by managerial and professional employees, and polarity is often assumed in that the ‘workforce’ includes those ‘other’ than the management, and that managers work for and workforce against, the organisation. Thomas and Davies (2005) however, argue that different focuses of power require different focuses of resistance and that resistance by managers must take a different form and emphasis over that of the workforce. It may also be pointed out that management takes many forms from supervisor to managing director and that rather than viewing a polarity between managers and workforces, there is a continuum which includes many different levels of management, with all but the top level subordinate and answerable to the level above.

**Culture and Control.** The trompe l’oeil of information presented to managers and senior staff is underpinned by collusion in deviations and workarounds by managers and workforce (Ferneley et al., 2005). In the Fire Service in particular, a working class, masculine culture prevailed. Firefighters saw themselves as brave men and heroes, they were unconcerned with the ‘paperwork’ of recording systems and emphasized their ‘proper’ work of facing danger to save lives and property. They were strongly unionised, protective of their masculine role as ‘breadwinner’ and resisted the introduction of female firefighters. A culture of suspicion and criticism of management motives and practices from people distanced from the coalface of firefighting arose. This stark separation between workforce and management paradoxically created and reinforced a culture of distance which increased their exposure to management prerogative and their vulnerability to managerial discretion (Collinson, 2003).

Studies in conformity show that people are preoccupied with themselves as valued objects in the eyes of those in authority, and subordinate their own subjectivity in the process (Collinson, 2003). The conforming aspect of following a personal career path in an organisation has been identified (Grey, 1994) and aspirant individuals may perceive organisational and social relations as instrumental to career progress. In this way, the workplace becomes competitive as hierarchical positions are chased by many and allotted to few. An aggressive and competitive culture emerges and individuals may not wish to ‘rock the boat’ by highlighting deviation, alienating subordinate colleagues and tackling a difficult and possibly insurmountable issue.
Another interesting point is that the relevant social groups in this study are identified by their job title and status in the hierarchy. Clearly these do not necessarily map across to the different elements of the same technological frame; there may be many senior managers in any organisation who feel that systems are imposed from above, that they have no ownership of the data, and that there are significant differences between what actually happened and the recorded version. In this way then, members of a particular relevant social group, who share attitudes, opinions and points of view over their interaction with technologies, may cut across management hierarchies, job titles and salary scales. Resistance can then be seen as multi-directional and in this way, can be seen as gradually erosion of the micro-politics of power, by the use of low levels but continuous and changing methods and manifestations which weaken, destabilize and undermine established power structures enabling the construction of subtly different power relations across an organisation (Thomas & Davies 2005).

6 CONCLUSION

Information from different groups across two single case study has been examined and reveals differences in attitudes perceptions and stances around information systems. The technological frames construct is used to contrast thoughts, opinions and mindsets of different groups towards non-compliance with information systems. Three indicators are employed to provide structure for the frames of reference and these were identified within the case study as precursors for non-compliant behaviour. The overlaying of technological frames theory and application of case study findings points out very clearly the differing attitudes, perceptions and expectations of the diverse groups, both to systems usage and to any non-compliant behaviour. The differing frames views of relevant groups indicate issues that are within the control of managers and developers and that could be addressed in future planning and implementation. In this way non-operational groups take responsibility for cultural attitudes, control of data entry, proceduralisation and systems acceptance.

The author suggests that issues surrounding non-compliance should not be dismissed as resistance but should addressed by managers and developers and become a skeleton or framework for understanding problems and developing organisationally aligned solutions. The contribution of this study then is to point out that case study findings can interlock and intersect across theoretical areas and the use of the technological frames of reference provides a useful way to clearly demonstrate the existence of relevant social groups and the congruence or otherwise of their technological frames, therefore clearly highlighting areas of concern.

The framework used by Orlikowski and Gash (1994) is augmented by three further subdivisions of proceduralisation, acceptance, and culture and control, which serve to focus more clearly on issues of non-compliance and seek understanding and accommodation of viewpoints rather than dismissal of issues important to users and to successful implementation of information systems across and organisation. Analysis of the data raised the issue of management collusion where managers are endorsing behaviours they know to be non-compliant and possible reasons for this are examined. The view that managers are somehow different from the rest of the workforce and are immune from the forces that underpin resistant behaviour is questioned. The conclusion is that most managers are are subject to the same antecedents as more subordinate workers in addition to those attributable only to their status and position. They are therefore under pressure to meet deadlines, match performance benchmarks or reach targets and are answerable to upper echelons where these are not met. They are at a disadvantage if they lay blame on the workforce they are managing, as this clearly reflects on themselves as managers and their effectiveness, achievements and success. As managers often need to describe their career path in terms of success in order to reach the next level of management in the same or a different organisation, it seems clear that individual managers would not wish to reveal difficult, and possibly insurmountable problems with resistant workers, it is in their own interests to keep the lid on the ‘can of worms’.

GOVERNMENT AND SELF-GOVERNMENT IN THE INFORMATION SOCIETY

Abstract

Research on the information society and the policies and strategies for its creation has tended to discuss them rationally as the national, and occasionally international or regional, responses to changes in the competitive environment. The predominant notion of the information society in various levels of governance has only rarely been critically examined. The paper provides a Foucauldian analysis of the constitution of the information society as a political and policy imperative at the level of the European Union and the multiple effects it had for its member states. Drawing on ideas on governmentality and regimes of truth, I argue that the European Commission continually shaped the rationality and identity of the information society it heralded, by managing to set itself as the legitimate locus of policy for the information society. In revealing the dominant discursive truths about the European information society, the research discusses how the truth claims about the construction of a particular version of the information society and the legitimate loci of its government shaped the degrees of freedom of the Greek policy makers through a range of disciplining and self-disciplining practices.

1 INTRODUCTION

The pervasiveness of information and communication technology (ICT) in all fabrics of the society and economy has dramatically expanded the domains in which it is being discussed. Notions of the knowledge economy and the information society have made their way into political discourse and government action. A wide range of policies concerning ICT have made their way into political discourse and government action. A wide range of policies concerning ICT have been the subject of academic attention, but the implicit assumption has often been that such institutional interventions arise rationally through the careful consideration of national needs and aspirations. Although this may be true for the technological innovators, there are reasons to question it for the countries which are technological laggards.

The paper discusses the normative and mimetic pressures that result in national initiatives for ICT adoption and innovation. I am arguing that information society policies originating at a regional or supra-national level play a significant role in national decisions to pursue particular types of actions with regards to ICT through processes of discipline and self-discipline. The paper discusses the way in which one such supra-national organisation, the European Union, through its European Commission, has shaped the form of legitimate national government action of one of its members, namely Greece.

The work is conceptually based on the theoretical problematizations of Foucault’s later studies on governmentality as the government and self-government of conduct. In particular, the paper will appropriate the concepts of regime of truth and practices and techniques of government to question the construction of the information society at the EU level and the implications for Greek policy makers.

In investigating the thought that is embedded in the discourse and the practices of government I attempt to reveal how Greek policy makers willingly assume the interpretation of the information society construed by their European counterparts and constitute themselves as subjects through discipline and self-discipline.

The purpose and contribution of the paper is to present a theoretically informed discussion of the construction of the information society through European policies, and its interplay with national problematizations on how to appropriate ICT. The paper is adding to the discussion of the information society and ICT policy, extending it through its parallel consideration of two levels of government simultaneously.

The paper is structured as follows. In the next section, I will be reviewing the literature on the information society and ICT policy, to highlight the lack of critical accounts as well as the limited efforts to provide a theoretical conceptualisation of the phenomenon. I will then introduce the concept of governmentality, which forms the overarching conceptual bridge of the paper, and explain the dimensions of truth, rationality, techniques and identity formation which will directly inform my analysis. In the following section a narrative of the case as it evolved over the past twenty years will be presented. In the Analysis, I will critically examine the information society policies as they evolved in the period 1994-2006, investigate the role of the European Union in making information society policies, and discuss the types of governable practices that rendered the information society an object to be governed and managed in a way that transgresses national borders.

2 LITERATURE REVIEW

The discussion about the role of IT in increased interconnectedness of states, polities and economies through the processes of globalization has primarily focused on the ability of multinationals to transcend national borders to create their own conditions of operation (Dunning 2002). However, in a seminal paper, King, Gurbaxani et al. (1994) point to the importance of government intervention to facilitate innovation in the production and use of IT.
The way the states have been implicated in intensifying connections through, and in relation to, ICT have received much less attention (Walsham 2000). Early research on the information strategies of advanced nations include Kahin (1997) on the US and Moore (1998) on the UK. The turn of the century has seen the emergence of academic literature on various national strategies for the information society (Cronberg 1997; Silva and Figueroa 2002; Iosifidis and Leandros 2003; Hall and Loefgren 2004; Chen, Gao et al. 2005; Miller 2005; Sadagopan and Weckert 2005). These studies have produced a wealth of information about the different approaches of information society policies followed by states worldwide, but have, been mostly descriptive, and have made little progress to theorise on the ways in which such policies came to be considered as political priorities at specific points in time.

Kubicek and Dutton (1997) do attempt to turn our attention to the political nature of the creation of such information society strategies and policies. They analyse the social construction of the national information infrastructure rhetoric, demonstrating the conscious and fortuitous choices made in its creation, and the impact it had on policies thereafter. Moreover, the role of donor agencies and multinational consultancies in determining national ICT strategies has been highlighted (Madon 2000; Soeftestad and Sein 2002; Ciborra and Navarra 2005). In a more critical vein, Godin (2005) critiqued the role of OECD for turning the knowledge society into an easily digested buzzword taken up and consumed by its member-states.

Despite these efforts to explain how information society policies have been shaped, there is a need to challenge the means-ends rationalistic assumption of the creation of information society policies, and to further explore the role of institutional actors in shaping them. I suggest that a closer inspection can reveal a layered and multifaceted phenomenon which challenges the reasons why national strategies and the resulting institutional interventions have risen in importance globally and more specifically in the European area.

3 THEORETICAL FRAMEWORK

The research is grounded on Foucault’s concept of governmentality, which he developed in his later lectures (2007), when he attempted to veer away from power and discourse as autonomous forces and bring agency back into the discussion. Governmentality reflects the concern with how government takes place, but addresses government in a broader way than the study of the institutions of government or even governance. It instead concentrates on the ways in which individual and collective behaviour becomes the object of government. The “conduct of conduct” (Foucault 1982), i.e. the way agents are constituted as subjects of a government rationale becomes the overarching theme.

Government is closely intertwined with thought and the production of truth. To govern means to govern based on a rationale, or a process of thinking, which in certain points in time assumes the status of truth. Thought congealed in practices of government becomes taken for granted and is rarely challenged (Rose 1999). The production and reproduction of truth determines the options that appear as feasible for individual action, and renders other options unthinkable. What becomes important, then, is to understand the thought, or rationality, of government in order to reveal the way agency is constructed.

Understanding the rationality of government requires the investigation of the material arrangements on which government is embedded. Rather than assuming the existence of invisible power relations enabling the government of agents, a Foucauldian analysis of government focuses on the practices and techniques which provide a material assemblage of heterogeneous elements, which allow the government of behaviour over a distance (Dean 1996; Dean 1999). Techniques of government, such as tools, procedures, vocabularies and technologies, make the government material, and help produce an analysis not merely of ideology, but also of the structures in which it is embedded (Kumar 2005)

Drawing from the above discussion, I will be appropriating the concepts of regimes of practice and regimes of government, techniques of governments and the idea of a field of visibility, i.e. a domain
which is rendered visible through particular practices and techniques of government, which might otherwise remain in obscurity.

The conceptual lens of governamentality allows the researcher to examine with an inherently critical eye the construction of the information society as a political and policy object in need of government attention in the European space, as well as the impacts this has had for the development of national information society policies that shape in various degrees the appropriation of ICT through the society and economy.

4 METHODOLOGY

The research is a historical case study (Mason, McKenney et al. 1997). This method of research allows the phenomenon to be examined in context over a period of time, so that the historical interconnections and patterns can be investigated. Studying the historical evolution of a phenomenon is in line with a Foucauldian tradition of research, as it allows the researcher to examine how social life is construed and thus challenge its current form.

The research draws on two sources with regards to empirical data. Firstly, a wide range of documents of policy was collected and analysed discursively. An analytics of government was pursued, in line with Foucault’s later works, according to which questions are asked of who governs, and under which truth claims and techniques (Dean 1999; Rose 1999). The aim was to understand the ways in which the information society was construed as a political and governable object, rhetoric, as well as an imperative for national action.

Secondly, semi structured in-depth interviews were conducted with a wide range of informants from the ICT policy domain in European Commission, as well as Greece. The informants’ accounts were critically examined to understand the value assigned to the information society policies and initiatives, as well as to challenge the rationality and techniques through which the information society was constituted as an object to be governed.

Analysing the data consisted of determining patterns, trying out causal chain scenarios, as well as establishing empathy with the protagonists of the story (Mason, McKenney et al. 1997). The researcher’s impressions were compiled in an analytical narrative, which highlighted important and recurrent themes, as well as temporal linkages.

The analytical narrative recounted the policies designed and implemented on ICT for almost two decades, from 1985 to 2006, tracking in parallel the history of Greek and European policies in ICT, focusing on the efforts to promote the wider use of ICT, rather than on the research and regulation aspects. For the purposes of the paper, the period from 1994 to 2006 is being considered. A narrative for this period is provided below, to form the background of the analysis.

In the Analysis section below, I address two questions. To begin with, I attempt to understand under which rationality the information society became an object to be governed, through the successive attempts to make it the object of policy at the European and national levels. In doing that, I explore how its identity was constructed and shifted through time. Secondly, I seek to explore how the Greek responses to the information society were shaped under specific regimes of truth and practices.

5 GOVERNING THE INFORMATION SOCIETY – AN EVOLVING REGIME OF TRUTH

Governing the technological artefact has always been within the aspirations of the EU. Even if not always in a visible political position, governing the deployment ICT, usually through research programmes, has been within the scope of the EU. In an insightful analysis of the role of technology in furthering the purposes of European integration, Barry (2001) has argued that the EU has attempted to
enforce homogeneity and inter-nation coordination through the creation of technical standards, while the construction of digital networks has advanced closer integration among member-states and the EU itself. Around the middle of the 1990s, the governing of the technological artifact emerged as a new object, the information society, which was to become the centre of public attention and policy. The information society was to be governed, measured and managed. Rendering the information society an object of government begets further questioning. By which rationality would this new object be governed? Who was to govern it and how?

In 1993, the information society as a rhetorical object was brought into the highlight in the Bangermann report, one of the most influential European policy documents in the domain of ICT, released under the title *Europe and the global information society*. It highlighted the role of ICTs in improving the competitiveness of the European economy, which faced the increasingly technology-based competition from the United States and Japan. The information society was constructed as primarily an economic object, and as such it needed to be managed according to the dominant neoliberal paradigm. As an economic object, the private sector would be “entrusted” with its creation (European Commission 1994, p.10). Its motor would be private innovation, produced to be marketed, and safeguarded by well-established patent systems. As an extension of the market, it needed to abide to the rules of competition; the national and regional governments needed to make sure of it. The advent of the information society was also understood to increase the urgency for further liberalisation and privatisation; market barriers needed to be lifted to allow an unmanaged European information society to face up to the challenge of global competition. Moreover, individuals were called to take ownership of the changes and take action and risks to respond to them. A distinct regime of truth emerged around the ‘European’ information society: the business in the information society was to be an innovative one and the individual an entrepreneurial one.

The European Commission’s action plan, in 1994 (European Commission 1994), detailed how the information society was to be governed. The private sector was to have “prime responsibility” for the financing and deployment of the information infrastructures, whilst member-states were urged to “promote the information society” to their SMEs. Moreover, timelines were set for the creation of European guidelines and regulatory frameworks on tariffs, intellectual property rights, competition, electronic protection, privacy and standardisation. This and only this was to be the legitimate area of action for the state in the information society.

The continuing policy-making activity, however, points to a desire, or perceived need, to make the information society the object of public policy. The action plan at a first level set a number of instructions for achieving a goal. More than that, however, it presupposed a level of knowledge about the information society and in this way attempted to render it programmable. The European Union’s action plan minimally attempted two things: it made the information society a distinct social arrangement whose nature and aspects are familiar and known, and which can thus be legitimately governed through specific instructions. Furthermore, by making the information society into a global social arrangement surpassing the capabilities of distinct states, it set the corner stone for rendering the European Commission itself as the appropriate locus of policy decisions.

In Greece, the *Greek strategy for the information society: Tool for employment, growth and quality of life* made its appearance in 1995. The product of advisors in the Ministry of Industry, Energy and Technology, it saw the information society as comprising an innovative private sector fuelling the economy with new digital products and services delivered over infrastructures created by the enterprises themselves. The SMEs would be managerial and innovative in order to survive in the particular vision of the economic and market conditions in the information society. The state was to take a light-touch approach, responsible for educating the population and ensuring fair distribution of the benefits.

Despite the heavy state-centric character of the country, and its limited technological base (Thomadakis 1995), the Greek strategy of 1995, which inaugurated the ‘information society’ as a rhetorical object for the first time in Greek policy-making, subscribed to a particular version of truth
about the information society, originating in the EU. It reproduced the discourse on the innovative business and the entrepreneurial individual as the pillars of the information society, even though it was succinctly at odds with the capabilities of the Greek public and private sectors.

The strategy was also drawn at a particularly high level. It set decade-long targets, but specified no actions or timelines to implement them in the short term. No programme of actions was specified, as if a level of knowledge about the discussed social phenomenon could not be achieved to lead to its being rendered programmable. Seeking an explanation for the reason of existence of this strategy, and of more to come, I return to this point when I look at the practices of self-government and discipline later on.

Back at the EU level, in 1999, the European Commission proposed the eEurope initiative as the new EU strategy for the information society. It was created by the newly founded Information Society Directorate General and was endorsed as an integral part of the Lisbon Strategy in 2000. Literature has already discussed the materially different character of this strategy from the previous one, particularly in the way it upheld the social and cultural dimensions, instead of the market and economic rationalities of the information society (Goodwin and Spittle 2002; Chadwick and May 2003; Berleur and Galand 2005). What is more pertinent to this analysis is the shift in what was held true for the information society and how it should be governed.

More specifically, the information society no longer revolved around the entrepreneurial individual and the innovative business; it was a different object to be governed. The information society was now fraught with the dangers of digital exclusion of the unconnected, of unemployment for the under-skilled, of consumer exploitation, and of obsolete government processes unresponsive to new demands. For these dangers to be addressed, private entrepreneurship and innovation, although necessary, were no longer considered enough. The information society was now in need of more governing; it was in need of overt government intervention (Berleur and Galand 2005; Liikanen 2005).

Two action plans, in 2000 and 2002, attempted to render the new vision of the information society programmable and governable. The action plans prescribed a list1 of e-priorities, with e-government, e-health and e-inclusion featuring prominently among others. A further list of twenty government processes to be modernised and offered over the Internet by all member-states was established. Interventions like these, most of them of a non-compulsory nature, needed to take place at the national level in set timelines. Data was also to be collected and collated by the European Commission documenting the progress at the national level. A new unit within the Commission was established to undertake this exercise of benchmarking across sectors and countries. Best practices were to be presented and shared in the Commission’s numerous fora attended by national policy makers.

The further attempts to govern the information society mark two important changes in the regime of truth. Not only was the information society now to be governed by the state, but the European Commission was to govern the governing of the information society. On the one hand, the state intervention for the creation of the information society became not only the legitimate, but also the recommended way of doing it. Taking a hands-off approach became a hard policy to justify nationally and internationally, as national backwardness was now visible to, and thought to affect, the whole Community.

On the other hand, the constitution of the Commission as a legitimate locus of governing the information society was further strengthened, but now something qualitatively different defined its role. Not only did the Commission legitimately speak of, and act upon, the information society, but it

---

1 The list included twenty government transactions, of which twelve targeted businesses and eight targeted citizen, and which were considered primary targets for reaping the benefits of the ‘information society’. Four stages of reform were specified: provision of information online, possibility to download forms, possibility to initiate the transaction online, but need to complete the transaction offline, and finally possibility to complete the transaction online. The stage of computerisation was understood to be an important measure of development of the information society.
could now govern the governing of the information society by national authorities too. Through discreet, yet effective, disciplining mechanisms, constituted through the action plans and strategies, the Commission attempted to assume the authority to determine the ‘correct’ national conduct for a phenomenon no longer presented as one of national sovereignty, but re-presented as one of global/European validity. How effective these disciplining mechanisms were and the extent to which they indeed managed to govern national conduct is taken up on in the following section.

In the national context, the White Bible for Greece’s Entry into the Information Society was created and publicised in 1999. The strategy, which effectively constituted nothing more than a non-binding white paper, documented its authors’ vision for the role of ICT in the progress country. The choice of name is quite emotive. It was neither a strategy, nor a policy, not an action plan. It was a bible, a document of conviction, of the dangers of not following a specific path and hopes of a better future in the opposite case. It was about rights and obligations: the rights of citizens in the information age, and the obligations of the state to ensure the future of its citizens and businesses in the new socio-economic arrangement.

As a bible, the value of the White Bible could not be discussed in terms of its merits, neither could it be challenged by counter-arguments but through the positioning of the discussant in a opposing paradigm, or, in a different regime of truth. But the White Bible reiterated the dominant at the time regime of truth about a state-led information society and the role of the state in fostering the transformation. It discussed e-services and e-rights for the new type of citizens turned consumers of public and private electronic services, and the state’s role as educator, protector and procurer. Challenging its dogma would have meant openly opposing a version of truth about how to pursue the information society that was made legitimate by important institutional players. It did not happen but much later in the day, when the Bible’s ‘doctrine’ was juxtaposed to the reality of implementation.

In 2003, the drafting of a new information society strategy began in Greece by two academics-turned-policy implementers for the information society, and keen to leave their distinct mark. The draft, which was never finalised, maintained the truth of the information society as shaped by social, instead of market values, but advocated the need for a more horizontal mobilisation of the civil society to compliment the vertical role of the state. An ‘improved’ vision of the information society is upheld, simultaneously drawing from the dominant regime of truth, and emergent regimes about the power of networks (mainly the Internet) to connect and empower discreet individuals into powerful collectives.

Back in the EU, a new information society initiative, i2010, produced in 2005, stressed the provision of favourable business environments through interventions and policy-making. It employed different discourses of media policy and digital convergence to suggest “proactive” intervention to enable market growth, innovation, and “quality of life”, understood as social and digital inclusion. Different discourses, same rationality of government. The emphasis on benchmarking as a technology of government had given its place to the need for harmonization of technical standards and regulatory frameworks to facilitate the emergence of a European information society. The Commission’s role of bringing about these changes was considered nearly commonsensical.

In Greece, a new strategy was initiated yet again in 2006, called Digital Strategy. The product of labour of very few policy advisors, it reframed the question of the information society in terms of quality of life and economic productivity. The discourses appropriated were very similar to i2010, but for the first time in the Greek policies on the information society, the Digital Strategy was more than a vague picture of a vision. It broke down the information society as an object into manageable pieces and time-boxed them. The document itself, which was printed in an impressive illustrated publication and circulated widely in the political, policy and business cycles, through its timetabled actions, rendered the information society into a object that was new, yet known and well understood. In a governable fashion, the state knew what the correct response of its functions, businesses and citizens was. The information society was being rendered governable at the national level.
6 THE INFORMATION SOCIETY WITHIN A REGIME OF DISCIPLINING AND SELF-DISCIPLINING PRACTICES

The previous section discussed the constitution of an evolving regime of truth about the information society through the production of a series of European policies and the way it was reproduced in Greek policy-making. I also argued that the Commission attempted to govern not only the information society through its constitution of an object of policy, but also the governing of the information society by the member states. In the following section, I go on to discuss distinct ways in which the Commission was partly successful in its attempts to govern the behaviour of at least one member-country, Greece, through mechanisms which had as a direct impact to govern the behaviour of the national policy-makers of the information society.

6.1 Shaping the degrees of freedom

The role of EU-produced documents as objects that rendered the information society a known, familiar and thus governable social arrangement, through the production of concrete action plans and timelines, was discussed above. Unlike these, however, the Greek information society documents, at least the ones up to 2006, made little effort to re-present the information as a well-known object to be governed, and thus could not effectively function as means of governing other actors’ conduct with regards to the information society and its national implementation. Their purpose then needs to be sought elsewhere.

Interviews with Greek policy makers revealed deep contradictions as to the reason of creating these documents. An example of this can be investigated in the case of the creation of the Greek White Bible produced in 1999. A key policy-maker behind the drafting of the White Bible found it “disgraceful” that, before the creation of the White Bible Greece was the only European country not to have an information society strategy, as if it highlighted a shortcoming of policy attention or shrewdness on the part of Greek policy makers in appreciating the magnitude of the impeding change. Pointing out that the White Bible was not the first Greek information society strategy, as the 1995 one preceded it by a few years, he dismissed it as inappropriate.

This can be interpreted as a question of legitimacy with regards to dominant truth on what the information society and the role of the state in fostering it should be at this specific point in time. In this respect, the 1995 strategy was not legitimate in 1999 on two counts. Firstly, because it was incompatible with the shifted dominant regime of truth about the particular version of the information society pursued by the Commission at the time. It was out of tune with the prevalent congealed thought about what kind of object the information society was and how it was meant to be governed. Secondly, because not creating a new strategy was incongruent with the expected national policy response to the object of the information society. For the Greek policy makers creating the White Bible in 1999 (and there is evidence that the same hold true for the two subsequent strategies) was thought to demonstrate a rational and purposeful approach towards planning and investing in ICT, which they believed to be congruent with what was expected of them by the Commission. The content of the strategy was less significant than its perceived symbolic value as the outcome and instrument of rational deliberation on managing and constructing an information society.

So, the whereas the purpose of the European documents was to render the information society an object that was known well enough to be governed through action lines and deadlines, the purpose of the Greek documents was less to act as a set of instructions, but rather to symbolically demonstrate to be compatible with the expected pattern of behaviour, and the accepted truths about the information society at specific, important in terms of timing, points in time.

The Commission’s attempts to govern the information society established a regime of practice where the creation of an information society strategy was the appropriate thing to do. The regime of practice
effectively defined the degrees of freedom of Greek policy-makers, who, working within the context of a country with limited capacity in technology policy, saw their options to be already defined.

What this further means is that the assumed position of the Commission as the legitimate governor of the governing of the information society was not challenged by the Greek policy-makers. They responded to the EU-originating regimes of truth about the information society by upholding the authoritative position of the Commission in speaking of, and initiating action on, the information society.

6.2 Mechanisms of discipline

The Commission employed benchmarking as one of the core methods of achieving compliance with the targets of its version of the information society, by “track[ing] progress towards the agreed targets” on a web space (European Commission 2000) and ensuring that well-performers were congratulated, and laggards made visible to all. Interviews with Greek policy-makers revealed the role that cross-comparison and benchmarking tables played in their decisions to act. As a mechanism of government, the benchmarking exercise has the capacity to re-define an array of disparate countries as a homogenous area of comparison. Re-presenting all European countries in the same space has the potential to create a European technological zone to be governed (Barry 2001).

The effects of the benchmarking exercise in governing the Greek policy makers’ actions have been however mixed. All of the higher-level policy makers interviewed in Greece were acutely aware of the “dire image of the country abroad” owning to its consistent positioning at the bottom of the benchmarking tables. The comparison with other Southern European countries, as well as the new accession countries was thought to be particularly damaging. Their efforts were “geared towards closing the gap”, which would then be rendered visible in the benchmarks. Interviewees in Brussels also extensively utilised the benchmarking tables in our meetings to point out that Greece consistently held the last position and that even their persistent efforts had not managed to reverse the situation.

Despite the prominent position of the benchmarking exercise in the rhetoric of Greek and European high-level officials, and the related discourses on catching up, the visible effects of its governing of practice on all but the higher-level policy-makers were more ambiguous. The practice of benchmarking was often deconstructed and challenged both discursively and in practice. For example, numerous interviewees in Greece brought up the list of twenty proposed government services to be offered over the Internet across Europe and utilised it as a yardstick for measuring the country’s progress towards the “information society”. The same informants were however often critical of the local relevance or success of these projects as well as of the way they were “imposed” on them and measured. The constitution of a unifying and comparable European technological space was in practice defied in favour of the uniqueness of national socio-economic conditions. The practise of benchmarking was relegated to a secondary role, which was more symbolic than governing.

7 DISCUSSION

The analysis above provided evidence in support of the argument that the information society was constituted as a political object to be governed by the Commission, which continuously shaped its identity and the claims of truth by which it would be governed. Through practices of discipline and self-discipline the degrees of freedom of Greek policy-makers in ICT were shaped through their interaction with the Commission’s information society policies.

The creation of information society strategies has been usually discussed as the purposeful response to the intensification of information production, processing and dissemination in the whole fabric of the society and economy. Their sudden proliferation at around the turn of the century has rarely been questioned. In an insightful critique, Mosco (2004) addresses this question by analysing the mythical aspects of the discourse on ICT, in order to explain how, repackaged into the information society or
the digital era, the ICTs captured the imagination of bricoleurs of governments around the world. His study reveals the consumption side of the discourses that imaginative bricoleurs of governments create, furthermore providing evidence for the disciplining and self-disciplining effects of these myths, a concept similar to this discussion of regimes of truth.

The research falls within the critical stream of thinking, in attempting to challenge the dominant perceptions of social reality through “providing alternative readings (Alverson and Deetz 2000, p.17). Providing alternative reading a Foucauldian lens requires more than analysing language to reveal the hidden notions of government. Language is constitutive of government, as government can only take place under a certain description. A regime of intelligibility is what allows government to govern specific parts of social life. As such, language does not only describe acts of government; it also makes them possible. Discursive practices are both part of, and help constitute a regime of practice, i.e. a specific way of making sense of the world. Regimes of practices define what holds true in different points in time and determine what legitimate social action is. The analysis has attempted to show the distinct ways in which language actively determined the government and self-government of people and artefacts. In doing that, it extends existing studies of the European information society (De Miranda and Kristiansen 2000; Goodwin and Spittle 2002; Chadwick and May 2003) which critique the ideology behind the European information society discourse, but make no reference to the impact this discourse for social action.

What the analysis has further revealed is the important and often neglected role of regional, supranational organizations in setting the agenda by filtering global trends and technological concerns for their members. Working alongside trends of globalization, such organizations effectively scan the technological landscape for solutions that match their aims and promote them, thus influencing a zone around them where ambiguity and available options are reduced. The EU helps isolate, in certain ways, member-states from the direct impact of globalization.

Finally, it is important to note that the arguments of this study are derived from an in-depth study of one European country. As such, they are not necessarily generalizable to the rest of the European countries which face a different mix of socio-economic conditions. For example it would be expected that not all countries subscribed to the dominant regime of truth claims and practices produced by the EU. Countries that find it hard to articulate a technological vision of their own may more susceptible to such interventions. It is expected that the influence of regional organizations will be reduced in countries with stronger technological traditions. However, further research would need to examine whether similar findings arising in other cases of financial, technological or policy interplay at different levels of governance, such as international donors and developing countries.

8 CONCLUSION

This paper sought to critically examine the constitution of the information society as an object of political and policy discourse, and challenge the rationalistic assumption that information society strategies respond to clearly defined needs, by revealing the dominant role of supra-national institutions in determining the available options for national governments. The paper critically discussed the constitution of the information society by the European Commission as a discursive political and policy object and examined the role it played in the emergence of national information society strategies.

The discourse analysis of the information society strategies has revealed how the construed identity of the information society and the rationality by which it would be managed shifted through time from more liberal to more state-centric. The regime of truth dominated the conceptions and interpretations of the information society in Greece, where strikingly similar versions of the truth were expressed. The analysis has further showed how seemingly apolitical practices and devices, such as the information society documents, have had highly disciplining effects on the Greek policy-makers’ decisions to bring about particular types of responses to the information society. Simultaneously, the
Greek policy-makers willingly subscribed to the regime of practice, reproducing similar truths about the information society and self-governing their behaviour, either because they felt that degrees of freedom were extraneously defined, or in order to pursue for instrumentally satisfactory outcomes.

The contribution of the paper lies in its theoretical conceptualisation of the way information society policies seem to have been constructed in a particular social context. The discussion of governmentality appears to have been a fruitful way to theorise the phenomenon and to provide propositions which could further lead to theoretical generalisations.

ABSTRACT:

Electronic government (e-government) has shown encouraging results in developed countries in the context of delivering electronic information and services to citizens. However, despite the many lessons that can be learned from the experiences of those e-government initiatives, developing countries are still faced with various issues pertaining to their implementation of e-government services. Like many other developing countries, the e-government initiative in the state of Qatar has faced a number of challenges since its inception in 2000. Using a survey based study this paper describes citizens’ behavioural intention in terms of applying the Unified Theory of Acceptance and Use of technology (UTAUT) model to explore the adoption and diffusion of e-government services in the state of Qatar. Analysis of the results indicates that there is significant positive relationship between performance expectancy, effort expectancy, social influence and behavioural intention to use e-government services for the citizens of Qatar. Implications for practice and research are discussed.

KEY WORDS: Adoption, Diffusion, E-government, UTAUT, Qatar
1. INTRODUCTION

The Qatari e-government initiative was launched in 2000. In global terms the UN e-government readiness report (2008) ranked Qatar’s e-government project as number 53 worldwide. As in many countries, the national e-government focus in Qatar is to achieve the highest performance in executing governmental transactions electronically, through streamlined business processes and integrated information technology solutions (IctQATAR, 2008). In 2004, ictQATAR was established to manage and develop the overall Information and Communication Technology (ICT) strategy in Qatar relating to infrastructure, service delivery and legislation of public services. A year later ictQATAR took overall control of the national electronic government initiative with an aggressive plan for e-government program parallel with e-health and e-education programs using a phased implementation plan. As part of this ongoing strategy to encourage accessibility of e-government services, free wireless internet access was introduced in 2007 in public parks. The Qatari government hopes that this concept will encourage more citizens to use e-government services and help bridge any digital divide that may exist in the state of Qatar by augmenting citizens’ participation and engagement in public services.

Given the above context, the rationale for this research is to gain a better understanding about the adoption and diffusion of ‘e-government services’ from Qatari citizen’s perspective. The relative newness of the e-government concept in Qatar and the lack of prior published research that explore the citizen’s perception of electronic government information and services offered the motivation and rationale for undertaking this research. Furthermore, initial research conducted by the authors indicates that the adoption and diffusion of e-government services has been slower than the Qatari government’s expectations (Al-Shafi and Weerakkody 2008;). Given this context, this research aims to examine the factors influencing citizens’ intention to adopt e-government services in Qatar. In order to achieve this aim a survey based quantitative research strategy is adapted. Since the primary aim of the research is to explore the intention of citizens to use e-government services in Qatar, this is achieved by examining their perceptions of ‘Ease of Use’ and ‘Usefulness’ in relation to the e-government services offered. To pursue this line of inquiry, this research uses Unified Theory of Acceptance and Use of Technology (UTAUT). UTAUT theorizes that an individual’s behavioural intention to use a technology is determined by performance expectancy, effort expectancy, social influence, and facilitating conditions (Venkatesh et al., 2003; 2008).

In an e-government context, Moon (2002) proposed that IT and web-based public services can help governments to restore public trust by coping with corruption, inefficiency, ineffectiveness and policy alienation. Conversely, lack of access to e-services (Chircu and Lee, 2005) and digital divide (Carter and Belanger, 2005; Carter and Weerakkody, 2008; Chen et al., 2006;) are challenges that can impact on trust and thereby impede the further take-up of e-government services. To bridge the digital divide, Reffat (2003) suggests that governments could help by providing computer education especially to elderly and younger people. It has also been found that younger people are accessing the internet more compared to the elderly (Kurunananda and Weerakkody, 2006). One of the main reasons is that younger people enjoy the use of the internet whereas the elderly find it difficult to learn and use. Also, the elderly do not want to be bothered with anything relating to technical matters (such as learning to use the mouse, modems, network connections and other peripheral devices) and software aspects (such as Internet Explorer).

The paper is structured as followed. In the next section a literature perspective of e-government is offered followed by an outline of the theoretical model used for the research. Then the empirical background to the research is presented. This is followed by the methodology used for the research and a presentation of the empirical results. Finally the paper concludes by analyzing the empirical results, discussing the research implications and identifying areas for future research.
2. E-GOVERNMENT IN THE STATE OF QATAR

The State of Qatar is a peninsula with a strategic position at the centre of the west coast of the Arabian Gulf. The total land area is approximately 11,437 sq km. The population estimated to be around 1,500,000 (The Peninsula, 2008; Al-Shafi and Weerakkody, 2008); however, only a minority of the population is citizens by birth, while the rest are residents who live or work in Qatar and are not Qatari’s by birth (Al-Shafi and Weerakkody, 2008).

E-government was launched in Qatar in July 2000 and the initial period of strategy formulation and implementation was laggard compared to e-government efforts during the same period in developed countries. However, with the establishment of ictQATAR in 2004 and their consequent takeover of the national e-government initiative a year later resulted in accelerated progress in the last three years. Parallel programmes were introduced in key areas such as health, interior affairs and education. The vision of ictQATAR states “Serve as independent and fair regulator, protecting consumers and businesses from unfair practices as Qatar transitions to a competitive telecoms market. And Lead the government’s ICT strategy, nurture innovative technologies to benefit those who live and work in Qatar, and help make people from all walks of life become comfortable with technology” (ictQATAR, 2008).

The Qatari e-government site offers many services, ranging from student registration and paying traffic violations to applying online for visas and permits (Al-Shafi and Weerakkody, 2008). In global terms the UN Global e-government readiness report (2008) ranked Qatar’s e-government project as number 53 worldwide, where as in 2005 it was ranked as number 62 worldwide (Al-Shafi and Weerakkody, 2008). In addition to this, the UN (2005) report considered the Qatari e-government project to be regional (West Asia) best practice. This implies that major improvements and developments have been made during recent times. As part of Qatar government’s ongoing efforts to increase accessibility to e-government services and bridge the digital divide, free wireless internet access in public parks – (iPark) initiative was launched in March 2007; this concept provides “Broadband for all” and aims to foster a knowledge based society. The primary goal of the initiative is to increase internet usage by establishing “hot spots” in public parks (IctQATAR, 2007). There are currently three designated wireless internet hotspots throughout selected public parks in the city; these parks are targeting visitors who have internet access available on their laptops, PDAs, and other internet-ready devices (The Peninsula, 2007).

3. E-GOVERNMENT ADOPTION: A LITERATURE PERSPECTIVE

With the popularity of e-government growing, various researchers have offered different definitions to explain the concept (Seifert and Petersen, 2002). However, these definitions differ according to the varying e-government focus and are usually centered on technology, business, citizen, government, process, or a functional perspective(Seifert and Petersen, 2002; and Irani et al., 2006). The definition considered to be most suitable for the purpose of this paper is one that defines e-government as making full use of the potential of technology to help put its citizens at the centre of the e-services provided and which makes its citizens its intention (Waller et al., 2001).

Like e-business, e-government promises to deliver a number of benefits to citizens, businesses and governments. The most significant benefits of e-government, according to the literature, are delivering electronic and integrated public services through a single point of access to public services 24 hours a day, seven days a week (Reffat, 2003); bridging the digital divide so that every citizen in society will be offered the same type of information and services from government (Huang, 2007); rebuilding customer relationships by providing value-added and personalized services to citizens (Weerakkody and Dhillon, 2008; Davison et al., 2005); fostering economic development and helping local businesses to expand globally; and creating a more participative form of government by encouraging online debating, voting and exchange of information (Davison, et al., 2005).

Like any other new technology or organisational concept, the introduction of e-government to a country will also result in a number of challenges for the citizens and the government alike (Seifert and Petersen, 2002; Zakareya and Irani, 2005). Lack of access to e-services (Chircu and Lee, 2005; Huang, 2007;
Carter and Weerakkody, 2008), security concerns (Harris and Schwartz, 2000), trust (Carter and Weerakkody, 2008; Welch et al., 2005; Al-Sebie and Irani, 2005), individual differences (Reffat, 2003) and digital divide (Carter and Bélanger, 2005; Chen et al., 2006) are challenges that can impact on participation and thereby obstruct the further take-up of e-government services.

From the aforementioned, this research will focus particularly on the influence that technology complexity and e-government services have on the intention to use a new technology. Similarly it will also examine the influence performance expectancy and effort expectancy has on the intention to use such services.

In terms of adoption, several studies have explored e-government acceptance in the United States (Carter and Belanger, 2005; Carter et al., 2008) and the U.K (Choudrie and Dwivedi, 2005; Carter and Weerakkody, 2008). However, no studies exist that examine factors that influence Qatari citizens’ adoption of e-government services. In this respect Lee et al., (2005) state that cross-national research on e-government is sparse in the literature and Dwivedi et al., (2006) and Carter and Weerakkody (2008) highlights the need for studies that investigate the adoption rate and behaviour of e-services. Given this context, this study attempts to address this gap in a Qatari perspective by integrating the aforementioned constructs from the Unified Theory of Acceptance and Use of Technology (UTAUT).

4. TECHNOLOGY ADOPTION: A THEORETICAL BACKGROUND

Researchers in the field of Information Systems and Technology have for long been interested in investigating the theories and models that have the power in predicting and explaining behaviour (Venkatesh et al, 2003). Various models were developed, such as the Theory Of Reasoned Action (TRA) (Fishbein and Azjen, 1975) and Technology Acceptance Model (TAM) (Davis, 1982). Each model has its own independent and dependent factors for user acceptance and there are some overlaps (Dillion and Morris, 1996).

TAM has received extensive support through validations, applications and replications for its power to predict use of Information Systems (IS) and is considered to be the most robust and influential model explaining IS adoption behaviour (Davis, 1982; Davis et al., 1989; Davis and Venkatesh, 1996; Lu et al., 2003). On the other hand, it has been found that TAM excludes some important sources of variance and does not consider challenges such as time or money constraints as factors that would prevent an individual from using an information system. Also, TAM has failed to provide meaningful information about the user acceptance of a particular technology due to its generality (Mathieson et al., 2001). Consequently, a number of modified TAM models were proposed which are applicable to contemporary technologies (Horton et al., 2001; Chau and Hu, 2001). However, researchers are confronted with a choice among a multitude of models. Hence, a new model was developed to address these limitations, which is named as the Unified Theory of Acceptance and Use of Technology (UTAUT) model and the aim of the model was to understand intention/usage as the dependent variable (Venkatesh et al., 2003).

The UTAUT model consists of eight theoretical models: the theory of reasoned action (Davis et al. 1989), the technology acceptance model (Davis, 1989), the motivational model (Davis et al., 1992), the theory of planned behaviour (Ajzen, 1991), a model combining the technology acceptance model and the theory of planned behaviour (Taylor and Todd 1995), the model of PC utilization (Thompson et al., 1991), the innovation diffusion theory (Rogers, 1995), and social cognitive theory (Compeau and Higgins, 1995). The UTAUT model combines the previous eight theoretical models and is made up of four key factors that act as determinants of behavioural intentions and usage behaviour. Also, UTAUT posits the role of four key moderator variables (Age, Gender, Experience, and Voluntariness of use). Moreover, UTAUT model has been found to be preferred to the abovementioned theoretical models as it is able to account for a high percentage of the variance (R²) in usage intention (Venkatesh et al., 2003).

Venkatesh et al., (2003) have tested the unified theoretical model in four different organizational settings for a period of six months and the study showed significant predicts intention (performance expectancy,
effort expectancy, social influence, and facilitating conditions), whereas attitude toward using technology, self-efficacy, and anxiety were theorized not to be direct determinants of intention.

5. CONCEPTUAL MODEL AND HYPOTHESIS

From the aforementioned factors that make up UTAUT, this research utilized three independent variables (performance expectancy, effort expectancy, and Social influence) and one dependant factor (intention to use) to formulate the research model used for the study.

Performance expectancy is defined as the degree to which individuals believe that using a system will help them improve their job performance and contains five variables: Performance Expectancy, extrinsic motivation, job-fit, relative advantage, and outcome expectations (Venkatesh et al., 2003). Effort expectancy is the degree of ease associated with the use of the system (Venkatesh et al., 2003). Venkatesh et al., (2003) identify three constructs from the eight models that make up the concept of effort expectancy: perceived ease of use, complexity, and ease of use. Additionally, Marchewka et. al., (2007) claimed that this construct can be significant in determining user acceptance of information technology.

Social influence is “the degree to which peers influence use of the system”, whether positive or negative, it is a very main factor in many aspects of the lives of young people and is likely to be powerful (Venkatesh et al., 2003).

Facilitating conditions are the degree to which an individual believes that an organisational and technical infrastructure exist to support the system (Venkatesh et al., 2003). Facilitating conditions are comprised of three root constructs: perceived behavioural control, facilitating conditions, and compatibility (ibid).

Due to the constraint on the length of paper, facilitating conditions and use behaviour that are originally in the UTAUT model are excluded from the proposed model in this research. Additionally, facilitating conditions is predicted to have a direct effect on actual usage instead of behavioural intention to use (Venkatesh et al., 2003).

Based on the aforementioned and the theoretical context offered, this paper will test the strength of the hypothesized relationships mentioned in the theoretical model outlined in figure-1 and the appropriateness of the model in predicting users’ behavioural intention to use e-government services in the State of Qatar.

### 6. RESEARCH METHODOLOGY

To explore the argument set out above and understand the context of the e-government services initiative in Qatar, brief informal open-ended interviews (Yin, 1994) were conducted with four citizens and three researchers who are engaged in e-government research in Qatar during August 2008. The interviews lasted around 30 minutes and provided the context to formulate a detailed survey questionnaire that was to be used to investigate the citizens’ perceptions of e-government services in Qatar. Questionnaires were selected as the primary data collection methods as it is inexpensive, less time consuming and has the ability to provide both quantitative scale and qualitative data from a large research sample (Cornford and Smithson, 1997; Miles and Huberman, 1994). Questions were compiled from IT adoption literature to represent the constructs in the proposed research model (figure 1) and wording of the questionnaire was modified to fit the research context and background information collected from the initial informal interviews mentioned above. 36 closed format questions were used limiting individual responses to multiple choice answers, for example, ranking using Likert scale (5-point scale) and ‘yes’ or ‘no’ answers (Hall and Hall, 1996; Saunders et al., 2002). This enabled the information to be grouped and analysed statistically (Leung, 2001; Hall and Hall, 1996) using SPSS V15. Since the answers can be influenced by the order the questions are presented, this was carefully planned with an introduction which explained who the researchers represent, purpose of the research and how and why the respondents were selected for the research, and the importance of their answers to the research. The main body contained topical questions ordered logically and in a manner non-threatening to respondents (Liinamaa et al., 2004). After the questionnaire was designed, a limited testing was done using six researchers and ten practitioners. This was important to improve the questions and to test respondents’ comprehension and...
clarity before the actual survey was administered (Saunders et al., 2002). The pilot testing led to the removal of two questions and modification to another one.

The survey questionnaire was distributed to a total of 250 citizens between the period of September and October 2008; 216 usable responses were obtained. The response rate was good with 86.4% responding. The protocol followed for data collection was as follows. First, one of the researchers approached students and members of academic and non-academic staff in the national university of Qatar and general citizens who use the services of two government agencies that have implemented e-government services. The researcher identified himself and provided a brief description of the research and the main purpose of the questionnaire. Then, the process of distributing and completing of the questionnaire began within the premises of the university and the two government agencies. Whilst distributing the questionnaire to users, a brief explanation of the purpose and contents of the questionnaire were offered to the respondents and participation was on a purely voluntary basis. The questionnaires were completed in an environment free from external pressures and at the respondents’ own pace. The questionnaires distributed in the two government agency premises were collected after a period of between 10 to 30 minutes, and the questionnaires distributed in the university were collected the following day.

6.1 Data analysis

The proposed research model (figure 1) consists of three independent variables, Performance Expectancy; Effort Expectancy, and social influence and one dependent variable, behavioural intention to use. To check the responses of the questions, the first stage of the data analysis consisted of checking the responses and tagging them with a unique number. The authors generated the descriptive statistics (percentage and tables) and used Linear Regression analysis by utilising SPSS (Version 15.0). Descriptive data analysis provides the reader with an appreciation of the actual numbers and values, and hence the scale that researchers are dealing with (Dwivedi and Weerakkody, 2007).

7. ANALYSIS OF THE RESEARCH FINDINGS

Of these 216 usable respondents, 41.7% were females while 58.3% were males. In terms of education, the majority of respondents (54%) hold undergraduate level qualifications degrees, 10% hold postgraduate degrees (Masters and PhD) and 36% hold equal or below secondary school certificates. As far as age, the results revealed that the majority of respondents (34%) were found in the age group of 18-24, followed by the age group of 30-44 constituting around 23.6%, then age group of 25-29 (22%), and finally age group of 45-54 composing around 13% of the total respondents. In contrast, the younger groups (less than 18) and older age groups (greater than 54) consisted together of 7.4% of the total respondents. Additionally, the study shows that the majority of respondents used e-government services for: emails (79.6%); Fun (58%); Research (62.5%); Purchasing (32%); and others (23%).

As found in the study (table 2), the average scores for respondents’ Effort Expectancy ranged from 3.70 to 4.20. Descriptive statistics show that these scores are quite high. For Performance Expectancy, the score ranged from 3.63 and 4.25, which is quite high. Concerning social influence, the score ranged from 2.98 to 3.94, indicating that the scale is average. The last score reached is 4.22 for behavioural intention to use, indicating that the scale is quite high.

EE5. Overall, e-government system is easy to use 4.06 .815

Social Influence

SI1. Important people to me think I should use the online government system 3.57 .893
SI2. I would use online government services if I needed to 3.94 .807
SI3. I would use online government services if my friends and colleagues used them 2.98 1.109
SI4. People around me who use the e-government system have more prestige 3.26 1.025

Behavioral Intention

BI. I predict that I will use e-government system in the future 4.22 1.001

*Scores range from 1 to 5, where 1 = Strongly Disagree and 5 = Strongly Agree.

Table 2: Descriptive Statistics

7.1 Reliability Test

Cronbach’s coefficient alpha values were chosen to examine the internal consistency of the measure (Hinton et al., 2004) (table 3). Cronbach’s results varied between 0.56 for social influence and 0.83 for the effort expectancy. Hinton et al., (2004) have suggested four different points of reliability, excellent ranges (0.90 and above), high (0.70-0.90), high moderate (0.50-0.70) and low (0.50 and below). The previous mentioned values show that all of the constructs got high reliability except social influence which resulted to high moderate within table 3. The high Cronbach’s values of the constructs means that constructs were internally consistent and the reliability is measuring the same construct.

Table-3: Reliability of Measurements

Table-4 also shows that the correlation is significant to these key factors, Performance expectancy (0.405), Effort expectancy (0.268), and Social influence (0.247). Whereas, other moderators such as age, gender, and internet experience were found to be insignificant.

### 7.2 Regression Analysis: Factors Influencing the Intention to use e-government services.

A regression analysis was conducted with the use of e-government service channels as dependent variable and Effort Expectancy, Performance Expectancy, and social influence as predictor variables. From a total of 216 cases that were analyzed a significant model emerged \{F (3, 216) =12.325, p < .001\} (Table-5). The second significant statistic that was obtained from the analysis is the $R^2$, which ranges from 0 to 1, with 1 being a perfect fit model. It was found that $R^2= 0.185$ for this analysis. This factor explains 18.5% of the changes in the behavioural intention to use e-government services. Other unidentified factors account for the remaining 81.5%. Also, table-5 shows that of all the factors, the following have no significant impact on behavioural intention to use e-government services: Performance Expectancy ($\beta = 0.202, p= 0.029$); Effort Expectancy ($\beta = 0.173, p= 0.065$); and Social influence ($\beta = 0.166, p= 0.032$).

### 8. DISCUSSION AND CONCLUSION

This paper discussed the results of a survey targeted towards e-government service users in Qatar and it provides a representative account of the citizens’ perceptions of the e-government services in the state. The significant and non-significant factors found in the study and their influences on practice are outlined below.
8.1 Significant Factors
Of the adoptions factors, performance expectancy, effort expectancy, and social influence all had a significant impact on intention to use the Qatari e-government services.

8.2 Non-Significant Factors
Gender, age, and internet experience were found to be insignificant in terms of predicting the behavioural intention to use e-government services.

8.3 Implications for Practice
Citizens using e-government may benefit from the services and consequently encouraged to adopt e-government. If the government provides more benefits to its citizens in terms of convenient access and prompt services, when compared to the old and traditional means, then possibly this practice might spread the use of e-government services throughout the Qatari society.

Furthermore, the conclusions that have emerged from the analysis presented in this study are as follow:

- Although research exists that explores citizen adoption of e-government services in many countries, the authors argue that currently there is no independent studies that examine e-government adoption in the State of Qatar.
- Three constructs (namely, performance expectancy, effort expectancy, and social influence) significantly influenced the behavioural intention of citizens for adopting e-government services in Qatar.
- Empirical finding suggests that the influence of the remaining three constructs (namely, Gender, Age, and Internet experience) on citizens behavioural intention of the e-government services in Qatar were non-significant.
- Five constructs (namely, performance expectancy, effort expectancy, social influence, age, and Internet experience) were found to have a positive affect on behavioural intention. Whereas, gender was found to have a negative affect on behavioural intention.

Given these findings, it can be concluded that the e-government services initiative in Qatar has been successful initially in promoting wider access to the Internet. This is encouraging from an e-government perspective. Yet, much more can be done to raise awareness of e-government in Qatar such as advertising and promoting the national e-government website and setting up citizen service centres to assist those who are less-computer-savvy to adopt e-government services. While the research findings are encouraging from a practical perspective for the Qatari government, from a theoretical perspective these results reconfirm that technology acceptance is influenced by key constructs such as Performance Expectancy, Effort Expectancy, and Social influence aspects of the e-government services used. From a practical perspective however, one has to recognise the fact that although the survey results are encouraging, e-government has yet to mature in the state of Qatar since its inception in 2000. This is sad considering the progress other countries in the region, such as Dubai and Bahrain have made during the same period. As our survey results reflect, some of the reasons for this can be attributed to the fact that citizens still do not fully trust e-government services, are concerned about security and some are hindered by the lack of internet access. Furthermore, it can be concluded that this study extends the theoretical knowledge in the area of citizens’ adoption of technology (in this case, e-government applications and services) by testing the UTAUT model in a developing country (Qatari) context. Future research can focus on extending this study to other gulf countries and draw comparative analysis of e-government efforts in different countries in the region from a citizens’ perspective.

Abstract

E-Government can be considered the key element when it comes to modernizing public administrations as result to rising demands of citizens towards the provided services. At the same time, the demographic change posed numerous challenges to the development of new strategies. The need for inclusive E-Government, as well as human resource issues and the general reorientation of services require substantial investments. However, depopulation leads to a reduction in tax income, resulting in an imbalance of public budget. Cooperation between municipalities can be a promising approach to reduce costs and thus deal with major challenges of demographic transition in both front office and back office. Our exploratory single case study analysis introduces auspicious solutions related to these aspects and discusses in how far they might be applied to other settings.

Summary of Arguments

- Literature identifies demographic change as a key future research theme for E-Government while it is hitherto considerably under-researched.
- Aging and depopulation are two major, often inseparable elements of the demographic change.
- The demographic change creates a dilemma for public administrations as it, on the one hand, increases the need for reforms and IT investments in inclusive Age-Aware E-Government solutions, and, on the other hand, decreases the financial means available.
- Cooperation both in front as well as back office E-Government – in the case study setting in terms of a shared service center, inter-organizational collaboration, and public-private-partnerships – is a possible mean to cope with demography-induced challenges.

Keywords: E-Government, E-Inclusion, demography, societal aging, depopulation, elderly.
1 INTRODUCTION

E-Government is gaining in importance due to rising demands of citizens towards their local administrations in terms of service improvement. In addition, cost pressure forces public administrations to look for innovative ways of service provision. As a consequence of the Lisbon-Agenda, all EU (European Union) member states committed to implement an E-Government-oriented strategy as an effort of public administration modernization. On the other hand, demographic change is a topic of greatest practical and theoretical relevance. Not only academic literature (Birg, 2005; Coleman, 2006; Kaufmann, 2005), also every bigger newspaper talks about critical demographics in industrialized countries and population projections tend to receive a more dramatic paint every time they are released. Almost all of Europe is subject to a vast reduction of fertility and an increase of live expectancy, resulting in both depopulation and demographic aging (Birg, 2005). Thus, inclusive and especially age-aware E-Government is gaining in importance in all industrialized countries and is discussed as one of the most current topics in research and practice (Kaplan, 2005; Becker et al. 2008a; Niehaves et al. 2009).

Especially senior citizens are still very much excluded from participation in electronic (European Commission 2006). Against this background, the EU initiative i2010 set up a comprehensive strategy to strengthen citizen-centric inclusive E-Government services, dedicating future E-Government measures to a set of broad policy guidelines. Amongst others it is focused upon an inclusive European information society. This reflects that socio-demographic change and its consequences for E-Government are discussed as one of the key future E-Government research themes (Wimmer, Codagnone and Janssen, 2008). Against this background, we seek to address the following research questions within this paper:

What are major demographic trends in industrialized societies – taking the example of Germany –, what are possible consequences for public administrations, and what could be possible means in E-Government to react to these challenges?

In order to address the research questions, the remainder of the paper is structured as follows: Section 2 builds the theoretical foundation of the paper by analyzing related work, specifically on the demographic transition, E-Inclusion, and the effects of aging in the E-Government literature. Section 3 elaborates the research methodology applied, here: explorative qualitative single case study analysis based on nine expert interviews. Background information on the demographic situation in the case of Alphaville (pseudonym is used for reasons of anonymity), Germany, as well as the selected qualitative interview data will be presented in Section 4 and discussed and interpreted in Section 5. Our paper concludes with a discussion of limitations, a summary of results and an argument on potentially fruitful avenues for future research.

2 THEORETICAL FOUNDATION

2.1 Demographic developments

According to Hauser & Duncan (1959), demography can be defined as „the study of the size, territorial distribution, and composition of population, changes therein, and the components of such changes, which may be identified as natality, mortality, territorial movement (migration), and social mobility (change of status)” (Hauser and Duncan, 1959, p. 2). Here, literature specifically identifies three major factors underlying the development of demography: a) fertility, b) mortality, and c) migrations (Kaufmann, 2005). Accordingly, demographic transition can be understood as the progressive alteration of these determinants. Especially fertility and mortality have undergone significant changes in most industrialized countries. On the one hand, fertility has been declining due to, for instance, changed life models or family planning and the possibilities of birth control and abortion (Hill and Kopp, 2000). Morgan & Hagewen (2005) state that fertility transitions “[…] are complete in many developed countries and are in progress in much of the rest of the world. The transition model has three stages: relatively high and stable fertility, followed by a period of fertility
decline, and then followed by relatively low and stable fertility.” (Morgan and Hagewen, 2005, p. 231)

Mortality on the other hand has been declining as well, mainly due to advances in medical care (Höhn, 2000). Many industrialized countries experienced this process of demographic transition in the past and are now only able to prevent a population decline by retaining a positive net migration. Therefore, those countries with a fertility rate below the replacement level and low external migration are most likely subject to depopulation. Additionally, structurally weak regions are frequently losing population due to selective emigration (Kröhnert, Medicus and Klinkholz, 2007). Especially young highly mobile people move out of these areas in order to have better chances to get a job. Furthermore, while life expectancy is rising and populated experiences normal aging, less young people are following up which results in an overall aging of the society in these countries, and here in specific regions. The old-age dependency ratio that sets the number of people aged over 60 years in relation to the number of people aged between 20 and 60 years dramatically increased by two to three times its size in some industrialized countries (Birg, 2005). Therefore, depopulation and aging can be identified as the two major consequences of demographic transition in industrialized countries.

2.2 Effects of Aging

Even though the demographic transition has an influence on most of the described gaps, aging is certainly one of the most important aspects to consider when creating or adapting E-Government strategies. According to Davis’ Technology Acceptance Model (TAM), the two main dimensions of technology acceptance are perceived usefulness and perceived ease of use (Davis, Bagozzi and Warshaw). The perceived usefulness on the one hand has the biggest influence on the actual usage. Older people are lacking the awareness of advantages related to ICT usage because they are easily satisfied with their current possibilities and cannot imagine how ICT could improve their lives (Morris and Venkatesh, 2000). They have a critical attitude towards the usage of new technologies because they did not get used to them throughout their working lives. They appreciate the face-to-face contact and fear that new media will contribute to their isolation.

The perceived ease of use, on the other hand, is usually declining with an increasing age. An impairment of vision implies difficulties in recognizing details especially if they are presented on a computer screen (Shirley, 2004). Furthermore, it is harder for the elderly to adapt necessary skills because they have problems to understand complex new processes. Recent studies show that elderly more often experience problems with ICT than younger persons (European Commission 2004a, 2004b). They are still very much excluded from participation in electronic services (for the case of Germany see Table 1, Niehaves & Becker 2008).

Table 1. Online Service Usage (Germany)

However, the degree of technology aversion differs between individuals within the group of senior citizens. Browne states in this context that “once elders become avid users, their online skills and activities do not differ much from other age groups” (Browne 2000). Bavec’s (2008) correlation analysis between E-Government use by individuals and selected socio-economic indicators revealed "regular use of internet services", "interest in science and technology", and "trust (social capital)" as major factors for E-Government usage. All these indicators, however, have relatively low values among the elderly. While the Internet usage is comparatively low within the group of senior citizens, major reasons for not using E-Government services where missing personal contact, the complexity of E-Government services, and concerns about additional costs (for the case of Germany see Table 2). All these reasons for non-usage have been mentioned more often by senior citizens than they have been mentioned by the entire population (Niehaves et al. 2008).

Table 1: Reasons for not Using E-Government Services (Germany)

2.3 E-Inclusion

These trends pose several challenges to the development of E-Government strategies. The societal aging is one factor that leads to what is called the digital divide, in this context understood as an emerging polarization phenomenon in society, creating a gap between those who do have access to and use the potentialities of information and communication technologies, and those who do not (European Commission, 2004a). Apart from the described demographic gap referring to the fact that senior people often do not use ICT on a regular basis (E-Aging) (Becker et al. 2008b), several other gaps can be identified. Disabiliites can debar people from actively using information technology. For the usage of online services the most important disabilities to consider are visual handicaps, cognitive defects and limitations of motor skills. Geographical differences refer to gaps in ICT usage between different regions. Socio-economic gaps include differences in occupation, income and education whereas ethnical and cultural gaps identify barriers in the ICT usage of migrants and ethnical minorities.

Here, E-Inclusion focuses on the elimination of these barriers for the use of ICT. The declaration of Riga gives the following definition of E-Inclusion: “‘eInclusion’ means both inclusive ICT and the use of ICT to achieve wider inclusion objectives. It focuses on participation of all individuals and communities in all aspects of the information society. eInclusion policy, therefore, aims at reducing gaps in ICT usage and promoting the use of ICT to overcome exclusion, and improve economic performance, employment opportunities, quality of life, social participation and cohesion.” (Ministers of the EU, 2006, p. 1) The main focus of E-Inclusion is on creating accessible services over ICT. This effort can be divided into accessibility and usability aspects (Kraner, 2004). It is stated that the design and delivery of key services and public service policies shall be user-centric and inclusive, “using channels, incentives and intermediaries that maximise benefits and convenience for all so that no one is left behind.” (European Commission 2006b) Finally it also proposes to ensure “that electronic documents are available in such a way that they can be used by people with disabilities in an appropriate and, where possible, EU-wide recognised” (European Commission 2006a) format. With these statements, declared by 34 member countries, eInclusion in eGovernment or inclusive eGovernment becomes a key issue in many EU countries.

The discussion of related work shows that current research on E-Government strategies mainly focuses upon front end issues to deal with the process of demographic aging. As of today, back office improvements in the area of E-Government in order to cope with the demographic challenge are thus far under-investigated. Furthermore, challenges and possible solutions regarding depopulation are under-researched as well.

3 RESEARCH METHODOLOGY

In order to investigate into our research question, we chose an exploratory case study as method of analysis. The following classification and methodological discussion refers to Yin (2003) and Benbasat et al. (Benbasat et al., 1987). Our research goal was to collect qualitative data as a basis for building a preliminary theory of demography-aware E-Government (initiatives). A holistic single case design in a local public administration was chosen in order to allow for a rich understanding of the
potentially various (stakeholder) perspectives. Thus, 9 semi-structured expert interviews were conducted, pre-informed and structured with the help of a prior literature analysis. The resulting interview guideline included questions on demography, E-Government, the local government website, E-Inclusion and human resource management. Each interview partner was addressed with a selection of those questions corresponding to his or her specific working area. Besides such specific questions, the interviews also included an open discussion on all of the above given topics and were as well open to other related aspects that the interviewee brought up.

The experts interviewed held the organizational roles of, for instance, head of IT department, E-Government responsible, webmaster, head of human resources, coordinator of demographic program and the governing major. All interviews were performed in German and later translated into English. The case setting Alphaville was chosen mainly for the reason that our pre-analysis of potential case candidates indicated that the city was heavily affected by depopulation and aging, the identified two major demographic trends in industrialized countries, including Germany. In order to frame the qualitative case study findings and to discuss the question of generalizability, we commence the case analysis with a brief case description, including available studies and quantitative data on the specific case demographics and their embeddedness in the overall societal demographic developments. Moreover, we conclude our case discussion addressing Lee’s (1989) key questions of in how far a) the setting variables and b) the setting conclusions might potentially be i) repeatable and ii) generalizable (Lee, 1989).

4 CASE STUDY RESULTS

4.1 Demographic Trends in Germany

Regarding the demographic development in Germany and specifically in terms of the case under investigation – the city of Alphaville –, two major demographic trends can be identified: depopulation and aging.

A) Germany – as most industrialized countries – is subject to significant depopulation. In 2006, the average number of births per women reached a historical low with 1.33 children (German Statistical Office, 2008). Already in the late 1960s, this index fell below the limit of 2.1 needed to remain a constant population level. For quite a while, immigration was able to compensate the resulting population loss. Nevertheless, this trend stopped in 2003 and Germany’s population is shrinking ever since (Kröhnert et al., 2007). According to the 11th coordinated population projection, the total number of inhabitants could reach a level of 68.8 million in 2050 (Eisenmenger, Pötzsch and Sommer, 2006). This will be down from around 82 million today. The trend of depopulation worsens especially in those areas that suffer from economic and structural problems. For example, regions in Eastern Germany and the Ruhr area – the case city of Alphaville is part of the latter – are facing depopulation related to regionally declining work opportunities. While young and often more mobile inhabitants are following the job market and emigrating, immobile senior inhabitants often stay in the specific regions. Such development contributes to a process of societal aging with a specific regional component.

B) Aging can be regarded as the second major trend of demographic change in Germany. Over the last centuries, life expectancy at birth has been significantly rising in Germany. From 1900 to 2006 it increased by more than 30 years for both boys and girls (German Statistical Office, 2008). Nevertheless, life expectancy of the 60-year-olds also went up within this timeframe. Along with the described lack of fertility this lead to a process of aging within society because “[…] improvements in survival mostly benefit the older population, making the population itself older.” (Coleman, 2006, p. 63) While fewer children are born, the elderly age-groups with high birth-rates are getting older and older. This trend will continue in the future. Recent projections show that the number of people older than 65 years will increase from 15.7 million in 2005 to 22.9 Mio in 2050 (German Statistical Office, 2008). Already today, Germany is the country with the third highest percentage of this elderly age group in an international comparison. By 2050, the share of the elderly will take up more than 30
percent of the German population. Already in 2010, the number of older people will exceed the number of younger ones.

4.2 Demographic Trends in Alphaville

A) Deindustrialization led to significant depopulation in Alphaville. Currently, Alphaville has around 64,200 inhabitants (09/2008) on an area of 37 square kilometers. In contrast to this, in 1975, a total of 70,645 people were living in Alphaville. The comparison of these figures states a loss of nearly 7.6 percent within the three decades (Strohmeier, Bader, Melzer, Schulz and Wunderlich, 2006). With the closing of coal-mines, Alphaville – the city with the former biggest coal-mining industry in the Ruhr area – experienced massive deindustrialization. While the number of available jobs decreased, the overall population started to decline (Kröhnert et al., 2007). According to recent projections, cities in the district of Alphaville will encounter a population loss of 8 to 15 percent between 2004 and 2020. Alphaville will be one of the most affected cities with a forecasted depopulation of 14.5 percent.

B) Selective migration and depopulation led to an aging of the population in Alphaville. While the loss of workforce needed led to general migration, many senior citizens were often not willing to move away from the area in which they have lived the greatest share of their lives. On the other hand, they were often not looking for new jobs and thus stayed in the region. This led to a trend of aging within the society of Alphaville. With the population percentage of children and juveniles aged under 18 years hitting a high of 26 percent in 1975, the same age group today only makes around 18 percent of the inhabitants. Moreover, the population share of citizens of age 65 years and older went up from 12 percent to around 22 percent within the very same timeframe (Strohmeier et al., 2006). This demographic trend has led to the situation that in Alphaville elderly today make a greater share of the population than children and juveniles. Most recent projections show that the age structure will continue to change dramatically. By 2020, the 30 to 49-year-olds will lose their majority of number to the 50 to 64-year-olds. Moreover, the share of people older than 80 years will in 2020 have almost doubled its size compared to 2003 (Bertelsmann Stiftung, 2008). Thus, Alphaville will continuously be subject to significant depopulation and aging in the future.

As a result, the city can be regarded as a case of rather dramatic economic change and demographic transition. While it is aligned with the national trends of decrease of fertility and increase of life expectation, Alphaville has suffered, more than many other cities, from an economic downturn and the selective migration (emigration) of younger inhabitants. In that regard, Alphaville can be seen as a rather typical case for those cities in Europe that have been affected by deindustrialization and resulting depopulation and aging.

4.3 Qualitative Case Data

The qualitative interview data shows that the two major demographic trends – depopulation and aging – confronted Alphaville with numerous challenges. The city therefore sees dealing with the demographic change as a cross-divisional task that affects the overall strategic orientation and decisions. An Alphaville public administration department head stated:

‘We see coping with the demographic change as a cross-functional and strategic task that affects all actions of the public administration.’

In Alphaville, a decrease in population led to a decrease in tax revenue. The city is not able to reduce costs to the same degree. Infrastructure, including public administration, is laid out for a specific number of citizens and contains a great share of fixed costs which cannot be cut back in the short- or mid-term. An Alphaville public administration department head stated:

‘It is impossible to close 10 percent of the schools if the number of students decreases by 10 percent. Neither are we able to close down a couple of traffic lights if the population declines.’
This is similar for most of the other infrastructure related expenses. Therefore, the tense financial situation of Alphaville has intensified in the move of demographic transition, here depopulation (see Roberts 2003 for a general analysis of aging-related financial stress). Discussing possibilities to cope with this financial strain, solely reducing the public administration personnel (costs) is not a possibility: it would mean less manpower for a rising number of tasks. An Alphaville public administration department head stated:

‘We won’t be able to cut back personnel in the same extend that we are losing population. [...] Considering that today we do have to take a credit of 50000 € per day in order to cover our over-the-budget expenses – and this is about the annual salary for an employee – we would have to fire one person a day in order to be ‘efficient’.’

Furthermore, population aging in Alphaville evokes the need for rethinking the existing E-Government services offered. Against the background of a larger share of senior citizens in the population, E-Inclusion becomes an important topic. The Alphaville.de webmaster stated:

‘Focusing on the elderly is important because it is evident that more and more seniors use the internet. For them it is a good possibility to participate in daily life even if they are not mobile anymore.’

This shift in focus leads to a rising number of tasks for the city. Providing services for the elderly requires additional thinking on usability and accessibility and therefore leads to a higher work load within the public administration. An Alphaville public administration department head stated:

‘In our city, this situation will intensify. Focusing on elderly people will become a crucial task in public administration’s work. [...] There are many additional things that have to be considered: Barrier-freeness, easy access, adaptation of consultation hours, re-formatting printed materials and so on.’

However, the city of Alphaville is turning their back on a purely E-Inclusion focused strategy for elderly service provision. Instead of getting the elderly to use E-Government services directly, establishing a mobile citizen service that can provide the needed services and assist the elderly is considered a promising approach. An Alphaville public administration department head stated:

‘We don’t know yet in how far the people that are currently 50 or 60 years old will adopt new media in order to retain their mobility when they turn 70, 80 or 90. Currently, we are planning to implement a mobile citizen service that brings the services to the elderly rather than taking IT to the care centers.’

In addition, the demographic change also has an internal effect. The aging population implies an aging workforce within the public administration. In Alphaville, there has been evidence that this development leads to a reduction in performance and especially in innovation potential. An Alphaville public administration department head stated:

‘We have seen problematic examples where employees aged somewhere around the mid fifties or late fifties would slowly surrender from what I would call ‘production process’ and were just looking to ‘sneak out’.’

This leads to a decreasing degree of knowledge transfer between the elderly and younger employees. Knowledge management systems are considered a possible solution to this problem. These, as well as needed changes for E-Inclusion measures, necessitate substantial IT infrastructure investments. However, the city of Alphaville lacks the financial power to push such reforms. Therefore, the demographic change poses a dilemma to the city. An Alphaville public administration department head stated:

‘We would have to do a lot more in order to cope with the challenges of the demographic change. This, however, is not possible with intensifying financial problems. [...] Depopulation has a very high negative influence on municipalities like us that are already facing severe financial problems.’
On the one hand, the aging population calls for an adaptation of online services offered and IT investments. On the other hand, depopulation intensifies the critical financial situation making needed investments impossible. As an attempt to cope with this situation, Alphaville uses innovative forms of cooperation to share costs, as the Alphaville CIO stated:

>'These [the cooperations] start with IT services that we operate together with other municipalities. Our payroll accounting is carried out in cooperation with the neighboring city [Betaville]. We receive IT services from a regional service center that is shared with other municipalities. Those are cross-city efforts that we do focus on in order to be efficient.'

Especially concerning IT cooperation, the city still sees numerous possibilities for improvement. Since calculating capacity can be shared across long distances, Alphaville looks over local boundaries in order to find cooperating partners. An Alphaville public administration department head stated:

>'IT opens up a lot of possibilities for cooperation. Instead of cooperating with our neighboring city [Betaville] we could also share IT capacity with, for example, Munich. This is no problem today.'

In addition to such models of cooperation with other cities, Alphaville also focuses on public private partnerships (PPP) as a mean of serving both cost reduction/efficiency and effectiveness (inclusive online services). The new website that was mainly developed in order to create accessible E-Government services has been implemented in cooperation with two partly city-owned service providers. Thus, Alphaville uses cooperative elements in both front office (PPP) and back office (shared service centres). In the future, the city plans to extend these models, especially in E-Government, in order to offer more efficient services to the citizens.

5 DISCUSSION

In the case under investigation, depopulation and aging have been identified as major demographic trends. They were caused by both societal demographic transition, as to be found in most industrialized countries, and regional developments, including economic downturn. While depopulation resulted in an immense pressure to reduce costs, the provision of age-aware inclusive E-Government services necessitates additional IT investments. Cooperation both in the back office and front office in terms of a Shared IT Service Center or a Public Private Partnership in E-Government were considered as feasible means to cope with such (demography-related) investment dilemma (for a depiction of case study results see Figure 1). In order to discuss the question of generalizability of the results, we conduct a brief case study discussion following Lee’s (1989) set of analysis questions (Lee, 1989):

1.) What is the initial case setting and in how far is it bound to specific situational and historical circumstances?

A core issue in the case study was the need for reducing costs within the public administration. Deindustrialization in Alphaville led to a decrease of jobs in the area and therefore to an emigration especially of young people. This resulted in a process of aging within the society. We identified that depopulation and aging were two demographic aspects which came hand-in-hand. Depopulation reduced the direct tax income of the city and worsened its financial situation. The inability to cut back infrastructure in the necessary extent puts the public administration in front of only two possible ways of reaction. Either the oversized infrastructure is maintained resulting in higher per-capita expenses, or the relevant institutions are closed down and rebuild in an adapted size which also creates high costs (Kröhnert et al., 2007). Both ways, decreasing revenues are offset by relatively steady costs. In addition, the aging workforce within the public administration requires a reorientation of human resources as well as an improvement of knowledge transfer to younger employees and thus investments in e.g. knowledge management and human resource systems. Bill (2007) stated in that context that strategic human resource management will be one of the most important adjustment screws to turn in order to create a future-proof and efficient public administration. All this leads to an imbalance of public budget. Population based algorithms for allocating federal taxes to municipalities
intensify this trend. Aging contributes to the financial aggravation because tax revenues from the senior citizens tend to be comparatively low (Bach, Borg, Krimmer, Raffelhüschen and Schulz, 2002). Furthermore, a rising number of elderly evokes the need for an adaptation of the existing E-Government services and necessitates the availability of financial means. Cities like Alphaville, that are subject to a distinct process of demographic change, therefore face a dilemma between the need for creating a new E-Government infrastructure due to aging on the one hand and less financial power due to depopulation on the other hand.

Figure 1: Demographic trends and their consequences for E-Government

2.) Which conclusions are drawn from the case study data and in how far are these conclusions bound to specific situational and historical circumstances?

Based on the case study observations, conclusions include that dealing with the challenges has to be considered a cross-divisional task that affects the strategic orientation of a public administration. Furthermore, focusing on cooperation with both other municipalities could be regarded as a possible way to cope with the demography-related E-Government dilemma. Cooperation is a considerable option to reduce costs for public services. High fix costs for specific E-Government services and infrastructure can be divided and distributed among the cooperating partners. Parishes of those regions have to look over their individual municipal boundaries and work in cooperation on both front and backend matters. These models do not have to be entirely reinvented but are already present in some public administrations and can be extended to the sector of E-Government (Stopper, 2008). Role models for this can be Shared Services Centers (SSC) as used in private enterprise cooperation. These centers are used to combine and centralize administrative tasks of different parishes while at the same time retaining decentralized core units in the participating municipalities. The concept therefore combines the advantages of centralization and decentralization (Hensen, 2005). Furthermore, the case study data revealed an orientation towards alternative channels. When thinking about how to cope with aging-related challenges, literature oftentimes assumes the principle value of information
technology to the elderly (e.g. Namazi & McClintic 2003). The i2010 EU action plan on inclusive E-
Government calls for “no citizen to be left behind” (European Commission 2006c). Thus, asking the
questions if IT really helps the elderly and if the provision of services for elderly could easier and
cheaper be achieved using a different channel is important. A promising approach of establishing E-
Government services for the elderly is the provision of Mobile Citizen Services. In this model,
administrative services are provided through citizen consultants on public places such as e.g. hospitals
or senior residences. Thus, it “[…] combines aspects of e-government services as well as the idea of a
central administrative contact point (‘one-stop office’)” (Buß et al. 2003). A possibility of E-
Government cooperation combining front office and back office aspects is IT cooperation. The key
goal of this concept is bundling of competences rather than technological redundancy (Arendt and
Biel, 2004). This can include projects for creating E-Government portals for a whole area or sharing
IT infrastructure like storage and application servers.

3.) In how far do other settings show similar features and, thus, in how far is the case study setting
generalisable?
The majority of those cities suffering from deindustrialization faces similar demographic trends and,
therefore, is confronted with equivalent E-Government challenges. Nevertheless, also rural and
structurally weak areas are subject to comparable tendencies. For instance, many rural municipalities
in Eastern Germany face excessive depopulation and correlated aging. When looking at the
development in other industrialized countries, it is to say that the identified trends are not only specific
to Germany but can also be found in most other European countries (24 out of the 25 oldest countries
of the world, measured by the population share of above-64yr-olds, are to be found in Europe) and
Japan (the oldest country in the above mentioned ranking (Population Reference Bureau, 2006)).
Projections show that such demographic transition will continue in the future and affect an increasing
number of countries. Depopulation and aging will therefore be challenges to many public
administrations, not only in Europe.

4.) Are the conclusions drawn from the case study setting transferable to other settings?
The main conclusions address the establishment of different forms of cooperation and pursuing a
strategy of participation within E-Government services. Especially the cooperative aspect was a
central element in the case study setting in order to cope with the demographic challenge. Reference
models for cooperative approaches as identified in literature (Schroth, 2008) might help to overcome
existing boundaries that prevent seamless interoperability. Cooperation might become increasingly
important for public administrations because depopulation and aging will widen (see discussion point
3). In addition, such cooperative attempts, e.g. in terms of Shared Service Center or Public Private
Partnership, might not only be feasible means to address demography-related challenges, but might
help to address general ambitions to decrease costs and increase effectiveness. Cooperation, as
observed in the case study, might thus have demographic transition as one, but not the only reason.

6 CONCLUSIONS & FUTURE RESEARCH

Due to the demographic transition two major trends can be identified in Germany as well as in most
other industrialized countries, especially in Europe: a) Depopulation affects rural and structurally weak
areas as well as cities that are subject to deindustrialization. b) Aging often comes hand in hand with
depopulation as a consequence of selective emigration of younger inhabitants in search for jobs. While
depopulation led to a decrease in financial means for the affected public administrations, the aging
society demands for a change in the public service infrastructure. The needed reforms in both front
office and back office often cannot be taken due to the financial situation. One possible way out of this
dilemma is focusing on cooperating with other municipalities in order to share costs. Especially
Shared Service Centers are a promising approach. Limitations of the presented study include that a
single case was taken into account and that it did not focus on age-aware E-Government services
(front-office), but followed a rather broad perspective allowing back-office organization to form a
major part of the analysis (instead of E-Inclusion and Technology Acceptance where there lies the
greater literature body of knowledge).
Hence, future research could contribute a more front-office oriented perspective and connect such to the above given findings. Moreover, comparative research is necessary, taking into account multiple cases – not only from Germany, but also from other demography-transition affected countries such as Japan, Italy, or Sweden. Here, analyses could explore other means applied in order to cope with the demographic challenge. Furthermore, future research could address an evaluation of alternative channels for public service provision. For instance, it could incorporate the development of a cost-benefit perspective on channels, both online and offline. In addition, concerning the aging workforce, the development and implementation of suitable and cost-efficient knowledge management systems to ensure conservation of knowledge could be an important topic. These aspects indicate that the study area of demography and E-Government offers greatest potential for future research. Demographic transition constitutes one of the most severe challenges to our societies and economies and it is against this background, especially from an E-Government perspective, certainly under-researched. This reflects the fact the given case study directly and indirectly addresses two major future E-Government research themes: a) governance of public-private-civic sector relationships, and foremost b) E-Government in the context of socio-demographic change.

Abstract

To actually gain organizational value from investments in Information technology (IT) is a widely known problem that many businesses today struggle with. This paper presents an interpretative case study of three public fire rescue service organizations in Sweden. The aim of the study is to investigate what problematic issues that could be raised in achieving organizational value of IT in public organizations. The study indicates that the absence of strategies and IT evaluation methods create fragmented, uncoordinated IT-investment activities, which in turn creates a frustration at all levels of the organization. The public sector invests heavy in IT, seemingly with poor management control. The consequences will be misuse of resources and unnecessary high IT costs. We argue that the use of formal evaluation methods would help the situation, but that economic methods are not enough as the sole solution. A combination of the economic and the Interpretative IT Evaluation approach seems more promising in order to capture both efficiency and effectiveness aspects.

Keywords: IT investments, IT value, IT management, Public sector, Evaluation.
INTRODUCTION

That IT investments not always deliver value or meet business and organizational goals is still a problem that concerns many businesses. An enquiry in Sweden 2006, answered by 307 IT managers within private and public sector concluded that 82% of all IT projects fail in delivering expected value, in 2005 the result was 72% (IT management, 2006). Furthermore, it is often not clear what the expected value is. This problem of achieving value of IT has in prior research been framed as the productivity paradox, originating from studies during the 1980s that found no connection between IT investments and the productivity (Solow, 1987; Brynjolfsson, 1993). Lately, the productivity paradox has been questioned, since there is also evidence that IT in fact provides positive impact on productivity (Dedrick et al. 2003). It has been argued that much of the uncertainty concerning the IT pay-off relates to weaknesses in measurement and evaluation in practice (Willcocks and Lester, 1996).

In this paper we report on an interpretative case study of the Swedish Fire Rescue Services where problematic issues are identified concerning organizational value of IT-investments among different stakeholder groups. We discuss what implications these findings will have on the concept of IT-value at firm level and on the evaluation of organizational value of IT. Thus, two questions are raised:

• What issues and problems are raised concerning organizational value of IT investments?
• What implications will these issues have on the organizational value of IT and how to assess it?

This study focuses on non-profit organizations in the public sector, from a management perspective, and a single IT investment. The research is conducted as an interpretative case study based on interviews in three Fire Rescue Service organizations. An IT investment is here defined as “any acquisition of hardware and software which is expected to expand or increase the business benefits of an organization IS and renders long-term benefits” (Apostolopoulos & Pramataris 1997).

The paper starts with a discussion of the concept of value and how it can be assessed. Then the research approach is outlined, followed by findings from the interviews. The findings are then used to further discuss the raised questions and finally a conclusion is given.

THE ORGANIZATIONAL VALUE OF IT

Since the role of IT initially, during the 1960s, was primarily to increase efficiency it is not strange that early evaluation methods (Hamilton and Chervany, 1981a, 1981b) mainly focused on measurable quantitative economic effects. Avgerou (2000) noted that since the role of IT has changed, the potential value of IT has also changed. The early computerization projects that substituted computer data processing for manual data processing had more or less clear efficiency objectives and intending to cause significant organizational change. These projects were assessed by using a cost-benefit analysis, and the value was related to an economic perspective. In the 1990s the value of IT was linked to the perception of IT as an enabler of organizational transformation, and assessing value of IT by a benefit-cost analysis seemed too limited (Symons 1991). Therefore in prior research economic methods based on economic theory has been criticized and instead evaluation methods based on the interpretative IT evaluation approaches have been suggested (Walsham 1999, Symons 1992, Jones and Huges 2001, Stockdale and Standing, 2006; Ward and Daniels 2006) Thus, the value of IT has moved from purely efficiency to an effectiveness enabler. But in practice management seems most concern about methods from an economic perspective (Ward and Daniel 2007).

Organizational value of IT as increased efficiency and effectiveness

The task of Management is according to Lewis et al. (2007) to “administrating and coordinating resources effectively and efficiently in an effort to achieve the goals of the organization”. Both effectiveness and efficiency are relevant measures to consider since the role of the involved organizations is to deliver services (pre-determined goals) to citizens in an efficient way. Efficiency
could be described as using the fewest inputs (people, material and money) to generate a given output and effectiveness concerns the degree to which goals are achieved (Lewis et al. 2007). Further Fitzgerald (1998) describes efficiency as doing things right. Productivity is a related concept that also has been widely discussed. According to Lewis et al. (2007) productivity is a measure of the efficiency with which the firm transforms inputs into goods and services. Effectiveness is a concept that can be seen as complementary to efficiency. Common to the different explanations is that effectiveness is related to the fulfilment of goals (Lewis et al. 2007) and doing the right things (Fitzgerald, 1998). These goals can be related to formal goals that have been stated in strategy documents, plans etc. (Modell and Grönlund 2006). One problem with this definition is that many organizations can survive long periods despite the fact that formal goals are not achieved. Within public organizations one common way to define effectiveness is whether formal goals are fulfilled or not. For a commercial organization, effectiveness may be judged by profitability, but for a public organization it would rather be judged by the fulfilment of mission and goals. But efficiency and effectiveness are often related to an economic perspective where efficiency includes measures such as productivity and effectiveness includes measures such as profitability (Lewis et al., 2007). Several researchers claim that an economic perspective is too narrow since the organizational value of IT by its nature is pluralistic (Guba and Lincoln 1990; Bannister 2001), multidimensional (Cronk and Fitzgerald 1999) and including a plethora of social issues.

2.2 Organizational value of IT as multi-dimensional and pluralistic

Value has been described by Guba and Lincoln (1990) as pluralistic and involves the view of different stakeholder groups. Cronk and Fitzgerald (1999), describe “IS business value” as the sustainable value added to the business by IS, either collectively or by individual systems, considered from an organizational perspective, relative to the resources required. Incorporating different stakeholders’ views, takes the organizational value of IT a step further compared to the pure economic focus.

Bannister (2001) argues that value of IT is multi-dimensional in its nature, encompassing economic, psychological, cultural and political aspects of value. According to Bannister (2001) we could distinguish three different concepts related to IT value: Values (with capital “V”, i.e. core values), value and benefit. Values are norms or modes of behavior that individuals, groups or organizations hold are right. They are visible in different cultural manifestations, in attitudes and beliefs, and in behavior. Value is then a “quality applied to a good, service or outcome which supports, meets or conforms with one or more of an individual or group’s Values” (Bannister 2001, p. 3). A corporation whose primary Value is to keep costs down and work in an efficient way, would value an IT-system that reduces head count. An organization like a fire rescue service, whose Value is to save life and property, may also value an IT-system supporting the operational work of fire fighters, i.e. increased quality. Benefits can then be seen as an operationalization of the Values. “Value is what we perceive, benefit is what we receive” (ibid.).

Given this brief discussion of value, it becomes evident that different stakeholder groups related to one organization will have different views on IT-value. Berghout and Remenyi (2005) note that the interpretative IT evaluation approach, considering different stakeholders views, has received the widest attention in the IT evaluation research field. However, in practice the economic approach is still the most popular (Ward and Daniel 2006; Frisk and Plantén 2004).

2.3 Organizational value of IT as economic and social

The economic approach takes an objectivist perspective, i.e. one presumes that there exists an objective reality, and that there is a subject-object dualism that implies that the observer can distance him from the phenomenon studied (Serafeimides, 2001; Guba and Lincoln, 1990). Thus, multiple interpretations of value, ambiguity, or other than economical dimensions cannot be addressed. Value in the economic approach can consider efficiency in terms of reduced cost but also effectiveness in
terms of profitability. This implies that both efficiency and effectiveness can be considered but only from an economic perspective. Also, these methods are summative i.e. they are not reiterative. In the research field IT evaluation the economic approach has received a lot of criticism. Serafeimidis (2001) argues that the economic stream suffers from a number of deficiencies such as limited consideration of organizational context and neglect of human aspects of evaluation. Jones and Huges (2001) are of the opinion that evaluation is a complex, multifaceted, difficult, continuous and social process. Further, economic evaluation methods have not kept pace with the shift in use of IS (Symons, 1991).

Since IT-evaluation is a social process, with multiple potentially conflicting views on the value of IT related to a specific context the interpretative IT evaluation approach has been put forward (Jones and Huges, 2001; Symons, 1991; Stockdale and Standing, 2006). The interpretative IT evaluation approach has been applied in varying shapes and forms: interpretive evaluation (Walsham, 1999), situated hermeneutic evaluation (Jones and Huges, 2001), CCP (concept, context and process) frameworks (Symons 1991; Stockdale and Standing, 2006), Benefit management (Ward and Daniel, 2006; Bennington and Baccarini 2004 Ashurst and Doherty 2003; Thorp 2001; Remenyi and Sherwood-Smith 1999) critical approach to evaluation (Klecun and Conford, 2005), to mention a few. In contrast to the economic approach, these IT evaluation approaches have been sparsely adopted by practitioners (Serafeimidis, 2001). The starting point of interpretative IT evaluation approaches is different stakeholders’ perception of reality (Walsham, 1995; Guba and Lincoln, 1990; Symons, 1991; Stockdale and Standing, 2006) and considers IT evaluation as a social process (Jones and Hughes, 2001) and value as an output from different stakeholders’ perceptions.

3 RESEARCH APPROACH

3.1 Organizational Setting: The Fire Rescue Services

On the national level the Swedish Rescue Services Agency (SRSA) is a government authority with expertise in different fields, including fire prevention. On the municipal level, the Fire Rescue Service is responsible for providing the population with services such as prevention, preparation, and response. The Fire Rescue Service is structured either as a Fire Rescue Service (FRS) or as a Fire Rescue Alliance (FRA). The main difference between FRS and FRA is that the former involves only one municipality. The relationship can be described as the FRS works in collaboration with the municipality it which the FRS acts. A FRA involves the collaboration of several municipalities but is structured and acts as its own municipal community. The economic pre-condition for FRA is given by the confederation (Förbundsdirektion) that is composed of politicians from the different municipalities that are part of the collaboration. The political goals are implemented in the responsible government agency (SRSA), and further by the municipal fire rescue services (FRS or FRA) in terms of:

1. The Legislated National Vision: "There must be fewer deaths, fewer injuries and less destroyed properties (10 years)
2. Political Priority, plan of action for the municipalities: Strategies for Prevention, to prepare, to carry out and to follow up (4 years)
3. Balance Scorecard, The Fire Rescue Services, Indicators within the four perspectives (year of plan)

The organizations involved in this case study differ in several aspects, see table 2. Also, organization C has outsourced the operation of IT to the municipality.

Table 1. Characteristics of the involved organizations
The main focus in this study was to interview the respondents with experience from IT investments used in the operative work. One example is Deadalos/IKAROS includes different modules such as: object register, resource handling and operative performance. Another system is RIB, a decision support system that includes information such as: how to deal with an accident, how the work of prevention can be planned, the risks when an accident has happened, and where the teams are located. Most of this kind of system can be related to decision support systems.

IT investments can be initiated in the budget process or spontaneously by employees or outside the organizations. Once a year a budget process takes place and then requests can come from different departments in the organization. The requests can be anything from a running band to a new IT system. Initiatives inside can also come spontaneously during the year from employees. Initiatives outside can be a new law or a system suggested from SRSA. The decision-making on IT investments is decentralized, and are often taken on the departmental level. But, if the costs exceed a specific amount, the decisions are taken by the officer of the FRS. Before such decision, the relevance of the IT investment is often discussed by the board. If the IT investment costs exceed regular budget restrictions, it becomes a political issue and the decision will be taken by the local government committee, appointed by the local municipality. Factors supporting the decisions are benefits, cost and techniques. Benefits are mostly argued from the requester’s perspective and not from an organizational point of view. The cost calculation consists mainly of costs for IT hardware, since costs for personnel are already a cost for the FRS/FRA. So, using the organizations own resources are not part of the cost calculation for an IT investment. Also, costs for running the system are seldom reflected upon.

### 3.2 Method

This is an interpretative case study (Walsham 1995) where data collection was done by semi-structured interviews and a workshop. Three organizations within the Fire Rescue Services in Sweden are involved. The study is based on the respondents’ perceptions and then the interpretation of the researcher (Klein and Myers, 1999). The study took place in 2005 and 2006, during a period of six months. It involved six to seven people in each organization. Eighteen persons from different organizations, levels and with different roles were interviewed in total (see table 2). In addition, one of the researchers participated over three days with a fire crew. During this time the researcher talked and interviewed the team members, approximately 20 persons. Managers at the top level and functional level selected the respondents attending the workshops. The managers had awareness of who had the experience from IT investments or assessing IT investments. The study involved at each organization six to seven managers from different levels. Examples of different roles attending the study are: At top level, Chief Manager, Vice Chief Manager and IT Manager; at functional level, Managers of department; at the operative level, Managers of the operative work force. Here means management someone who has an overall responsibility for the organization, the department, or for a team alternative the turnout.

*Table 2. Different roles of the respondents participating in the interviews.*

Each interview lasted for approximately two hours. The questions concerned their perceptions of the value of IT investments, how evaluation of IT investments is managed, why value of IT investments is
not achieved and how IT evaluation of IT investments might be improved. The interviews were recorded, transcribed, and finally analyzed. The analysis was performed by first reflecting upon the respondents’ answers and then clustering these into similar themes. First the responses within an organization were compared and then the findings were compared between the different organizations. After that the results were reported back to each organization in the form of text reports that was emailed to all respondents. A follow-up meeting was arranged where the results were discussed. The purpose with the report was to create understanding for if the findings were correctly interpreted. The respondents agreed on the results. No coding tool has been used. Walsham (2006) notes that using a coding tool can take too much attention itself so it is not always a necessary tool.

4 FINDINGS: CHALLENGES IN ACHIEVING VALUE FROM IT

From the interviews we did find a set of issues that tended to come up in various forms. We have here clustered them in five themes.

4.1 Diversification of IT value at different organizational levels

The perception of value of IT seems to differ between different organizational levels. On a strategic management level, IT is described as a cost rather than delivering value:

“…even if you try to rationalize with IT, some other costs pop up and you do not get the expected value”.

On a tactical level, IT is described as a valuable tool that gives information for better analyses. On an operational level, some respondents have difficulties in seeing the value of IT and one opinion is:

“you can’t fight fires with computers”.

However, several respondents also emphasize the importance of seeing value of IT from an organizational point of view and also related to the citizens. Today the perceptions were that IT value too often is seen from an individual point of view.

4.2 Narrow perspective on the value of IT

If IT investments are assessed from mainly a cost and a technical perspective and not from an organizational perspective, the risk is that decisions on IT investments are based on poor facts. It was considered important to pay attention to how the IT investment will affect the organization. Further, a “citizen perspective” is considered to be important in order to avoid only the internal focus, since most of the initiatives seem to have a cost, technical and/or a “gadget” focus:

“It is important to assess IT-projects initially if the IT-investment should benefit the organization and not only some individuals.”

“The internal discussion often concerns techniques, technical platforms and systems, but questions should be raised such as, what needs should be fulfilled, what do we want to achieve, and how should we proceed?”

“When we talk about IT we should talk about what we really would like to achieve in the public sector and not only technique.”

4.3 Lack of co-ordination

4.3.1 Lack of co-ordination on national level

NRSA do not give imperative guidelines to the Swedish Fire Rescue Service on what kind of IT, or how IT should be used in order to achieve legislation, national visions, or organizational goals. Instead
Each FRS/FRA is responsible for its own choice of IT solution. This has been criticized in the interviews since the perceptions are that each FRS/FRA has its own ad-hoc development workshop, and that this is both expensive and ineffective. Some collaboration exists but it could, according to the respondents, be room for more.

4.3.2 Lack of co-ordination on municipality level

Also decisions on departmental level are taken without any organizational co-ordination. This has contributed to an ad-hoc development of IT systems since the same problem or possibility can be solved by different technical solutions. One opinion is:

“Unfortunately we give priority to individual desires instead of the total picture. We can’t, for example, agree on one brand for digital cameras or digital calendars”.

Also, historically, the FRS/FRA’s are not so constrained by money. This has contributed to an ad-hoc development of IT since there are limited demands to show the benefits and costs of IT-investments. The respondents’ perceptions are that decisions on new IT investments are in favor of: “those who shout the loudest”. This brought about a culture that permits individuals to demand IT investments for their own interests, resulting in limited co-ordination and no alignment with the need of the organization.

4.4 Absence of strategy

Respondents from all organizations perceived that their organizations are lacking a visible strategy for the organization as well as for IT. According to the respondents this is one important cause for not achieving value from IT investments. Instead they suggested that organizational goals should direct the choice and decisions of new IT investments. One respondent stated that:

“We don’t know the plans for the coming two years, which means that the persons who are most anxious for new information systems or information technology get their requests approved.”

The respondents are of the opinion that the lack of organizational strategies as well as IT strategies, have contributed to an ad-hoc development of IT. This in turn has lead to a very difficult situation for the IT-department, since they need to be experts on many different systems. Also, the costs for IT operations are increasing fast.

Several of the respondents claimed that IT should contribute more to the organizational development by considering IT as a strategic resource. Today IT’s main function is to rationalize, and no discussion of IT’s strategic role is taking place.

4.5 IT evaluation issues

4.5.1 No consideration of the total costs

Actual cost for an IT investment should be further clarified. Costs for hardware and software were calculated, but seldom the cost for operational work, staff, education etc. Several respondents had observed that within their organizations there was a tendency to buy new IT instead of upgrading the old. The opinion was that a proper calculation of actual costs would gain a better understanding of the costs of used resources and give a better ground for comparing the benefits between investing in new IT or upgrade existing IT.

4.5.2 No follow-up of the IT investments

Today, IT investments are rarely followed-up and the perceptions are that there exist no guidelines for what criteria to consider, how to perform and when to evaluate. Some practical examples from buying IT systems that were not so successful, was when one of the organizations bought a Geographic
Information System, and a system called “Managing Risk and Analyses”. None of the systems are in use. The perceptions were that, despite a lot of good ideas, there were no process in place to take care of them:

“We had a lot of good technical ideas and solutions, but what do we do with it”?

Using a formal evaluation process were called for by several respondents:

“... not for catching the bad guys just to be able to tie up, to do a reflection and to learn.”

Another argument is to be able to do better priorities between the different IT investments and also between different kinds of IT investments.

4.5.3 Too few stakeholders in the evaluation process

The respondents perceive that no guideline that makes explicit who should be involved when evaluating IT investments exists. It was considered important to include the opinion of the users and the IT department in the evaluation process. The IT department will secure that the IT investment will fit into the infrastructure and existing systems, and also to eliminate the risk of unnecessary high operational costs for IT. A relevant question for several respondents were:

“Could the new system communicate with other systems or is it a different system which is built upon a different platform”.

Also, the respondents advocated that different stakeholders’ view should be involved in the evaluation process. Stakeholders’ meaning those who will be affected by the system, but also the “citizen perspective” is mentioned as an important perspective to consider.

4.6 IT affect power relations

Several respondents considered IT to be “charged”, i.e., IT gives people power. This could contribute to the development of IT on wrong grounds, being motivated by individual power interests instead of the need of the organization. The decisions-makers should be aware of these aspects, and therefore take an organizational view when evaluating new IT-investments, and not only a cost or technical perspective.

5 DISCUSSION: THE MISSING VALUE OF IT

We will now discuss the findings in terms of four themes: efficiency and effectiveness; the pluralistic nature of IT-value; the evaluation of IT-value; and IT-value in public organizations.

5.1 IT value as increased efficiency and effectiveness

One relevant question to ask is whether value of IT investments in terms of efficiency can be evaluated without any connections to the effectiveness i.e. overall goals and strategy of the organization?

Effectiveness has in overall been described as fulfilment of goals, doing the right things (Fitzgerald 1998). According to the respondents, effectiveness was not considered when evaluating value of IT investments. A risk when evaluating value of IT from only an individual perspective and neglecting the overall goal and context of the IT system, (Symons 1991; Jones and Huges, 2001; Stockdale and Standing 2006), is that the IT development becomes ad-hoc, which is a fact at particular one of the involved organizations. This ad-hoc development and lack of visible organizational goals could in turn contribute to transmission of resources (Modell and Grönlund 2006) and outputs that have no connection to the overall organizational goal and strategy. In the long run that give less valuable outcome, effects to the taxpaying citizen.
Organizational value of IT should include both a dimension of efficiency and a dimension of effectiveness i.e. do things right and do the right things. Also, since an IT investment affect different levels differently within the organization, such as the top-level, the tactical level and the operational level, and one level can receive benefits while another department or level can receive disadvantages, it is important to make the value visible for all levels. Another important factor to take into consideration is that a public organization cannot always dismiss resources, just allocate resources. Therefore effectiveness and efficiency need to interplay in the IT evaluation process, none should be considered by their own since the public organization is foremost driven by pre-determined political goals that should be achieved, and not by the “bottom-line”. Further efficiency should include both an economic and a qualitative dimension.

When respondents spoke about the need for organization they meant that IT investments should be related to overall organizational goals and strategy. But since no strategy was in place for the organizations, several respondents argued that IT investments have too much individual and internal focus instead of the mission for the citizen. When no strategy is in place there is a risk that IT investments mostly will be used for changing the use of resources’ and outputs without any connection to the organizations overall goal. Then, how is efficiency/productivity to be measured if the outputs are not related to the outcomes? This is an important question and in particular since there is a great uncertainty what could be consider as proper targets and measures in public sector (Modell and Grönlund, 2006). If no strategy is in place there may be a risk that core values may come in the background for individuals’ interest.

5.2 IT-value as pluralistic

The respondents describe value of IT from their own perspective and role in the organization. One exception was IT management, who related value to the overall goals and strategies of the organization i.e. effectiveness. On top level, the respondents (not IT management) relate IT-value to reduced costs, i.e. efficiency. On tactical level several respondents relate value of IT to better analysis of the organization and to improve the decision-making i.e. quality. On operational level first-line managers have difficulties to relate how IT has improved their work. Instead they perceive IT as time consuming since today the IT systems require more input of information than previous and the respondents were uncertain to what extent that information contributed of value to the organization. For example, the respondents have to give the same input to accident reports, irrespective of the size of the accident. Also the firemen seem more interested in investing in better vehicles that could contribute to both a more efficient and qualitative work. Most of the respondents also mention the citizen as an important stakeholder that should be considered in the IT evaluation process. But stakeholders such as government, politicians, community, union, suppliers, and other collaborators etc, received less attention when it comes to the value of IT investments. In the case of public sector organizations the pluralism of IT-value becomes especially complex due to the many stakeholders outside the organization. The value or effects of an IT investment needs also to be visible for all levels in the organization since value (output alt outcome) and input and output value is not always acting together at the same organizational level. Potential conflicts of interests are inherent in this pluralism both among different levels and groups in the organization, and between the organization and the stakeholders outside it, as well as between management and other stakeholders.

5.3 Implications for IT-evaluation

The identified problems such as strategic match, coordination of resources, proper calculation of costs, involving different stakeholder groups in the IT evaluation approach indicates that both the economic and the interpretative IT evaluation approaches complement each other since efficiency and effectiveness needs to be considered from an economic and stakeholders view. In prior research the economic approach has received a lot of criticism, e.g. for limited consideration of organizational context and neglect of the social and human aspects of evaluation (Serafeimidis, 2001, Jones and
Huges 2001; Stockdale and Standing 2006) However, the economic approach should not be abandoned rather it should be complemented. The economic methods are tools that provide valuable economic information such as costs and cash flow that is existential for many companies. The purpose is not to regard the organization as a social process it is to consider economic information. These methods can indicate future costs, cash flow, and must, continually be updated as other information. So, evaluating IT investments from an economic perspective will continue to be an important perspective in the IT evaluation process if it is used properly. The danger to such methods is that they can manipulate the cost items and the user can choose what items to add. Therefore, an Interpretative IT evaluation approach can complement such approach and create understanding from different stakeholder groups increased understanding for the organizational value of the IT investment.

In order to create understanding for organizational value, the use of resources must be related to the output and the outcome. The output compared to the use of resources can be described in a cost and benefit analysis. But the value must also relate to the outcome of the organization i.e. the goals, mission and strategy of the organization. This could be done by using an interpretative IT evaluation framework like CCP (Context, Concept, Process). CCP focuses on explaining: why (context) this IT investment should be done; according to the stakeholders what (content) should be followed up; the IT evaluation process (Serafeimidis, 2001; Jones and Huges, 2001; Guba and Lincoln, 1999; Remeny and Sherwood-Smith, 1999). The interpretative IT evaluation approach could therefore improve evaluating organizational value of IT investments in the public sector since the approach considers the context (which relates to strategy and co-ordination), content (involves different stakeholders view) and an IT evaluation process that follow up the IT investment in use (Symons 1991; Jones and Huges, 2001; Stockdale and Standing 2006).

5.4 IT-value in public organizations

The question of organizational value of IT-investments is in much a question of communication: how could one demonstrate and articulate the value for money from IT investments? If it is not communicated, it does not exist. With regard to public sector this often becomes a question of value for taxpayer money. In UK for example, a legislation of Best Value (BV) was introduced in year 2000. BV states that all public sector organizations (e.g. the police and fire services) must ensure that their IT-systems perform well and that they are delivered in a cost efficient way. Efficiency and economic aspects as value for taxpayer money is however not the only important question. Too much focus on economic issues will potentially downplay other important dimension such as the strategic value of IT. In the context of a public organization this may be related to outcome, not just output. In the case of the fire rescue services an example of outcome is “fewer deaths, fewer injuries, and less destroyed properties”. Relating national and regional visions to organizational value of IT is not a straightforward process, but without this discussion, the value of IT will remain unclear.

The general discussion of IT-value in public sector tends to be mainly focused on efficiency (do things right), and we have argued for a stronger orientation towards effectiveness (do the right things). However, if the value achieved is low in any of these two dimensions, the total value will be low as well. In order to create value for the public organization both internal and external factors needs to correlate since the organizations are driven by political goals. Output must correlate to outcome, strategy with the operational level. In summary it is important that IT-value is related to both the core operations (outcome) and to the operative work (output/efficiency) on different levels such as the top management, tactical and operational.
6 CONCLUSIONS

This paper has addressed issues in the achievement of the expected organizational value of IT, and what implications this may have for the assessment of that value.

Two points are important regarding IT value. First, to take the concept seriously, to problematize and define what is meant by IT value. Secondly, the usefulness of an IT-investment to the organizations should be in the foreground, not the value of technical features of the system. Furthermore, organizational value of IT should include a consideration of both efficiency and effectiveness. This is especially important in the public sector since it is driven by political goals and not by the “bottom line”.

Regarding IT-evaluation, the main point is that both economic and interpretative approaches are needed. Evaluating IT investments from an economic perspective with monetary items will continue to be an important perspective. The problem here is that the economic approaches are general, and not developed for specific use in IT-investments. The calculation of cost in these methods must be further developed. The interpretative IT evaluation approach could contribute positively to the IT evaluation process in the public sector since it considers strategic issues, co-ordination, stakeholders’ involvement and views evaluation as a formative process. Thus, it relates to several of the problematic issues identified in the study. Another issue that needs attention is how to take care of power and politics in the IT evaluation process.

The findings described above are particularly important for the public sector since no traditional income statement will validate the choice of used resources to the outcome. In a profit organization the income statement will sooner or later give indications if business is on the wrong track. Who will have this insight in a public organization? If a public organization does not co-ordinate its output to the outcome there could be a redistribution of resources to non-productive output, i.e. output not related to the expected outcome of the public organization. This could in turn be a serious waste of tax money on wrong output. Thus, achieving value is not only an evaluation problem it also demands management to address issues such as strategy, co-ordination, and cost control.

A DELPHI STUDY ON COLLABORATIVE LEARNING IN DISTANCE EDUCATION

Journal: 17th European Conference on Information Systems

Manuscript ID: ECIS2009-0134.R1

Submission Type: Research Paper

Keyword: Computer-mediated communication (CMC), Computer supported collaborative work (CSCW), E-learning, Collaboration
Abstract

Collaborative Learning (CL) is increasingly being used in Distance Education (DE), as it has been identified as an effective solution to known weaknesses such as high average rates of dropout and low quality of learning attainment. Information Technology is a core component of this type of learning as it not only provides the means to collaborate over distance but also has the potential to enable higher learning outcomes. There are a rapidly growing number of technologies in use today and the importance of these to collaborative learning initiatives, and the role they play, is an area of active research in the Information Systems (IS) community. IS educators and practitioners face an increasing challenge therefore to successfully implement CL in DE, precipitated not only from technical advances but also from wider social and organisational concerns. Using a Delphi study, this research is the first to investigate the factors that influence collaborative learning in distance education by surveying the opinions of an expert panel in this area. The aim was to produce an integrated list of the most important implementation factors and to investigate the role technology is perceived to contribute. The findings identified seventeen of the most important factors. These factors cover a range of themes including course rationale and design, instructor characteristics, training, group dynamics, the development of a learning community and technology. The potential of technology however does not seem to be fully realised and newer technologies such as multi-user environments would seem to be of limited use in practice, according to the expert panel.

Keywords: Collaborative Learning, Distance Education, CSCL, Delphi Method, IS Education.
1 INTRODUCTION

Distance Education (DE) is a broad term that refers to delivering a curriculum to learners who are not physically present on campus. Recent technological advances, along with changing learner demographics have triggered a significant rise in the popularity of this type of education. As distance education has evolved, it has become inextricably linked to technology (Garrison 1985) and as such information systems involving communication and information technology have become the underlying core of current and future DE innovations and trends (Lockwood 2001).

In conjunction with the advances in technology, DE is becoming increasingly popular throughout the world (Brandon and Hollingshead 1999; Oblinger 2001; Beldarrain 2006) with its market share growing rapidly (Salas, Kosarzycki et al. 2002). However there are still problems with its practice, including high average rates of dropout and low quality of learning attainment (Bernard, Rojo de Rubalcava et al. 2000). Various causes have been attributed to these problems including: feelings of isolation; lack of two or three way communication; procrastination; and difficulties associated with self-regulation (Bernard, Rojo de Rubalcava et al. 2000). New internet-based learning environments offer ways to overcome some of these shortcomings (Beyth-Marom, Chajut et al. 2003) for example, by providing means for asynchronous and synchronous learning with new technologies being used to foster student interaction and collaboration (Beldarrain 2006). Changes in the pedagogical approach are also happening with a move from instruction-based learning models to a constructivist (rather than being transmitted, knowledge is created, or constructed) or collaborative learning approach (Leidner and Jarvenpaa 1995). Numerous studies have demonstrated the superiority of collaborative learning (CL) over traditional modes of learning (for examples see Hiltz 1988; for examples see Alavi 1994; Leidner and Fuller 1997) and it has been identified as a potential solution to the weaknesses of traditional distance education courses (Bernard, Rojo de Rubalcava et al. 2000).

Collaborative learning emerges through the interaction of individuals with other individuals, knowledge is created through these interactions as individuals ‘exercise, verify, solidify, and improve their mental models through discussion and information sharing’(Leidner and Jarvenpaa 1995). Collaborative tasks can include decision-making, problem solving, report production, or experimental projects. When students work together collaboratively, they not only learn themselves, but they are also contributing to the development of the group (Salas, Kosarzycki et al. 2002). The collaborative learning model assumes that individuals’ learning is enhanced when they create knowledge by actively constructing a representation of the material being taught working on the assumption that ‘individuals learn better when they are forced to discover things themselves, rather than when they are told or instructed’(Leidner and Jarvenpaa 1995). Working in groups is not just a valuable way of learning but also develops the abilities for cooperative work, which is essential in the modern working place. Incorporating collaborative activities into modern distance education courses should produce graduates who can work effectively and efficiently with others, while also understanding the role of modern information technologies in collaboration, communication and knowledge creation.

Computer-Supported Collaborative Learning (CSCL) deals with how technology can be used to support collaborative learning and draws primarily from two contributing fields of inquiry; collaborative learning theory and Computer Mediated Communication (CMC) theory and research (Brandon and Hollingshead 1999). CSCL focuses on frameworks and tools to assist in collaborative learning along with the implementation of actual educational systems, collaborative learning activities and new pedagogical approaches. The use of technology therefore is more than a mere supporting infrastructural component. Technologies that promote communication and interactive can add value to the learning process by enabling the development of higher-order thinking skills, increased involvement, interest and motivation and overall the attainment of higher learning outcomes (Piccoli et al., 2001). Although emerging technologies offer a vast range of opportunities for promoting collaboration, distance education programs face challenges that may influence the implementation of these technologies (Beldarrain 2006).
Clearly, without technology the use of collaborative learning in distance education would be severely restricted however, technology is not the only influencing factor and the organisational processes and human interactions surrounding it are also of crucial importance in the implementation of CL in DE. A number of studies have investigated the factors which are relevant to CL in DE, mostly focusing on specific areas of interest, for example; CL and computer supported groups (Brandon and Hollingshead 1999); student preferences (Beyth-Marom, Chajut et al. 2003); social interaction (Kreijns, Kirschner et al. 2003); issues with CL in DE (Bernard, Rojo de Rubalcava et al. 2000); Computer Supported Collaborative Learning (CSCL) (for examples see Silverman 1995; English 1999; for examples see Beldarrain 2006); success factors of CMC technologies (Tolmie and Boyle 2000); system characteristics (Pituch and Lee 2006) and emerging themes in distance learning (Salas, Kosarzycki et al. 2002). The literature reviewed indicated that several factors impacted CL in DE, although each independent study considered only a limited number of factors. In general, the factors can be grouped into themes such as; course rationale and design; instructor characteristics; learning community; student characteristics; group dynamics; support and training; assessment and technology. Each of these themes have a number of factors associated with them, however an integrated list of a full range of the contributing factors does not seem to have been previously researched.

The aim of this research therefore was to develop an integrated list of the most important factors, with the aim of establishing the key issues involved in the implementation of CL in DE. Using the factors identified from the literature as a basis (see table 2.3), a panel of experts in the area ratified, expanded and ranked what they believed to be the most important factors. This study further elicited the view of the expert panel regarding their perception of the role technology plays in this type of education in order to explore whether the potential of information technology is recognised and fully exploited in practice.

2 RESEARCH DESIGN

A Delphi survey was chosen as the methodology for this study, as it is a technique for collecting opinions that aim to overcome the weaknesses implicit in relying on a single point of view. By involving a group of experts in the area, the study ensures that the results are not based on a single experience of collaborative learning in distance education. Delphi surveys have the benefits of group interviews without the need to gather the experts together in one location (Clayton 1997). They also allow the participants to express their opinion without undue pressure from others in the group, while the iterative nature of the technique provides the opportunity to clarify or change views based on others perspectives (Clayton 1997; Schmidt 1997). There are a number of permutations of the Delphi method and a ranking type Delphi study, designed to elicit the opinion of a panel of experts through iterative controlled feedback, was chosen for this study. The framework used was based on non-parametric statistical techniques, as outlined by Schmidt (1997), and aimed to answer the following research questions:

RQ1: What are the most important factors that influence the effective use of collaborative learning in distance education?
RQ2: What is the perceived role of technology in this form of education?

2.1 Panel Description

Rather than focus on a homogenous group (such as lecturers) a cross section of expertise was sought. This was to ensure that the factors identified as most important considered a range of perspectives and not just the views of a particular group.

The panel selected was composed of 18 panellists from three geographical regions: Ireland, USA, and UK. They represented collaborative learning through three distinct groupings; nine programme
directors using collaborative learning in distance education courses; five lecturers who are currently using collaborative learning techniques in distance education courses; and four academics with experience in the area of computer supported collaborative learning. Because the success of the Delphi technique relies upon the use of informed opinion, random selection was not considered when selecting the Delphi participants (Wicklein 1993). However, educational qualifications were taken into account, all of the panel were educated to a minimum of Masters Level, with fifteen having Doctorate qualifications.

Twelve universities were represented: Carnegie Mellon University, (United States); Middlesex University, (United Kingdom); New Jersey Institute of Technology (United States); National University Ireland, Galway (Ireland); Oscail, Dublin City University (Ireland); Penn State University (United States); University College Cork (Ireland); University of Edinburgh (United Kingdom); University of Leicester (United Kingdom); University of Hawaii (United States); University of Limerick (Ireland); and The Exploratorium, San Francisco (United States).

Criteria used in selecting the participants were based on their involvement with collaborative learning, distance education and computer supported collaborative learning. The average number of years experience in the area of Collaborative Learning was 7-10 years, with 50% of the panel having over 11 years experience. The panel were also highly qualified in the field of distance education with the average number of years experience 7-10 years and 44% of the panel having over 11 years experience. The average number of CL courses managed or taught was 4-7, as was the average number of DE courses managed or taught. The selected participants are considered to be well informed, leading authorities in their field by their colleagues, supervisors and peers. Overall the panel can be considered highly qualified and well equipped to provide opinions on the factors relating to CL in DE, as qualified by the following section.

2.2 Identifying Experts

The identification of ‘experts’ for the Delphi panel was based on a multiple-step approach suggested by Olaki & Pawlowski (2004). Initially a knowledge resources nomination worksheet (KRNW) was prepared which included details of the desired background or skill sets required. The KRNW was populated by going through each of the desired skill sets and identifying a key contact in the area. Personal contacts of both the researcher and supervisor were used as the initial contact point in each of the categories. Using the ‘snowball’ sampling method (Skulmoski, Hartman et al. 2007) the initial contacts were asked to provide recommendations for other potential participants in the study. The qualifications and skill sets of the named experts were ranked according to exposure and experience with collaborative learning initiatives and distance education. As a variety of perspectives were required the experts were ranked based on their experience and to ensure a selection of viewpoints. This provided a list of 46 experts to be invited to partake in the study.

These potential candidates were contacted, by email, and invited to participate in the study. The subject of the study was explained along with the procedure and the commitment required. To minimise non-response, one of the initial contacts introduced both the researcher and the topic of research to a number of the potential candidates, as suggested by Hsu and Sandford (2007). Delphi group size depends on group dynamics rather than statistical power and panels of 10-18 experts are recommended (Okoli and Pawlowski 2004). Of the forty six invitations, eighteen candidates accepted and this was considered ideal, as it would allow the study to start with the top end of the range. During the study two panel members dropped out, leaving a panel of sixteen who completed all stages of the study.

2.3 Survey Rounds

The initial survey was sent on the same day that an expert agreed to serve on the Delphi panel, as recommended by Okoli and Pawlowski (2004), using email as the communication channel. Following
the approach used by Kasi et al. (2008) rather than have the panellists participate in a brainstorming session, a list of potential factors identified from the literature was provided (table 2.3). This list provided the panellists with a structured instrument to begin the Delphi process and contained 28 factors for the initial ratification and discussion.

Table 2.3 Initial List of Potential Factors

Each participant was asked to select the factors that they deemed to be important to CL in DE. They were also asked to provide details of any factors that they considered to be important but were not on the original list. Along with the list of potential factors the panel were also sent a short survey outlining a number of technologies currently in use in the area. They were asked to identify those technologies that they currently used for CL initiatives and add any technologies that they use but were not on the original survey. The purpose of this additional questionnaire was to gain a snapshot of the technologies currently in use by the panel.

The results of the initial survey involved the panel removing 9 factors from the original list and adding a further 26. The additional items were reviewed and a new consolidated list of 45 factors was developed. As the target size for the ranking of the factors was around 20 items (Okoli and Pawlowski 2004) a second survey was required to narrow down the consolidated list. The questionnaire was randomly ordered to cancel out bias in the order of listing of the items (Brancheau, Janz et al. 1996). Each panellist was asked to select (but not rank) at least 10 of the most important factors (Schmidt 1997). Due to the nature of the topic and the diversity of the panel, a wide range of opinion on the factors was expected. An analysis of the results of the second survey suggested that opinion was
spread over a number of factors. A cut-off point of 40% was determined the most appropriate level for paring down the list as this ensured that the list contained a suitable number for ranking (less than 20, as suggested by Schmidt (1997) and also ensured that important factors were not dismissed at this stage. This list highlighted the 17 most important factors, from an initial list of 54 potential factors (original 28 plus the 26 added by the panel).

Once this list of most important factors was identified, the first of the ranking rounds was sent out. The aim of this phase was to determine the level of consensus on the ranking of the relevant factors. The pared list, from the second survey, was arranged in random order, and the respondents were asked to rank all the items (Schmidt 1997). Four different randomised versions were produced and divided among the panellists, as suggested by Branchan et al. (1996). The questionnaire also asked experts to submit comments explaining or justifying their rankings as it is suggested that experts ‘should arrive at consensus more quickly if provided with some sort of feedback about the panellists’ reasoning’ (Okoli and Pawlowski 2004).

The ranked lists were measured using Kendall’s $W$ coefficient of concordance, as it is recognised as one of the best ways for measuring non-parameter rankings (Schmidt 1997; Okoli and Pawlowski 2004). The values of $W$ range from 0 to 1, with 0 indicating no consensus, and 1 indicating perfect consensus. The value of $W$ obtained from this first ranking round was 0.148, which suggested weak agreement on the rankings and thus a second ranking round was necessary. As suggested by Okoli and Pawlowski (2004) the second ranking round was listed in order of the mean ranks obtained in the first round. For each item, the following information was provided to the panel: (1) an indication of the current level of consensus (based on the value of $W$) (2), the mean rank of the item; and (3) a column providing details of the views of the other panel members on each factor. Based on this, each expert was asked to revise their rankings for each item, again asking them to explain their rankings and revisions. A separate column was provided for these additional comments.

The response to the second ranking round indicated that the majority of panellists did not wish to change their opinion, with only four of the panel members revising their rankings. However, a number of additional comments were obtained and Kendall’s $W$ improved to 0.221. At this stage it was decided that further ranking rounds would not be required. Dissensus, or lack of agreement is a valid finding for a Delphi study (Skulmoski, Hartman et al. 2007). The diversity of the panel, and the subjective nature of education, highlighted by the detailed comments obtained in the survey, clearly identified a number of viewpoints on the factors considered most important. The panel had agreed on the most important factors, the lack of strong consensus was on the priority, or ranking, of these factors.

The first ranking round also included an additional questionnaire, which detailed the technologies currently being used by the panel (identified in the first stage of the survey) and asked each member to rate (using a likert type scale) how useful each technology was to collaborative learning.

3 FINDINGS

3.1 Most Important Factors

This study identified the top 17 of the most important factors from a comprehensive list of 54. The following table provides the results of the final ranking round and outlines the factors in ranked order, along with their mean rank and interquartile range (IQR). The IQR shows the range of opinion on the ranking of the factor; the higher the IQR the greater the range of opinion.

</table>

Table 3.1 – Results of Delphi Ranking Round

By reviewing the comments and rankings for each factor received, it was possible to group them into the themes originally identified from the literature and classify the most important factors within these themes.

- **Course rationale and design** - the design of the activity needs to promote collaborative learning and (#1) there needs to be an appropriate rationale behind its use (#7). Prior design of the collaborative tasks is also considered important (#12) along with the development of teamwork skills explicitly built into the design (#13).

- **Instructor characteristics** – the instructor teaching style should encourage involvement and participation (#2) with the tutor assuming a facilitator role (#5).

- **Learning community** - the development of a learning community should be encouraged and nurtured (#3) and while there should be opportunity for social communications in the early part of the course (#15), this is not seen as high a priority.

- **Assessment** – personalised, detailed and quality-controlled feedback on assessment work is seen as of high importance (#6), but considered relevant to all forms of education and not just CL.

- **Support and training** – tutors should be trained for their role (#8) and this is seen as an important factor. Support, both technical and institutional, is not deemed to be as high a priority and did not make it to the list of most important factors.

- **Group dynamics** - Promotive interaction refers to the quality of interaction among group members and is seen as important (#9) along with positive interdependence, which means that group members must see value in working together for collaborative learning to occur (#10). Group size and the interpersonal skills of the group, are not perceived to be as high a priority and while ratified from the literature did not make it through to the most important factors.
Technology – of high importance is the fact that the technology should be accessible by all students (#4), and while this may be considered obvious, is an essential component to CL in DE. Also the learning environment itself should be user friendly and kept simple (#11). Other technological factors are also considered important: it should enable multiple means of communication (#14), including asynchronous communication (#16) and should support multiple learning styles (#17). While technology factors did come in near the bottom of the final rankings, it is clear that they are still considered highly important as they made up almost 30% of the final list of ‘most important’ factors.

3.2 Collaborative Learning Technology

The technology questionnaire sent out with the Delphi study further provides a snapshot of the technologies currently in use for CL in DE, and their perceived usefulness. The following table provides a summary of the results.

Table 3.2 Technology and Collaborative Learning

It would seem that Virtual Learning Environments, including online forums and bulletin boards are of most use to collaborative learning in distance education. The entire panel uses this technology and it received a high level of support on its usefulness. Collaborative document tools are also considered ‘extremely useful’ by the panel, with 78% of them using this technology. The majority of the technology is considered ‘moderately useful’ including audio conferencing and email, even though these had a high percentage of usage. It is interesting to note that some of the newer technologies such as Multi-User Virtual Environments and group conferencing appear to have limited usefulness in practice according to the expert panel.

4 DISCUSSION

The Delphi study enabled a group of experts in the area to identify and discuss the most important factors contributing to CL in DE. Using a base list of 28 factors identified from the literature, the panel
suggested an additional 26 factors based on their experience in the area. These factors were ratified and discussed during the rounds of the Delphi exercise, cumulating in agreement on 17 of the most important factors, albeit with differing opinions on the rankings of these factors.

4.1 Most Important Factors

In line with the literature (Brandon and Hollingshead 1999; English 1999; Tolmie and Boyle 2000; Kennedy and Duffy 2004) course rationale and design is considered highly important. Personalised, detailed and quality-controlled feedback on assessment work should be provided as it is also seen as of high importance. The literature also suggests that the rationale behind the use of Computer Mediated Communication (CMC) technologies is considered important (Tolmie and Boyle 2000), however this study did not find it to be a high priority, perhaps because in DE it is necessary to use CMC technologies. While there are a number of suggestions around course content discussed in the literature (Silverman 1995; Brandon and Hollingshead 1999; Bernard, Rojo de Rubalcava et al. 2000) course subject matter was not found to be particularly important by this panel of experts.

The role of the tutor, or instructor, is significant to CL, with ‘teaching style’ considered to be a ‘most important influence’ on involvement and participation (Salas, Kosarzycki et al. 2002). The expert panel would seem to agree with this as one of the highest-ranking factors directly related to instructor teaching style, suggesting that it should ‘encourage involvement and participation’. Learner-centred courses require the instructor to assume a facilitator role, and again this is suggested as important in the literature (Silverman 1995; English 1999; Bernard, Rojo de Rubalcava et al. 2000). The panel concurs with this agreeing that the tutor should assume a facilitator role, and also receive training for the role. Support, both technical and institutional, is not deemed to be as high a priority and did not make it to the final list of most important factors.

It would also seem that, in line with the literature (Hiltz 1998; Kreijns, Kirschner et al. 2003), the encouragement and development of a learning community is considered highly important to the effective use of CL in DE. While there should be opportunity for social communications in the early part of the course, this is not viewed as high a priority. The importance of the group to collaborative learning has been regularly discussed in the literature (for examples see (Hiltz 1988; Brandon and Hollingshead 1999; English 1999; Tolmie and Boyle 2000; Kreijns, Kirschner et al. 2003); the results of this study would seem to concur with the literature, at least with regard to the importance of promotive interaction and the fact that group work should promote positive interdependence. However, other aspects deemed important in the literature, for example, group size (Tolmie and Boyle 2000; Kreijns, Kirschner et al. 2003), were not supported by this panel. This may be due to fact that the technology available today allows large groups to work quite well. As one panelist pointed out ‘perhaps bigger groups enable the work to be sustained when some of the group are inactive for long periods’. Group interpersonal skills were also not deemed to be of major importance, while individual accountability was seen as important but not ‘most important’ and did not go through to the final list.

Student characteristics are regarded as important in the literature with Bernard et al. (2000) suggesting that that ideally ‘developing a profile of the learner’s knowledge, skills and experience, as well as their perceived needs’ will aid in the design and implementation of effective DE courses. Learner differences involve both the way that students will interact with the technology as well as affect the degree to which they will participate in online collaboration activities (Salas, Kosarzycki et al. 2002). However, the panel did not concur with the literature; they did not consider student characteristics an important factor in the effective use of CL in DE. It was agreed that while students may have a preference for certain learning styles these can be overcome and adapting learning styles to suit course requirements is part of the learning experience itself.
4.2 Role of Technology

The results of this study highlight the importance of technology by identifying five factors as being among the most important factors. Accessibility to the technology has been highlighted as important in the literature (Bernard, Rojo de Rubalcava et al. 2000) and this has been upheld by the panel, placing this factor among the top five most important factors. Enabling asynchronous communication (Silverman 1995) was also considered important enough to make it through to the final list. The panel members themselves added the three other technological factors in the initial phase.

The lower ranking of the technology factors would seem to be due to the fact that it is deemed a supporting role and less critical than good design and tutor characteristics. While not considering the technology unimportant, the point was made that:

‘with a good plan, and buy-in from teachers, the technology should not matter. Of course there is a need to match the technology to the task – but perhaps we are getting to the position that we are doing this in what seems like an intuitive and natural way. The technologies are (relatively) mature and powerful, so we can achieve our ends with a range of different technologies’.

While the above comment recognises that the technologies are now relatively mature and powerful, it would seem that technology is not being fully utilised. One factor that had a wide discordance concerned the ability of technology to cater for different learning styles. While the majority of the panel did not consider this to be a high priority, one panel member fully supported this and felt that the rest of the panel was overlooking it.

‘Tools need to reflect the multiple styles for learning and not assume that students should adapt to purely linguistic ones. This doesn’t mean we have to test and understand every student’s primary learning style, only that we have to design environments that appeal to multiple styles in a variety of ways’.

Alavi and Leidner (2001) point out that ‘the role of IT in enabling individualized learning methods, while not new, has received strikingly little attention’; this study supports this view and further indicates that the potential of IT has still not been recognised in practice. The potential of technology to provide an individualised, effective learning environment is not recognised or utilised by the majority of this panel of experts. A recent study (Menchaca and Bekele 2008) identified that ‘the availability of multiple tools added flexibility to the learning environment’ which helped ensure a successful DE programme, as did the use of technology tools that appeal to multiple learning styles. Perhaps as more research identifies the usefulness of these technological tools they will be utilised more fully in practice. From an IS perspective it would seem that in practice, there is suboptimal use of technology in this educational environment. In particular, newer technologies such as multi-user environments, group conferencing and social networks are perceived to be of limited use in practice. These technologies have the potential to enable collaborative learning to take place over distance and as such their perceived lack of usefulness is of concern. If these technologies are to be fully optimised as an enabling factor in collaborative distance education then their educational benefits need to be more strongly highlighted to practitioners.

5 CONCLUSIONS

The motivation behind this study was to develop for the first time a comprehensive list of the most important factors that influence the effectiveness of collaborative learning in distance education. As an Information Systems study the role that technology plays was of particular interest and part of the study included pulling together a snapshot of the technologies currently in use in the area. A panel of experts worked together to ratify and consolidate the factors and the study achieved its aim of producing the integrated list. While the actual rankings of the factors did not achieve strong group consensus the lack of agreement highlighted the diverse views and opinions on which factors are of highest priority. The study highlighted the 17 most important factors and also provided an understanding of the perceived role of technology in this educational area.
5.1 Implications for IS Research

While the study established that technology is among the most important factors, it also highlighted the fact that it is viewed more in a supporting role than as an enabling factor. In particular, the use of technology to support multiple learning methods is an area that is not currently optimising the potential of technology. Further research into the role of technology in collaborative learning might consider how the technology is being used and why it is not being fully utilised in practice.

The perceived usefulness of the technologies could also be further explored, in particular the lack of support for some of the newer technologies. The fact that Multi-User Environments are used by less than 50% of this panel, along with the suggestion that it is of limited use warrants further research. As these new technologies can actually enable collaborative learning to take place, rather than just support it, it is important to establish why they are not being considered particularly useful in practice.

As with any Delphi study, the results are based on a limited number of subjects. While these subjects were chosen following rigorous guidelines, one must be cautious in generalising. The sample is relatively diverse in terms of perspectives on CL in DE and this diversity may have influenced the lack of consensus on the priority of the items. Further research could be carried out with panels of similar perspectives to determine if the results would hold.

5.2 Implications for practitioners

The main aim of this research was to develop an integrated list of the most important factors, relevant to the effective use of collaborative learning in distance education. The opinion of an expert panel provides practitioners with a comprehensive, expert opinion on the factors that are deemed highly important in the area. This final list of 17 factors provides details of the areas to focus on when implementing such an initiative.

Practitioners can also use this study to gain an insight into the role technology plays and gain an understanding of its importance, based on the opinion of experts in the field. The snapshot of the technologies currently in use can provide details of which technologies are perceived to be most useful along with those which are considered of limited use.

Overall the study provides a practical guide for those considering implementing collaborative learning in distance education, along with some motivation for future research for the IS community regarding the suboptimal utilisation of technology in practice.

Abstract

The use of the Wikis in both post-graduate and undergraduate teaching is rapidly increasing in popularity. Much of the research into the use of this technology has focused on the practical aspects of how the technology can be used and is yet to address why it is used, or in what way it enhances teaching and learning outcomes. A comparison of the key characteristics of the constructivist learning approach and Wikis suggests that Wikis could provide considerable support of this approach, however research into the motivations for using the technology is required so that good teaching practices may be applied to the use of Wikis when utilized in the higher education context. This study articulates a research design grounded in the Technology Mediated Learning (TML) paradigm that could be used to explore teachers and students’ motivations for using Wiki technology to enhance teaching and learning outcomes. Using the ‘Uses and Gratification’ approach, a popular technique used for understanding user motivation in technology adoption, a two-stage research design is set out. Finally, the paper concludes with a discussion of the implications for both information systems researchers and higher education.

Keywords: Wiki technology, constructivist learning, uses and gratifications approach (U&G), technology-mediated learning (TML), motivations
1 INTRODUCTION

The introduction of Web 2.0 technologies into the university teaching environment is transforming the traditional e-learning world (O'Reilly 2006). The shift from static Web 1.0 technologies to the interactive potential of Web 2.0 provides the opportunity of improving the learning behaviors of the learners as they are no longer just consumers of preconfigured content, but participants in the creation, collation and sharing of the learning content, playing a much more important role in the entire learning context (Ebner & Walder 2007).

Of the various applications that fall under the Web 2.0 umbrella, Wiki is the one that has most rapidly proliferated in higher education (Choy & Ng 2007, Elgort 2007). As “a social networking adaptive technology that emphasizes a more task-oriented collaborative editing of content and development of ‘collective’ interlinked knowledge” (Duffy & Bruns 2006), Wikis have been put to a wide range of uses in a broad range of contexts. Research into Wikis use in academia is relatively new (Parker & Chao 2007) and although some research has examined Wikis in learning (Bruns & Humphreys 2005, Cook 1998, Duffy et al. 2006, Elgort 2007, Elgort, Smith & Toland 2008), these studies have tended to focus on characterizing Wiki learning activities or establishing guidelines to aid in the implementation of Wikis (Forte & Bruckman 2007).

Two significant gaps are evident in the research. Firstly, there is a gap in the understanding of the use of Wikis in learning as it relates to people’s motivations with respect to that use (Wagner 2004). This deficiency mirrors that found in most research into Technology-Mediated Learning (TML), in which there is seen to be little consideration of the important internal social and psychological process through which learning occurs (Alavi & Leidner 2001). These authors call for greater depth and breadth of TML research in the Information Systems (IS) domain in order to understand how technologies can enhance learning. In this regard, the ‘Uses and Gratifications’ (U&G) perspective to the study of technology use has been found to offer some insight into the reasons why people adopt an emergent technology (Flanagin & Metzger 2001), although the level of granularity used when studying the Internet may have damped the results. The other ‘gap’ relates to understanding the way in which Wikis enhance a learner’s learning as, despite its use as a teaching tool, it is not clear how, and in what contexts, a learner’s use of Wikis enhances his/her learning (Forte et al. 2007).

It is understandable that these areas are yet to be investigated, given the newness of Web 2.0 technologies in university teaching, but as Flanagin and Metzger (2001, p154) point out, “this rate of change, however, only underscores the importance of a rigorous examination of new communication technologies’ development and use.” This study sets out a research design by which these two knowledge gaps can be investigated and hopefully addressed. It employs the U&G approach to examine (1) what motivates educators and students to use Wiki technology in teaching and learning, and (2) which groups of motivations does Wiki technology fulfil best? The paper commences by defining Wiki technology and discussing its adoption in the education sector. An overview of good teaching practices then follows. The potential role of Wikis in that practice is then explored followed by an explanation of U&G perspective. The research questions are then posed and the research design by which the proposed research questions could be investigated is then articulated and discussed. The paper concludes with an outline of the anticipated implications of the proposed research.

2 WIKI TECHNOLOGY: DEFINITION AND USE IN EDUCATION

Wiki, a term that means “quick” in Hawaiian, was originally developed by Ward Cunningham and further defined by Leuf and Cunningham as a “freely expandable collection of interlinked Web pages, a hypertext system for storing and modifying information—a database where each page is easily editable by any user with a forms-capable Web browser client” (Leuf & Cunningham 2001, p14).
According to Duffy and Bruns, (2006), the key characteristics of Wikis are:

- A website that allows a user to add content, and allows that content to be edited by any other user.
- Can be personal, but are usually open to collaborate.
- Involve the creation of documents without the user having a detailed knowledge of HTML.
- Tend towards expressing ideas as relationships between pages, thus creating a network of interrelated topics that is based on a topical approach.
- Are a-temporal, that is, the nodes (or interlinking textual references) change not according to time, but by way of development of the evolving and edited text.
- Track the changes to individual pages over time and allow users to browse the history of a page.
- Encourage cross-linking and are dominantly spatial in structure.
- Provide a space where knowledge becomes networked (situated, contextualized) but remains ephemeral; it changes, and can be changed and mediated by the community.

Wiki technology has been found to be useful in teaching, especially where collaboration and knowledge sharing are important (Raman, Ryan & Olfman 2005) and has been used to support activities such as project management (Xu 2007), developing and maintaining software projects (Malani & Dwyer 2005), supporting writing instructions (Lamb 2004), arranging information and sharing knowledge (Elgort et al. 2008), online teaching and assessment (Bruns et al. 2005), and online collaboration in the e-learning environment (Raitman, Augar & Zhou 2005).

3 GOOD TEACHING PRACTICES

In seeking to understand the role that Wikis can play in higher education, this study assumes a constructive perspective of learning, with the deep approach to learning and student-focused approach to teaching being important contributions of the constructivist paradigm of learning.

A student’s approach to learning is typically categorized as either a surface learning approach or a deep learning approach. The surface approach to learning involves the students seeking to avoid failure but having no inherent desire to work too hard. This approach usually leads to satisfactory performance in assessment but to very poor learning outcomes over the longer term (Biggs 2003, Gibbs 1992, Ramsden 1992). The characteristics of the surface approach to learning include: the intention to complete task requirements; memorizing information needed for assessment; the failure to distinguish principles from examples; treating task as an external imposition; focusing on discrete elements without integration; and unreflectiveness about purpose or strategies (Entwistle 1987). In contrast, the deep approach to learning involves students being intrinsically motivated, seeking integration between components and between tasks, playing with ideas (Gibbs 1992), engaging with the materials of the subject and re-constructing their own world view as a consequence of what they have learned (Biggs 2003, Gibbs 1992, Ramsden 1992). The major characteristics of the deep approach to learning include intention to understand; vigorous interaction with content; relating new ideas to previous knowledge; relating concepts to everyday experience; relating evidence to conclusions; and examining the logic of the arguments (Entwistle 1987). The deep learning approach is seen as superior as it is considered to produce better performance in assessment and deliver better learning outcomes over the longer term (Biggs 2003, Gibbs 1992, Ramsden 1992).

An educator’s approach to teaching can be classified into five different types (Trigwell, Prosser & Taylor 1994):

1. A teacher-focused strategy with the intention of transmitting information to students;
2. A teacher-focused strategy with the intention that students acquire the concepts of the disciple;
3. A teacher/student interaction strategy with the intention that students acquire the concepts of the disciple;
4. A student-focused strategy aimed at students developing their conceptions;
A student-focused strategy aimed at students changing their conceptions.

The teacher-focused strategy focuses on teachers and represents teaching as being mainly about passing on knowledge, whereas student-focused strategy focuses on students and represents teaching as helping the students develop their own knowledge (Trigwell et al. 1994).

The teacher-focused strategy has been found more likely to encourage students towards a surface learning approach than the student focused strategy (Trigwell & Prosser 1996), hence suggesting that the student-focused approach to be the preferable approach. Trigwell, Prosser and Waterhouse (1999) give the key characteristics of student-focused teaching strategy as:

- The teacher believes that what the student does and not what the teacher does determines what the student learns;
- The teacher is one who encourages self-directed learning;
- The teacher is one who makes time for students to interact and to discuss the problems they encounter;
- The teacher is one who assesses to reveal conceptual change;
- The teacher is one who provokes debate and raises and addresses the taken-for-granted issues;
- The teacher is one who uses a lot of time to question students’ ideas, and to develop a “conversation” with students in lectures.

These views are consistent with Biggs’s writing on how a learning environment can be transformed to achieve quality outcomes: good teaching as the encouragement of a deep approach to learning (Biggs 2003). The key component in this transformation is the transition from teacher-centered practice, where student learning is seen as a result of what the teacher does, to student-centered practice, where student learning occurs as a result of what the student does (Housego & Freeman 2000). Four key elements being identified as a good teaching are (Biggs 1989):

- Motivational context: deep learning is more likely when students’ motivation is intrinsic and when the student experiences a need to know something;
- Learning activity: students need to be active rather than passive since deep learning is associated with doing;
- Interactions with others: it is often easier to negotiate meaning and to manipulate ideas with others than alone; and
- A well-structured knowledge base: without existing concepts it is impossible to make sense of new concepts.

Both the deep approach to learning and student-focused approach to teaching are important contributions of constructivist paradigm of learning. In this paradigm knowledge as well as meanings are seen as constructed rather than given (Jonassen 1999, Parker et al. 2007) and are seen to embody a number of key principles (Miers 2004, p.4):

- Active and manipulative: engaging students in interactions and explorations with learning materials and providing opportunities for them to observe the results of their manipulations;
- Constructive and reflective: enabling students to integrate new ideas with prior knowledge to make meaning and enable learning through reflection;
- Intentional: providing opportunities for students to articulate their learning goals and monitor their progress in achieving them;
- Authentic, challenging and real-world (or simulated): facilitating better understanding and transfer of learning to new situations;
- Cooperative, collaborative and conversations: providing students with opportunities to interact with each other to clarify and share ideas, to seek assistance, to negotiate problems and discuss solutions.

Constructive perspective of learning has become the dominant paradigm of learning and its implications for how educators teach and learn to teach are seen as considerable, but necessary if the students within each educator’s charge are to succeed (Jonassen, Hernandez-Serrano & Choi 2000).
4 USE OF WIKIS TO FACILITATE CONSTRUCTIVE LEARNING

Information technologies have been used extensively to enhance learning outcomes and a great deal of research has examined the influence of various technologies on instructional methods and learning outcomes (Alavi et al. 2001, Jonassen et al. 2000). Predominately these studies have focused on the influence of technology features on learning outcomes by comparing various forms of technology mediated learning with traditional learning environments (Alavi et al. 2001) and while these studies have answered questions of ‘does the technology enhance learning?’, they have not readily provided answers on ‘how the technology enhances learning?’ The framework proposed by Alavi and Leidner (2001) (set out below in Figure 1), addressed this issue by shifting the attention to explicit examination of the relationships between technology features, instructional strategy, and psychological processes that impact learning outcomes in a given learning context. As they argued, "it is not the technology features, in and of themselves, that matter. It is the mutual influence of technology features, instructional strategy, and psychological processes that impact learning outcomes.” (p.6)

From a student-focused, constructivist perspective, learning technologies are tools for mediating the practice of learning (Jonassen et al. 2000). Jonassen (1997) emphasized that “technologies should be used to keep students active, constructive, collaborative, intentional, complex, contextual, conversational, and reflective. Current popular online course delivery and management systems, such as WebCT, do not support constructivist perspective of learning (cf: Miers 2004, p.9).

Wiki characteristics and features make it possible to facilitate constructive learning (Bruns et al. 2005). The left hand columns of Table 1 below present the key characteristics of a constructivist learning environment (Miers 2004) as well as learning resources, activities, or supports required to facilitate such a constructivist learning environment (Oliver 2001). And the right hand column of Table 1 provides a list of wiki features found in the literature. We propose a possible link between these two parts. In other words, in order to empirically examine how Wikis can be used to enhance learning outcomes, we attempt to identify various reasons (motivations) for teachers and learners to use various Wiki features in the learning contexts. If motivations for using Wikis are consistent with characteristics of the constructivist perspective of learning and associated activities (left hand columns in Table 1), it will help answer our questions of how and why Wikis can enhance learning outcomes.

5 USES AND GRATIFICATIONS APPROACH

Derived from the mass communication literature, the U&G approach provides a user-centered perspective on the relationship between users and technology. The U&G perspective focuses on explaining the social and psychological motives that shape why people use technologies and that motivate them to select certain technologies in order to gratify a set of psychological needs behind those motives (Katz, Blumler & Gurevitch 1974, Rubin 1994). According to Katz et al (1974), one basic assumption of this approach is that media users are goal-directed in their behavior, and the personal use of media is an active choice made to satisfy needs. The second assumption of this approach is that media users are aware of their needs and select the appropriate media to gratify those needs.

The U&G approach has found to be a useful vehicle to explore people’s motivation for engaging one specific mediated technology over another (Newhagen & Rafaeli 1996, Ruggiero 2000). Technology studies that have taken a U&G approach have focused on a number of technologies, such as television, VCR, telephone, cable TV, and the Internet (Ruggiero 2000). Indeed, the U&G approach has been used to investigate users’ motivations for using a particular mediated technology whenever a new technology becomes available (Elliott & Orosenberg 1987).

<table>
<thead>
<tr>
<th>Constructivist Learning Environment Characteristics (Miers 2004)</th>
<th>Learning Resources, Activities, or Supports that Facilitate Constructivist Learning Environment (Oliver 2001)</th>
<th>How does Wiki Technology Support These Resources, Activities, and Supports?</th>
</tr>
</thead>
</table>
| **Active and manipulative** | - Learning objects, animations and simulations that allow students to explore content, test their hypotheses and obtain feedback  
- Websites that facilitate exploratory, non-linear learning  
- Intuitive navigation that between activities and resources that guides and scaffolds but enables learner control | - Wikis versioning capability can show the evolution of thought processes as students interact with the site and its contents (Duffy et al. 2006, Wagner 2004).  
- Wiki pages are highly flexible in structure. Pages can cite other pages based on a powerful back link function (Wagner 2004, Xu 2007).  
- Navigation varies. Users can organize Wiki pages in any predetermined order to enable control (Duffy et al. 2006). |
| **Constructive and reflective** | - Concept mapping software such as inspiration to record prior knowledge  
- Chat and forums to share and discuss prior knowledge and reflect on learning and receive feedback  
- Online journals/weblogs to share learning  
- Note taking form on a webpage that enables notes to be saved, viewed, added to and reflected on form any location | - Once a Wiki has been created it will persist and can be built up as a knowledge repository (Hester 2008, Raman et al. 2005).  
- Wiki is a discussion medium for group work. Students can easily get instant feedbacks from peers or instructors (Wagner 2004).  
- Online journals are provided (Rauschmayer 2008).  
- Wikis are being used as e-portfolios, a tool for collection and reflection at any time, from anywhere (EduCause Learning Initiative 2005) |
| **Intentional** | - Microsoft Word or online rubric generators to construct rubrics to record negotiated learning outcomes and monitor progress  
- Calendar a tool to enable teachers to inset important dates | - The ability of Wiki to export notes to Microsoft Word makes reporting easy (EduCause Learning Initiative 2005)  
- Calendar tools are provided or integrated with external applications which help students to keep track of their own learning process |
and allow students to add their own dates to keep track of their learning
- Concept mapping software such as Inspiration to record learning goals and reflect on them
- Collaborative opportunities to discuss learning goals and obtain constructive feedback from the teacher and peers by means of private email and email listservs
- Online self-assessment surveys or quizzes to evaluate and reflect on learning
- Teacher and peer assessment opportunities through the ability to upload, edit and exchange files as well as make and attach notes

(Richardson 2008, Schwartz, Clark, Cossarin & Rudolph 2004).
- The asynchronous written mode of Wiki web pages enables self-paced study by students (Elgort et al. 2008).
- Wiki as a knowledge repository can support reflection on previous learning (Elgort et al. 2008, Hester 2008).
- Email and group discussion is provided to facilitate efficient communication between instructors and students (Buffa 2006, Schwartz et al. 2004).
- Online self-assessment surveys or quizzes can be set up by instructors. After students’ response, instructors can easily add comment (Liu, Chen & He 2008).
- The functions such as uploading, editing and exchanging files and attaching notes are provided (Challborn & Reimann 2005).

Table 1: Key characteristics of a constructivist learning environment and corresponding Wiki characteristics, and features

| Authentic, challenging and real-world (or simulated) | Problem-solving, task-based activities in which learners are actively engaged in dealing with open-ended questions inquiries and tasks such as: online projects, slam-dunk digital lessons, learning quests, and ask an expert. |
| Cooperative, collaborative, and conversational | Discussion groups to pose and discuss questions, share ideas, seek support and negotiate issues |
| | Forums to pose questions, provide opinions and gain exposure to other ideas |
| | Group collaboration on a task |
| | Chat to discuss and share ideas informally |
| | Online journals/weblogs to record and share thoughts, ideas and learning |
| | Interactive whiteboard for collaborative sharing |
| | Online notice-boards that enable both the teacher and the learner to share ideas |
| | Online polling tools to question, canvass and survey student opinions on a variety of issues |
| | Video-conferencing tools that enables students to see the instructor or other students in a chat session |
| Wiki pages can be linked to external information sources such as web sites relevant to a particular topic/problem (Duffy et al. 2006). |
| Wikis support exploratory learning by providing problem manipulation space (Wagner 2004). |
| Wikis enable collaborative content creation, peer assessment; individual as well as group reflection on learning experiences, user-centric up-to-date information regarding changes in collaborative spaces which all facilitate knowledge sharing and group collaboration (Duffy et al. 2006). |
| Online journals/notice-boards are provided to enable feedback and ideas sharing among peer or between students and instructors (Duffy et al. 2006). |
| Collaborative projects enabled by Wikis can help promote “pride of authorship” and ownership in the team’s activities (EduCause Learning Initiative 2005, Raitman et al. 2005). |
| Online polling tools can be integrated with Wikis to support survey and assessment (Yang, Wu, Koolmanojwong, Brown & Boehm 2008). |
The characteristics of active choice of technologies and user-centered nature make the U&G approach particular useful for understanding motivations to use Internet-based technologies (Kuehn 1994, Morris & Ogan 1996, Ruggiero 2000) and studies that have focused on this area have found a range of motives at work. Garramone and Anderson’s (1986) investigation of electronic bulletin boards in politics found that the needs for surveillance, personal identity and diversion were equally explanatory in that context. Korgaonkar and Wolin (1999) established five motivation factors for the web users: escapism, information control, interactive control, socialization, and economic motivations. Papacharissi and Rubin (2000) also developed a scale of Internet usage motives that consisted of five primary dimensions: interpersonal utility, pass time, information seeking, convenience, and entertainment. Other new gratification dimensions have included: problem solving, persuading others, relationship maintenance, status seeking, and personal insight (Flanagin et al. 2001). Collectively, the U&G perspective has been very useful in understanding motivations and needs for using the Internet.

These studies did however look at the Internet in very general terms, seeing it more as a single technology rather than as the bundle of applications and functions (Parker & Plank 2000). These studies also tended to use previously defined mass media gratifications items rather than developing and using the gratification items uniquely associated with Internet technological context. Understanding the teachers and students’ motivations associated with using Wikis, through the use of the U&G perspective, coupled with the consideration, from a constructive perspective, of the learning context in which this Wikis will be deployed, should lead towards a better appreciation of how Wikis can be best used to enhance learning. The following research questions formally operationalize the research objectives of this study.

RQ1a: What motivates university teachers to use Wikis in their teaching?
RQ1b: What motivates university students to use Wikis in their learning?
RQ2a: Which groups of teachers’ needs do Wikis fulfill best?
RQ2b: Which groups of students’ needs do Wikis fulfill best?

6 RESEARCH DESIGN

Due to the lack of research in identifying users’ motivations for using Wikis in the learning context, this study will adopt Kuehn’s (1994) two-stage research approach for U&G profile development for a comprehensive examination of users’ motivation. Specifically, an initial study will be conducted using interviews to identify the different ‘need statements’ of both university teachers and students. These ‘need statements’ are motives that shape both teachers and students’ Wiki usage patterns in the learning contexts. Then, both teachers and students’ Wiki use motivations identified in the first step will be further examined separately in a large scale survey in order to group these statements into profiles representative of specific motivation dimensions for technologies of each user group.

6.1 Stage 1: Understanding the motivations for using Wikis

In order to identify motivations for teachers to implement Wikis to facilitate their teachings and motivations for students to use Wikis in their learning, 15-20 teachers and students will be interviewed using the Repertory Grid Technique (RGT). These staff and students will be purposefully recruited from the Engineering and Business schools at a large Australian university.

RGT was developed by Kelly (1955) to study personal construct systems and is predicated on the idea that individuals use their own personal constructs to understand and interpret events and that these constructs are influenced by each individual’s background, personal experiences, beliefs and value systems (Napier, Keil & Tan 2007). RGT involves the generation of a list of concepts (elements) about things or events to be studied and the forming of attributes (constructs) based on the list of concepts (Zhang & Chignell 2001). It is a structured interview process with procedures for uncovering the
cognitive constructs of individuals (Tan & Hunter 2002), and has been widely used in organizational and IS research (e.g., Hunter 1997, Napier et al. 2007, Phythian & King 1992).

The output of this stage includes two parts:

- A comprehensive list (elements) of current technologies (including Wikis) utilized by teachers and students in the learning contexts.
- A set of motivation statements (constructs) unique to both teachers and students in the university context for these technologies (including Wikis).

Content analysis will be used to interpret the RGT data, as content analysis allows for the creation of thematic categories from the constructs described in the interviews (Neuendorf 2002). For the categorization of constructs, an adjusted generic core-categorization procedure outlined by Jankowicz (2004) will be used, thus allowing research questions 1a and 1b to be addressed.

6.2 Stage 2: Investigating the relationships between motivations and Wiki uses

Second stage aims to: 1) provide empirical verification and validation of the stage one results; and 2) explore the relationships among learning technologies, teaching strategies, and learners’ psychological learning process, as depicted in Figure 1.

Participants will be asked to complete a questionnaire designed to assess their usage of technologies for satisfying their various needs/motivations (as identified in stage one). Respondents will be asked to rate their level of agreement with the motivations for using each of the technologies identified in stage one in learning contexts on a scale of 1-9 (where 1 = “Strongly Disagree”, 5 = “Neutral”, and 9 = “Strongly Agree”). For each of included technologies, participants will be asked to report their levels of expertise, level of accessibility, frequency of access and weekly usage. Both teachers and students who have experience of using those technologies will be invited to participate.

Research questions 1a&1b will be further validated by using a principal component factor analysis with varimax rotation to extract and interpret potential motivation dimensions (factors) (Papacharissi et al. 2000). Research questions 2a&2b can be then assessed by using MANOVA with the motivation dimensions of teachers and students separately, as the independent variables, and the mean satisfaction ratings as the dependent variables.

7 IMPLICATIONS AND CONCLUSION

A number of limitations are noted for this proposed study. First, this project may be limited to participants who are studying at one university with the majority of them majoring in business and engineering. Students’ majors and university technology use culture may affect their experience with and motivations for using them. Thus, generalizability of the results and conclusions drawn from this study will need to consider the demographics. The U&G perspective has been criticized as being too individualistic by providing little explanation on the formation of social and psychological needs or ignoring the social implications of technology use (Elliott, 1974, Ruggiero 2000, Zhu 2004). To address this issue, a study investigating the psychological and social factors that affect individual’s motivations for using technology and the consequences of technology-related behaviors will be conducted in the future.

The proposed research will be of significance to practice in a number of ways. In general, an improved understanding of the social contexts of technology use in universities, from both a teachers and students’ perspective, should help the implementation of technologies and flexible teaching and learning models into the learning environment. From a teaching perspective, a better understanding of both the motivation for using Wikis and the efficacy of using Wikis should provide a useful prompt for the rethinking of good teaching practices in the pursuit of supporting socially constructed learning practices (Duffy et al. 2006). When educators understand the motivations that guide student
interactions with the technology, they will be able to accommodate those needs more responsively in their teaching strategies.

This proposed research will contribute to the research effort regarding technology use in education in a number of ways. First, it will demonstrate the usefulness of the U&G approach in this area of research, especially in regard to Web 2.0 technologies. It will be amongst the first studies to conceptualize how both teacher-specific and student-specific technology use motivation scales are constructed by employing a multi-method approach. Most importantly, this proposed study will make progress towards understanding why technologies can be used to enhance learning outcomes by examining the links between technology features and instructional variables that might influence learning outcomes.

University students are among the most computer-savvy and “connected” users of the Internet (Aiken, Vanjani, Ray & Martin 2003). Using various technologies has become so pervasive in the lives of this young generation, that it has become a natural extension of themselves (Hoffman, Novak & Alladi 2004). These students will simply expect that new technologies, such as Wikis, will be an integrated part of their learning. It is important then that we understand how to best harness these technologies so that they enhance good teaching practices and allow us to prepare these future engineers, software developers, business leaders and the like, with the critical, creative, collaborative, and communicative capabilities that are required for their professions (Duffy et al. 2006). Understanding how technologies can be used to facilitate and development of those skills is of considerable importance to educators.

Abstract

This study presents particular issues concerning the acceptance of e-Learning in a major Greek bank. A generic unified analysis framework is developed based on dominating theories of individual information systems acceptance, integrating also the organizational and work-context dimensions. Concerning the organizational level, management of employees’ development, training culture, and alignment with corporate strategy raise particular significance. On the work-social context dimension, Training Department, branch managers and corresponding supervisors, as well as colleagues, consider the main key stakeholders. Additionally, time resources and work overload appear as critical when designing this type of training interventions. Last, in the individual level, perceived usefulness and ease of use, personal innovativeness with information technology, computer anxiety, self-efficacy, and intrinsic motivation to learn affect in broad terms the attitudes employees formulate towards e-Learning in this organization. All these issues, in the various aforementioned levels, must be taken into account when designing and maintaining technology-supported training interventions, in order to mitigate resistance and maximize the potential benefits.

Keywords: e-Learning, information systems acceptance, case study, longitudinal data.
1 INTRODUCTION

The advent of the knowledge economy and related technologies has created a wave of IT interventions in the area of human resource development (HRD). In this novel information systems adoption context, critical adoption drivers shift from the pursuit of operational and/or managerial efficiency and effectiveness to the challenging areas of human capital development and employee motivation and engagement. As with other IT systems, the introduction and implementation of HRD systems into contemporary organizations agendas necessitates the recognition, acceptance and support from various stakeholders in order for them to provide the full benefits and functionalities they carry.

As Gartner (2008) says¹, in the reality of commoditized banking products and increasing global regulation, IT professionals and business leaders in the banking industry must invest in the right technologies to support growth, preserve margins and aid compliance of human capital with corporate objectives. Human resource systems contribute significantly in all these priorities, as they sustain the human capital improvement and effective utilization of personnel, reduce costs, and - especially the training programs - consider a valuable aid towards achieving competitive advantage.

Workplace training concerns a systematic approach towards learning and human resource development, in order to improve individual, team, or organizational effectiveness (Goldstein and Ford, 2001). Nowadays, this activity is supported by the various types of “technology-enabled learning” interventions, one of which is e-Learning. This training delivery mode exploits the power of web networking and capitalizes on corporate technology infrastructures in order to deliver instruction and achieve particular objectives (Rosenberg, 2000).

This study unfolded from a research project which intended to the total improvement of the development of employees working in a large Greek Bank, as well as to surface particular deficiencies of current training operations. The bank is a part of a large financial group, operates in the Greek market and has more than 650 branches worldwide, employing more than 7000 people. Its strategy focuses on becoming the leading bank in the wider region of South Eastern (SE) Europe, a rapidly developing and profitable market of 60 million people, with profound implications to human capital development. Generally speaking, the small size of the Greek market, the maturity levels it has approached, the fierce competition, mergers, acquisitions, and the last global economic deficiencies, have motivated several banks to expand to the SE Europe and Turkey. Those markets provide them particular opportunities for growth, for differentiating their sources of incomes and portfolios, and for increasing their size, which is relatively small to their competitors operating in the EU. All these conditions, as well as new products, services, business process reengineering projects towards establishing customer-oriented philosophies, and the compliance with National legislation and European Central Bank, create particular training needs for banks’ geographically dispersed employees.

Although the primary objective of the project was to produce a training needs assessment methodology in the context of technology-supported learning, soon the interest of both researchers and the Bank was shifted to the wide human capital development practices generally, and to e-Learning specifically. To this end, the specific project protocol and the particular needs of the Bank, specified the goal of identifying the particular factors that affect e-Learning operation and adoption. To this end, a double research agenda unfolded. The first concerned the organizational acceptance of e-Learning, which had to do with the management of human capital development. The second concerned the acceptance of e-Learning from employees, who operated the same time as users of e-Learning courses and learners. The planning and implementation of the project spanned more than four years, from March 2003 to July 2007. However, at several junctures during the implementation, the evolution of the project was hindered by various internal management changes.

¹ http://www.gartner.com/it/products/research/industries/industries.jsp#bank
The starting point of the changes that raised the interest of the research team was a huge Business Process Reengineering project, which was implemented in 2001. It generally included the business transformation from a process-oriented to a customer-oriented approach. Just after the reengineering, an innovation occurred to the training function of the bank. E-Learning was established as a mode of training in the form of blended learning (Trasler, 2002), covering the gaps of traditional, on-the-job, and self-training. A well known Learning Management System used to deliver the asynchronous self-based e-Learning courses was acquired. Off-the-self courses as well as other outsourced and custom developed for the specific needs of the bank were also acquired. As e-Learning adoption requires a lot of resources, willing, and careful design, various worries raised to the researchers forming the initial research questions, at least in broad terms (Mintzberg, 1979).

- What issues were affecting the acceptance of the initiative both from the organization and the individuals?
- Were there any particular context-specific characteristics that were facilitating or inhibiting the initiative?

These queries formed a priori the units of analysis, which were the organization and the employees, and the method of work, the case-based research approach. In the following section we specify potential important variables based on extant literature and the experience of the research team.

2 THEORETICAL FOUNDATIONS

2.1 Information systems acceptance

Information systems are introduced to an organization for various reasons: automate procedures, improve efficiency and effectiveness, and increase workforce performance. Some systems are adopted in order to establish a particular way of doing business, through making their use mandatory and inevitable. Other times, using the system is not obligatory and depends on the voluntary use of employees. To this end, people tend to use an application or not based on their beliefs whether it will enhance their job performance (Davis, 1989). Between these two border lines, there is a continuum characterized primarily by the level and the degree of actual effective and efficient use of the system. Thus, the case observed in practice is that, the more particular systems are used, the greater impact they can have (Trice and Treacy, 1988). As these systems usually demand significant resources to be implemented and maintained, organization have to employ aggressive tactics to encourage themselves and users to expand and take advantage of the installed technological systems (Jasperson et al., 2005).

Upon organization’s decision to adopt a new technology, individuals’ perceptions and attitudes affect the success of the initiative (Leonard-Burton and Deschamps, 1988). Generally speaking, people are sometimes unwilling to accept and use systems, even if they would improve their job performance or relieve them from demanding and time-consuming tasks (Mathieson, 1991). Literature indicates that people tend to resist to MIS because of their own internal factors (people-determined), because of poor system design (system-determined), and due to the interaction between specific system design characteristics and the related (organizational) context of use (Marcus, 1983). Focusing on the first of the aforementioned dimensions, as systems become useless when people do not use them “the right way”, i.e. effectively an efficiently, it worth to examine how they decide whether they will use them or not (“the right way”). This is examined in the literature of information systems under the umbrella of Information Systems Acceptance. Moreover, the organizational context of use, motivate us to examine the particular work-related characteristics that may affect acceptance and use.

In this aim, Information Systems acceptance research has developed, empirically tested and shaped many alternative models to the research community and practitioners, focusing on the user/individual level. The main focus of various theories and models appear in the area consider the intention or actual usage as the dependent variable. The Theory of Reasoned Action (Fishbein and Ajzen, 1975), the
Theory of Planned Behaviour (Ajzen, 1991), and the Technology Acceptance Model (Davis, 1989) dominate in this area.

According to the Theory of Reasoned Action (TRA), Behavioural Intention is the primary determinant of an individual’s behaviour. Moreover, his intention to adopt an innovation is influenced by a personal factor (Attitude) and a social influence factor (Subjective Norm). Attitude is an individual’s positive or negative belief about performing a specific behaviour. Subjective Norm is the perceived influence of social pressure on an individual to perform or not perform the behaviour. The TRA has been used in practice (e.g. Becker and Gibson, 1998; Chen and Chen, 2006), but not appropriately some times (Sheppard et al., 1988).

The Theory of Planned Behavior (TPB) (Ajzen, 1991) is an extension of the TRA, which was developed in order to overcome the limitation of dealing with behaviours over which people have incomplete volitional control, introducing the concept of perceived behavioural control. As many behaviors present difficulties in execution that may limit volitional control, perceived behavioral control predicts also directly the behaviour, serving as a “proxy” for actual control (Armitage and Conner, 2001). The concept is is strongly interrelated with the concept of self-efficacy (Bandura, 1977), which seems to be a crucial parameter of motivation (Hodges, 2004). The aforementioned ideas are supported adequately by various studies in various domains (Courneya et al., 1999; Mathieson, 1991; Trafimow et al., 2002; Sutton, 1998). Alongside, various implementations and alterations of the TPB have been proposed in the literature (e.g. Taylor and Todd, 1995; Crespo and del Bosque, 2008; Pavliou and Fygenson, 2006).

TAM originates from the two aforementioned theories, including only a proportion of them. Since its invention, TAM has been used extensively, in various contexts, and has been enhanced with various other factors (e.g. Davis and Wiedenbeck, 2001; Legris et al., 2003; Lu et al., 2008; Ngai et al., 2005; Van Raaij and Schepers, 2008). Additional variation of the aforementioned model include the TAM2 (Venkatesh and Davis, 2000), the Unified Theory of Acceptance and Use of Technology (Venkatesh et al., 2003), and combinations of the aforementioned models (Taylor and Todd, 1995; Yi et al, 2006).

2.2 Scrutinizing human behaviour

The common and main as well concept of the aforementioned theories is attitudes, which attract continue research in various disciplines (Ajzen, 2001). Attitudes reflect the individual’s positive or negative evaluations of performing a particular behavior, and their formation is based on the Expectancy-Value Model (Fishbein and Ajzen, 1975). In the context of information systems, literature has indicated a number of beliefs and associated outcome expectations, like the perceived ease of use and perceived usefulness (Davis, 1989), the personal innovativeness with IT (Agarwal, and Prasad, 1998; Lian and Lin, 2008), trust (Pavlou and Fygenson, 2006), etc. Subjective norm refers to the individual’s perceptions of general social pressure to perform (or not) the particular behaviour. The claim here is that, if the individual perceives that significant “referent” others – whose beliefs may be important to the individual – approve or disapprove the behavior, it is more (or less) likely to perform it. “Referent others” are people.

Additionally, other issues also have been proposed as facilitating or inhibiting factors in the creation of intentions. Computer anxiety, intrinsic motivation, gender, and personal IT innovativeness to learn can be categorized as individual factors that affect intentions to use information technologies through attitudes and perceived behavioural control (Harris, 1999; Taylor, 2007; Thatcher and Perrewé, 2007; Thatcher et al., 2007; Venkatesh and Morris, 2000; Ong and Lai, 2006; Tharenou, 2001; Davis et al., 1992). Additionally, work specific factors as work overload (Ahuja et al., 2007; Moore, 2000), and time resources (Pavlou and Fygenson, 2006) have been also proposed in the literature as issues affecting indirectly the intentions.
2.3 e-Learning

E-Learning is typically employed through online learning courses, in synchronous (e.g. virtual classrooms) and asynchronous formats, and in the context of Web 2.0 through informal learning tools, like wikies and blogs. This technology can be used stand-alone or complementary to other training modes, in order to mitigate the skill shortage that several banks are recently facing as a result of particular organizational transformations, e.g. from bureaucratic to customer-oriented (Neirotti and Paolucci, 2005; Regini et al., 1999).

Study of various cases demonstrates that there are particular characteristics of e-Learning used in corporate training. First, organizations seldom use “pure e-Learning”, but they prefer the so called “blended learning” which consists a new and promising learning approach (Williams, 2003), as well as the dominant way of using e-Learning effectively and efficiently (Kim and Choi, 2004; Finn and Bucceri, 2006), maximizing also the ROI in HRD interventions (Oakes and Green, 2003). Blended learning is the effective integration of various learning techniques, technologies, and delivery modalities to meet specific communication, knowledge sharing, and informational needs (Finn and Bucceri, 2006). The most comprehensive approach of the different blended learning dimensions has been proposed by Patti Shank (2004) and many studies indicate the right mix as one of the critical success factors (Trasler, 2002; Williams, 2003; Oakes and Green, 2003).

3 RESEARCH METHODOLOGY

3.1 Research method

Given our interest in the continuous alterations as well as the hazy process initiation and management concerning the training and e-Learning function in the Bank, an exploratory, qualitative, longitudinal case-based approach with participant observation was selected and followed (Yin, 1994). Typically, a case study investigates a phenomenon in its natural setting, using multiple methods of data collection in order to gather information from various units (people, teams, organizations, etc.). Case studies also allow the researcher to answer “how” and “why” questions, in order to understand and decode the complexity of the processes taking place. These critical questions appear both in interpretive and positive studies (Walsham, 1995). Last, it appears to be quite useful when there are few studies on the issue in the particular context, as happens in this case (Benbasat et al., 1987). The case study was conducted in order to understand the dynamics presented in the case organization (Eisenhardt, 1989), primarily by the two authors, and supplementary by five other persons, with various backgrounds, forming an insider-outsider research team as recommended by Eisenhardt (1989).

The primary sources of information for the case study were stakeholders’ semi-structured interviews with the upper and line management of the human-resource related departments, the operation team of e-Learning, tutors, and employees working both in branches and corporate headquarters. Moreover, internal documents were reviewed (e.g. strategy and process-related documents), reports, and meeting minutes. The interviews were conducted from May 2003 until March 2007. Twenty two interviewees sat for a total of fifteen interviews, with the time frames varying between 1.5 to 2 hours. These semi-structured interviews were based on predefined research agendas already delivered to interviewees before the meetings, and reflected the key issues of research. Depending on the issues, the interviewees varied between the upper management and staff of the Training sub-department and related corporate functions, to employees working in the branches. Moreover, the same day after each interview, the research team was conducting an internal meeting to clear and agree on the new information acquired and lessons learned. The interview data were used to uncover the particular hidden aspects of the interviewees’ words, create a common understanding between the research team, and to identify critical issues for research. Frequent discussions between the researchers were also taking place in order to reflect on the newly acquired knowledge, especially after studying related
scientific material on the topics analyzed in section 2. The meeting minutes and internal documents were additionally used to understand the issues identified during the case analysis. Moreover, the meeting minutes were also reviewed by the interviewees in order to reduce bias.

3.2 Data collection and analysis protocols

In this study, a multiple levels of analysis perspective were adopted (Yin, 1994; Lee, 1989). First the authors aimed at gaining deeper understanding about the actions of the main stakeholders concerning the management and operation in human capital development in the Bank, as their experiences were important and critical in the particular context of action (Benbasat et al., 1987). Moreover, as e-Learning consists the most promising system in corporate training, the main characteristics, as well as the way it was introduced and used (“pushing” vs. “pulling” activities) was reviewed. To this end, a second level of analysis was created, focusing on the perceptions of individual individuals towards the technology intervention in their learning. In other words, the authors aspired to the double nature of employees, i.e. users of IT and learners, in order to develop meaning on this innovative behaviour.

In this research an inner context and process driven approach through time was pursued, consistent partially with the work of Pettigrew (1990) on contextualism. Outer context was willingly excluded from this study as training the employees concerns an internal topic of each organization, although affected by the economic, social and sectoral changes. Moreover, particular emphasis was given to provide meaning on the various emerging issues. To this end, the study emphasized towards the importance of embedding e-Learning in corporate training agenda, and studying the change occurred and the various reactions of different stakeholders. Moreover, it located changes in past, present and future time (occurred and prospective changes), and explored the relation between context and action.

Due to particular project constraints, a single site analysis was ensued. Although contextualism research sustains the comparative method, this approach (i.e. single site) has also been widely applied in practice in order to develop deep insights (Boudreau et al., 2001; Orlikowski, 1996). Alongside, a triangulation methodology was applied in practice, through the in-depth interviews with various stakeholders, document reviews and the multiple researchers’ perspective.

4 FINDINGS AND DISCUSSION

The issues analyzed for the need of the research were developed around the questions established before. In order to mitigate complexity, a multiple levels of analysis approach was selected for studying the inner context (Pettigrew et al., 2001). These include the managerial context, the work-social network and particular work-setting characteristics, and the individuals. For presentation reasons, the analysis framework is presented in this point, and is used for case analysis and discussion in the following sections.

![Figure 1. The proposed framework of analysis](image-url)
4.1 The Human Resource Development function

Human resource management and development in the Bank was the first complicated issue identified. A legacy Personnel department was responsible for all traditional HR-related activities apart those included in the developmental agenda, e.g. training and development, organizational development, human resource planning, and career planning (Wilson, 1999). This department was supervising two separate sub-departments, the Human Resource Development and the Training department. Whereas the former was conducting all the aforementioned issues except training, as well as some training needs analyses, the latter was responsible for developing, managing and delivering training and e-Learning to the employees, with the main objective of serving efficiently the branch network training demands. This corporate function appeared to be the most promising and active in relation to the others, as it was also conducting training needs assessment and proactive training. Actually, it was aspiring at undertaking all employees’ developmental activities, formulating a new corporate function with the HRD department. The aggressive nature of tactics was sustained by its brilliant leader, who was talking in passion about his (team, not personal) objectives,

“We operate under fierce competition ... the branch employees need up-to-date information and training in order to enhance customer satisfaction. On the other hand, the HRD department is small and slow, and usually we have to search in employees records for the eligible ones to participate in training. Moreover, we continually watch the competition, we try to learn from the achievements and failures of others, and formulate accordingly our unit’s strategy. Moreover, we often discuss with other unit’s managers in order to learn in advance about the new products and services, or even organization-wide initiatives, and develop proactively the supplementary training interventions. Last, we conduct official surveys and unofficial discussions with branches’ managers and employees, in order to improve our services, and convince them about the significance and benefits of training generally, and e-Learning in particular.”

Obviously, the overlapping and the same time partially dispersed human resource-related functions, operated in a context of internal competition. On the one hand we meet a creative Training department, which introduces and use modern technologies to accomplish its tasks. On the other hand we see a legacy Personnel department, which does not even have in place a modern human resource information system to manage employees (Ceriello and Freeman, 1998). Actually, the information applications used by the latter were mainly spreadsheets and legacy applications formulating islands of automation (Applegate et al., 1999).

Apart from that, the Training department was continuously trying to establish its strategic position in the HR agenda to the upper management committee of the organization, with which it cooperated frequently, and sustained its short (one year) and long-term (three years) strategic plan. The departmental strategic plan was tied up to the corporate business plan.

Examining the case, particular grains of training culture surfaced. Apart from the technological innovations, the Bank was undertaking particular activities that contributed to the total improvement of its personnel, e.g. hiring knowledgeable employees, implementing job rotations, and undertaking actions towards career development (Gilbreath, 2008; Preskill and Donaldson, 2008). Additionally, all the subject-matter experts were educated in international business schools and accredited from international organizations. These people operated also as an unofficial knowledge management system, as they contributed both to the corporate strategy planning as well as the facilitation of daily work duties of employees through answering their questions.

The aforementioned activities were conducted in order to create and sustain a corporate culture towards the uptake of the human capital as well as the establishment of a concrete and knowledgeable workforce. Apparently, and as the Training Manager underlined,

“Our objective is to transform the Bank to a learning organization (Senge, 2006). Apart from developing the line staff, we have also to train the branch managers, as their role in people
management is crucial for daily operations. Unfortunately, they usually don’t know what their subordinates know. To this end, we try to convince them to participate in training, even join a university to acquire a masters degree or attend an HR conference!”

Apparently, the branch managers and directors, as well as the subject matter experts, consisted the main stakeholders in the motivation of employees to attend e-Learning. The former were forming a critical role in the work-social network of employees, approving their request for participation in training and e-Learning, and motivating them to join it. On the other hand, subject matter experts were responsible both for training content, and the traditional training in the classroom, which complemented the e-Learning modules.

4.2 Social network and other work settings issues

Despite the recognized need for training, particular issues inhibited the effectiveness, efficiency, and finally active and concentrated participation of employees in training. The first related issue appeared back to 2003 and concerned the desire of the Training Department to foster employees to attend e-Learning outside the work context (e.g. from home). Before that, the bank had created the so-called “e-Learning kiosks” inside many branches, where each employee could go to attend e-Learning during the working hours. Soon the idea was abandoned. As a teller mentioned, “I did it some times when there was not much workload and after the agreement of the branch manager but, when customers came, they were not served adequately fast and started screaming “why don’t you call an additional employee to serve us”? I had to stop immediately”. 

Although attending e-Learning from home seemed to be a very good idea for the upper management, employees expressed different opinions. As a female branch network employee stated, “We are in a panic all day. Who has time to attend e-Learning during working hours? They offer access from home also but, I am a mother and although I’m tired when I get back home, I must help my children to study and take care of the household. Sorry, no time for e-Learning”. 

Obviously, both persons raised the issue of the limited time resources for attending e-Learning during working hours (Pavlou and Fygenson, 2006). Moreover, the lady focused on the issue of creating a work-family conflict, a characteristic of inadequate psychosocial healthy work environments (Gilbreath, 2008) and critical antecedent of work exhaustion (Ahuja et al., 2007). 

To this end, a survey was conducted from the Training department in order to motivate employees to attend e-Learning outside the work context. The study was conducted in 2003 with the use of a questionnaire filled in by 479 employees (58% response rate). The participants were 60% female, another 60% were working at the bank more than 10 years, and were employed in all levels and roles. 

Despite the previous negative concerns, employees indicated their positive attitudes towards e-Learning (> 80%), the moderate perceived usefulness (55%), the need to attend e-Learning outside the work context (70%) due to heavy work load and limited time resources, and need to avoid interference of work to their personal lives (27%). Actually, the 75% denoted the family affairs and the 63% the fatigue due to heavy work load as the main inhibiting factors for attending e-Learning from home. Additionally, there were indications of lack of training culture in the branches, an issue that was defined through the reduced participation in e-Learning in branches, the moderate attitudes towards technology, and the lack of connection between learning and career development. Interestingly, employees had already participated in e-Learning were denoting their intention to re-use it. Additionally, only 22% of trainees declared that they preferred the classroom-based training, in order to maintain physical contact with other trainees and the tutors. The main outputs of this study implemented in practice through marketing activities towards e-Learning benefits.

Another main stakeholder of the work-social network of the employees were their supervisors and branch managers. These people were challenged daily to serve customers and achieve corporate objectives utilizing fully the capabilities of the staff they managed. Although most of them presented
significant experience, they usually did not have to attend the courses that their subordinates had. They didn’t even know the particular knowledge of each employee! Moreover, as some clerks mentioned, they didn’t motivate them to attend e-Learning.

4.3 Employees and e-Learning: the sovereign in a contest

The results of e-Learning acceptance from employees appeared to be quite interesting. Reactions of employees towards e-Learning courses were quite positive, requests for access were continually increasing and direct and indirect training costs were reduced. Moreover, the absence of employees from the position was decreased too due to e-Learning. Alongside, an internal survey conducted in the end of 2003 revealed the significant usability of existing e-Learning courses (Nielsen, 2000). Actually, data indicated the increased content completeness (72%), visual design (93%), interactivity (62%), navigation (82%), moderate to easy access (68%), and moderate control (58%). Main findings also included the decreased motivation for searching for additional material (30%), moderate lack of additional learning resources (49%), and limited capabilities for collaboration with other learners (30%). Totally, the 65% of the trainees appeared to be satisfied with the existing e-Learning courses, an issues that raised inquires about the remaining 35%. As the design of e-Learning courses and the content were satisfactory, what issues could hinder the total acceptance? To this end, next we focus to – negative or positive – issues presented by the interviewees that may explain this discrepancy.

Literature indicates the need for IT competencies for bank employees, as well as managerial practices that facilitate the adaptation of human capital to technological change (Neirotti and Paolucci, 2005). In this regard, we assume that e-Learning necessitate the aforementioned skills also. Thus, acceptance of e-Learning from employees should be affected by the knowledge of related skills. Moreover, as e-Learning is considered as an innovation in corporate training agenda – due to its technology dimension – people should present adequate innovativeness in using this IT. To this end, the issue of Personal Innovativeness with Information Technology emerged (Agarwal and Prasad, 1998). This claim is also documented by the words of an employee,

“I like e-Learning. I can learn on my own time, even from the office – although a little difficult some times – or usually from home during the weekends. Generally speaking, I like very much the computers and the Internet, my friends call me “technology freak”!”

Apart from the dimension of technology, this employee place the issue of controllability, setting the route towards the construct of perceived behavioural control in the Theory of Planned Behaviour.

On the other hand, literature indicates the anxiety that various people feel when they use computers (Thatcher and Perrewé, 2007). As an employee stated,

“I have to use computers for my work, I can say that I feel comfortable, although a little strange some times, as I learned to operate computers in the bank. But, I don’t use them extensively at home”

Last, various studies recognize the importance of intrinsic motivation to learn in participating in training sessions or using related systems (Davis et al., 1992). This issue appears also in this case,

“I like to learn new things. I read books, and I want to do a part-time masters! I know to handle computers and navigate to the internet, and I use it daily. I have used e-Learning to learn, and I think it is easy for me to do that!”

To this end, we see that the issues of perceived ease of use, perceived usefulness, personal innovativeness with information technology, computer anxiety, and motivation to learn have been mentioned as critical from the employees in the bank. To this end, these issues may formulate particular individual characteristics that may affect attitudes and control of the behaviour of employees in the formation of e-Learning acceptance.
5 CONCLUSIONS AND LIMITATIONS

Although the comparative and a multiple-site approach is encouraged by Pettigrew (1990) and is applied in other studies (e.g. Edmonson et al., 2001), this study was conducted in one organization an issue that implies particular limitations for the generalizability of results (Lee, 1989). Though, this research site was fulfilling the demands of the particular research topics and the questions being posed. Moreover, as it was presented in the previous section, it included particular critical incidents and dramatic glimpses into the current human resource development processes, which may act and support adequately the meaning elicitation through an in-depth case study. Additionally, the selected organization employs high experience levels of the phenomenon under study as banks constitute knowledge-intensive organizations, and the particular bank constituted a pioneer in e-Learning in the Balkans (i.e. extreme case (Eisenhardt, 1989)).

A limitation of various studies in the area is that, they are conducted in academic settings, where students are the participants (Venkatesh et al., 2003). Only a few studies are based on data acquired from employees (Plouffe et al., 2001), and to this end, the presented study differentiates from other works.

This study reviewed the organizational, work-related and individual characteristics surrounding the training generally and e-Learning specifically in a Greek bank. Initially two research questions were deployed; the first was focusing on the issues affecting the acceptance of e-Learning as a corporate training means both from organizations and employees. The second question imposed concerned the identification of context factors that were facilitating or inhibiting acceptance. Data indicated interesting finding in the aforementioned issues, and were presented with the formulation and use of a particular framework.

Generally speaking, the e-Learning could be characterized as effective and well accepted in this organization. Data proved partially this claim, but pinpointed also particular deficiencies that hinder its total acceptance. The main findings and strenghts of this research – in-progress – are as follows; first, the analytical proposed framework integrates both the organizational, work-social context and individual aspects, formulating a unified approach for studying information systems acceptance generally, and e-Learning in particular. The common frameworks used by now cover only the last dimension. Second, the key organizational characteristics identified in the organizational level – including the management functions which were operating in a complicated way, the particular training culture characteristics, and the alignment of corporate and training strategy – consist an issue that facilitate the initial adoption and future expansion of e-Learning efforts of an organization, leading to the issue of e-Learning readiness (Borotis and Poulymenakou, 2004). Third, work related issues arised, including time resources and work overload, as well as the organization of social context which could affect the acceptance and operation of e-Learning contribute to the formulation of contemporary psychological healthy working environments with respect to the balance between working and personal life (Gilbreath, 2008). Main stakeholders in this context that must be taken into account when designing these environments include the training department, the branch managers and corresponding supervisors, and the pure employees. Last, the particular individual characteristics identified and could affect attitudes formation included the perceived ease of use and usefulness of the e-Learning programs, personal innovativeness with IT, computer anxiety, intrinsic motivation, and self-efficacy of learning through e-Learning.

The aforementioned issues, as presented in Figure 1, may formulate an extended version of the Theory of Planned Behaviour, which takes into account the organizational level of acceptance. Future work should test with quantitative data the aforementioned proposed model, in various organizations coming from different industry sectors. The authors believe that the particular work-context issues emerged in this case, are common in various others work domains, due to the fundamental characteristics of contemporary organizations.

Abstract

This study examines the relationship between operation-level agility and firm performance in service industries. The study is augmented by investigating the role of IT resources and competence to achieve this specific type of agility. As of to date, most of the published literature in this stream of research has focused on manufacturing industry. This research is an early attempt to examine the strategic value of IT-enabled operational capabilities in service industry. We propose a theory-based model of the positive relationships among IT service competence, operation-level agility, and firm performance. Survey data of medium to large-size enterprises in service industries in the United States were used to validate the proposed model. The results indicate that operation-level agility is a significant driving force of firm performance in the service industries and that IT service competence significantly determines the operation-level agility. The results emphasize that IT-supported operation-level agility significantly leads to a better performance.

Keywords: Operation-Level Agility, IT Competence, IT Resources, Firm Performance
1 INTRODUCTION

Globalization and the advancement of information technology (IT) have produced an intensely competitive, dynamic, and unstable business environment. This competitive landscape is often shaped by escalating competition and strategic maneuvering based on price-quality positioning, attempts to establish market advantage, and pressure of new knowledge creation (Hitt & Keats & DeMarie 1998, McNamara & Vaaler & Devers 2003, Shi & Kunnathur & Ragu-Nathan 2005). For example, industries such as electronic goods and finance face challenges by short lifecycle of products and rapid technology diffusion.

Agility, the ability to rapidly respond to external changes, has been proposed as a solution to such changing environment (D'Aveni 1994, Sambamurthy & Bharadwaj & Grover 2003). Agility has been examined at various levels in the literature, such as enterprise-level agility, business function-level agility, project-level agility, and system-level agility (Lee & Banerjee & Lim & Kumar & van Hillegersberg & Wei 2006, Overby & Bharadwaj & Sambamurthy 2006, Prewitt 2004, Sambamurthy et al. 2003). In this study, we focus on agility at the operational level, the ability of a firm to achieve speed, accuracy, and cost economy to realize emerging opportunities for operational innovations.

During the last two decades, operation-level agility has received considerable attention in the manufacturing industry (Narasimhan & Swink & Kim 2006). In manufacturing settings, agility has been emphasized in terms of leanness and flexibility of operational processes, such as resource procurement, manufacturing, quality control, and product delivery (Burgess 1994, Ettlie 1998, Gerwin 1993, Llorénsa & Molinaa & Verdúb 2005). This capability has been discussed as a driving force for firms' exploitation of changing market opportunities, thus leading to competitive market position. The capability of people to exploit their knowledge to cope with market demands, internal process changes, and interactions with suppliers has been addressed as another factor impacting business process agility (Grover & Cheon & Teng 1996, Hamel 1994, Pavlou & El Sawy 2006). Research on agility in service industries, however, remains sparse while there has been a pressing need to cope with growing and evolving service sector of the economy (Roth & Menor 2003).

The service industry is different from manufacturing in many ways. As pointed out by Roth and Menor (2003), business processes in manufacturing firms affect consumers mainly through their products which are usually physical goods. Hence, in the manufacturing settings, operation-level agility is usually restrained by physical constraints such as locations, resource availability, and delivery time. In contrast, the service offerings and delivery involve processes enhanced by support amenities, facilitating information, and implicit services, e.g., psychological benefits (Menor & Roth & Mason 2001). Moreover, while the direct interaction with customers in the service settings makes it easier to collect market intelligence, the customers' demands are more complex and likely to change due to the dynamics of direct interaction with individual customers (Roth & Menor 2003). Due to the rapidity of change in competition, market dynamics, and customer preferences, the breadth and pattern of responses required in the service settings are much broader, more frequent, and sometimes more unpredictable (Beidleman & Ray 1998, Menor et al. 2001). To the best of our knowledge, little has been done to understand operation-level agility in the service industry. Menor et al. (2001) investigated agility in banks. However, by treating agility as a one-facet concept in their study, they could not fully explain the role of operation-level agility in competitive performance of service firms. Due to the lack of research on operation-level agility in the service industries, the role of IT as an enabler for this significant business capability is also unclear.

In this research we address these knowledge gaps by answering the following research questions:

- What is agility at the operational level in the service industries?
- What is the organizational influence of operation-level agility?
- As essential assets in current business, what are the IT competences that support operation-level agility?
This paper is organized as follows: Section 2 defines the key constructs and develops the hypotheses and research model; Section 3 discusses research methodology followed by the discussion on data analysis. The paper is concluded with implications and discussions.

2 RESEARCH MODEL AND HYPOTHESES

Figure 1 shows the research model of the study.

![Research Model](image_url)

2.1 Operation-level agility and firm performance

The notion of agility has been discussed extensively in the literature. There is a general agreement that when facing a turbulent environment, enterprises must adapt to changes. Otherwise, they lose their competitive advantages. In service industries where competition is severe, a key business competence is to acquire market information and respond to changes in an effective and timely manner (Overby et al. 2006). Prior research has proposed agility at different organizational levels. For example, Sambamurthy et al. (2003) describe enterprise agility as one of the important dynamic capabilities in a turbulent environment. In their study, agility is defined as “the ability to detect opportunities for innovation and seize those competitive market opportunities by assembling requisite assets, knowledge, and relationships with speed and surprise” (p. 245). According to this conceptualization, agility encompasses the capabilities related to interactions with customers, deployment of internal operations, and utilization of its external business partners. Similarly, Overby et al. (2006) define agility as “the ability of firms to sense environmental change and respond readily” (p. 121). This definition emphasizes two capabilities: sensing and responding. Hence, agility includes the ability to detect, anticipate, and sense market opportunities, evolving conditions, and other environmental changes. At the same time, it also includes the ability to seize the opportunity with speed and implement new solutions. Similar to the study done by Sambamurthy et al. (2003), Overby et al. (2006) argue that agility applies to both strategic and operational levels within a firm.

In this study, we focus on agility at an operational level, namely operation-level agility, which is defined as the ability of a firm to achieve speed, accuracy, and cost economy to realize emerging opportunities for operational innovations (Cao & Dowlatshahi 2005, Sambamurthy et al. 2003). It emphasizes the effectiveness and efficiency of a firm’s actions in response to changes in their daily operations. For the purpose of this study, we define operation-level agility as a composite of three interrelated capabilities: market responding capability, process reconfigurability, and supplier management capability. We argue that these capabilities combined would enable a firm to seize opportunities, respond to internal and external changes, and sustain its competitive operational edge.

Market responding capability refers to the ability of firms to sense emerging opportunities and threats and respond to the market to deliver products and services valued by their customers (Grewal &
Operation-level agility is the response to changes in the market. It requires firms to be aware of changes and then seize the opportunities by tailoring their business solutions. Hamel (1994) has argued the market-related capability is one of the core competences in the business. It allows a firm to stay close to its customers, identify emerging needs quickly, and deliver new services in a timely manner (Hamel 1994, Ravichandran & Lertwongsatien 2005, Wang et al. 2004). As an organizational capability, market responding capability integrates multiple functional capabilities such as intelligence collecting, market research, and customer relationship management to tailor services for new tastes of customers. This capability is necessary to help firms sense and realize emerging opportunities for operational innovations.

Process reconfigurability refers to the ability of firms to transform and reconfigure their resources and processes in order to accommodate changes (Pavlou & El Sawy 2006). Transformation and reconfiguration of resources are catalysts for change. While market responding capability helps the firm identify the necessity for change, process reconfigurability allows it to deploy new configurations of functional competences that better match the environment (Pavlou & El Sawy 2006) and ensures that the firm can rapidly redesign and modify existing processes for new market conditions (Sambamurthy et al. 2003). Firms’ ability to integrate and combine existing resources into “novel” combinations to better match their product-market areas helps them respond to changes and deliver new services effectively.

Supplier management capability refers to the ability of a firm to modify or adapt its extended enterprise network (e.g., supply chain) when it needs access to assets, competences, or knowledge not currently resident in its business itself (Dyer & Singh 1998, Sambamurthy et al. 2003). When implementing changes, firms may not possess all the required knowledge, skills, and resources. Nowadays, more and more businesses have decided to outsource some of their business functions and focus on their core competences (Shi et al. 2005). To better leverage the resources of their suppliers and/or clients, businesses form strategic alliance with their business partners to coordinate across firm boundaries and exploit opportunities together (Grover et al. 1996). Therefore, the capabilities to manage suppliers are more important than ever in the current business environment. Any internal changes may require corresponding changes in suppliers in a timely manner. Building missing resources will cause delay and loss of opportunities. To be effective in the acquiring and/or cooperating process, firms need supplier management capability to quickly locate needed resources, negotiate terms, and be able to trust and rely on partners for speed and quality. Therefore, in order to respond quickly to changes, firms must not only reconfigure internal resources and processes, i.e., process reconfigurability, but also acquire high-quality products/services from their partners in time to accomplish the changes. This capability also helps firms respond to changes at the operational level.

In all, we argue that operation-level agility focusing on change implementation in business operations is made up of (a) market responding capability, (b) process reconfigurability, and (c) supplier management capability. This operation-level agility is deemed critical to firms’ performance. Specifically, in fast-cycle industries, operation-level agility leads to more competitive actions in a rapid pace leading to an improved business performance (Meyer 2001, Sambamurthy et al. 2003, Venkatraman & Camillus 1984, Weill & Subramani & Broadbent 2002). In contrast, lack of operation-level agility implies a lack of responsiveness to the environment and the presence of inappropriate, outdated business activities and processes, thus resulting in poor performance. Therefore, especially in service industries where uncertainty and unpredictability are normal, the performance of a firm highly depends on its operation-level agility.

**H1. A higher level of operation-level agility will lead to a higher level of firm performance in service industries.**

### 2.2 IT service competence and operation-level agility

IT is fundamental to the growth of a business. IT has the potential to provide competitive advantages for businesses (Ravichandran & Lertwongsatien 2005). However, IT *per se* may not generate a
sustainable advantage since it can be easily acquired and imitated (Carr 2003). Also, investments in IT may not result in better firm performance since some IT investments can be wasted (Davern & Kauffman 2000). Instead, the implementation of IT competence, the extent to which a firm is knowledgeable about and effectively utilizes information technologies within specific business contexts, can create competitive advantage (Tippins & Sohi 2003).

Recent researchers argue that the relationship between IT competence and business values can be deconstructed through the presence of business competences. For example, Soh and Markus (1995) examine the need for effective deployment of appropriate IT assets to create business value. They argue that the effective use of these IT assets leads to intermediate effects, such as better business competences and processes, which, in turn, influence firm performance. Similarly, Ravichandran and Lertwongsatien (2005) argue that IT capabilities which support core competences of the firm such as market access competence, integrity-related competence, and functional-related competence can contribute to better performance. Tippins and Sohi (2003) confirm that business competences, such as organizational learning capability, mediates the relationship between IT competence and performance. These studies emphasize the importance of understanding the relationship between IT competence and business competences when understanding how IT influence business performance.

In this study, we argue that **IT service competence**, defined as the extent to which a firm can effectively utilize IT to support their businesses and facilitate operation, plays an important role in enhancing business performance by improving operation-level agility. We conceptualize IT service competence as a second-order construct, formed by IT service infrastructure, standardized application platform, and IT service management skills, arguing that IT service competence is central to operation-level agility.

**IT service infrastructure** is the sharable technical and common enterprise-wide platform, such as networking, database services, and standardized operation support, which enables initiatives, such as cycle time improvement and cross functional processes (Bharadwaj 2000). As the foundation of shared IT capabilities upon which the entire business depends, IT service infrastructure is crucial to operation-level agility (Byrd & Turner 2000). It links business units, implements common transaction processing, expedites business operations, allows to quickly access and share business data across the firm, and creates synergies across business units (Bharadwaj 2000, Ravichandran & Lertwongsatien 2005). A non-integrated IT infrastructure can severely restricts an organization's business choices and slow down business process, thus hindering operation-level agility.

**Standardized application platform** refers to enterprise-wide integrated software application platform and standard IT applications (Bharadwaj 2000). Developing standards for IT platform has been considered a priority in both research and professional communities (Markus & Steinfield & Wigand & Minton 2006). By providing uniform technical specifications, interfaces and criteria, it makes it easier to integrate new IT components and improve synergies between work units. It also has been long recognized that modularization is a good software development practice (Byrd & Turner 2000, Ravichandran & Lertwongsatien 2005). It constructs software from separate parts, called modules that separate logical boundaries between components. Such approach allows easy modification for new business processes and integration of new technologies with existing platforms, thereby allowing the IT unit to deliver new capabilities quickly and cost effectively, thus improving operation-level agility.

**IT service management skills** refer to the skill set of IT personnel to manage IT resources to deliver organizational IT services (Tippins & Sohi 2003). It includes knowledge and experiences of IT workers in dealing with daily operation of information systems (IS), handling requests from business users, and monitoring performance of IS to ensure that they meet business needs. Strong IT service management skills can help communication between the IT division and business users, integrate IT and business processes effectively, improve reliability and quality of IT, reduce cost of development and maintenance, and decrease delivery cycle time (Bharadwaj 2000, Byrd & Turner 2000). Therefore, IT service management skills are important part of IT service competence in the context of operation-level agility.
In all, we argue that IT service competence formed by (a) IT service infrastructure, (b) standard application platform, and (c) IT service management skills can support and enhance operation-level agility.

**H2. A higher level of IT service competence will lead to a higher level of firm performance in service industries.**

### 3 RESEARCH METHOD

A large-scale cross-sectional survey to collect firm-level data was conducted in the United States.

#### 3.1 Measurement development

The measurement development process involved three stages: (1) operationalization of research constructs, (2) item development, and (3) validity tests. First, research constructs were operationalized based on the definition of each construct as well as of relevant constructs in the literature. Second, every attempt was made to make use of existing measurements which have good psychometric measurement properties. Modifications of the existing items were also made to suit the context of the study. Table 1 provides a summary of the measurement items used in this study and their sources.

$^1$ This variable was adopted to control the potential compounding effect of available resources or managerial diseconomies on organizational high-level capabilities and performance (Tanriverdi 2005).

---

**Table 1. Measurement Sources for Research Constructs**
3.2 Research design

We conducted a large-scale cross-sectional survey with firms in service industries in the United States. The United States has experienced a fast growth of service industries and a nation-wide industrial transformation from manufacturing to service. Hence, it is considered as a viable background for examining the research framework of this study.

We applied a series of criteria congruent with the context of the study for the selection of the target samples. First, we focused on service industries which to a significant extent require IT support for their business operations, such as banking/finance, insurance, healthcare/medical, and consulting. Second, we excluded companies with fewer than ten employees from our target sample because such small companies do not provide a background appropriate for investigating capabilities in their operations and IT service.

After the target samples were defined, a cross-sectional survey was conducted using a web-based survey tool. Survey invitations were made to business executives, e.g., president, chief executive officer, chief operating officer, business director, and IT executives, e.g., chief information officer, chief technical officer, and IT director, of the sample firms in the target industries. Around 700 executives in an industrial respondent pool were invited to participate in this survey and a total of 147 complete data samples were achieved after removing small companies, incomplete data, and other inappropriate data, such as non-management positions and non-full-time employees. The final data represents 7 service industry types, such as healthcare/medical (70), banking/finance (32), consulting (21), insurance (17), and others (7). Their firm size varies; less than 250 (55), between 251 and 1000 (26), more than 1000 (66).

4 RESULTS AND ANALYSES

Partial least squares (PLS), a structural equation modeling technique, was used to analyze the data. This technique does not require a large sample size (Chin 1998). In addition, it is appropriate for early stages of theory development (Howell & Higgins 1990). Given that this study is an early attempt to develop a theoretical model that explains how a firm’s competence in IT services enables its operation-level agility leading to firm performance, PLS was considered to be appropriate for this study.

4.1 Measurement model evaluation

The validity of the measurement model was established prior to testing the structural model (Byrne 1998). The convergent validity of the reflective measures is determined in three ways: (1) the item reliability of each item, (2) the composite reliability of the construct, and (3) the average variance extracted (AVE) by the construct.

<table>
<thead>
<tr>
<th>Construct</th>

</tr>
</tbody>
</table>

Table 2. Result of Convergent Validity Test
Based on the results reported in Table 2, it was concluded that all the items demonstrated adequate convergent validity. Table 3 shows that the square root of the AVE for each construct was larger than the correlations between itself and the other constructs. This implies that each of the constructs shared greater variance with its own block of measures than with other constructs representing a different block of measures (Chin 1998). Therefore, this result demonstrates that there is good discriminant validity for the items used in this study.

Table 3. Result of Discriminant Validity Test

4.2 Structural model analyses

The estimated path effects and the associated t-values were calculated using the Bootstrapping routine in PLS-Graph (version 03.00 build 1126). Since the operation-level agility and IT service competence were formulated as second-order constructs, the latent scores for each of the first-order constructs were calculated and used as measures for each construct (Chin & Gopal 1995). Figure 2 shows the results of the model analysis.

As shown in Figure 2, all paths were significant. The operation-level agility ($\beta = .554$, $t = 6.981$) was found to be a significant determinant of firm performance at the .01 level. It explained 29.8% of the variances of firm performance. On the other hand, the IT service competence ($\beta = .469$, $t = 6.191$) was found to be a significant determinant of the operation-level agility at the .01 level. It explained 25.4% of the variances of operation-level agility. All second-order loadings (loadings of the 1st order constructs) were highly significant. Therefore, all hypotheses H1 and H2 are supported. Interestingly, firm size, the control variable, was negatively significant ($\beta = -.181$, $t = 2.359$) at the .05 level in determining operation-level agility while it was not a significant determinant of firm performance.
4.3 Implications

The results indicate that a specific set of IT resources forms service organizations’ IT competence to support business needs, hence leading to a higher level of agility in their operations. In turn, this operation-level agility positively influences the competitive performance of the firms. To confirm these causal relationships among IT service competence, operational-level agility, and firm performance, we further conducted a post-hoc analysis of mediator test. Following Baron and Kenny’s (1986) four steps, we stepwise tested (1) the significant effect of IT service competence (IV) on firm performance (DV) without operation-level agility (MV) ($\beta = .344, t = 4.478, p < .01$), (2) the significant effect of the IV on the MV ($\beta = .468, t = 6.587, p < .01$), (3) the significant effect of the MV on the DV ($\beta = .553, t = 10.298, p < .01$), and (4) the insignificant effect of the IV on the DV in the copresence of the MV ($\beta = .099, t = 1.060$). According to Baron and Kenny (1986), the results indicate that operation-level agility is the full mediator between IT service competence and firm performance. Therefore, the post-hoc analysis results also confirm our research model proposed in this study.

In particular, our study shows that a firm’s IT service competence, formed by IT service infrastructure, standardized application platform, and IT service management skills, is a significant driving force for the firm’s agile operations which are represented by its rapid market responses, flexible process reconfiguration, and effective supplier management. The findings are consistent with Bharadwaj’s (2000) perspective that a firm’s IT resources, technology and human IT resources, are the sources of its latent capacity to build and provide the requisite IT services. Furthermore, the findings also provide an empirical evidence of the conceptual premise that IT is a digitized platform of business agility (Overby et al. 2006, Sambamurthy et al. 2003).

The study also shows that IT-supported operation-level agility significantly leads to a better performance, particularly in terms of sales growth, profitability, return on investment, and customer retention. The findings are consistent with the premise of the role of IT-enabled agility in generating higher performance of a firm in a turbulent environment. Considering the context of the study, i.e., the service industries, the findings are deemed important as well as useful to both academics and practitioners. Traditionally, the value of operation-based capabilities has been discussed in manufacturing settings. For example, many techniques of operational leanness and flexibility have been suggested under the settings of manufacturing, such as just-in-time manufacturing (JIT), total quality management (TQM), and lean manufacturing (Burgess 1994, Ettlie 1998, Gerwin 1993, Llorénsa et al. 2005). However, with regards to the recent catastrophe in the financial industries in the United States, it is likely to be more true that operational capabilities, such as operation-level agility, are crucial for firm success under the settings of service industries.

5 CONCLUSION

In this study, we concentrated on the service industries and theoretically proposed a positive relationship among IT service competence, operation-level agility, and firm performance. To capture the combinative values of IT resources and operation-level capabilities which form IT service competence and operation-level agility respectively, the second-order approach was adopted in conceptualizing the core research constructs. Survey data of small- to large-size enterprises in service industries of the United States were used to validate the proposed model. The results indicate that operation-level agility, consisting of market responding capability, process reconfigurability, supplier management capability, is a significant driving force of firm performance. The results also indicate that IT service competence, consisting of IT service infrastructure, standardized application platform, and IT service management skills, serves as a base for the operation-level agility.

This study has several limitations which involve cross-sectional research design and single respondent survey approach. First, this study used a cross-sectional research design. Such a snap-shot approach
may have limitations in terms of studying the causal relationships or time effects between research variables, such as the lead-time of the IT impact (Bharadwaj 2000). Second, single respondent bias has been discussed as a potential source of common method variance (Podsakoff & Organ 1986). To avoid this, various techniques have been suggested in the literature, such as separating survey questionnaire to ask specific expertise with different positions (Lee & Lim & Sambamurthy & Wei 2007). While our sample data are not thought to suffer from this issue\(^2\), multiple-respondent survey may provide more generalizable findings.

Regardless of the aforementioned limitations, this study makes several contributions to the literature. First, this study, both theoretically and empirically, reveals how firms can develop their operation-based agility. The findings of the study indicate the significant role of IT competence in achieving this specific type of agility. Since prior studies in IT-enabled agility have seldom provided empirical evidence, the theory-based models and the empirical findings of the study are both interesting and useful to academics in this research area. Second, this study has a potential contribution to the literature by addressing an unexplored, yet emerging issue of the role of operational capabilities in service industries. Since most of prior studies in operational capabilities have focused on the settings of manufacturing industries, this study may open a new area of discussion among academics and practitioners. Lastly, through this study, we develop new measurements having good psychometric properties. The measurements used in this study can serve as a base for further research in this research area. This study also has some practical contributions by providing guidance for practitioners to strategically invest their IT resources to achieve their agility at operational level.

This study can be extended in several directions. First, this study mainly focuses on operation-level agility in the service industry. Future research can examine another type of agility such as strategic agility. Second, this study investigates IT service competence, including IT service infrastructure, standardized application platform and IT service management skills. Future research can continue to study IT skills of business users that may also have influence on agility. Third, the unit of analysis of this study is the organization. It evaluates overall agility and its impact on the performance of an organization. However, in some large organizations, some divisions may be more agile than others. Future study can explore the topic at department or team levels. Fourth, our study adopts the survey methodology and measures the performance of an organization using historical/present data. Future research can develop a longitudinal study following the effectiveness of business capabilities.

Reference

\(^2\) Harman’s single-factor analysis was conducted to test a potential of common method variance in our sample data. This test involves an exploratory factor analysis (EFA) of all measurements to determine whether the majority of the variance is accounted for by one general factor. The principal component analysis using varimax rotation revealed that a total of seven distinct factors emerged with Eigen value of over 1. The results revealed that each of the seven principal components explained similar amounts of the total variance of 76%, ranging from 5% to 14%. This result indicates that our data does not suffer from common-method bias as indicated by Podsakoff et al. (2003).

UNDERSTANDING AGILITY IN SOFTWARE DEVELOPMENT FROM A COMPLEX ADAPTIVE SYSTEMS PERSPECTIVE

Xiaofeng Wang, Lero, the Irish Software Engineering Research Centre, Limerick, Ireland, xiaofeng.wang@ul.ie
Kieran Conboy, National University of Ireland, Galway, Ireland, kieran.conboy@nuigalway.ie

Abstract
Agile software development methods have emerged in recent years and have become increasingly popular since the start of the century. While much research claims to study agile methods, the meaning of agility itself in software development is yet to be fully understood. Agility is viewed by some as the antithesis of plan, structure discipline and bureaucracy. This study aims to develop a better understanding of agility, using the key concepts of Complex Adaptive Systems as a theoretical lens. The study explores agility from several different angles, including autonomous team, stability and uncertainty, and team learning. A multiple case study research method was employed. The findings of the study emphasize that agility is manifested as stability and discipline, which are just as desirable as flexibility, and context sharing is of the same value and importance as knowledge sharing. In addition, the collective nature of learning is underlined.

Keywords: agility, complex adaptive systems, autonomy, stability, team learning
1 INTRODUCTION

The last ten years or so has seen the emergence of agile software development methods as a response to the inefficiency of existing software development methods in rapidly changing environments (Highsmith 2002), e.g. eXtreme Programming (XP) (Beck 1999) and Scrum (Schwaber & Beedle 2002). A brief reflection on the history of the agile software development movement, however, reveals that agile methods originated as a set of techniques and practices, and the term agile is more a post-rationalization to justify a set of existing “light-weight” methods. Agility in software development has been interpreted in many different ways in practice. Skepticism and criticism of agile methods place agility to the opposite of plan, structure and discipline which are generally considered the core components of more traditional waterfall methods (Rakitin 2001, Stephens & Rosenberg 2003).

To clarify the meaning of agility, Conboy and Fitzgerald (2004) conduct a review of the literature on agility across several disciplines including manufacturing, business and management, and carefully distinguish several intertwined concepts, including flexibility and leaness. Based on the comparison and contrast of these concepts, they provide a broad definition of agility as “the continual readiness of an entity to rapidly or inherently, proactively or reactively, embrace change, through high quality, simplistic, economical components and relationships with its environment” (Conboy & Fitzgerald 2004, p.40). Lyytinen and Rose (2006) explore agility in an information systems development (ISD) context. They claim that ISD agility is concerned with why and how ISD organizations sense and respond swiftly as they develop and maintain information system applications. They outline a theory of ISD agility drawing upon a model of Information Technology (IT) innovation and organizational learning which adopts March’s (1991) concepts of exploration and exploitation. Their empirical study shows that the concept of ISD agility is more multifaceted and contextual than conceived so far in the literature. It relates to being nimble in terms of the velocity to absorb base innovations and innovate with IS products; the velocity to shift from one innovation regime to another (organizational flexibility); the velocity to learn from experiences (trial and error learning); and the velocity to deliver IS solutions. Each one of these demands different competencies and expects managerial shaping of alternative organizational goals and incentives. Their findings suggest that the dynamics and interactions between these four types of agility form different ecological niches. Each one follows a different organizing logic. Managers must view the meaning of agility differently in each niche.

While these studies help to understand agility, and do highlight the lack of theoretical foundation regarding agility in an ISD context, they do not address specifically how agility is manifested in software development environments. Based on this observation, this study investigates the meaning of agility in software development using the lenses of Complex Adaptive Systems (CAS), an important branch of the complexity study which provides insights of how a system can be adaptive to its environment. (Note that in the following sections the full phrase complex adaptive system is used to refer to an instance of a complex system that demonstrates an adaptive nature, while CAS is used to refer to the study and theory of such systems.) The empirical part of the study employs a multiple-case study approach. The remaining part of the paper is organized as follows. Section 2 introduces the key concepts of CAS and builds a conceptual framework based on CAS which guides the empirical investigation; Section 3 describes the research method and the context of the empirical study; then the findings are presented in Section 4 and discussed in Section 5. The paper ends up with a conclusion section where the implications and limitations of the study are reviewed and the future work summarized.

2 A COMPLEX ADAPTIVE SYSTEMS PERSPECTIVE ON AGILITY

A complex adaptive system, roughly defined, consists of a large number of agents, each of which behaves according to some set of rules. These rules require agents to adjust their behaviour to that of other agents. They interact with, and adapt to, each other. CAS seeks to identify common features of
the dynamics of such systems or networks in general (Stacey 2003). There is no single and definitive account of CAS. Anderson (1999), Mitleton-Kelly (2003) and Stacey (2003) provide valuable introductions to CAS in the context of organization and management. Four key concepts of CAS in the centre of these accounts are of particular relevance to this study: inter-connected autonomous agents, self-organization, the edge of chaos and emergence. These key concepts provide a new perspective to investigate different facets of agility as a desirable property for software development teams in constantly changing environments.

The concepts of inter-connected autonomous agents and self-organization suggest that, to be agile, a software development team should be composed of autonomous members who have their own schemata, which generally refer to norms, values, beliefs, and assumptions that are held by individuals (Senge 1990, Schein 1997). Team members are interconnected in such a way that a decision or action by any individual may affect related individuals and the team. A team composed of autonomous but inter-connected members can spontaneously come together to perform a task (or for some other purpose); the team decides what to do, how and when to do it; and no one outside the group directs those activities (Mitleton-Kelly 2003). To do so, a team needs energy imported into and constantly flowing within it, which can be interpreted, partly, as the sharing of information, knowledge or other resources needed to sustain self-organized activities.

The edge of chaos provides organizations “with sufficient stimulation and freedom to experiment and adapt but also with sufficient frameworks and structure to ensure they avoid complete disorderly disintegration” (McMillan 2004, p. 22). Brown and Eisenhardt (1998) contend that, to compete at the edge, organizations must understand what to structure and what not to structure, to foster communication and to capture cross-business synergies. The edge of chaos concept suggests that being agile is neither chaotic nor static. It needs stability but not so much that order prevails and innovation is stifled. It is a delicate balance of both.

The concept of emergence sheds new light on learning, which can be seen as a collective behavior of creating new patterns of thought at the team level based on the interaction of individuals, instead of often seen exclusively as the provision of individual training. Learning means not only training or the acquisition of new skills, but also the gaining of insight and understanding which leads to new knowledge and behavior. When learning leads to new behavior, the team can be said to have adapted and evolved (Mitleton-Kelly 2003). An agile team facilitates team learning and generation of new knowledge. In addition, new knowledge needs to be shared to generate further new learning, knowledge and behavior.

In summary, this study investigates the meaning of agility from three facets: autonomous but sharing team, stability with embraced uncertainty and team learning, as shown in Table 1.

### 3 RESEARCH APPROACH

This study adopts an interpretivist stance, emphasizing that agility are situational and can be better understood through the understanding and sense making of people who are involved in software development. In particular, this study employs a qualitative approach, treating agility as a qualitative...
property of a software development team that can be better studied through words and the meanings people ascribe to them rather than numbers or frequencies. The specific research method used in this study is case study, which is an appropriate approach when a research phenomenon is investigated in its real-live context (Yin 2003). A multiple-case design is employed. Given the research focus of the study, the level of inquiry is at the team level, so it seems appropriate to take a software development team as a case. The unit of analysis is the software development team. Three software development teams - XPTeam A, XPTeam B and WaterfallTeam - from two different companies were chosen as the cases. XPTeam A is a representative case; XPTeam B is a confirming case of the first one; and WaterfallTeam is a contrasting case, following the strategy suggested by Yin (2003). The profiles of the three cases are shown in Table 2. XPTeam A is a software development team in SecureSoft, a small software house specialized in network security and management systems development. XPTeam B and WaterfallTeam are software development teams in WorldTech, a major IT company providing both IT projects and services.

Table 2. The profiles of the three cases

Two rounds of data collection are conducted. The interval between the two rounds is six months. The main data collection method used is semi-structured face-to-face interviews. The questions are all open-ended. The members of each team are interviewed. Each interview lasts between 30 minutes to two hours. In all the cases, most interviewees are interviewed twice. Table 3 lists the people interviewed in each team. Documents regarding the development processes of the case teams are collected when available. Some non-participative observations are conducted as the opportunities occur. Field notes are taken during both rounds of data collection.

Table 3. Two rounds of interviews

The data analysis includes two steps: within-case analysis and cross-case comparison (Eisenhardt 1989). The emphasis is on the cross-case comparison, in which an analysis tactic suggested by
Eisenhardt (1989) is used: the three cases were divided into two groups, XPTeam A and XPTeam B in one group as the cases using agile approach, while WaterfallTeam in the other group as the case that uses waterfall approach. XPTeam A and B are compared firstly for similarities and differences, and then they as a group are contrasted with WaterfallTeam for similarities and differences.

4 MANIFESTATION OF AGILITY IN THE THREE TEAMS

This section presents how agility has been manifested (or shown to be absent) in the three cases.

4.1 Autonomous but sharing team

Team autonomy in XPTeam A and B firstly is shown as competences relevant to software development being distributed among team members. The members of the two teams are involved in all development activities of their projects, and all have to deal with the customers, analyse user requirements and write code together. There are no traditional roles such as system analyst, designer or programmer. Each team member is able to assume all the roles, since comprehensive competences are required to work with user stories, the implementation of which is self-contained and encapsulates different development activities:

“The problem is not to have three persons for analysis, or two persons for design, but a user story inside has to resolve analysis, developing, and, etc., everything.” (Project manager/XPTeam A)

For example, when XPTeam B started the project, there were big gaps among team members in terms of Java related knowledge and skills. With the project going on, the developers with less Java experience learnt quickly from those more experienced, and the team members reached fairly the same level of competence. As a result, there is no dependency on a particular individual, since each team member gets exposure to different areas of a project. Distributed competence is shown in the case of WaterfallTeam too, although the team uses waterfall approach. Like the other two teams, there are no specific roles like analyst, designer or coder in the team. The developers are not specialized on specific tasks. Everybody has chances to do different things.

Team autonomy is also manifested as a disciplined team in XPTeam A and B, which is seemingly contradictory to the idea of autonomy. However, both teams reckon the importance of disciplines. As a member of XPTeam B describes, disciplines are necessary components of an agile process, and they come from the process the team uses:

“There is a set of rules really, and you may not adopt them, you probably adopt most of them, and those rules kind of direct you really, it’s like you need to formalize it so you can be more flexible.” (Test manager/XPTeam B)

Team autonomy does not mean the team members are working on their own; instead, there is constant sharing among them. XPTeam A considers sharing an important aspect of team working. They believe that, as a team, they have to face every moment in any case without barriers. Sharing is also seen as a contributor to a team’s agility by WaterfallTeam who works with the waterfall approach. The difference is that sharing in the two teams using agile processes goes beyond simply knowledge sharing. It extends to context sharing and the sharing of achieved results. What is shared among the team members is not only the technical knowledge related to different areas of a project, which helps to distribute competences among them. It is also the knowledge about who knows what, which is particularly important for a bigger team like XPTeam B, and helps the team members self-organize to implement tasks:

“I think the ten o’clock stand-up meeting is definitely good, because you know what everybody else on the project is working on, and you might say ‘I’m working on this and I’m not sure how to’… and someone says ‘oh yeah actually I did it yesterday’.” (Developer B/XPTeam B)
In XP Team A and B, the developers are attentive to what happens around them, with the help of the open space the teams are working in:

“When you are doing something, you have to listen what the pair, or the single one if you are in pair, what he's doing, what they are saying, you have one ear in this way and the other (in the other way).” (Developer A/XP Team A)

Collective ownership of results is another kind of sharing. The two teams using the agile processes both endorse the collective ownership of code, as suggested by XP. A developer of XP Team B, however, warns that collective ownership can become collective irresponsibility sometimes, which means no one claims to be responsible if there is some problem with a piece of code. In the case of XP Team A, in addition to collective ownership of code, the team also owns collectively other forms of working results, such as designs, solutions, etc., which helps the team to have a sense of common achievement.

4.2 Stability with embraced uncertainty

Stability for software development is a desired property by all three teams, which is seen as an indispensable component in responding to change:

“There has to be some limitation of what you are doing, you cannot be so flexible that things are chopping and changing every single day.” (Test manager/XP Team B)

Stability first of all is demonstrated as a short-term certainty in all the three teams. The short-term certainty means a team has a very clear idea of what they have to do in a short time frame, such as one-week or two-week iterations in the cases of XP Team A and B. Waterfall Team also realizes the importance of the short-term certainty to deal with constant changes from the management:

“Well I guess in terms of uncertainty, you don't know really tomorrow you are going to work on the same project, so on a phased approach you can complete one phase and then this is done. And say after tomorrow, let's say the next phase is cancelled because of the management decision, then you still have a product that works.” (Developer A/Waterfall Team)

In the cases of XP Team A and B, stability is also shown as a sense of frequent achievement and satisfaction. The two XP teams realize that, with their agile process, the team members can be motivated more easily than with the waterfall method, since the developers can see the result of their work at the end of each iteration, rather than working for six months without anyone has ever seen or used the code produced as what can happen in traditional processes. There is evidence to suggest that the developers of Waterfall Team also recognize the importance of motivating people, and believe that a satisfied and motivated team is a source preventing a project from falling apart:

“If someone is not happy with what he's doing, he's not going to do his job well. If he doesn't like it, he doesn't like to co-operate, if he's not happy with people, he wasn't going too far... So the main thing is with people, keep them happy... because if people are unhappy, the project falls apart.” (Developer A/Waterfall Team)

In addition, a team focused on working is also a sign of stability. A focused team has several meanings in the two XP teams: one meaning is to focus on work in a short but appropriate amount of time. It can be an iteration, as in XP Team A and B. Another meaning of being focused is to focus on current work, not wasting time to do future-proof work, which has been emphasized particularly in XP Team B. The third meaning is to focus on development activities and not to mix them with personal desires of learning new things. For example, XP Team A is very attentive of keeping the team focused on development activities by reserving daily studying time to satisfy the developers’ desires to learn.

Last but not least, stability shows as team working at a sustainable pace, with ease and without anxiety, is another aspect of the stability for development. A developer of XP Team A associates this working state with agility directly:
“I think agility is a state of mind... you don't have to feel anxiety, you have to be relaxed when you approach a problem, and XP or Scrum is just a method to obtain this kind of relaxation... If you are happy on what you are doing, if you are not stressed, I think you can say you are agile.” (Developer B/XPTeam A)

Stability co-exists with uncertainty which is unavoidable in the teams using agile methods. Uncertainty needs to be embraced. Embraced uncertainty is manifested firstly as the probability to change directions in the cases. All the teams believe that the iterative nature of their processes gives them more possibility to change directions when needed, including WaterfallTeam, since they use iterative phases within the waterfall process. But the probability to change should be complemented by having a whole picture of the project, which has been emphasized in the two XP teams. XPTeam B observes that having a whole picture of the project occurs not only to the developers, but also to their onsite customer.

4.3 Team learning

XPTeam A understands that learning means doing things differently. If a team wants to be adaptive and evolve, they have to learn. In the two XP teams, learning happens as team learning rather than individual learning, which means a team as a whole acquires new knowledge and competences, and the results of learning are shared among team members. Compared with WaterfallTeam, team learning happens continuously and mutually, through using agile practices in the two XP teams. It happens in daily development activities. It is a continuous experience for the team members. Meantime, since learning happens through interactions among the developers, it is generally bi-directional. A developer of XPTeam B comments:

“I think it (XP) is a very good way of learning as well, because with pair programming which is part of it, you are learning from somebody different every day, and likewise you're able to teach somebody else for you've been doing the day before ... it gives a sense of shared, the project is shared... There's more, definitely more knowledge been shared.” (Developer C/XPTeam B)

Besides, learning is not a daunting experience due to the fact that the teams using the agile processes generally work on small pieces of tasks. The developers learn gradually through implementing them, sometimes with the help of others. The team lead of XPTeam B observes that:

“Because it is down to granular level, it's easier to put better workload over people and also easier for people to get involved, it’s also easier for people who don't have skill learn gradually on the smaller story rather than having to develop something big on their own, so I think it's easier to get a higher level skill without being overly complicated... They are not huge chunk of piece to take on.” (Team lead/XPTeam B)

Due to these attributes, team learning is seen more efficient than individual learning:

“The learning, when we do pair programming it's more efficient. In one year I learn a lot of things that I didn't think (I could do) when I was in the university.” (Developer B/XPTeam A)

Table 4 summaries the findings.

5 DISCUSSION

As shown in this study, agility in the context of software development is highly multifaceted and ambiguous. In this section the different facets of agility demonstrated in the cases are discussed by drawing on relevant agile literature.

5.1 An autonomous but sharing team

Despite the suggestion by advocates of agile that software development processes should be organized to improve and distribute both technical and social competences continuously (Cockburn & Highsmith
2001), few empirical studies in agile research have supported this stance. Only Auvinen et al. (2006) highlight an increased competency in a team where several agile practices are piloted. Similarly, no empirical research in the reviewed literature focused on discipline in agile processes despite the emphasis many agilists place on its importance (e.g. Beck & Boehm 2003).

*Table 4. Manifestation of agility in software development*

This study suggests that a team composed of autonomous but interacting developers has a tendency to be agile. Each of them is able to solve various development issues and to interact with customers. Competences are not concentrated on few people so that there is no bottleneck in the development process. Team members are confident and courageous in the interactions with customers and with each other. They are also mature and willing to try new things. An autonomous team, however, does not mean team members can be completely amethodical and ill-disciplined. On the opposite, it is composed of disciplined, self-responsible and committed individuals. Discipline is an essential component of an autonomous team, and is drawn from the interactions among peer team members.

Sharing is a common theme investigated in several agile studies, though most are focused on knowledge sharing (Fredrick 2003, Melnik & Maurer 2004, Poole & Huisman 2001, Schatz & Abdelshafi 2005). Context sharing has also been observed, but is somewhat understated in agile literature. Melnik and Maurer (2004) believe that the so-called “background knowledge” about a project is important to achieve effective communication. It is important for all team members to have a common frame of reference - a common basis of understanding. Poole and Huisman (2001) observe that, in the organisation they studied, there was a measurable increase in the visibility of what everyone was doing on the team subsequent to the adoption of the agile practices. In fact, this improvement in visibility is considered one of the greatest successes the company has achieved. In terms of results sharing, Fredrick (2003) reports the experience of collective ownership of codes. When it is realized, even the most complex business problems can be easily figured out. In contrast, it was found that individual ownership of code made people defensive - people took it personally when someone suggested their code did not work. Schatz and Abdelshafi (2005) also document the collective ownership in their experience report where developers took ownership of the features they created and took pride in showing their work to the stakeholders during sprint reviews. Rising and Janoff (2000) notice that in a team they have studied, at every meeting, as small tasks were completed and the team could see progress toward the goal, everyone was more satisfied with their work and project progress.

The findings of this study confirm that sharing in an agile team not only means knowledge sharing. Context sharing is equally important. To effectively self-manage, a team needs to share the understanding of their working context. Context sharing is a precondition to provide effective feedback, interpret them in a sensible way, and take appropriate actions. Sharing also means results
sharing, such as collective ownership of code and solutions, which reduces the risk of knowledge loss and increases the sense of being a true team.

Another type of sharing, namely problems sharing, is reported by Rising and Janoff (2000) but does not emerge in this study. In the team they have studied, when one team member raises an obstacle in the Scrum meeting, the entire team’s resources come together to bear on that problem, and the entire team immediately owns any one individual’s problems.

5.2 Stability with embraced uncertainty

Several agile studies have noticed team satisfaction and motivation in agile processes (e.g. Rising & Janoff 2000, Poole & Huisman 2001, Drobka et al. 2004). For example, Drobka et al. (2004) conduct a survey of a team using XP and find that it creates a surge in morale since XP provides constant feedback to the developers and at the end of each day the team has a working product. Team members gain a sense of accomplishment from their daily work, because they immediately see the positive impact their efforts have on the project. When morale is high, people are excited about their work, leading to a more effective, efficient development team. Short-term certainty has also been noticed in agile studies, though not so extensively. Murru et al. (2003) claim that XP enhances programmers’ sense of project control. They find that programmers with the experience of Rational Unified Process (RUP) felt that XP’s planning game gave them a stronger feeling of control than traditional planning did. They knew where their project was going and whether it was delayed. Furthermore, programmers were more aware of keeping the project’s strategic goals in focus. This knowledge improved the programmers’ motivation.

The role played by uncertainty is acknowledged by agile advocates (Highsmith & Cockburn 2001, Williams and Cockburn 2003). Williams and Cockburn (2003) believe that uncertainty is inevitable in all software development. Many changes occur during the time that the team is developing the product. It is highly unlikely that any set of predefined steps will lead to a desirable, predictable outcome. It is necessitated short “inspect-and-adapt” cycles and frequent, short feedback loops. Agile software development is about change and feedback. Highsmith and Cockburn (2001) claim that agile organizations and managers understand that to demand certainty in the face of uncertainty is dysfunctional, and agile practices encourage change rather than discourage it. In turbulent business situations, the change tolerance of a development process must be geared to the change rate of a specific environment, not some internal view of how much change is acceptable. Despite these claims of agile proponents, however, few empirical studies of agile processes have focused on uncertainty and how it is embraced, with the exception of Elssamady and Schalliol (2002) who suggest that, when using the XP practices, especially the simple design, one should look ahead and do things incrementally, in order to have a big picture.

This study emphasizes stability as a desired property of development teams that have to deal with continuous changes due to close relationships with customers and evolving requirements. A team needs stability, needs to find a proper heartbeat for their development process so that it would not be dissolved into turbulence. Stability gives developers a sense of security and control over what they are working on. It can be drawn from a short-term certainty provided by a time-boxed development process. Stability for development also means a team is working at a sustainable pace, focused and motivated, working with ease and satisfaction. Certainty and security is only for a short term, however. Uncertainty is inevitable in software development. It comes from both the environment a team is embedded in and the development process itself. Managing uncertainty does not mean to predict what is going to happen and do future proof work today. It is to ensure the probability to change the direction a team goes towards but meantime not to get short-sighted. Team members need to have a whole picture of the project in mind.
5.3 Team learning

Learning is a common theme explored in much agile research (e.g. Dingsoyr & Hanssen 2002, Drobka et al. 2004, Hunt & Thomas 2003, Meso & Jain 2006), but the focus is mainly on individual rather than team learning. In a survey conducted by Drobka et al. (2004), it was found that XP can reduce the learning curve for new team members. Fifty-five percent of the developers believed that using XP shortened their initial project-learning curve. Hunt and Thomas (2003) emphasize that learning in an agile process is a continuous process, and it means learning about more than just the technology involved. It covers how the team works together (or how it doesn’t) and team members themselves, which leads to behavior and mental model change.

Learning means doing things differently. One important consequence of learning for an individual and a team is to change either their behavior or mental model. It is a prerequisite for organizational evolution and co-evolution (Mitleton-Kelly 2003). This study suggests that team learning is different than individual learning, though closely related and dependent on it. From the CAS perspective, team learning is emergent from the interactions of team members. Team learning is a collective result, which means a team as a whole acquires new knowledge and competences, and results of individual learning are shared among team members. In an agile team, team learning happens constantly, mutually and gradually.

6 CONCLUSION

This study investigates how agility is manifested in agile software development through studying the software development processes of three teams, two using XP, one using waterfall approach. Taking the key concepts of CAS as theoretical lenses, the study explores the true meaning of being agile from several different angles, including autonomous team, stability and uncertainty, and team learning. Compared with the existing agile literature, the findings emphasize that stability and discipline are as desirable as flexibility, and context sharing is of the same value and importance as knowledge sharing in agile processes. In addition, the collective nature of learning is underlined. The main theoretical contribution of the study is the understanding of agility in software development which is both theory-informed and empirically grounded. Drawn on CAS, the study lifts the understanding beyond the advocational literature found in agile field (Baskerville & Pries-Heje 2004). The discovered agile properties enrich the understanding of agility in software development. The practical implication of the study is that the findings indicate the desired effects of using agile methods. The agile properties provide a software development team with observable agile indicators from different facets of software development.

One limitation of the study comes from using CAS as the theoretical basis of the study. CAS has originated in natural sciences. There is a deeper concern whether CAS is appropriate to the study of human organizations. A combination of CAS theory with appropriate social theories might be a promising avenue for future research. Some limitations are associated with the case study research approach. One concern is the uniqueness of corporate, team and project characteristics of each case which makes valid comparison and theoretical generalization of the case study results difficult (Kitchenham et al. 2002). Specific to this study, an affecting factor is the diversity of the team profiles (as shown in Table 2). To increase the validity of the study, the contextual information of the cases has been taken into account in the data analysis. Another limitation is that only one agile method, XP, has been involved in our case studies. Future work would be to verify if the findings apply to teams using other agile methods, such as Scrum, Lean system development, etc.

Abstract

A principal objective of agile development methods is to reduce risk thereby resulting in more successful and effective information systems. However, while there is an extensive body of academic literature on risk management, very little research has attempted to rigorously apply this as a lens to study risk management in agile development projects. The purpose of this research was to ascertain the extent to which risk management practices are incorporated into agile development projects. A case study was conducted involving a change management consultancy firm whose main business involved the deployment of agile approaches. The study found that while there is a perception that risk management practices are not carried out in agile environments, the extent to which risk management is conducted on these projects is in some cases just as substantial to that carried out on traditional projects. In fact, in this case it appeared that the teams were more rigorous in their risk management than is often the case.
1 INTRODUCTION

In ISD, the rapidly growing use of agile methods shows the urgency of organisations to adapt to change at a more speedy and efficient pace where practitioners have “developed methodologies and practices to embrace, rather than reject higher rates of change” (Williams and Cockburn, 2003). Many agile methods have emerged in recent years to address this issue e.g. eXtreme Programming (XP) (Beck, 1999), the Dynamic Systems Development Method (DSDM) (Stapleton, 1997), Scrum (Schwaber and Beedle, 2002), Crystal (Cockburn, 2001), Agile modelling (Ambler, 2002), Feature Driven Design (FDD) (Coad, de Luca et al., 1999), and Lean Software Development (LSD) (Poppendieck, 2001), along with variants of each e.g. XP-Lite (Aveling, 2004). Agile methods are known for their use of iterative development, active user involvement and their acknowledgement of the need to incorporate changing system requirements and “focus on generating early releases of working products using mostly collaborative techniques” (Reifer 2002). This is a stark contrast to the traditional model for systems development which promotes “elicitation and freezing of requirements in advance” (Fitzgerald 2000) with no overlap between project phases of analysis, design and implementation (Walters, Broady et al. 1994).

A principal objective of agile methods is to reduce well-known risks associated with common ISD project failures by for example, accepting that requirements will change. The first “truly agile method” (Abrahamsson, Warsta et al. 2003) is known as the Dynamic Systems Development Method (DSDM) which promotes the idea that “instead of fixing the amount of functionality in a product and then adjusting time and resources to reach that functionality, it is preferred to fix time and resources and then adjust the amount of functionality accordingly” (Abrahamsson, Warsta et al. 2003). This highlights the element of flexibility in DSDM with regard to adjusting system functionality where system requirements are open to change. However, no matter what the nature of change, there will always be associated risks involved be it either a systems development change or a business operational change.

1.1 Motivation For Research

The idea of being proactive to change is becoming increasingly important across all industries due to an increase in project failures. There are infinite examples across the literature of project failures and media reports of “major engineering and development projects running late or exceeding their budget” (Coppendale 1995). Risk management has been described as the “activity of identifying and controlling undesired project outcomes proactively” (Smith and Merritt 2002). One of the main reasons highlighted for the increasing failure in software projects is that “managers are not taking prudent measures to assess and manage the risks involved” in their projects (Keil, Cule et al. 1998). According to Smith and Merritt (2002), a lack of proactiveness with regard to risk management is one of the main reasons for project delays, increased project running costs and/or eventual project failures.

While there is extensive literature on risk management, research in relation to risk management in agile ISD projects is non-existent. This is surprising considering how quickly agile methods are being adopted in ISD. Many books on agile methods “have remarkably little to say about how a development team determines the risks it faces, prioritises them or takes action to negate their effects” (Smith and Pichler 2005). Essentially, agile methods must “tailor conventional risk management approaches meant for years-long projects into a risk driven agile iteration lasting only seven to thirty days” (Smith and Pichler 2005). How agile projects go about doing this remains unknown.

The primary objective of this research was thus to develop a better understanding of risk management practices in agile ISD projects and the level of formality with which these practices are executed. Specifically, this research focuses on three main elements of risk management, namely risk identification, estimation and evaluation.
2 THEORETICAL BACKGROUND

In an ISD context, Barry Boehm highlighted the concept of managing risks and giving them priority as far back as 1988. Ten years later, Hall (1998) described Boehm as being “the father of software risk management.” Boehm proposed a move away from the ‘staged’ SDLC (Systems Development Lifecycle) to a more iterative or incremental process and this proposed concept in software development is an attempt to lower project risks (Powell and Klein 1996). Boehm’s aim was to eliminate any software difficulties or risks mainly by deriving “risk-driven documents” and “incorporating prototyping as a risk-reduction option” (Boehm 1988). It resulted in what was called the ‘Spiral Model’ that essentially created “a risk-driven approach to the software process rather than a primarily document-driven or code-driven process” (Boehm 1988).

Many authors highlight distinct approaches and frameworks for dealing with risk management. The approaches used can be formal or informal. In an informal environment “much risk identification is undertaken by managers and associated staff without any aiding techniques: they rely solely on experience, intellect and imagination to generate a comprehensive risk list” (Powell and Klein 1996). Formal approaches include methods such as brainstorming or Delphi techniques, which can involve numerous stakeholders. In the literature, there is no universally accepted approach to risk management. This however, is a reasonable and understandable finding in that the process of risk management will differ across various industries and projects. As Raz, Shenhar et al. (2002) state “one cannot expect that a single, universal risk management process and its supporting set of tools and techniques would be applicable to all types of projects” and “just as there are different types of projects, we should expect to see different kinds of risk management practice.”

Risk management fundamentals however remain the same and are consistent across disciplines. The literature shows similar emphasis on the most important activities in risk management namely, those identified by Rowe (1977) and Charette (1990) - the early practitioners of risk management - who outline the three main elements of risk assessment as (i) Risk Identification, (ii) Risk Estimation and (iii) Risk Evaluation.

2.1 Risk Identification

Risk identification is the reduction of descriptive uncertainty (Rowe 1977) which involves “surveying the range of potential threats” (Charette 1990). This element of risk assessment involves detecting issues which could jeopardise or threaten the success of a project (Coppendale 1995; Grey 1995). Chapman (1998) states that “the risk identification and assessment stages have the largest impact on the accuracy of any risk assessment.” As a result, risk identification is the most important stage of the risk management process. Of particular importance to ISD is the early identification of risks where “identifying and dealing with risks early in development lessens long-term costs and helps prevent software disasters” (Boehm 1991). Many software disasters could have been avoided by early identification of any high-risk aspects (Boehm 1991). It is imperative to understand that “the identification of risks carries on throughout the life of a project” (Grey 1995). In other words, risk identification is an ongoing, continuous process that requires regular screening and monitoring.

An important aspect of risk identification is categorising the risks organisations encounter. According to Coppendale (1995), “depending on the size and the complexity of the project there might be between five and fifteen” categories of risk. Categories attempt to group certain types of risk under a particular heading and in doing so “can help you find global risks that can be solved together” (Williams, Walker et al. 1997). Two dominant ways of categorising sources of risk have been identified by Frame (2002). The first way of categorising risk is by function. Schwalbe (2000) identifies these functional categories as Market, Financial and Technological. For example, market risk may be a failure of user-acceptability of a product. The second approach is to categorise risk as internal or external. For the purposes of this research, it was the author’s opinion that an analysis of
the literature in relation to internal and external sources of risk would provide a broader examination of the risk identification process.

There are many sources of risk, some of which include senior management, the client or customer, the project team, organisation of the project itself and finally laws and standards which directly impact the project (Mantel, Meredith et al. 2001). These sources can be placed into their respective categories as being either internal or external risk as follows:

<table>
<thead>
<tr>
<th>Sources of Project Risk</th>
<th>Internal</th>
<th>External</th>
</tr>
</thead>
<tbody>
<tr>
<td>Senior Management</td>
<td>Acts of Nature</td>
<td></td>
</tr>
<tr>
<td>Project Team &amp; Management</td>
<td>The Client</td>
<td></td>
</tr>
<tr>
<td>Organisation of the Project</td>
<td>Laws and Standards</td>
<td></td>
</tr>
</tbody>
</table>

Table 1: Categories and Sources of Project Risk

The two most dominant sources of internal risk identified across the literature are Senior/Project Management and Project Team. The dominating external source of risk is the client. All of these were collectively identified by Mantel, Meredith et al. (2001) and are represented in the above table.

Every source of risk can have numerous risk factors. A risk factor is “a condition that forms a serious threat to the completion of an IT project” (Keil, Cule et al. 1998). Some internal risk factors include project conflict and resource boundaries, which can be linked to sources of project team and senior management risk respectively. There are an infinite number of risk factors (even if one was to analyse just one industry) and a study of all these was beyond the scope of this research. The following table however, shows some of the most dominant risk factors identified by Wiegers (1998), who categories these factors by sector:

<table>
<thead>
<tr>
<th>Project Sector</th>
<th>Risk Factor</th>
<th>% Of Projects at Risk</th>
</tr>
</thead>
<tbody>

<td>50</td>
</tr>
<tr>
<td></td>
<td>Harmful competitive actions</td>
<td>45</td>
</tr>
<tr>
<td></td>
<td>Litigation expense</td>
<td>30</td>
</tr>
</tbody>
</table>

Table 2: Most common risk factors for various project types (Wiegers 1998)

On analysing the table, some direct link between sources and risk factors is evident. For example, the sources of ‘management’ risk or ‘organisation of the project itself’ could be linked to the risk factor of ‘inadequate configuration control’ due to a flaw in the project’s arrangement and organisation. However, the most interesting correlation is that of the ten risk factors listed in Table 2, at least six of these can be linked to the client as a source of project risk.

Finally, a dominating feature in recent literature deserves recognition where there is strong support among authors that an actual ‘source of risk’ can provide a ‘source of opportunity.’ Chapman and Ward (1997) state “it is only once risk is seen as a good thing people begin to look for opportunities.” Very few people would acknowledge ‘opportunity’ as being a facet of risk as naturally there are negative connotations associated with risk. Hillson (2001) however, states “the decision to encompass both opportunities and threats within a single definition of risk is a clear statement of intent, recognising that both are equally important influences over project success, and both need managing
proactively.” In a general sense the above ideas represent something we all know and understand about risk and the nature of taking gambles – people and organisations usually undertake risks with the aim of benefiting from potential opportunities (Schwalbe 2000). Taking on any form of risk can be a daunting task but as DeMarco & Lister (2003) state, “if a project has no risks, don’t do it.”

2.2 Risk Estimation

At this stage it is hoped that the project team have identified all potential risks and they can now move on to estimating those risks. Risk estimation is the reduction of measurement uncertainty (Rowe 1977) where “the values of the variables describing the system are determined, the various consequences of an event occurring are identified” and finally, “the magnitude of the risk is determined” (Charette 1990). According to Charette (1989) “the basic difficulty in estimating software engineering risks is that most prospective project risk estimates being made are unique” because there are so few comparable projects which were conducted in the past. This aspect of estimation is extremely applicable in ISD environments where there are many generic risk occurrences but very few instances of projects operating under similar circumstances. Therefore, future estimates will undoubtedly be different.

Risk estimation attempts to estimate “the chance (or probability) of potential loss” as well as “the exposure to potential loss i.e. the consequences or magnitude of the identified risks” (Charette 1989). The chance of potential loss is essentially the process of attaching a probability of occurrence to any identified risk. As Hall (1998) states “estimation is the appraisal of risk probability and consequence.” Probability is categorized as being greater than zero and less than one hundred while consequence is decided relative to cost, schedule and technical goals (Hall 1998). If an event is certain to occur it has a probability of exactly one (McManus 2004) or one hundred percent. Calculating the probability of occurrence of a risk factor means calculating “the likelihood that this risk will actually happen” (McManus 2004). According to McManus (2004) probability data should be used to compute the risk. When no actually data on probabilities exist, estimates by individuals most familiar with the project, its risk factors and overall problems are a good substitute (Mantel, Meredith et al. 2001).

According to Frame (2002) and Hall (1998) addressing the consequences of risk factors can be carried out in two ways – either by qualitative or quantitative risk analysis. Qualitative data involves subjective units such as ‘high’, ‘low’ or ‘critical’ while quantitative data uses numerical units such as ‘workdays’, ‘staff months’ or ‘monetary units’ (Smith and Merritt 2002). Informally, the literature reveals that qualitative analysis is based on subjective risk estimation while quantitative analysis is based on objective risk estimation. For example, Mantel, Meredith et al. (2001) outline how approaches that are qualitative in nature include “subjective assessments based on experience or intuition” while quantitative approaches are “bases on mathematical and statistical techniques” which are objective in nature.

2.3 Risk Evaluation

Risk evaluation is an ambiguous term. Many authors use it to describe the process of evaluating the entire risk management approach while others use it to encapsulate the ideas of risk response. For example, Marchewka (2003) states how “evaluation should consider the entire risk management process.” Charette and Rowe however, outline how risk evaluation is the final stage of the risk assessment process where “responses to the risks are anticipated” (Charette 1990). The latter perspective is the stance to which this research has taken. According to Rowe (1977), risk evaluation involves “risk aversive action, which can result in risk reduction or risk acceptance.” Risk aversive action is essentially any mission that is undertaken to control a risk (Rowe 1977). At a glance, the purpose of risk evaluation is to amalgamate the results of the risk estimation phase (Chapman and Ward 1997) and then decide the best action(s) to take. This means that risk evaluation requires input from numerous stakeholders including senior management “in proactive reduction of risk” signifying
the importance of risk action either before a project commences or long before a risk becomes uncontrollable (Thomsett 1993).

According to Charette (1989) risk evaluation consists of the following three steps:

• Establish the ‘acceptable’ level of risk
• Understand how the various risks interact (which may provide a single referral point for the project)
• Determine the action that needs to be taken with the project in relation to these risks

The acceptable level of a risk will depend on “individual propensity to take risks” (Rowe 1977), which lies in the hands of the project manager and as a result is difficult to specify. By avoiding any risk action however, we are eliminating any proactive risk management. This means that if the risk occurs, reactive approaches will be applied such as contingency planning (Frame 2002). Secondly, interacting the various risks to provide a single referral point to the project is a worthwhile exercise as “risks tend to be interrelated with a lot of overlap existing between categories” (McManus 2004). This can make the risk evaluation process more efficient as risk responses can be “grouped according to their intended effect on the risk being treated” (Hillson 2001). Finally, actions that need to be taken will be in the form of risk mitigation, risk avoidance, risk acceptance and risk transfer which are the response options available (Chapman and Ward 1997).

2.4 Incorporating Risk Management into Agile ISD

According to Remenyi (1999) traditional IS developments initially set out to avoid or reduce the changes to a system which is regarded as a huge fallacy and now “the only way forward to a higher degree of success is to identify potential changes as early as possible and to lay down suitable plans for coping with them.” This involves carrying out proactive risk management. In ISD some of the most dominant risk reduction techniques include prototyping, benchmarking or surveying (Boehm 1991) where managers tend to carry out risk action alternatives on an ad hoc basis (Powell and Klein 1996). According to Powell and Klein (1996), “prototyping and incremental development is often used to reduce project risks, for example by developing knowledge, by breaking the project into digestible bits, by reducing time between specification and delivery and by reducing the impact of change requests.” These concepts have triggered a new wave of development approaches, the most notable of these being agile methods.

The growing prevalence of agile methods has been increasingly documented with the use of such methods as XP, SCRUM, Crystal and DSDM. Organisations are using these methods primarily to assist them in responding to change more rapidly and as risk management is a proactive change mechanism, it makes sense that these two practices should be associated with one another in agile ISD literature. There are several agile methods and a detailed analysis of all these methods was beyond the scope of this research. However, in order to put agile methods into context for the reader, the author will give a brief overview of one of these methods, namely, the Dynamic Systems Development Method (DSDM). The author has chosen this as an example as it is considered to be the first “truly agile software development method” (Abrahamsson, Warsta et al. 2003). It is also a worthy example to use because the method not only focuses on systems development from a coding or technical perspective but also places emphasis on higher-level business perspectives.

2.5 Dynamic Systems Development Method (DSDM)

According to Abrahamsson, Warsta et al. (2003) the main idea behind DSDM “is that instead of fixing the amount of functionality in a product and then adjusting time and resources to reach that functionality, it is preferred to fix time and resources and then adjust the amount of functionality accordingly.” The DSDM Consortium advocates that because each organisation is different none of its practices are detailed and the method itself provides complete support over the entire life-cycle phase (Abrahamsson, Warsta et al. 2003). DSDM phases are made up of a functional prototype iteration, design prototype iteration followed by actual implementation with each iteration stage identifying,
agreeing, creating and reviewing the prototypes (Beynon-Davies and Williams 2003). However before any iteration begins, a project will always start with a feasibility and business study. This highlights that the method is not just focused on technical deliverables but it remembers to place importance on business aspects where the business should always be the driver of technological developments.

DSDM has an active community and is developed and used mainly by its Consortium members and although the method is fully available, access to white papers which outline the specific use of the method is limited to such members (Abrahamsson, Salo et al. 2002). Therefore, the extent to which DSDM incorporates risk management in practice is unknown. Empirical evidence of the method is enclosed in such white papers, which are not publicly available.

For the purpose of this research, a member of the DSDM Consortium who participated in this study, kindly provided the researcher access to information regarding DSDM’s fundamental principles for conducting risk management. Without access to these white papers the researcher would not have been able to document the following information in relation to risk management in DSDM whereby its principles are primarily built around the following concepts:

<table>
<thead>
<tr>
<th>Suitability Risk List</th>
<th>Risk Identification</th>
<th>Risk Log update</th>
<th>Monitor</th>
<th>Alert</th>
<th>Assess</th>
</tr>
</thead>
</table>

All risk management practices conducted in DSDM projects are driven by the processes outlined above. The suitability risk list determines at the outset how compatible a particular project is for the use of DSDM and outlines its associated risks. The suitability list is analysed as part of the first formal risk management activity. A risk log is then created, maintained and updated throughout the life of the project (DSDM Consortium 2002-2006). It is well known that agile methods like DSDM were mainly introduced to help combat common ISD project failures, which revolved around time or cost overruns, or a failure to meet business needs. This is also clear from what the DSDM Consortium (2002-2006) has stated whereby “systems that meet the needs of the business are delivered through the incremental and iterative approach with its continuous feedback from users” while “cost and time overruns are avoided by the use of timeboxes.”

As a result many would propose that methods like DSDM would not need to incorporate a high degree of risk management into their processes because the very reason for their existence is to reduce common risks associated with these well-known project failures. However, it appears from this literature research from the DSDM Consortium, that DSDM itself gives no less consideration to risk management than what has been documented for traditional projects. The extent, understanding and application to which these procedures are applied however, required greater investigation that took the form of a case study analysis detailed in the following sections.

### 3 RESEARCH METHODOLOGY

This research utilised a single case study to analyse the present levels of risk identification, estimation and evaluation in the well-known agile method, DSDM. The case study focused on an Irish change management consultancy firm that utilise DSDM in their commitment to delivering client value. All participants in the study also had extensive experience using traditional systems development methodologies and could therefore make accurate comparisons between the practice of risk management on both agile and traditional systems development projects.

A qualitative research approach was chosen for this study because of its greater exploratory nature and therefore its applicability to this research domain because it focuses “on gaining familiarity with the subject area” and gains “insights for more rigorous investigation at a later stage” (Collis and Hussey 2003). This was essential in light of this study because there is very little research conducted in the area of risk management in agile ISD. The researcher’s aim was to fully understand, determine and describe the existing situation of risk management in agile ISD, which goes beyond purely scientific restricting research. Therefore an interpretive stance was taken.
3.1 Data Collection

There were a variety of options available for collecting research information in this study however due to the fact that there was little pre-existing theory on the phenomena being studied (Bonoma 1985) and as the researcher needed to focus on a qualitative methodology, the data collection technique needed to “emphasise meanings and experiences related to the phenomena” under investigation (Collis and Hussey 2003). As such, for the purpose of conducting primary research the author decided to use semi-structured, personal one-to-one interviews, which were carried out with the company founder and managing director as well as four of its key consultants and analysts. Each interview had a duration of approximately one hour. The researcher felt that in choosing this approach it ensured maximum quality and reliability of data as all interviews were tape-recorded and therefore allowed for subsequent accurate analysis of the data. The semi-structured interviews ensured that the researcher maintained control over each interview, without discouraging the discussion of any valuable, additional information.

3.2 Company Background

The company involved in this case study was an Irish change management consulting firm with operations throughout Ireland. It focuses on delivering technologies to clients through the utilisation of DSDM. The managing director has over twenty five years experience of project management and has participated in many change-management initiatives varying from traditional techniques to agile development techniques. The dominating feature of this company was its great success and confidence in utilising and deploying the ideas of agile development to deliver client value. In 2006, the company were also one of the 1666 members of the global Agile Alliance.

4 FINDINGS AND ANALYSIS

The company involved in this study is an active member of the DSDM Consortium and conformed to the principles of risk management outlined by the Consortium, which was discussed previously in section two. Each interviewee expressed how the practice of managing risk can never be curtailed whether the project is agile or traditional based. In fact, one of the consultants interviewed emphasised how in their experience there is a greater level of exposure of the importance of managing risk on agile projects due to high-level stakeholder involvement and collaboration. Strong emphasis on stakeholder collaboration improves the degree of managing risk in agile methods such as DSDM. The managing director explicitly stated:

“Techniques of agile methods themselves are about reducing the risks of project failures and no matter what the nature of the agile method, a risk management framework will always be in place”

This interviewee also expressed how in their experience, due to the turbulent nature of business environments that “risk management has become progressively better because of project environments and the large amount of project failures.” Therefore, risk management procedures are gradually being considered with greater importance in ISD, regardless of the method being agile-based or otherwise. Such statements are important to consider for the remaining findings relating to risk identification, estimation and evaluation as all participants in this research have transitioned from traditional roles to agile but the extent to which their experience of risk management has progressed is relative to the progression of risk management in project environments over time. An experienced workshop facilitator and consultant with the company noted how they bring DSDM risk management practices into traditional project environments, which reinforce any risk methodologies already in place by the client. As stated by this interviewee, because risk management is incorporated into DSDM “it highlights the need for it even when the client does not have a strict risk management methodology.”
4.1 Risk Identification in DSDM

It became evident from all interviews that risk identification is an integral part of the risk management process for the successful completion of a DSDM project. The interviewees generally spoke about three main aspects of their risk identification process, which revolved around an early suitability filter; ongoing workshops and risk log updates. Their comments showed strong association with the formal practices outlined in section two. One interviewee explained that before commencing a project, the suitability filter aims to identify how appropriate DSDM is for a proposed project. The very existence of this suitability filter is a strong indication that DSDM clearly recognises the potential for associated risks when using the method on incompatible projects. Furthermore the managing director noted how even in a scoping workshop they “try and very quickly identify risks from all stakeholder perspectives” and later they would conduct more “formal risk assessment, which may be part of another workshop.” This conveys how risks are considered with importance even at the very early stages of DSDM projects.

As indicated in section two, continuous risk identification is an important aspect throughout a project’s life cycle. Interview participants predominantly referred to the risk log as their main medium for continuous monitoring and updating of risks. Again, one interviewee working as an analyst explained how “risks would be reviewed on a weekly or fortnightly basis in conjunction with status reports that are carried out. What’s outstanding on the risk log would be included in the status report.” The researcher was given access to one of the organisations risk logs which contained a risk number, category, description, colour code (for high, medium or low risks), assignment of risk, date, proposed action and follow-up control.

In section two, client risk involving scope creep was documented as being the main source of project risk across literature. This however, was not the main finding in this research where all interviewees strongly declared how “resourcing” would be their most dominant risk across projects. In particular, obtaining and retaining key personnel in a given project is the single biggest risk across all projects encountered in this case study where a key consultant stated how “resourcing availability is the classic risk we encounter because there are so many competing projects in operation across the organisation.” This risk is associated with the project team risk documented in section two. With regard to overcoming client risk, this consultant stated how:

“In a DSDM project you actually manage scope creep. There are specific DSDM techniques such as prioritisation of requirements and timeboxing, which helps you to manage it. Within each timebox you set the scope upfront and agree that you’re not going to go outside the breadth of what you have at that point.”

In terms of risk categorisation, the literature revealed two main ways of categorising risks – either by function or as being internal or external (section two). The findings in this study revealed that in DSDM risks are typically categorised according to function and “according to the project team stream that owns the risk because effectively this is how the risk gets allocated and it determines who has ownership of the risk.”

Finally, in section two the author discussed a relatively new feature in literature, which promoted aspects of opportunity in risk identification whereby a source of risk can often be a source of opportunity. When all respondents were questioned about this they expressed how they would never associate risk with opportunity in this way. However, when discussing this with the managing director a very interesting concept was put forward whereby:

“Risk management is really another way of identifying a business requirement. You can take a risk approach to develop more business requirements because mitigation of a risk is something that you actually have to do to develop the product so it becomes part of requirements.”

The researcher found this to be a very interesting and valid viewpoint in that if the resolution of an identified risk results in an additional needed requirement, a project might easily find itself embracing
an opportunity by fulfilling this requirement. However, based on this interviewee’s experience these requirements are more often a necessary feature required to make the project work instead of an innovative idea bringing about opportunity.

4.2 Risk Estimation in DSDM

The DSDM Consortium (1999-2003) outlines how the ‘level of risk’ is equal to the likelihood of its occurrence multiplied by the severity of impact, which supports literature in relation to risk estimation. The process was also evident in this case study where risks would be prioritised on this basis. An experienced workshop facilitator stated how their “main mechanism for prioritising risks would use a probability by impact approach.” In contrast however, the managing director stated that they would prioritise a risk relative to the prioritised requirement to which the risk effects. The researcher concluded that while some respondents referred to the main concepts of risk estimation, the nature to which they believe risks are prioritised was extremely dependent on each interviewee’s project role and experience. For example, the most junior team member stated how they would “prioritise risks and identify which are actual show-stoppers but estimating risk probabilities or allocating percentages to the impact on a project is something I haven’t had experience of.” Finally, the approach adopted for risk estimation in this case study showed that both quantitative and qualitative estimation techniques are used and are project dependent and vary from client to client.

4.3 Risk Evaluation in DSDM

A general consensus emerged in this study in that it is not considered feasible to carry out action for all risks because as a leading consultant stated “it just wouldn’t be practical and in some cases this may be more expensive to the project than what it would have to endure if the risk actually occurred.” However, all respondents agreed on one important point when discussing responsive actions and this involved the importance of responding to the highest prioritised risks in the same manner as they would respond to the prioritised ‘must-have’ requirements in specific timeboxes. The researcher noted something important about this level of clarity in that the principles set down by the Consortium for requirements prioritisation and timeboxing have been made applicable to the approaches taken for managing and responding to risks. As one interviewee stated:

“Procedures or actions would not be carried out for all identified risks but only those which have the appropriate priority in the same way as a ‘should-have’ requirement would not be an immediate necessity as would a ‘must-have’ requirement. When actions are taken however, they may include risk reduction, transfer or contingency planning.”

5 CONCLUSIONS & FURTHER RESEARCH

This research was based on the concept of managing risk where the researcher sought to discover the extent of risk management practices in agile ISD projects utilising DSDM. This analysis involved a decomposition of the primary elements of risk management namely risk identification, estimation and evaluation. An analysis of the literature revealed little evidence on the extent of use of risk management practices in agile methods. However, it is widely recognised that agile methods themselves were introduced to combat well-known risks associated with ISD project failures such as scope creep, cost overruns and schedule pressures. Their use of incremental development and active user involvement is an attempt to combat such risks.

Nevertheless, the findings of this research shows that the extent to which risk management is conducted in DSDM is in no way inferior to that carried out on traditional projects. In fact, DSDM shows a strong presence of risk management activities and in some instances shows more rigour for managing risk that what has been documented for traditional projects. The DSDM Consortium have specified the need for formal risk management procedures involving the use of an early suitability filter for example, which specifies project fit with DSDM as well as ongoing use of a formal risk log.
In addition, the research participants involved in this study showed a clear appreciation for the importance of managing risk on projects outlining how the insistence which DSDM places on stakeholder collaboration has a huge impact on risk management as it promotes the formal management of business risks, improves overall awareness of risk management among the project team, increases the number of risks identified throughout the project and ensures logical ownership of risks.

While the research produced many interesting findings there is much scope for further research as follows:

- Given the diversity with which methods are adopted across organizations, a large-scale quantitative study may identify more generalisable themes regarding the adoption and deployment of risk management practices across a large number of projects.
- The case adopted in this research focused solely on one agile method, namely DSDM. Given the diversity that exists across the agile method family, there is a need to examine the extent to which risk management is facilitated by other methods.
- A final potential area for further research may be a comparison between the existing state of risk management in agile project environments and traditional project environments. This form of research may produce interesting findings in relation to risk management maturity over time.

IN-HOUSE DEVELOPMENT AS AN ALTERNATIVE FOR ERP ADOPTION BY SMES: A CRITICAL CASE STUDY

Abstract

ERP systems are increasingly accessible to small and medium-sized enterprises (SMEs). If the potential benefits of these systems are significant, the same applies to the risk associated with their implementation. The majority of ERP studies relate to software packages supplied by large vendors such as SAP and Oracle and by smaller vendors; but until now, few have studied the adoption of ERP systems developed “in-house”. Furthermore, few studies have explicitly focused on minimizing the risk of these systems at the adoption or pre-implementation stage. Presenting a critical case study which analyzes the adoption of an in-house ERP by a SME in the agri-food industry, this article proposes and tests a process framework of ERP systems adoption, based upon a literature review and a conceptual framework centered on risk minimization. The study shows that 1) in-house ERP seems to represent a credible alternative for ERP adoption by SMEs, 2) to minimize risk at the adoption stage, a SME can proceed in a rather intuitive and unstructured manner, based however upon certain principles, policies and practices. The successful ERP implementation in this case indicates that it is not always necessary to resort to formalized project management in order to minimize implementation risk.

Keywords: ERP, in-house development, adoption, implementation risk, SME.

1 INTRODUCTION

Despite the fact that ERP adoption is one of the most important phenomena “in the corporate use of information technology in the 1990s” (Davenport 1998, p. 122), their adoption by small and medium-sized enterprises (SMEs) is a relatively new phenomenon (Everdingen, Hillegersberg and Waarts 2000). Recently, Light and Sawyer (2007) have found some weaknesses in ERP research with regard its theoretical foundation, also noting the scarcity of research focused on non-commercially licensed ERP software such as open source ERP and “in-house” or custom-developed ERP. In this last alternative, the organization develops its own ERP system, made-to-measure to satisfy its specific needs, with or without the assistance of a third party. The availability of new software development tools and methods (Wirfs-Brock 2008) as well as the wide adoption of open standards by developer communities make the in-house development of ERP systems feasible (Olsen and Saetre 2007). Certain characteristics of this alternative make it attractive for SMEs: greater adaptability, no vendor lock-in, property of the source code, cost comparable to the other alternatives (Olsen and Saetre op. cit.). Furthermore, most of the studies on ERP adoption tend to examine large enterprises and their findings cannot easily be extended to SMEs because of the fundamental differences between the two (Dandridge 1979).

The growing importance and risk of ERP projects, in SMEs in particular, imply that researchers must “focus on ways to improve ERP implementation” (Robey, Ross and Boudreau 2002 p. 19). With regard to risk minimization, Kliem (2000) emphasises the efficiency of risk management when it is
introduced at the earliest possible opportunity in the system life cycle. In response to the appeals stated above, and building on past research, the present study attempts to answer the following research question: *What can be done to minimize the risk of ERP system implementation in a small firm, from the adoption stage onwards?* To obtain initial insights on this question, a positivist case study was made of a small firm that has developed and implemented an in-house ERP system. The objective of the study is three-fold: a) contextualize and describe the various stages in the SME’s in-house ERP adoption process, b) identify the firm’s management practices that reduce the ERP development and implementation risk, and c) understand the determinants and effects of these practices. This research builds upon Boudreau and Robey’s (1999) theoretical framework in using four theoretical lenses to discuss the case, that is, organizational change theory (Robey et al. 2002), diffusion of innovation theory (Rogers 2003), complexity theory (Cohen 1999), and the resource-based view (Beard and Sumner 2004).

2 RESEARCH FRAMEWORK

While the notion of risk is deemed to be important for IS researchers and practitioners, there is as of yet no consensus on how to define, measure and manage IS risk; and most risk management models do not have a theoretical foundation (Alter and Sherer 2004). In the present study, based upon Barki, Rivard and Talbot’s (2001) model founded on contingency theory, it is proposed that the success of an ERP implementation will be influenced by the degree of alignment or “fit” between the SME’s risk exposure level and its risk management profile.

In reviewing the literature on ERP system adoption, we found that most of the models are without any theoretical foundation with the exception of Verville and Halingten’s (2003) model. The framework developed for the present study is thus based on this model because of its theoretical and empirical foundation and on Esteves and Pastor’s (1999) because it is somewhat complementary to the first.

A number of IT implementation studies have used Tornatsky and Fleischer's (1990) technology-organization-environment (TOE) framework to characterize the implementation context, emphasizing three groups of contextual factors: 1) characteristics of the environmental context such as external pressures from the firm's business partners, 2) characteristics of the organizational context such as the firm's structure, and resources, including managerial and entrepreneurial (in the case of SMEs) factors, given the key role played by certain individuals in the implementation process, and 3) characteristics of the technological context, including the information technologies already implemented by the firm.

Given the lack of consensus on the nature of IS risk factors and on the principal components of such factors (Alter and Scherer 2004), a review of prior studies led to the identification of six categories of risk exposure, namely organizational, business, technological, entrepreneurial or managerial, contractual and financial risk (Austin and Nolan 1999, O'Leary 2000, Caldeira and Ward 2003, Bernard, Rivard and Aubert 2002, Ariss, Raghunathan and Kunnathar 2000).

Figure 1 presents the initial research framework derived from a review of the scientific and empirical literature. The framework was initially validated by 13 academic and professional ERP experts through a two-round Delphi procedure. According to this framework, the ERP adoption process in a SME is influenced by a general context and a specific context (Ross and Vitale 2002, Kumar, Maheshwari, and Kumar 2003). The process itself can be broken down into seven stages (Verville and Halingten 2003). The dynamics of change that allow the organization to move from one stage to the next is explained by “motors” of organizational change and by the form of the change (Boudreau and Robey 1999). The choices available as a result of the process are the six alternatives proposed in the framework (Alshaw, Themistocleous and Almadami 2005), one of which is in-house ERP development. Lastly, the fit between exposure to risk and risk management profile (Barki et al. 2001) has an impact on the quality of the new system, on user satisfaction, on individual managers and employees, and on the organization (Gable, Sedera and Chan 2003).
CASE STUDY RESEARCH METHOD

The field of knowledge on ERP, while continuing to grow, had achieved a certain level of maturity (Botta-Genoulaz, Millet and Grabot 2005). Chen and Hirschheim (2004) note that when a field becomes more mature, one expects that research efforts will tend more to “theory-testing” than to “theory-building”. The present test of a research framework on the adoption of in-house ERP thus seems opportune. As the phenomenon under study is hardly separable from its context (Ross and Vitale 2000) and the adoption of in-house ERP is relatively recent and rare, a single “critical” case design was taken (Gallivan and Keil 2003). As is shown in Table 1, the firm selected for the case study, Bio-Epsilon, a small (31 employees) Canadian firm in the agri-food industry, adopted its ERP system at the end of a 6-month process.

Table 1. Adoption of an in-house ERP solution at Bio-Epsilon.

This case is based on actual facts and existing firms. A transposition has been made to preserve the anonymity of these firms and the confidentiality of the data.
For purposes of internal validity in case study research, evidence was obtained from three different sources: semi-structured interviews, written documents, and a questionnaire (Dubé and Paré 2003). The main source of the data collected consisted of four interviews conducted at Bio-Epsilon’s premises in August 2006 by one of the researchers. The four “key informants” met were the owner-manager, the marketing manager, the quality control manager, and the sales manager (Patton, 1990). Each interview lasted approximately one hour and a half. The selection of these informants was based on a “snowball” sampling procedure. Saturation was achieved at the third interview (Lincoln and Guba 1985).

Similarly to Sarker and Lee (2001), an informal interview was also held with the consultant who accompanied Bio-Epsilon along the adoption process. The documents consulted were essentially promotional material on the firm’s activities and products, information on its markets, project documentation and documentation from the consulted ERP suppliers. The questionnaire was filled out immediately after the interview by both, the owner-manager and the marketing manager with the assistance of the researcher.

Data processing and analysis were based on the interactive model proposed by Miles and Huberman (2003). Prior to data collection, a list of four pre-determined categories and eleven sub-categories was established from the literature review and the initial research framework (Paré 2004). Given the flexibility inherent to the case study method (Dubé and Paré 2003), this list was modified during and after data collection and “room was made for modifications dictated by the data itself” (Lapointe and Rivard 2005, p. 470). Coding was done initially by the researcher who did the interviews, then done anew by a second researcher, following which discrepancies were resolved. Use was also made of “pattern matching” (Yin 2003) as well as the following process data analysis strategies: narrative, visual mapping, quantification, and temporal bracketing (Langley 1999).

4 RESULTS

Bio-Epsilon is a Canadian SME specialised in the commercialisation and distribution of food products originating in biological agriculture. Created in 1996 by a conglomerate on the initiative of two entrepreneurs, Bio-Epsilon was a subsidiary of Global-Delta until June 2005. That same year, for financial and fiscal reasons, the chief executive and until then minority shareholder bought back the greater part of the shares from the parent firm and thus became majority shareholder. Today, 96% of the equity is held by the management team and 4% by the ex-parent firm.

4.1 Global and specific contexts of ERP adoption at Bio-Epsilon

Bio-Epsilon has two types of customers. On one hand, food retailers specialised in the selling of food products originating in biological agriculture to which it sells finished products constitute approximately 80% of its turnover. On the other hand, it sells semi-finished products to a number of craft or industrial producers in the biological agri-food sector. From these semi-finished products, these last customers make biological food products that compete with those of Bio-Epsilon. This relationship based on simultaneous cooperation and competition (Shen 1997) is accepted by Bio-Epsilon’s owner-manager. The firm’s business environment is characterised by strong pressures with regard to the price of products sold and to ever-increasing requirements with regard to the quality of products and services. The customers’ demands manifest themselves in terms of time of delivery and availability of products.

---

2 The interview guide and the questionnaire are available from the authors upon request.
Bio-Epsilon is a firm whose commercial dependency upon its customers is rather weak, but it is rather strong upon the Global-Delta firm, which is its main supplier. The ex-parent firm provides 77\% of its supplies. Today, Bio-Epsilon processes over 30,000 order lines per year and forecasts an annual growth rate of 15\%. With such growth objectives and also with objectives of increasing the quality of services rendered to its customers, the firm decided to invest in the construction of a new building adapted to its operational needs. The acquisition of a new ERP system is part of this organisational project. This investment is accompanied by quantified objectives in terms of customer satisfaction. More precisely, these objectives should translate into fewer complaints lodged by customers and in the delivery of products within no more than 24 hours after reception of a customer’s order.

Bio-Epsilon is an organisation whose size is small and whose organisational structure is simple and decentralised. Certain important decisions are taken jointly by the owner-manager and the marketing director or on the basis of a consensus. Bio-Epsilon has 31 salaried employees, including five managers, and had a turnover of 14 million dollars in 2006. Due to its strong growth, this number of personnel has doubled in the last three years. To increase the flexibility of its operations, Bio-Epsilon out-sources the transportation and delivery of its products to three firms.

To do business, Bio-Epsilon mainly relies on a “niche” type strategy. The firm distinguishes itself from its competitors by its responsiveness and the diversity and quality of its products, whose brand is recognised, and by the quality of services rendered to customers. It also distinguishes itself by its marketing, justifying its employment of a full-time graphic artist dedicated to designing the products’ packaging and leaflets and to the firm’s marketing communication.

The owner-manager and marketing director both have university degrees and more than twenty years’ professional experience in the commercialisation of food products. The owner-manager has a positive attitude toward IT and IT management procedures. His management style is of the participative-management type.

As soon as the new building construction project started to take form, Mr. Nelson, Bio-Epsilon’s owner-manager, mandated an outside consultant to assist the firm in formalising the new work organisation and the new workstations. This project lasted for approximately 12 months.

Previously, the firm’s applications portfolio consisted of a “best of breed” ERP (Light, Holland and Wills 2001), composed of the following elements: marketing and sales, and financial management modules provided by a large software supplier, Bestofapps. It also included a specific application developed in the 4D technology environment to complement the functionalities of the Bestofapps software with regard to warehousing management. Payroll processing is out-sourced. There are no personnel dedicated to IT, but most employees use IT tools intensely. As a result, Bio-Epsilon’s level of IT use and IT management sophistication is high. Most management processes are automated through a relatively rich but poorly-integrated applications portfolio. Thus data are captured more than once in the various administrative units, generating numerous errors despite multiple redundant verifications. The information system had thus become an obstacle to the attainment of the firm’s quality objectives. One example illustrates this:

The marketing director indicates that when promotional materials are to be posted to customers, only 50\% of these appear automatically due to database inconsistency. “For example, when we want to send promotional materials, half of our customers do not appear because they are not all entered in the same way in the database. This looks trivial but the consequences are enormous. It’s of great concern because we have to manually process more than 1000 records each month.”

---

3 4D is a software publisher (integrated development environment, databases, application servers and web servers) whose products are meant to accelerate the development and deployment cycles for professional applications (www.4D.fr).
The triggering factor in the idea to adopt an ERP system lies in moving to a new building especially constructed to house Bio-Epsilon’s head office and warehouse. Initial motivations to acquire such a software package were operational in nature (Ross and Vitale 2000). Management wants to be able to localise product batches in the new three-storey warehouse in a more precise manner.

In addition to the essentially operational motivations previously cited, objectives of a strategic and technical nature also appeared. Bio-Epsilon’s management hoped that a new ERP system would also allow it to improve the quality of services rendered to customers. It also wanted to avail itself of a unique technical platform to manage all of the firm’s activities.

Eight organisational stakeholders participated in the process of identifying the needs relative to the new ERP system, as mentioned by Mr. Nelson: “7 or 8 out of 31 employees, that’s not too bad, that means a quarter, knowing that the firm’s small size allowed everyone to express themselves”. User participation was organised at two levels. First, in each department, one or two representative users were charged with gathering the users’ needs and assure the liaison between the project and the latter. Then, information and consultation meetings with the representative users were held.

During the adoption process, Bio-Epsilon followed one guiding principle: adapting the system to the organization. The principles represent the highest level of abstraction for an architectural approach composed of three levels, that is, principles, policies and practices (Colbert 2004).

### 4.2 The ERP adoption process at Bio-Epsilon

As presented in Figure 2, the ERP adoption process at Bio-Epsilon can be decomposed into six phases: the adoption decision, planning, search for information, evaluation of the proposed solutions, choice of the best solution, and negotiation.

![Figure 2. Dynamic of ERP adoption at Bio-Epsilon.](image-url)
In the first phase, the decision was jointly taken by the owner-manager and the marketing director, given the limitations of the present (legacy) information system to support Bio-Epsilon’s operations, limitations that would be accentuated when the firm moves to its new building. These two individuals were guided by one principle, that is, “the new system must be adapted to the organisation”, and by five policies, that is “no operating system other than Mac OS”, “work with an ERP supplier that can assure the system’s continuity”, “work with partners whose size is small”, “work with people we know”, and “work with a responsive supplier”.

In the second phase neither the budget nor the schedule of the next phases of the ERP adoption project were formally planned. However, management fixed an objective of deciding on the choice of an ERP system no later than March 2006 in order to dispose of sufficient time to implement it. This milestone allowed Bio-Epsilon to put the new system into service during the summer of 2006 such that it would be up-and-running by the time the firm moved into the new building, planned for November 2nd, 2006. While the amount of investment had not been formally estimated, Mr. Nelson had estimated the time required by the ERP adoption process. The budget for the acquisition of the new system was to be in the 75 000$ to 90 000$ (CAD) range.

In the third phase, the search for information was made “on the fly” in the words of the owner-manager. In total, Bio-Epsilon collected information on ERPs from five main sources:

- Contacts with the ex-parent firm, Global-Delta. This organisation had been using AlphaMIS’s ERP for the last six years. AlphaMIS is one of the three largest ERP suppliers in the world. For Mr. Nelson, while the implementation was done “without pain”, a lot of work and investment was needed as it took a number of years before the system performed adequately. He took from this experience that the implementation of an ERP system provided by a large supplier such as AlphaMIS would be a complex task for Bio-Epsilon. Nonetheless, he was attracted by the idea of adopting the same ERP as Global-Delta to benefit from the compatibility between systems supplied by the same provider, and from an online access to Global-Delta’s inventory and other information. For this reason, he then contacted AlphaMIS.

- Contacts with a large supplier. Mr. Nelson sent an email to AlphaMIS. A few days later, he was contacted by a sales representative who presented him with AlphaMIS product offer to SMEs. It came out from this discussion that Bio-Epsilon could acquire an ERP system for approximately 75 000 dollars (CAD). In concluding, the sales representative promised to send a proposal to Bio-Epsilon.

- Contacts with the informal network. Mr. Nelson’s discussions with other owner-managers of SMEs that have implemented an ERP in their firm seem to have confirmed his worries. Two points come out of these discussions, one being that the choices made when initially setting the system’s parameters are difficult to change afterwards, and the other being that the cost of implementing an ERP is quite high. In relation to this last point, certain accounts of other owner-managers made him remember his own bad experience with Bestofapps with regard to the quality of service provided.

- Contacts with SMESoft, a firm that had implemented the Bestofapps software package at Bio-Epsilon. On one hand, given the difficulties encountered in the search for information on Mac OS-compatible ERP systems, and on the other hand given the good quality of the relationship with this partner, Mr. Nelson has decided to seek advice from SMESoft. Besides, it is this firm that had always been charged with maintaining Bio-Epsilon’s applications portfolio, computer network and workstations. It had been SMESoft that had implemented the first Macintosh computer at Bio-Epsilon, eleven years before. SMESoft’s chief executive indicated that they could develop a solution to respond to Bio-Epsilon’s requirements because, as software developers, they knew how to do so.

The ERP proposed by SMESoft, a small firm, was the only solution found by both the CEO and the marketing manager to be truly attractive and Mac OS-compatible. While he was interested at the outset to work anew with a service provider and software developer that knew his firm « on the tip of its fingers » and with which he had had close collaboration in the last eleven years, Mr. Nelson
thought that it would be rather imprudent to make such an important investment simply on this basis: “So I was keen on that solution, except that I said to myself, for such an important investment, it would be irresponsible to start out only with a ‘feeling’.”

- Call to an experienced outside consultant. Being uncertain of his choice, Mr. Nelson called upon an outside consultant within his informal network to give him advice on the adequacy of the ERP system proposed by SMESoft, given Bio-Epsilon’s needs. As the consultant was employed by OpenSoft, an integrator of open source solutions, he seized this occasion to propose OpenSoft ERP, an open source software package, to Bio-Epsilon. Consequently, the mission of the consultant was transformed into assistance in the choice between two ERP solutions: SpecificSoft ERP (in-house development) and OpenSoft ERP (open source).

Another consultant from OpenSoft was given the task of preparing the integrator’s proposal to Bio-Epsilon. So, Bio-Epsilon met itself with a de facto shortlist made up of two alternatives: an in-house ERP or an open source ERP. Afterward, both systems were evaluated by the external consultant and Bio-Epsilon’s eight user representatives. Detailed specifications were prepared by the consultant and sent to each supplier along with an invitation to proceed to a demonstration of their product. The functional scope of the ERP system as defined in the specifications covered the following functions: customer relationship management, sales administration, purchasing, quality and control, warehouse management and accounting.

During the demonstration, Bio-Epsilon representatives asked questions principally related to firm’s core activities. The result of this initial demonstration favoured OpenSoft which differentiated itself from its competitor by the quality of its presentation, particularly its scenarios, and the extent of its ERP system’s functional coverage. Having noticed that a number of important questions had remained unanswered by both candidates at the end of this demonstration, it was decided to send them renewed specifications in order to have another demonstration. After the second demonstration, Bio-Epsilon’s management and user representatives as well as the consultant prepared a list of about twenty selection criteria to enlighten the decision. Both suppliers were then evaluated on the basis of these criteria and on the impression made during the demonstration. Following several discussions, a consensus emerged in favour of SpecificSoft, the in-house ERP development solution.

Prior to initiating the implementation of the new ERP system, the owner-manager engaged in negotiations with SpecificSoft to obtain a fixed price that included not only the system’s development and configuration but also the training of all system users. The contract signed between both parties granted the property of the source code to Bio-Epsilon.

The system was put in service during the summer, a more tranquil period for Bio-Epsilon in terms of customer orders. The new system functioned in parallel with the legacy system for one month after going live. Overall, users show themselves very satisfied with the ERP system adopted. They are most satisfied with the system’s user-friendliness and comprehensibility, and with the support provided by the supplier. At the organizational level, it is the integration of business processes that is perceived as being the most important impact of the new ERP system. At the individual level, it is the productivity gains generated by the system via the elimination of redundant tasks that are most valued.

5 DISCUSSION

During the ERP adoption process, Bio-Epsilon seems to have been attracted by the “shared vision” (Slevin and Pinto 1987) of its functioning in the new building that would be enabled by the new system. In fact, photos and plans were sited on the walls of most of the headquarter offices. At Bio-Epsilon, the consideration of the risk of implementation from the adoption stage was based on a reactive, informal, intuitive and incremental approach (Bili and Raymond 1993). Bio-Epsilon’s risk management profile can be described as an intuitive, fairly informal and apparently unstructured approach to risk, based on specific principles, policies and practices. An assertion of the owner-
manager illustrates this fact: “I was guided by events ‘on the fly’. I gathered information right and left. It was difficult to obtain information on MacOS-compatible ERP systems because 95% of companies use PCs.”

Such as presented in Table 2, the principles, policies and practices employed by Bio-Epsilon had an effect at different stages in the adoption process, on the envisaged alternatives and on the firm’s exposure to ERP implementation risk.

The ERP systems supplied by large vendors such as AlphaMIS were definitively eliminated from consideration, as they were perceived to be in conflict with the “ERP system is adapted to the organization” principle and the “work with a small-sized supplier” policy. The competition between the two remaining potential solutions brought to the foreground the most adequate choice for Bio-Epsilon. Furthermore, the answers to “field questions” put between both demonstrations as well as the work realized by the competitors between the two demonstrations allowed Bio-Epsilon to measure the responsiveness of every supplier. SpecificSoft’s and OpenSoft’s ERP solution were both in accordance with the previous principle and policy as well as with the “no operating system other than MacOS” policy. On the other hand, only SpecificSoft’s solution turned out to be more in accordance with the “work with a responsive supplier” and “work with people we know” policies. As an organizational metaphor can be a powerful yet subtle way of conveying meaning to results (Patton 1990), one can say that SpecificSoft was more capable than OpenSoft of overcoming the “virtual barrier” protecting the organization against ERP implementation risk, that is a barrier whose architecture was made-up of the principles, policies and practices employed by Bio-Epsilon during its ERP adoption process. Data analysis indicates that the architecture of principles policies and practices employed by Bio-Epsilon to minimize risk forms a whole, a “configuration” (Fiss 2007) whose internal consistency led to a successful implementation of the ERP system. Consequently, rather than the “profile deviation” alignment perspective posited initially, following Barki et al. (2001), it is the “gestalt” alignment perspective (Viliyath and Srinivasan 1995) that seems more appropriate to the case studied. In this perspective, equifinality is assumed in that different internally consistent
configurations of risk exposure and risk management profile may be equally effective, that is, may minimize ERP implementation risk.

According to Rogers (2003), five characteristics of innovations may affect their rate of adoption: relative advantage, compatibility, complexity, trialability, observability. Evidence from this case confirms the influence of three characteristics of the “in-house” ERP solution that turned out to be most important: greater compatibility with the firm’s processes and business model, less complexity; better trialability and greater evolutionary capability. The requirement for an evolutionary capability of the ERP system originates in Bio-Epsilon’s previous ERP experience and in the firm’s growth perspectives. Finally, diffusion of innovation theory explains neither the firm’s search for compatibility with regard to the size of organization (small size), nor with regard to a dominant trait of its strategic orientation (responsiveness) as indicated by the case data. This interpretation suggests that diffusion of innovation theory needs to be extended when applied to the adoption of a complex innovation such as an ERP system, in the context of SMEs.

According to Cole (2002), social processes constitute examples of complex phenomena. As ERP adoption is a social process in which the technology represents only one of the dimensions (Jones and Hughes 2001), it is thus a complex process. Consequently, the ERP adoption process may exhibit observable patterns of behaviour (Choi, Dooley and Rungtusanathan 2001). Data from the case indicate a pattern composed of five phases. With regard to Bio-Epsilon’s evolution from phase to phase along the adoption process, it is the shared vision of the functioning of the organization in the new building that acted as “an attractive vision of the future” (Elenkov, Judge and Wright 2005, p. 668) and urged it to look for a new ERP system. This vision was also a referred to all during the adoption process. Hence the “strange-attractor” motor stemming from complexity theory (Nutt and Backoff 1997) appears to be adequate in explaining the dynamic that moved Bio-Epsilon from one phase to another during the adoption process. The strange attractor is a configuration towards which tends the behaviour of a complex system in the long term (Capra 2005). Similarly, the “evolutionist” motor (Boudreau and Robey 1999) appears to be relevant in explaining the emergence of SpecificSoft and its ERP system as the suitable choice for Bio-Epsilon, as the result of competition during the adoption process.

As one can say that the “attractive future” of the organization envisioned by Bio-Epsilon’s CEO is made-up of a combination of experience, physical infrastructure, human capital resources, organizational resources, and business results, it appear that the resource-based view as applied to ERP (Beard and Sumner 2004) is a complementary theoretical lens for explaining what happened in this case. In summary, following Caldeira and Ward (2003), the outcome of the adoption process at Bio-Epsilon is valuable because adopting the ERP system applied to the core competitive processes of the business. It is also rare because it is based on a “custom” ERP system integrated in an enterprise vision. It is imperfectly imitable because of a personal relationship/partnership with the IT supplier for mutual long-term benefits. It is non-substitutable because of Bio-Epsilon’s continuous incremental innovation in partnership with IT suppliers to enhance its products and the services.

6 CONCLUSION

In an environment characterised by globalisation and based on knowledge, many SMEs are subjected to increased pressures with regard to competitiveness, innovation, flexibility, quality, and information processing capability. In attempting to respond to these challenges, a number of these firms have adopted an ERP system, and some of them are doing so by developing their system in-house. As a complex evolutionary phenomenon, ERP adoption is deemed by common wisdom to involve substantial risk. This study has demonstrated that it is nonetheless possible for SMEs to manage this risk, albeit through a single case. In attempting to describe and understand the dynamics of the ERP adoption process within change management and risk management perspectives, it is hoped that this study has provided a significant conceptual and practical contribution.

Abstract

Biometrics can unequivocally verify a person’s identity and, thus, have significant potential to curb the crime of identity theft, which costs individuals, organizations, and society billions of dollars annually. While financial institutions may be highly motivated to examine the feasibility of adopting biometrics for identity verification, research regarding consumer acceptance of this technology is limited. This paper proposes and empirically validates a research model for consumer acceptance of biometric identity verification for financial transactions. Additionally, conditions of voluntariness and user control are explored for their effects on user attitudes within this context. Implications for theory, practice, and future research are outlined.

Keywords: biometric verification, privacy, security, attitude, control, voluntariness, adoption, trust
1 INTRODUCTION

Biometrics refer to a host of physiological or behavioural characteristics that are used to uniquely identify or verify the identity of individuals. Despite the fact that the biometrics industry is still in its infancy, it has experienced tremendous growth in the recent past (IBG 2007). This growth has been spurred by governments in the interests of national security. This attention on the part of governments around the world has resulted in increased government funding for research and development in this area. This has inevitably lead to biometric devices becoming not only more reliable, but also less expensive. As a result, organizations that are strictly constrained by traditional cost-benefit analyses now see the viability and potential of biometrics across a variety of applications.

One possible application of biometrics is to help slow the growth of identity theft (IDT). In the United States alone, the losses attributed to identity theft were estimated to be over $50 billion dollars during 2006 (Javelin 2006); and this figure represents only the direct costs of the crime without considering the plethora of associated indirect costs. For the individual, there are the very real and often significant costs to repair their finances and credit rating, obtain new identification documents, etc. In addition, even though the average time required for an individual to repair the damage after their identity has been stolen is estimated at 40 hours (Javelin 2006), in the more extreme cases it can extend into hundreds of hours (Petouhoff 2006). There are also the associated costs of all the resources, in both the private and public sectors, required to prevent, detect, deal with, and prosecute identity theft perpetrators.

Typically, it is financial institutions (primarily banks) that absorb many of the financial losses incurred by their customers as a result of identity theft. Therefore, in an effort to curb the growth of this type of crime, financial institutions are highly motivated to examine the feasibility of adopting biometric identity verification methods. However, like most for-profit organizations, banks are extremely cognizant of the importance of maintaining customer satisfaction and, therefore, must be mindful of the degree to which customers will accept the introduction of any new technology, especially if it is unknown and/or misunderstood. Therefore, any feasibility study for using these technologies must investigate consumer attitudes towards, and their potential acceptance of, biometric verification as a method of establishing identity for financial transactions.

Although extensive research exists with respect to the technical aspects of biometric technologies (Lease 2005), research regarding consumer acceptance of biometrics is sparse. This may simply be a reflection of the relative immaturity of the biometrics market (Lease 2005). The purpose of this research is to explore the impact of several antecedents upon consumer attitudes towards using biometrics, for identity verification purposes, within the banking industry. This paper starts with an overview of biometrics and relevant literature to support a proposed research model. The model, which examines the factors that influence bank customers’ attitude toward using biometrics for financial transactions at ATMs, is validated through an empirical study. The results of this study are presented with implications for researchers and practitioners.

2 BIOMETRICS

The word biometrics is derived from the Greek words bios (life) and metrikos (measure). Biometrics is the science of measuring either physiological or behavioural characteristics (Zorkadis and Donos 2004) for the purpose of determining or verifying identity (Bolle & Connell & Pankanti & Ratha & Senior 2004, IBG 2007). Verification answers the question “Am I who I claim to be?” In this context, the system verifies the identity of that person and makes a yes/no decision based upon a one-to-one comparison between the newly scanned biometric data and a previously stored version (Jain & Ross & Prabhakar 2004). Identification, on the other hand, answers the question “Who am I?” In this case, the newly acquired biometric information from an individual is compared to all available biometric data files in the database using a one-to-many comparison process (Prabhakar & Pankati & Jain 2003).
In terms of computational requirements, verification is much easier than identification; in addition, the former is much more accurate than the latter.

Biometric measurements fall into two categories: physiological and behavioural (Zorkadis and Donos 2004). Physiological traits that have been used include fingerprints, hand vein pattern, fingernail bed, iris, retina, body odor, skin reflection, ear shape, teeth, DNA, hand geometry, palm, and face (Bolle et al. 2004, Jain et al. 2004).Behavioural measures include voice, gait, signature, keystroke dynamics, and lip motion (Bolle et al. 2004).

This paper focuses on fingerprint verification in financial transactions for several reasons. First, although fingerprint verification is less reliable than iris or retinal scans, it is more reliable than voice recognition. In addition, relative to iris and retinal scans, fingerprint verification is considerably less expensive. Third, while there may be some stigma attached to fingerprints given their association with criminals, it is also better understood by the general public relative to other biometrics. Finally, it is also a more mature technology when compared with other forms of biometrics.

3 THEORETICAL DEVELOPMENT AND RESEARCH MODEL

Ajzen (1991) defines attitude toward behaviour as “the degree to which a person has a favourable or unfavourable evaluation or appraisal of the behaviour in question” (Ajzen 1991, p.188). Within the context of technology adoption, the behaviour of interest is use of the system, which in this case is biometric identity verification to access one’s bank accounts at an automated teller machine (ATM). Consequently, attitude towards behaviour is a potential user’s affective net assessment of the costs and benefits associated with using the new technology (Morris and Venkatesh 2000). In the context of biometrics, privacy and security are primary concerns (or costs) while perceived usefulness is a primary benefit. Trust in the institution is also a relevant factor that could impact the attitude of biometric use in this context.

3.1 Privacy and Security Concerns

Flavián and Guinalíu (2006) see the concepts of privacy and security as highly interrelated. “Privacy is linked to a set of legal requirements and good practices with regard to the handling of personal data...Security refers to the technical guarantees that ensure that the legal requirements and good practices with regard to privacy will be effectively met. For example, the company may promise that the data will not be given to third parties without the consumer’s consent. Yet hackers might get hold of the data and hand them over to malefactors. His invasion or privacy can only be prevented by the use of suitable security measures” (Flavián and Guinalíu 2006, p.604). It is these types of nuances between the two concepts that make it unclear in the minds of consumer as to where privacy ends and security begins. This lack of distinction on the part of consumers may be due to their perception that it is not relevant to them and perhaps too technical (D’Hertefelt 2004). This confusion has been further exacerbated by legislators and companies (Flavián and Guinalíu 2006).

Throughout e-commerce adoption literature, the related aspects of privacy and security have garnered considerable attention (Park and Kim 2003, Flavián and Guinalíu 2006). It has been empirically established that, despite the tremendous growth in e-commerce over the recent past, it would be that much greater if privacy and/or security issues were addressed more adequately in the eyes of the consumer (Park and Kim 2003). It is estimated that, in 2000, online retail sales were reduced by $18 billion due to privacy concerns and that 92% of households with internet access do not trust online companies to keep their personal information private (FTC 2000). Over two thirds of Americans are concerned about cyber crime and hackers (McCrohan 2003). In another study, 52% of respondents simply abandoned an online purchase over privacy concerns (Ranganathan and Grandon 2002). If consumers are reluctant to provide information to e-vendors, it is reasonable to surmise that consumers will regard the request for biometric information from their financial institution with even more concern, as biometrics are extremely personal by definition.
Given the preceding discussion, perhaps the semantic distinction between privacy and security is immaterial to consumers. Therefore, perhaps treating privacy and security concerns together is a more appropriate approach. Similarly, this interdependence of related yet different elements with no overriding single concept, also suggests that the construct is formative. To test whether this was the case, a survey was conducted that asked 402 people to answer an open-ended question as to their concerns with respect to using biometrics for identity verification at ATMs. Of the 253 respondents that identified privacy and/or security concerns, almost 60% cited multiple considerations that drew from security and privacy dimensions. Based upon the results of this survey, privacy and security concerns were operationalised as a single, formative construct and used items based upon those given by Pavlou & Liang & Xue (2007). As the findings that privacy and security concerns do impact consumer use of the internet for banking and purchases, combined with the highly personal nature of biometric information, the following hypothesis is proposed:

**H1:** Individuals with a higher degree of privacy and security concerns will demonstrate a less positive attitude towards adopting biometric verification technology for accessing their bank account(s).

### 3.2 Perceived Usefulness

An individual’s perception with respect to the usefulness of technology has been demonstrated to be a key determinant in shaping an individual’s attitude towards the behaviour of adopting said technology (Davis 1989). Perceived usefulness has also been shown to influence consumer intention to adopt the Internet as a shopping channel (Gefen & Karahanna & Straub 2003). Using biometric identity verification in financial transactions holds several potential benefits to consumers including convenience, speed, and improved security. Hence, perceived usefulness should have a positive influence on consumers’ attitude towards using this technology. Therefore, the following hypothesis is proposed:

**H2:** Individuals with a higher degree of perceived usefulness will demonstrate a more positive attitude towards adopting biometric verification technology for accessing their bank account(s).

Within the context of biometrics, consumers must weigh the perceived usefulness of biometric verification against concerns they may have with respect to disclosing this type of highly personal information. Featherman and Pavlou (2003) demonstrated that consumer beliefs about risk reduce not only their intention to use an e-service, but also their perceived usefulness of this service. As surrendering any personal information exposes oneself to both potential privacy and security risks, and given the highly personal nature of biometric information, the following hypothesis is proposed:

**H3:** Individuals with a higher degree of privacy and security concerns will demonstrate a lower degree of perceived usefulness towards biometric verification technology for accessing their bank account(s).

### 3.3 Trust

Consumers will be more willing to interact with and purchase products from a vendor if they can trust that the vendor’s word can be relied upon that their vulnerabilities will not be exploited (Geyskens & Steenkamp & Scheer & Kumar 1996). For example, there is a wealth of empirical research suggesting that a heightened perception of trust positively influences consumer attitudes and intentions to purchase from a website (McKnight & Choudhury & Kacmar 2002, Gefen et al. 2003, Hassanein and Head 2007).

Considering the reluctance of consumers to share personal information with e-vendors, one would presume even more dissonance could be evoked by their financial institution’s request for biometric information as a means of identity verification. Just as trust is a salient belief when dealing with e-vendors in general, and when sharing personal information in particular, it is reasonable to suggest that trust could also play a significant role in whether or not consumers would be willing to surrender their biometric information in order to access their bank accounts. For example, trust has been shown to
increases one’s intention to share personal information with an e-vendor (McKnight et al. 2002). Thus the following hypotheses are presented:

**H4a:** Individuals with a higher degree of trust in their bank will demonstrate a more positive attitude towards adopting biometric verification technology for accessing their bank account(s).

**H4b:** Individuals with a higher degree of trust in their bank will demonstrate a lower degree of perceived privacy and security concerns with respect to using biometric identity verification technology for accessing their bank account(s).

The above discussion and hypothesis considers the dimension of trust towards the consumer’s bank, or what McKnight et al. (2002) refer to as institutional trust. Various studies have demonstrated that an antecedent to institutional trust is predisposition to trust (Dinev & Bellotto & Hart & Russo & Serra & Colautti 2006, Kim & Ferrin & Rao 2008). As the phrases imply, institutional trust is contextual and/or specific to an entity, while predisposition to trust is a person’s tendency to be generally trusting irrespective of specific contexts and/or entities. People with a higher tendency to trust in general typically demonstrate a higher degree of trust in a specific entity; conversely, people that have a lower tendency to generally trust are likely to demonstrate a lower degree of trust in a specific entity (Dinev et al. 2006, Kim et al. 2008). Also, extending the reasoning above that institutional trust may reduce perceived privacy and security concerns, it is reasonable to suppose that predisposition to trust may have the same effect. Therefore, the following hypotheses are proposed.

**H5a:** Individuals that have a greater predisposition to trust will demonstrate a higher degree of trust towards their bank.

**H5b:** Individuals that have a greater predisposition to trust will demonstrate a lower degree of perceived privacy and security concerns with respect to using biometric identity verification technology for accessing their bank account(s).

### 3.4 Personal Innovativeness in Information Technology (PIIT)

Based upon the marketing literature, Agarwal and Prasad (1998) define Personal Innovativeness in the domain of Information Technology (PIIT) “as the willingness of an individual to try out any new information technology” (p. 206). They suggest that people with higher PIIT are more likely to experiment with IT innovations, demonstrate a higher degree of comfort, confidence, and expertise in their evaluation process, and are usually first to adopt them (Featherman & Valacich & Wells 2006). In addition, early adopters of new technology tend to be more comfortable with increased levels of uncertainty and, by extension, tend to be risk takers (Rogers 1995, Agarwal and Prasad 1998). Thus, individuals with higher PIIT are more likely to take risks; and as the use of biometrics for identity verification may be perceived as risky, in the minds of consumers, due to the potential breach of privacy and/or security, the following hypothesis is proposed.

**H6:** Individuals that have a higher degree of PIIT will demonstrate a lower degree of perceived privacy and security concerns with respect to using biometric identity verification technology for accessing their bank account(s).

The proposed research model and hypotheses 1 through 6 are depicted in Figure 1 below.
3.5 The Roles of Control and Voluntariness

Control is seen as “central to the concept of privacy.” (Van Dyke & Midha & Nemati 2007 p. 68) This position is also held by Fried (1984), who states (p. 209): “Privacy is not simply an absence of information about us in the minds of others, rather it is the control we have over information about ourselves”. Information privacy may be defined as the right that individually identifiable information not be disseminated to other individuals or organizations without consent; however, in cases where personal information is held by another party, the individual should be able to exert substantial control over both the data and its use (Clarke 1999). Most consumers define privacy as “ownership and control of personal information.” (Acquisti and Grossklags 2005, p. 28) Singh (2006) sees it as a lynchpin connecting a variety of interrelated constructs. “[The] control of personal information connects security, trust, privacy, and identity.” (Singh 2006, p. 74) While there are a variety of divergent views of where control, and/or empowerment, lies in relation to privacy, research suggests that it is extremely salient in the minds of consumers when deciding whether or not to part with their information (Olivero and Lunt 2004). Within the context of biometrics, one would expect to see the same results, especially given their highly personal and sensitive nature. Therefore, the following hypotheses are proposed.

H7: Consumers with a higher degree of control over their biometric data will have a more positive attitude towards the use of biometric identity verification technology for accessing their bank account(s).

Voluntariness may be defined as “the extent to which the adoption of an innovation is perceived to be under an individual’s volitional control” (Plouffe & Hulland & Vandenberg, p.68). Voluntariness has been demonstrated to influence technology adoption intention in work environments (Venkatesh & Morris & Davis & Davis 2003) and with respect to smart card-based electronic payment systems (Plouffe et al. 2001). Extending this concept to the current context, we hypothesize that:

H8: When the use of biometric identity verification for accessing one’s bank account(s) is voluntary, consumers’ attitude towards its use will be more positive than where it is involuntary.

4 METHODOLOGY

4.1 Experimental Design and Procedure

Most biometric verification applications are not yet widely used and/or available such that they have not been experienced first hand by consumers. Therefore, scenario-based research is appropriate for this investigation (Sheng & Nah & Siau 2006). Additionally, the scenario method allows the researcher to ascertain which of the contexts examined will have a higher degree of acceptance to consumers (Bria & Gessler & Queseth & Stridh & Unbehaun & Wu & Zander 2001, Sheng et al. 2006). This has implications for both researchers and practitioners. In the case of the former, it will add to theoretical understanding and highlight those areas that should be examined further; and for the latter, it will allow for better decision making in terms of the allocation of scarce resources (Bria et al. 2001, Sheng et al. 2006).

Control and voluntariness were the two factors (each with two levels) manipulated in the scenarios presented to subjects in this study. The concept of the consumer having less control was operationalised as the bank maintaining a consumer’s complete biometric; while more control was operationalised as the bank maintaining half the biometric identifier while the consumer retained the other half of their biometric identifier on a smart card. Voluntariness was operationalised as the consumer having the option of using biometric identity verification or a debit card to gain access to their ATM, while involuntariness was operationalised as the bank using only biometric identity verification for ATM use. In order to minimize potential bias as respondents moved from one scenario to the next while answering the same questions, a between subjects design was used in which respondents were given only one of the four scenarios (Keppel 1991). In addition, respondents were
asked the questions regarding predisposition to trust, PIIT and trust in the bank prior to being given their scenario in order to establish the level of these traits independent of the scenario, thereby reducing any potential bias the latter might have on these pre-existing conditions.

4.2 Subjects

Subjects were recruited from the MBA programs of two major Canadian universities and included both fulltime and part-time students. To participate in the study, subjects had to 1) be over 18; 2) not work for a bank; 3) have a bank account; 4) live in Canada; and 5) use an ATM at least once a month. Participants were randomly assigned to the four scenario groups. Approximately 700 students were contacted which ultimately yielded 275 usable surveys. Of the 275 respondents, 160 were male and 115 were female. In terms of age, 65 were 18-24 years old, 159 were 25-34 years old, 43 were 35-44 years old, and 8 were 45-54 years old. The response across the scenarios was relatively even. Scenario 1, 2, 3 and 4 had 77, 59, 72 and 67 usable surveys respectively.

4.3 Instrument Scales and Validation

With the exception of Privacy and Security Concerns, which is a formative construct, all the other constructs in the proposed model of Figure 1 are reflective. In the case of formative constructs, indicators are considered to cause the latent variable and, as such, the direction of causality is from the indicator to the construct. In the case of reflective constructs, the reverse is true (Kim et al. 2008). This has ramifications with respect to evaluating construct quality and validity. In the case of reflective constructs, the use of principal components analysis and the examination of factor loadings, cross-loadings, average variance extracted (AVE), Cronbach’s α-values, etc., are required to evaluate convergent and discriminant validities. Such is not the case with formative constructs as their indicators do not need to correlate and are assumed not to co-vary. In fact, formative constructs must be examined for multicollinearity since, if the items are too highly correlated, then they are essentially measuring the same thing (Bollen 1989).

To evaluate the external validity of the Privacy and Security Concerns formative construct, both linear regression and a PLS model were run using a two construct Multiple Indicators, Multiple Causes (MIMIC) model (Diamantopoulos and Winklhofer 2001, Jarvis & MacKenzie & Podsakoff 2003). A linear regression was run using ten indicators for Privacy and Security Concerns (obtained from a variety of literature sources and through experts in the field) as independent variables and the mean of the Attitude items as the dependent variable. Using the suggested cutoff value of 3.3 for variance inflation factors (VIF) (Diamantopoulos and Siguaw 2006), four items of the initial ten items were eliminated. The remaining six items had VIF values ranging from 2.07 to 3.24.

A two construct MIMIC model was developed in PLS using Privacy and Security Concerns (with the six items that remained as a result of the linear regression) as the exogenous construct and Attitude as the endogenous construct. This construct demonstrated good composite reliability (0.967) as well as a significant path coefficient (β = -0.711, t-stat = 20.689) on Attitude.

Looking at the reflective constructs, PIIT, Predisposition to Trust, Trust, Perceived Usefulness and Attitude came from existing literature (Table 1), where they had been repeatedly shown to exhibit strong content validity. Convergent validity was assessed using a principal factor analysis with Varimax rotation, as shown in Table 2. Hair & Anderson & Tatham & Black (1995) suggested that an item is significant if its factor loading is greater than 0.50. Using this threshold, one item (Usefulness 4) was dropped due to high cross-loadings with other constructs. Construct reliability was also assessed using Cronbach’s α-values. As shown in Table 2, α-values ranged from 0.818 (for Trust) to 0.956 (for perceived usefulness). Nunnally (1978) recommends that the Cronbach α of a scale should be greater than 0.7 for items to be used together as a construct. Therefore, all our reflective constructs passed the test of construct reliability. Furthermore, discriminant validity is demonstrated in Table 3 as the square-roots of AVE (the diagonal values) are greater than the cross-correlations, as per Fornell and Larker’s (1981) criteria.

5 RESULTS

The model proposed in Figure 1 was tested using SmartPLS (v 2.0.M3). The results are shown in Figure 2 and summarized in Table 2. Approximately 66% of the variance in the attitude towards adopting biometric verification technology for accessing bank accounts was accounted for by the variables in the model ($R^2=0.661$). All path coefficients of the causal links in our hypothesized model are significant. These findings support hypotheses 1 through 6 at a minimum $p<0.05$ level.
Figure 2. The proposed structural model

Table 4. Hypothesis validation for structural Model

Based upon the results of an ANOVA test comparing the means of Attitude towards using biometrics for identity verification at ATMs, control does have a significant impact, \( (F = 8.328, p = .004) \) which supports H7. In the situation where an individual’s biometric information resides exclusively with the bank, the Attitude mean is 4.054 versus a mean of 4.560 when part of the information resides with the bank and part is maintained by the customer in the form of a smart card. The same cannot be said with respect to voluntariness. The results of that ANOVA test comparing the means of Attitude when the customer has a choice as to whether or not they will use biometrics as a method of identity verification versus it being made mandatory demonstrated that choice had no effect \( (F = 1.339, p = 0.248) \). The mean Attitude score with biometrics being involuntary was 4.182 versus 4.387 with it being voluntary. Therefore, H8 was not supported.

In a further analysis, an ANOVA test was run with scenario as the fixed factor and Attitude mean as the dependent variable. Interestingly, the scenario in which Attitude was the highest (mean = 4.674) was scenario 2, in which the consumer shared control of their biometric information, but participation was mandatory. Scenario 4 (shared control and voluntary) had the second highest Attitude score (mean = 4.459), scenario 3 (bank control and voluntary) was third (mean = 4.319), and scenario 1 (bank control and involuntary) was a distant fourth (mean = 3.805). In addition, the post hoc Bonferroni test shows that the attitude means between Scenario 1 and Scenario 2 are significantly different, as are the attitude means between Scenario 1 and 4.

6 CONCLUSIONS

From an academic perspective, this research makes important contributions by developing and validating a research model for consumer acceptance of biometric identity verification in financial transactions. This acceptance was also tested under various conditions (i.e. control and voluntariness) using a scenario based approach. The empirical results of this research represent an important first step in understanding consumers’ attitudes towards using biometrics as a means of identity verification in
financial transactions. Some interesting and salient findings from this study, which can spur future research and provide initial direction to practitioners, include:

- The significant negative influence of privacy and security concerns on both attitude and usefulness suggest that the threat of biometric information being compromised, either inadvertently (i.e. a security breach) or intentionally (i.e. being shared with other entities) is a top-of-mind issue for consumers. Banks wishing to employ biometric verification should target their marketing campaigns at educating consumers with respect to the superiority of biometric technologies relative to other forms of identity verification, as well as addressing any concerns about what is actually stored (e.g. encrypted version of fingerprint as opposed to actual fingerprint image).

- It appears that consumers understand the value of using biometrics for identity verification at their banks. However future research should explore if the positive effect of usefulness upon attitude outweighs the negative effect of privacy and security concerns, under varying scenarios and contexts.

- Institutional trust was found to influence attitude both directly and indirectly. While the direct impact of institutional trust on attitude was significant (p<.05), it appears to have a more indirect influence through privacy and security concerns. This mediation effect should be examined further in future research, under varying scenarios and contexts.

- As expected, an individual’s predisposition to trust and personal innovativeness in the domain of information technology had a significantly negative effect on privacy and security concerns. Hence, privacy and security concerns of biometric use for bank account verification are somewhat mitigated for individuals that are more trusting in nature and/or more daring to try new technologies. This could have implications for which segment of customers banks would choose to market their biometric verification programs to first as early adopters.

- Consumer’s attitude towards using biometric identity verification at their banks was significantly higher when they felt they had more control over their biometric data (by sharing the biometric data so that banks only kept a partial piece of their biometric). The same was not true for voluntariness. However, when voluntariness was combined with control to generate four scenarios, there was an impact. In particular, when enrolment in a biometric verification program was voluntary, the effect of control was negligible. While further investigation is needed to fully understand this phenomenon, one explanation could be that when the program is voluntary, the aspect of consumer control becomes less relevant. Alternatively, the fact that the entire program is voluntary gives the consumer de facto control in the sense that they don’t have to use it in the first place. The interaction of control and voluntariness could provide for some interesting future research that could provide practitioners with valuable insights of deploying biometric verification technologies.

As with any study, there are limitations. In this study, fingerprints were used as the method of identity verification. Given their association with the criminal element, this biometric may make consumers feel they are being equated with criminals which might have impacted their responses to our survey. That being said, there is the potential that any biometric could result in similar misgivings (e.g. people may worry about the long term medical implications of iris and retinal scans). The sample for this study consisted of graduate business students which limits generalizability. Also, this study was conducted in Canada where biometrics use in consumer applications is virtually non-existent and there are no national identity cards. It would be worthwhile doing an international study that varied these two aspects as some countries do have very strict national identity card programs and/or use biometrics for various government and private sector applications.

Abstract

The present study explores the relationship between the e-business maturity and the perceived benefits from (Information and Communication Technologies) ICT at the firm level. We aim to debunk this relationship in terms of its strength and stability, and to explore the conditions which may influence it. Taking an economic approach, we hypothesise that the relation between e-business maturity and perceived benefits from ICT adoption will be influenced the costs of intra-organisational adaptations due to ICT. Using data from an European survey on ICT adoption and e-business maturity of the firms (N=7,072) we show that the correlation between the e-business maturity and the perceived benefits from ICT adoption is indeed positive, significant and stable over countries, industries, firm size and age. Further, the findings confirm the hypothesis that intra-organisational adaptations due to ICT moderate the positive correlation between a firms’ e-business maturity and perceived benefits from ICT.

Keywords: e-Business maturity, ICT adoption, perceived benefits, European survey.

1 INTRODUCTION

Recent international studies reveal that European countries are in the highest ranks of e-readiness and ICT growth rates (Economist Intelligence Unit, 2006; Economist Intelligence Unit, 2008; EITO, 2007). Still, the adoption of ICT within Europe strongly varies between countries and sectors. Over the last decade, the European and national policies particularly focus on stimulating ICT adoption by the small and medium sized enterprises, the SMEs (Castaings and Tarantola, 2008; Castaings et al., 2007; European Commission, 2002; Nardo et al., 2004; Renner et al., 2008). This sector structurally lags behind the ICT diffusion rates of large firms. Although from a scale perspective this might not seem a problem *per se*, the more fundamental problem observed is the low awareness, or even mistrust, of SME firms about the potential benefits of IT (Lucchetti and Sterlacchini, 2004). The problem, an over-critical and sceptical attitude towards the potential benefits of ICT, is not only a matter by SME firms. It actually draws back to the many uncertainties when investing in ICT, both at the costs and benefits side. Although the ‘productivity paradox’ (Solow) and ‘IT doesn’t matter’ (Carr) discussions have passed, still the number of studies that report failure of the ICT adoption and implementations remain large (cf. Ward and Peppard, 2003). Quite ironically, the national governments that firmly stimulate the uptake of ICT, represent organizations that particularly seem to fail in getting value from ICT. The Dutch government for example, struggle with several public examples of ICT disasters and mis-planning (Court of Audit, 2008).

So from both a policy and scientific perspective, a key challenge within area of IS adoption and uptake is to improve the understanding of how managers actually *perceive* the benefits from ICT adoption, and how this relates to their actual investments in ICT, e.g. e-business applications. It seems obvious that the firms which have invested much in ICT may perceive more benefits from these investments than the others, but this relationship is not trivial. There are firms which might have ‘under-invested’
in ICT, while there are other firms which might have over-invested in ICT. In the context of IS adoption research, the current market observations raise some questions about the nature of the relationship between the investment (i.e. ICT maturity) and the perceived benefits for the different types of firms.

The present study builds upon the increasing knowledge about organisational adoption of ICT (for a thorough review see Venkatesh et al., 2003), and economic analysis of ICT in the organisational context (Zhu and Kraemer, 2005). Motivated by these two perspectives, we conduct a comparative analysis of European firms’ perceptions of benefits and impacts of ICT and their e-business maturity. Empirical data from the e-Business W@tch project, a cross-national survey sponsored by the European Commission among 7,000 firms from 10 different EU-countries, are used. The main research objective is addressed by two research questions:

- How do the perceived benefits of ICT adoption relate the e-business maturity of the different types of European firms?
- How does intra-organisational impact of ICT affect the relation between the perceived benefits of ICT and the e-business maturity?

In order to answer these research questions we develop hypothesis and measurements that enable us to describe and explain the European landscape of e-business maturity. The study contributes to the IS adoption research by shedding some light on the relationship between perceived benefit of ICT and e-business maturity, while exploring potential differences in the relationship for firms from different countries, industries as well as firms of different size and age. The study results indicate a positive relationship between the e-business maturity and perceived benefits from ICT adoption which is moderated by the intra-organisational adaptations due to ICT. The positive relationship is stable across firms from different countries and industries and despite their different size and age.

The paper is structured as follows. The next section presents a brief literature review of the adoption theories and models and the economic elements used in the proposed research. Then the data and measurements of the study are described. The following section presents results from the bivariate and the multivariate analysis. The paper concludes underlining the main findings, limitations and proposing some future research directions.

2 THEORETICAL CONTEXT

2.1 Some basic theoretical insights on the adoption of ICT

One of the most widely used theories in the Information Systems, which attempts to explain the reasons behind innovation adoption, is diffusion of innovation (DoI) (Rogers, 1995; 2003). DoI (1995) has been used to study the adoption of many computer-related technologies. The model contains four main elements: innovation, communication channels, time, and the social system. Rogers’ model is prominent in addressing the role of change agents, individuals who influence clients’ innovation-decisions in a direction deemed desirable by the change agency (2003).

Since e-business systems involve high costs for the organisation, the adoption decision is an authority innovation-decision type. This means that the decision to adopt or reject the system is made by a relatively few individuals in the organisation who possess status, power, or technical expertise (Rogers, 1995). The top management in the organisation is mostly involved in the selection of e-business systems and in charge of providing the resources for its implementation. They delegate other decision-making tasks to other members of the organisation. Besides, they can influence the way the rest of the organisation views the system and its changes.

According to Rogers (2003), and other rational diffusion theorists (Agarwal and Prasad, 1997; Moore and Benbasat, 1991), there are certain characteristics of innovations which affect their rate of adoption. These characteristics can be applied to e-business. First, the relative advantage of e-business solutions relates to cost savings in time and effort by improving business processes. Second,
compatibility of e-business solutions may relate to synchronization of data with suppliers and customers and increases the adoption probabilities. Third, e-business solutions may be characterised by complexity which decreases the adoption probability because of the high cost of implementation and customisation. Fourth, e-business solutions have a very limited trialability since they can only be seen in other adopter organisations, and this in turn decreases the adoption probability. Finally, observability is low for e-business solutions and this decreases the adoption probability. Most observations of e-business come from indirect paths such as media and hearsay. These sources usually give evaluations of e-business which are used in the decision making process.

Diffusion of innovation theory has been criticized for not taking into account the particularities of complex information technologies (Lyytinen and Damsgaard, 2001). The different approaches in the study of ICT diffusion (such as Baskerville and Pries-Heje, 2001; Cooper and Zmud, 1990; Edquist, 1997) seem to take a narrow perspective while emphasising specific topics of interest with no single theory being able to explain the particularities of the different technologies (Jones and Myers, 2001). Besides, researchers used theories from social psychology to investigate organisational adoption of the innovation. The most commonly used theories are Technology Acceptance Model (TAM) (Davis, 1989), the Decomposed Theory of Planned Behaviour (Taylor and Todd, 1995) and the Unified Theory of the Acceptance and Use of Technology (UTAUT) (Venkatesh et al., 2003). These models aim to explore the user attitudes or intentions, and thus technology adoption and use through various social, personal and technical constructs. However, they do not investigate the value elements affecting the adoption decision process or the economic implications from ICT adoption to the organisation.

The present study focuses on e-business applications and it uses theoretical insights from industrial economics to get further insight into ICT diffusion and the perceived value of ICT (Wilkins and Swatman, 2006). In particular, it builds upon the notion of relative advantage as postulated by Rogers and it investigates the firms’ perceptions of the benefits from ICT adoption and the relationship with e-business maturity.

2.2 An economic approach to ICT adoption and its perceived benefits

Most of the research on the adoption of an inter-organisational system (IOS) focuses on the expected operational benefits (e.g. Zhu and Kraemer, 2002). The firm using the Internet infrastructure to connect with other partners is expected to increase its operation efficiency, which in turn leads to more efficient information processing and a decrease in the transaction costs, search costs and other direct and indirect costs involved. These costs savings have been depicted as some of the expected benefits from the adoption of EDI systems as well (e.g. Zhu and Kraemer, 2002). Recently this theoretical discussion has been extended to include open standards IOS. In such case, additional benefits for the firm include the ability to find new partners and to exchange information, reaching new customers and expanding to new markets as well as the improvement of the value chain co-ordination (Zhu et al., 2006b).

The adoption of ICT products also involves network-related value (Kauffman et al., 2000). Research on industrial economics has highlighted the importance of increasing returns in the adoption of a new system (Arthur, 1989; Davis, 1992). In particular, there are positive network effects when the user’s value from the use of the system increases as the number of users at the same or compatible systems’ users increases, since the firm can exchange information with them (Katz and Shapiro, 1994). Network effects may accelerate or impede the diffusion process. For example a user of a legacy system, enjoying the benefits of network effects by exchanging data with other firms which adopted the old system, would expect to be able to maintain those benefits when using a new system. The adoption of a new incompatible technology may limit network effects for users of the old technology (Farrell and Saloner, 1986). Further, the compatibility between systems shifts the focus of attention from the overall services package, which includes the network size, to specific component cost and
performance characteristics (Economides, 1989; Katz and Shapiro, 1994; Matutes and Regibeau, 1988).

As firms gradually invest in e-business applications and they climb the e-business maturity ladder, they may increasingly experience the advantages and benefits from ICT adoption. Eventually, it has become a basic notion that it takes time to actually ‘see’ the benefits of ICT – especially with major ICT-investments such as ERP (cf. Poston and Grabski 2001). We expect that the same holds for e-business as a next wave in terms of ICT maturity (Ward and Peppard 2003). According to this notion the first hypothesis we propose for the present study is:

$H_1$: There is a positive relationship between firm’s perceived benefits from ICT and the level of e-business maturity.

ICT adoption may change business activities and it may create new opportunities or new needs for the firm. This in turn generates significant costs to the firm. Apart from the financial costs involved in the investment decision for the new system (e.g. Zhu et al., 2006a), the adoption costs are related to the managerial complexity and the risks involved for the firm changing processes when adopting the new system. We can refer to numerous studies that report about misinvestments because of underestimation of the organisational consequences of ICT (cf. for ERP: Hong and Kim, 2002; Rajagopal, 2002).

In a classic study, Brynjolfsson and Hitt (1995) show that firms only benefit from IT investments if they align these investments with their organisational structure. Specifically, they demonstrate that the firms which invested in computers and they decentralised organisational structure at the same time, outperformed other firms in terms of their market value. In line with these findings an extensive stream of literature on business/IT alignment emerged in the nineties, highlighting the importance of mutually adjusting the organisational/business domain and the IT domain (Henderson and Venkatraman, 1993; Luftman and Brier, 1999; Luftman and Kempaiah, 2007; Papp, 1998; Papp et al., 1995). Following the basic argument of Brynjolfsson and Hitt (1995), we expect that the relation between the perceived ICT benefits and the e-business maturity will be at least ‘blurred’ if firms experience intra-organisational changes due to the adoption of ICT. Intra-organisational adaptation may put a hold on the potential benefits of ICT. The firms that grow in ICT or e-business maturity without intra-organisational changes are likely to be those who had their processes and structures already in place. These firms may benefit relatively more and/or earlier from ICT, compared to those that are forced to execute significant intra-organisational adaptation. Hence the second hypothesis of the present study is:

$H_2$: The positive relationship between the perceived benefits and e-business maturity is negatively influenced by the perceptions of the intra-organisational impact of ICT

3 RESEARCH APPROACH: DATA AND MEASUREMENTS

3.1 The dataset

The data used for this study were collected by Empirica that coordinates the e-Business W@tch project of which a number of European wide surveys is an important part (Selhofer et al., 2008). The data collection was based on telephone (CATI) interviews with IT managers employed at firms from 15 different sectors. The e-Business W@tch survey project started in 2002 in the 15 EU member states at that time. New EU member states were included in later waves along with additional questions. Besides, the survey expanded to include additional industrial sectors.

Field work of the E-Business W@tch project was executed by national market research organisations. The standard procedure for each country was to sample enterprises that “were active at the national territory of the country”, “have their primary business activity in one of the sectors specified by NACE categories” and “can be defined as a business organisation of one or more establishments comprised as
one legal unit” (European Commission, 2008). Each national sample was drawn from “acknowledged business directories and databases” and stratified by economic activity (one or more of the NACE-defined economic sectors) and employee size. Size was of specific importance for stratification because the e-Business W@tch survey particularly aimed to estimate the accurate level of usage and adoption of IT for countries and industries. The company size was strongly correlated with the IT investments because of scale and scope of activities. In practice, three employee size strata were defined for each country and industry: to include a share of at least 10% of large companies (250 employees or more), 30% of medium sized enterprises (50-249 employees) and 25% of small enterprises (10-49 employees). Besides, the so-called “micro enterprises” with less than 10 employees were also included (by 35%).

This study used the 2006 e-business w@tch dataset. As country and sector are important variables for the analysis. Thus, it was ensured that the sectors surveyed in the 2006 wave were equally represented in each country. Besides, firms with 10 employees were selected. This resulted in a pre-selection (see Table 1) of 7,237 firms, from 10 different countries and 10 different sectors (i.e. Food = Food and beverages, Foot = Footwear, Pulp = Pulp and Paper, ICT = ICT Manufacturing, Elec = Consumer electronics, Ship = Shipbuilding and repair, Cons = Construction, Tour = Tourism, Tele = Telecommunications, Hosp = Hospital activities).

Table 1. Country and industry composition of the 2006 e-Business W@tch dataset used for this study.

According to Table 1, the spectrum of countries and industries seems to be sufficiently diverse to cover different national level of economic development, geographical spread, including a relevant spread of manufacturing versus service-oriented industries.

3.2 The measurements

3.2.1 E-business maturity

From the e-Business W@tch survey we selected 11 questions which addressed the use of ICT (web) applications to support inter-organisational (B2B) activities. The questions explored the inter-firm collaboration in general, or specific processes such as invoicing. The response scale was categorical including “Yes”, “No” or “Don’t know”. The latter category appeared in a small number of the cases (less than 2%), which were removed from the dataset. The 11 dichotomous variables were analysed on their inter-correlations, but as the different e-business applications were not logically interrelated, (e.g. firms might invest in one type of e-business without investing in another type) we did not aim at exploring the scalability or a latent factor model for this set of 11 dummy variables.

Table 2. Measurement of the E-business maturity concept: frequencies, inter-correlations and factor loadings of 11 indicators (N=7,237)

We added the scores of the 11 indicators to create one construct, which we labelled ‘e-business maturity’. Factor loadings from the PCA were used to allocate weights for the 11 indicators. According to Table 2, most of the e-business application were used by a minority of the firms (‘yes’ varies between 11% and 29%), except from the use of online ordering. This means that the constructed factor was skewed to the left-hand side of the distribution as nearly half of the firms answered ‘yes’ to none or only one of the 11 indicators (skewness=1.38, kurtosis=1.49).

3.2.2 Perceived ICT benefits

The e-Business w@tch questionnaire included questions asking the respondents’ perceptions of ICT benefits for their business on six different performance areas: (1) revenue growth, (2) business processes efficiency, (3) internal work organisation, (4) procurement costs of supply goods, (5) products and services quality, (6) customer service and (7) productivity. We considered these items as
indicators of one latent concept, and we explored whether they could be aggregated to a single e-business maturity scale. Principal Component Analysis (PCA) was first applied to test construct validity. The Kaiser-Meyer-Olkin test and the Barlett’s Test of Sphericity were used to determine whether the sample size was sufficient relative to the number of items, and the correlation matrix was not an identity matrix. Both tests were passed (KMO statistic is 0.894, Bartlett’s Test is significant, p <.001). As a result of the PCA, the one factor solution holds an eigenvalue of 3.75, while all factor loadings were above 0.50 and all inter-correlations were significant at the 1%-level (see Table 3 below). In addition, the Cronbach’s Alpha over the 11-item set, by 0.86, supported scale reliability (Nunnally and Burnstien, 1994).

3.2.3 Intra-organisational impact of ICT

The respondents were asked about the importance of ICT on four organisational aspects of their company: (1) the organisational structure, (2) task and job descriptions, (3) education and training of employees, and (4) outsourcing decisions. Categorical responses of “yes” and “no” were collected and analysed; while responses in the category “don’t know” were excluded. Again PCA, correlation and scale analysis were executed to explore whether these dichotomous items could be aggregated to one factor. Based the results (eigenvalue of the 1-factor model is 2.42, Cronbach’s Alpha is 0.78) a sum score factor was subsequently constructed (see Table 4).

3.2.4 Control variables

Control variables were treated as background characteristics of a firm which might potentially influenced either e-business maturity, or perceived ICT-benefits, or both. The control variables were:
- Industry type including 9 categories or branches (see Table 1);
- Country of firm’s location including the 9 countries represented in the dataset (see Table 1);
- Firm’s size, measured by the number of employees

The size indicated the ‘scale’ of a firm, which might be positively correlated with e-business maturity. The firm’s age might be correlated to e-business maturity, because the ‘older’ organisations might be restricted by earlier investments in pre-Internet technologies, and they probably employed older and less e-skilled employees. With regard to the relationship between industry and country on one hand, and e-business adoption on the other e-Business W@tch reports (European Commission, 2008) revealed Scandinavian countries and the UK were front-runners in e-business application. This might be related to the cultural differences and the public policies developed to stimulate technology and innovation. However, the effects of culture on the ICT adoption should be investigated by cross-national analyses (e.g. Miller et al., 2006; Van Everdingen and Waarts, 2003). Besides, industries such as the ICT manufacturing and telecommunications were known as early adopters of e-business because they involved products and services which were inherent to their own business domains (European Commission, 2008).

4 ANALYSIS: RESULTS AND FINDINGS

We first explore the relationship between e-business maturity and perceived ICT-benefits to test the first hypothesis (H1). Table 6 shows the (Pearson) correlations, controlling for country and industry by split sampling, and controlling for size and age by calculating partial correlations.

Table 6. Results from correlation analysis testing hypothesis H¹ (N=7,072)

All correlations are significant (p<.001). Controlling for firm size and age does not change the size of the correlation coefficient, nor does country and industry. These findings support the first hypothesis H¹ indicating that there is a positive correlation between perceived benefits from ICT adoption and e-business maturity of the firm.
Table 7 presents the results from the regression analysis, including the same variables. From the total sample column, we can conclude that hypothesis $H^1$ is confirmed again ($\beta = 0.327, p < 0.001$). To test the second hypothesis ($H^2$), we explore the influence of the intra-organisational changes due to ICT on the relationship between the perceived benefits and the e-business maturity. We primarily aim to test whether this influence is a moderator that affects the strength of the relationship between perceived ICT benefits and e-business maturity (Gonzalez-Benito, 2007). To this end we compare the explanatory power of the regression model for different stages of the moderator – i.e. the level of perceived intra-organisational impact of ICT. The dataset is split into three groups of equal size, distinguishing between organisations with relative low, medium and relative scores on the variable that measures the intra-organisational changes due to ICT. Table 7 presents the results.

Table 7. Results of OLS regression analysis testing hypothesis $H^1$ and $H^2$ (N=7,071)

$***$ p<.001; $**$ p<.01; $*$ p<.05

$^a$ Low = mentioned none of the four intra-organisational domains (see section 3.2.3); medium = mentioned one or two; high = mentioned three or four

$^b$ ICT manufacturing = category of reference, all other categories coded 0/1

$^c$ The Netherlands = category of reference, all other categories are coded 0/1

$^d$ log transformed

The three subsample analyses shows that with the three subsequent categories of intra-organisational impact of ICT, the strength of the relationship between the e-business maturity and the perceived ICT-benefits decreases (beta drop from +.26 to +.18). These findings support the hypothesis $H^2$. It should
also be noted that the explained variance of the total model decreases along the three groups (from 15% to 10%). Thus, the intra-organisational influence of ICT creates costs (e.g. due to the technology complexity), which moderates or counterbalances the perceived benefits of e-business maturity.

5 DISCUSSION AND CONCLUSION

The present study used survey data from over 7,000 European firms, to demonstrate that the organisations which have invested on ICT and display e-business maturity perceived more benefits from ICT than the firms with lower e-business maturity. This result is remarkably stable over 10 different European countries and 10 different industries. It also remains stable when controlling for age and the size of the firm. However, there might be firms which experience small benefits from ICT while having invested heavily in e-business. Those firms are a minority. Overall we can derive a quite a ‘positive message’ with regard to e-business development from the study’s results.

In this study we also found indications that when the ICT strongly influences intra-organisational domains of a firm the perceived benefits from ICT hold a weak relation with e-business maturity. This implies that firms should be made aware of the necessary organisational changes when adopting e-business applications. Depending on the ‘as it is’ intra-organization situation, the benefits from ICT may not be evident from the start, as they require resources, investments and – in terms of attitude – patience. Hence, the public policies should be focused on facilitating firms in handling both the respective benefits and costs from ICT adoption. In turn, if firms’ perceptions of the benefits related to ICT become more positive, this may further stimulate investments, ICT adoption and increase e-business maturity.

Limitations and further research

The empirical part of this research is based on a secondary analysis of an existing dataset (i.e. data from the organized 2006 E-business w@tch survey). A limitation is therefore that the measurements do not fully match the intended concepts from our hypotheses. This applies, for instance, to the limited number answer categories in measuring ICT adoption (‘yes’, ‘no’) and the general formulation of ‘ICT’ in measuring their perceived benefits. In further research these measurements could be improved by specifying the type of software or applications used, the history, intensity and goal of usage, and so on. Related to this, it is recommended to further validate scales to measure e-business maturity, perceived benefits from ICT and intra-organisational changes. As European firms become more mature in terms of ICT and e-business, this requires new maturity measurements and likewise new explanatory research frameworks (cf. Aryee et al, 2008).

In addition, also our results are subject to limitations, but provide drivers for further investigation. Table 6 showed that European countries only slightly differ in the correlation between e-business maturity and ICT benefits, but Table 7 displays different levels of perceived ICT benefits by country. This is an interesting subject to explore further, e.g. on the fact that e-business measurement is rightly assumed to be generic. It might be the case that respondents from different countries do differ in their level of technical knowledge to answer technology specific questions properly. Extending this study through cross-national comparison implies the analysis of other cultural and socio-economic factors on e-business adoption (Miller et al. 2006), maturity and perceived benefits from ICT (Agourram and Ingham, 2003).

Abstract

In this paper we discuss the challenges of dealing with interdependencies in complex assemblages of heterogeneous and interconnected information systems (IS), which we conceptualize as organization-wide information infrastructures. We draw on Perrow’s studies of complex technological systems, where interactions, mechanisms, and couplings are emphasized. We base our paper on an empirical case study from a Norwegian hospital, where a seemingly trivial project aimed at the introduction of scanners turned out to be more complex than expected. This we claim is partly due to the interdependencies and tight couplings between information systems, actors, and work practices in the hospital environment. The paper’s main focus is on describing what it entails in practice to deal with these interdependencies during and after implementation. We emphasize the work of sorting out and dealing with various types of interactions and couplings.

Keywords: Interdependencies, information infrastructures, couplings, health care.
1 INTRODUCTION

Organizations today rarely operate with isolated, task-specific information systems (IS). In general, they have interconnected collages of multiple and different systems, intended to support multiple work tasks, interaction and communication (Ciborra 1997; Star 2002). Some systems can be large, monolithic, and generic, such as enterprise systems, whereas others can be smaller and more dedicated. Legacy systems abound and thus the collection of systems span several technological generations. In addition, there is usually some degree of attempted, achieved or at least wished-for integration of these systems (Hasselbring 2000).

Much has been written about the implementation and use of IS in organizations. Studies have looked at changes in organizational practices (Vaast and Walsham 2005), collaboration and communication flows (Avgerou et al. 2004), and power structures (Robey and Boudreau 1999; Silva and Backhouse 2003; Howcroft and Mitev 2000) with the implementation of IS. Furthermore, researchers have studied the meanings that users ascribe to technology and how users’ attitudes and perceptions relating to new technology are socially shaped (Orlikowski and Gash 1994; Davidson 2006). In the existing literature on IS implementation and use, however, we only find limited accounts of how new IS are related to and get intertwined with the existing portfolio of systems in the organization, also known as the installed base already in place and conceptualized as information infrastructures (Ciborra et al. 2000; Star and Ruhleder 1996). In contrast to isolated and task-specific information systems, information infrastructures pose particular challenges for the organization (Hanseth and Lyttinen 2004; Monteiro and Hanseth 1995) as they are characterized as being large, complex, heterogeneous, and emergent. There has been surprisingly little emphasis on the impact of interactions and tight couplings between the various systems that make up the information infrastructure.

In this paper we address the challenges of extending the existing portfolio of systems already in place in the organization, and of reorganizing work routines accordingly. We consider the installation and post-installation period where a new technology is to be integrated into current work practices (Jasperson et al. 2005). We emphasize the role of interdependencies and tight couplings between the new system and the pre-existing information infrastructure. The paper’s main focus is on describing what it entails in practice to deal with these interdependencies during and after the implementation of new technology.

We illustrate these challenges by analyzing a case study from health care, where the issues of managing multiple IS (each of which contains parts of the relevant patient information) are highly relevant. We report on findings from a longitudinal study following the introduction of an Electronic Patient Record (EPR) system at a major Norwegian hospital. Most of the empirical material presented here comes from a seemingly trivial project where scanners were introduced in order to scan paper documents. The project turned out to entail more deep-going organizational changes and to be more time-consuming than expected. This we claim is partly due to the interdependencies and tight couplings between IS, actors, and work practices in the hospital environment. Issues such as these, we believe, constitute one significant reason for why the digitization of health care is complex and has been protracted. Consequently, we wish to examine this complexity that is evident even with seemingly simple projects.

For this we employ the information infrastructure perspective, which is presented in the next section. This is followed by a presentation of concepts used by Charles Perrow that help us conceptualize and discuss issues related to complex technological systems. Next, we present the research approach and the empirical case study, and finally we discuss the findings and their implications for the field of IS implementation studies.
2 ORGANIZATION-WIDE INFORMATION INFRASTRUCTURES

We base our work on a theoretical perspective that has its focus on the complexity of socio-technical assemblages. The information infrastructure perspective, as presented by e.g. Hanseth and Lyytinen (2004) or Monteiro and Hanseth (1995), has been developed to address the large-scale, heterogeneous, interconnected collections of systems. This way of conceptualizing the phenomenon emphasizes the long-term, gradual development of an information infrastructure. Rather than being implemented, it evolves over time through expansion, extension, and replacements. It is a socio-technical and heterogeneous collection of elements and it encompass much more than just the technological infrastructure. Star and Ruhleder (1996) argue that information infrastructures extend beyond human skills and materiality to include social, organizational, as well as moral elements. In contrast to the notion of IS, an information infrastructure is used by many for different purposes, not just one specific task. Thus an organizational information infrastructure is not “discrete, stable, independent and fixed” (Orlikowski and Iacono 2001), but multiple, evolving, and interconnected. Often information infrastructures span multiple inter-organizational contexts where they mediate interactions among several organizations (Gal et al. 2007).

Interventions in interconnected and complex environments can only be planned and rationally executed to a limited degree. Studies of information infrastructures tend to describe unintended effects of actions and the consequential slippage and “drift” of the processes and results (Ciborra et al. 2000). The same kind of phenomena is emphasized in the improvisational model for change (Orlikowski and Hofman 1997), which is claimed to be particularly relevant for open-ended and customizable technologies. Orlikowski and Hofman emphasize that implementing new information systems is not a one-time event, but an ongoing learning and adaptation process. Everything cannot be anticipated ahead of time, but the degree, depth, and complexity of changes is only fully understood when implementation is underway. Consequently, they see the resolution to this as lying in approaches that “enable organizations to systematically absorb, respond to, and even leverage unexpected events, evolving technological capabilities, emerging practices, and unanticipated outcomes. Such a model for managing change would accommodate – indeed, encourage – ongoing and iterative experimentation, use, and learning. Such a model sees change management more as an ongoing improvisation than a staged event.”(Orlikowski and Hofman 1997, p. 12)

In this paper we emphasize the need for such adaptive or learning-oriented approaches when dealing with the interconnectedness of the organization-wide information infrastructures. In order to analyze the nature and consequences of the interdependencies, we have chosen to draw on Charles Perrow’s conceptualization of complex socio-technical systems, where the role of complex interactions and tight couplings is emphasized (Perrow 1984). In laying the ground for the “normal accidents theory”, Perrow conceptualizes complex systems along two axes:

- The first axis concerns the character of interactions between the parts or elements of the system. The different parts of the system (e.g. organizational units) may collaborate through simple, linear relations. The linear interactions are expected and planned, and they stand out as clearly visible and understandable. Alternatively, the parts may collaborate through more interactively complex mechanisms with multiple dependencies and feedback loops. The complex interactions are unfamiliar, unplanned, and unexpected. They are not visible and not easily comprehensible (Perrow 1999 [1984], p. 78).

- The other axis concerns whether the linkages between the parts of the system are loose or tight. If the linkages are tight it means that action at one location has immediate and given effects elsewhere. When for instance the steps of action are tightly prescribed in advance, or when there is no slack in the production that allows for flexibility in handling disruptions, we have a tightly coupled system. On the other hand, a loosely coupled system may be slower to respond to interventions, but also more robust with respect to fault recovery due to its slack and buffer resources.
Perrow exemplifies how systems can differ with respect to their type of interactions and couplings along the two axes. For instance, a post office is characterized as a routine bureaucracy where the interactions between work practices, actors, and information systems are relatively linear and loosely coupled. In such a system, the order of sequences is straightforward. Changes in one part of the system can take place without having any prominent impact on other parts, e.g. mail can pile up without undue alarm. In contrast, a power grid system is also linear but tightly coupled, and disturbances in one network segment will immediately affect the other segments. Perrow suggests that universities are examples of organizations that exhibit complex interaction mechanisms, but are loosely coupled, while a nuclear plant is characterized by complex interactions and is also tightly coupled. Many unexpected interactions are possible and changes in one part of the system may have considerable consequences in other parts. This insight is the basis for Perrow’s major thesis that accidents are unavoidable (hence “normal accidents”) if the systems are complex and tightly coupled.

In this paper we use the information infrastructure perspective to define our research object: we do not study one single stand-alone information system, but rather an extended, socio-technical network that evolves gradually over time. We complement this view with the concepts of interactions and couplings used by Perrow to discuss the complexity in various forms of socio-technical organizations. We see Perrow’s concepts as helpful because they complement the information infrastructure theory with a more fine-grained “lens” to examine the interdependencies of the different parts in information infrastructures. Also Perrow’s conceptualization reminds us that different “configurations” of the socio-technical imply different forms of complexity and may have different effects. In the following we illustrate how the aspects of interaction mechanisms and couplings in the organization-wide information infrastructures had a practical impact on the implementation of a small project.

3 RESEARCH METHOD

Our empirical material emerged from longitudinal research collaboration between researchers at the University of Oslo and the IT department at a major Norwegian hospital in Oslo (Rikshospitalet, Oslo). The hospital is a highly specialized university hospital with regard to complicated treatments. In 2006 it had almost 8000 employees and treated more than 300 000 patients.

As a part of the implementation of an Electronic Patient Record (EPR) system at the hospital, a scanning project was initiated in 2003. This project was studied from November 2003 to October 2005. The study site was one of the four pilot departments – the Women’s Clinic, one of the largest departments at the hospital and a major user of the patient record archive’s services. The first author conducted seven formal interviews with the project management group and with staff from the IT and archive department. These interviews focused on the project’s progress and the interviewees’ perceptions of obstacles and opportunities. The interviews lasted for between 45 minutes and 1.5 hours and were usually taped and partly transcribed.

The study of the scanning project was a “side activity” related to a more structured and general study of the EPR implementation. This meant that no new formal research project was defined, and the access to the field site was more informal. For instance the researcher participated in 6 meetings at one of the pilot departments for the project and in return for access wrote minutes from the meetings. Some of the meetings were project meetings where IT staff was present, while others were internal meetings with only staff from the department. In addition, the researcher assisted the personnel in compiling detailed information about document flows in the department and documented the actual scanning work through time studies, including existing errors and problems etc. These results were fed back to the department and the project management. In total 17 hours of participant observation were conducted, and during this work a number of informal conversations were carried out; these added to the background perception of the process. Based on transcriptions of the interviews and field notes, we built a storyline of the scanning project and analyzed the material on the basis of the conceptualizations that we have presented above.
4 THE STORY LINE OF THE SCANNING PROJECT

4.1 Background of the case study

The transition from a paper-based patient record to a complete EPR system started in 1996 with a few departmental installations of the EPR system. The process was delayed because the hospital moved into new facilities in 2000, but in 2001 the EPR system was installed in all clinical departments.

The functionality of the EPR system, however, did not allow it to fully replace the previous paper-based system. The EPR consisted to a large extent of textual information and a large part of relevant clinical information was still on paper or stored in other specialized systems. Due to this, the legally valid record was still the paper-based record and all entries in the EPR were thus printed on paper and archived with the corresponding paper patient record. The vendor seemed unable to deliver updated and improved versions within the time frame expected by the hospital (contractually, the EPR system should have been fully developed by 1999). In 2003, this situation caused a critical space problem in the archive. Only limited space was allocated to the central archive in the new facilities as it was expected that a fully functional EPR system would be in place. While waiting for the full version of the EPR, the hospital management decided to scan both the existing patient record files in the archive and the individual paper documents in the clinical departments to decrease the paper flow to the archive.

The Scanning Project started in the spring 2003 with a bid for tender on scanners as well as software that imported the scanned documents into the EPR system. The plan was to select, test and finalize a solution over the summer, start the scanning in early autumn, and stop the flow of paper documents to the archive by January 2004. The project was perceived as a minor, straightforward, and problem solving project aimed at solving the archive crisis. The estimates predicted the employment of one support person from the IT department with a 50% position for 6 months. In December 2004, after some delays, the scanners were installed in four pilot departments and the secretaries started testing scanners and software. Most of 2004 and 2005 were spent on teasing out the actual work practices associated with digitizing the work flow within the departments and the hospital. The volume of paper being sent to the archive started to decrease more than a year later than initially expected.

Figure 1. Chronology of the scanning project: The dotted line indicates dependencies on actors beyond the local context (i.e. the Women’s Clinic, in the middle)
We enter the case in December 2003 and look at the scanning project in one of the pilot departments, the Women’s Clinic. We describe three events (events 1, 2, and 3 in figure 1 above) that made the project deviate from its planned course and somehow complicated the process.

4.2 Event 1 (2003-2004): Resolving local procedural and technical constraints

During the first pilot period (December 2003 - January 2004), bugs were identified and fixed and the employees at the Women’s Clinic developed routines for how to arrange the scanning. The first documents targeted for scanning were the incoming referral letters, which are letters sent by external doctors to request a patient’s admission to the hospital. These letters could be several pages long and usually all of the pages were scanned and saved as one file in the appropriate folder in the EPR and tagged with the date of reception. In some instances the referral letter was incomplete. For instance the letter would mention that additional examinations had been performed and that the results would be forwarded to the hospital when they were ready (e.g. when received from the laboratory). In such cases, the forwarded documents arriving later would logically belong to the same referral letter; however, it was not technically possible to append the after-sent documents to the previously scanned referral letter. The scanner software generated images using the TIFF file format, and in order to create one file, the different pages had to be scanned at the same time and joined before exporting them to the EPR system. Thus in the case of incomplete referral letters, an additional file had to be generated for the separate (after-sent) documents. The only way to link these documents in the EPR was to tag them both by date of the referral letter. To do this properly, the person who scanned the documents had to figure out which referral a particular document belonged to and use the same date for storing it. Initially, this work routine was accepted in the pilot departments, but it was later debated again. After some discussion, it was decided that after-sent additional information should be stored in an EPR folder called “External correspondence, miscellaneous”.

The scanning activities were also shaped by other technical characteristics of the existing information infrastructure. The activities required cooperation between three different software systems: the scanning software, the Electronic Patient Record (EPR) system, and the Patient Administrative System (PAS). Before a document could be scanned, a digital record had to be created in the patient’s name in the EPR system. However, even before the record could be created in the EPR system, the patient information had to be entered into the patient administrative system (PAS). Initially, it was assumed that the speed of the process would improve if the same person was responsible for all these steps; however, the PAS application was running on the hospital’s Windows NT network. The new scanning application required Windows 2000 and was installed on separate machines initially, while waiting for the eventual upgrading of the whole hospital network. Consequently, the two applications were running on different machines in different work places, and at least two persons had to be involved in conducting the task.

Thus we see that the redesign of work practices did not happen freely “from scratch” but had to start from the given constraints, in this case constraints posed by the software, the operating systems, and the existing network technology. The redesign furthermore necessitated cooperation with actors beyond the department. The temporary workaround utilizing different workstations and different network segments involved the hospital’s IT department. Furthermore, negotiations with other departments were required to establish common work routines with respect to the scanning. But still these issues did not entail dependence on actors beyond the hospital (i.e. external actors), such as the next example illustrates.

4.3 Event 2 (2004-2005): Dependence on external vendors

Some procedures for improved mail handling were drafted and implemented in the Women’s Clinic during 2004, primarily to ascertain that incoming letters were distributed as efficiently as possible within the department, and that the evaluation was speedy. However, major changes could not be carried out because the EPR system, according to the contract specification, was not yet ‘complete’.

Proceedings ECIS 2009
The EPR system primarily served as a document repository and did not yet offer much work process support. For instance, the system did not have a message functionality that could be used to notify the doctor when a referral letter was awaiting evaluation. The paper letter would be physically placed in the doctor’s mail shelf, and thereby serve to notify the doctor about the task to be handled (i.e., the evaluation of a referral letter). Ideally, the paper letter should be removed from the workflow after scanning; however, that was not possible since the notification functionality was not yet implemented in the EPR system. When asking for this functionality in March 2004, the project team in the Women’s Clinic was told (jokingly) by the IT department representatives that it would probably be a Christmas present. Then again in November 2004, they were told that it was a part of the version being currently tested.

The point we want to emphasize here is that the provision of this functionality was not within the mandate of the project, or even of the hospital. The vendor would make the decision of whether and when to implement this functionality based on weighing costs of development against a potential increase of market share and income generation. Thus not all wishes from the various customers (hospitals) were fulfilled. In practice, this dependency on the vendor meant that the doctors continued to receive paper letters in their mail shelves (even if these letters were also being scanned). When finally implemented in 2005, the notification functionality allowed the removal of the scanned paper documents from the workflow. The problem illustrated here is just one example of how the clinical workflows were complicated with the introduction of scanners and how changes were dependent on external partners. In this case, we see how the use of scanners did not immediately live up to the initial aim of reducing the amount of paper. Rather, it complicated the work even further as the healthcare professionals now had to work with both paper-based and electronic documents.

4.4 Event 3 (2005-): Defining departmental and hospital-wide standards and procedures

The various clinical departments were expected to reorganize their work processes. The hospital can be considered a professional bureaucracy (Mintzberg 1983) and no-one in the administration had detailed and extensive knowledge about the idiosyncrasies of documentation practices and work patterns. This necessitated a decentralized approach to workflow redesign. Still, there existed a need to coordinate these redesign activities at an organizational level, since local changes in work practices could have consequences for other collaborating actors at other levels. The reorganization was initiated in the beginning of the project but it was becoming increasingly formalized by the end of 2004 and in 2005.

The local project team at the Women’s Clinic was requested by the project management to develop procedures within given time frames. The project team drafted procedures for e.g., incoming mail handling, for evaluation of referral letters, and for detailed instructions as to which documents should be scanned and which not. These procedures were formally part of the organizations’ quality assurance system, and thus this request had some legitimacy and became a rather well-working way to get the department to actually design changes. The procedures also served to standardize learning across the multiple departments. The standardization was achieved through a lengthy process where numerous versions of multiple procedures (both departmental and general, hospital-wide) were circulated and discussed. The project team asked for general template procedures in order to accomplish this task. The templates were made and circulated, and the project team worked with them for some time before sharing the drafts and discussing revisions with other departments. The required coordination of the redesign was thus achieved through a process where the local or departmental idiosyncrasies were exposed and adjusted, and where the overall requirements (central as opposed to local/departmental) also were met.

These discussions were not always straightforward. For instance, the general rule was that all incoming mail should be opened at once and processed immediately to avoid delays. In the Women’s Clinic, the mail was distributed to the four sections before it was opened and processed. Initially, the involved persons thought it would be a good idea to centralize mail handling and scanning. Later in
the process, other secretaries became involved, and they voiced objections to this model. The personnel in one section handled sensitive personal information (e.g. related to gender identity disorders, anonymous semen donors etc.) and they registered this information in a version of the EPR which had strictly limited accessibility. They wanted to continue to open their mail themselves in order to maintain the patient privacy. The general rule was also a problematic issue in the delivery section, which received more applications than it could grant. They rejected approximately half of the yearly 5000 applications from women wanting to give birth there, and these referral letters were forwarded to other hospitals. The hospital’s established procedure (to scan incoming referral letters at once) worked well for most departments. But in the delivery section it would not be appropriate, as it would necessitate the unnecessary creation of around 2500 files in the EPR system for women who would not be admitted after all.

Several of such special cases were brought forth in the ongoing discussions in the project meetings, and the job of distinguishing between what should be general, hospital-wide procedures, and what should be specific to each local department took several months. This process needed to allow for local variations in the procedures (e.g. as the case of the delivery section shows), but also to eliminate these variations when they were not necessary and considered counter-productive.

5 ANALYZING THE FINDINGS

We have described some concrete examples of how a seemingly trivial project of implementing scanners turned out to take much longer time than expected and was dependent on a multiplicity of actors and actions. We do not offer this account as an example of negligent estimation or suboptimal project management. Neither is it an example of an unusual IS project. The case is rather trivial, even banal, and certainly not dramatic. The story illustrates the impact of interactions and couplings; issues that are crucial, we claim, but of such a mundane character that they are often overlooked by IS researchers trying to conceptualize IS-related change processes. In the discussion below, we focus on these interactions and couplings as well as the strategies employed to manage them during the scanning project.

5.1 Linear or interactive interactions, tight or loose couplings

In some instances described above, the type of interaction was simple and linear whereas in others, they were highly interactive. Event 2 illustrates how the hospital was dependent on the vendor to develop and deliver the notification functionality of the EPR system. The relation between the hospital and the vendor can be characterized as simple; the vendor was the only one who could provide a solution, and as long as it was not provided, a delay occurred with respect to the particular usage pattern of the EPR system. The difference between the scanner software’s requirements (Windows 2000) and the existing Windows NT network, as illustrated in event 1, was another example of a linear and simple relation. This time, the dependence was on another entity (the IT department) within the hospital organization, not an external actor. Nevertheless, the project team in the Women’s Clinic could only wait for the change to happen. They did not have any power to change the timeline for network upgrading as this was a separate process in the organization. In the meantime, they needed to design a workaround to deal with this issue. The possibility to design workarounds and tolerate delays in this process shows that the couplings were loose, not tight. There were multiple ways for the organization to keep on working, despite the delays introduced by the other actors and processes.

The definition of procedures for the new work practices showed a more interactive pattern as illustrated in event 3. The various departments needed to sketch the new procedures and try them out locally. At the same time, the employees at the Women’s Clinic had to discuss with the other departments in cases where the procedures were dependent on or had consequences for them. The procedures were tightly linked with the documents associated with the internal patient transfer between departments. In addition, the hospital’s quality system imposed a structure of distinguishing between general and local procedures, and we witnessed a degree of interactively sorting out the
procedures that belonged to the hospital versus the departments. Experiences from the pilot departments were collected and compared in the process of sorting this out. With respect to the difficulty of replacing the referral letter, it was discovered that a single artifact (i.e. the paper letter) served two functions simultaneously; it was both an information carrier and a “signal” for action in the process. One of these functions could easily be digitized, while the challenges of digitizing the other were discovered along the way. Such double- or multi-mode functioning is, according to Perrow (who called it “common-mode functioning”), one of the major reasons behind interactively complex systems.

5.2 Sorting out and dealing with interdependencies

Most of the interdependencies accounted for in the case description were not predicted in advance. This is not to say that they were impossible or even difficult to predict. For instance, it could easily have been foreseen that the TIFF file format would exclude appending the test results to a referral letter, if anyone had asked the question. However, even if predicted, it was doubtful whether the product, a commercial off-the-shelf application, would have been changed. In principle, these issues (at least some of them) could have been predicted if the organization had run a process where they used for instance storyboards or use cases. However, the introduction of scanners was not considered a major project that required involvement from IT professionals. Since the process was handled by the workers themselves, storyboards and use cases were unknown techniques and were not used, except for quite simple drawings with boxes and arrows in order to show the work flow. In practice, these dependencies were only realized as the actual and practical work progressed. This is not necessarily because they were complex and intractable; rather, there were just too many and too small dependencies, and it was a task in itself (“beside” the primary project work) to find out what to look for and to realize who needed to be involved.

It is the work of sorting things out and dealing with interdependencies that we wish to draw the reader’s attention to. In the case, we see that the discussions often centered on sorting out what to take first and second, and what to prioritize and what to downplay. This process was linked to the uncertainty in the process because of its links beyond the local context. The team members needed to sort out a number of issues such as: What are the preconditions and consequences (upstream and downstream)? What are the limiting factors and what are the constraints of change? What can we do and not do? Where do we have any impact and what is beyond our scope of influence? The actors also needed to consider how to run a changed procedure in parallel with maintaining the pre-existing paper-based ordering so that the Women’s Clinic could still interact with the non-pilot departments. In response to our inquiry on the progress of providing a feature that the users had requested, one of the project managers from the IT department replied: “No, we haven’t fixed that and we will not do that for the time being. Remember, we’re trying to eat an elephant here. We cannot take it all at once”.

The changes had to occur in a coordinated way so that the ongoing work of patient care would not suffer during the transition process. This interlinked nature of the organizational routines and the dependencies on other actors, both internal and external, delayed the process compared to the initial estimates.

5.3 Infrastructural implementation

We believe it is significant in this respect that the implementation of scanners was not considered a strategic and important project. Infrastructural technologies are expected to just “be there” and support the core organizational activities. In a hospital, the activities are centered on patient treatment and care, and the information infrastructure is seldom considered to be of strategic importance in its own right. Especially this goes for the ongoing incremental extension or replacement of the elements of an information infrastructure, which is often seen as necessary maintenance. This may have the effect that change processes (both implementation and assimilation) associated with them receives low organizational attention, priority, and allocation of resources.
The change process was by necessity decentralized, but the clinical staff lacked expertise and applicable models for how to handle the required changes, as these were not related to their core competency. Thus, when no external resources (such as consultants) were available, the process may be handled in a suboptimal way. Since no resources were allocated, the actors perceived these tasks as additional to their ordinary work burden, and they easily defected the meetings and activities. This character of the process may be a challenge since it delays actions and dissipates the change momentum in the organization.

6 DISCUSSION AND IMPLICATIONS

In this paper we have argued that the existence of interconnections and dependencies is a fundamental trait of the information infrastructures of today’s organizations. While these interdependencies can be of many types and degrees, we have focused on the mundane and trivial types of interdependencies rather than large-scale and dramatic ones. When changes occur in the organization, small interdependencies may become significant enough to have an impact on larger organizational processes.

In our case study, we emphasized how the actors involved in the project resolved the challenges associated with the interdependencies. This was a cumbersome process of sorting out the consequences of them. It involved negotiations with other actors (outside the project), coordination of multiple local changes with one another, and coordination of local with overall changes (i.e. both cross-site and cross-level negotiations).

We claim that IS implementation studies have to a limited degree focused explicitly on how new IS are related to and get intertwined with the existing portfolio of systems in the organization. The emphasis is usually rather on project management and reception in the organization. This orientation is also reflected in how failures and problems are conceptualized. Common “folk explanations” for delays or failures of IS implementation often emphasize incompetent project management, inappropriate design, or lack of user involvement. In addition, IS researchers have emphasized the importance of upper-level management support (Myers 1994), the role of users’ resistance due to various reasons, such as badly designed systems, or organizational politics (Markus 1983; Keen 1981). Failure to learn from previous experience or to transmit learning between projects has been seen a major reason for IS failures (Lyytinen and Robey 1999). Also with Orlikowski and Hofman’s improvised change model, the need for learning-oriented and adaptive approaches is emphasized (Orlikowski and Hofman, 1997).

Our study does not lead us to disagree with these insights. On the contrary, we argue that our emphasis on minor instances of interactions and interdependencies are complementary to these studies. We believe that such details are important in any project, although they may be overlooked or abstracted away in the accounts that are produced. We want to draw attention to this specific issue since we believe attention to this can contribute with conceptualizations that are practically useful in IS projects. These conceptualizations need to describe how we can identify and deal with the issue of interdependencies that emerge because of the infrastructural character of an organization’s systems portfolio. Our empirical case study could be considered as a first step in this direction.

The question now is how actors, who are involved in similar projects where multiple types of interactions and couplings are encountered, may act and react? The answer is not straightforward, and we will not be able to provide managers or other actors involved in IS implementations with clear-cut answers and a list of best practices. However, one way of acting in such a context is suggested by the “bootstrapping” strategy proposed by Hanseth and Aanestad (2003). In discussing how to establish information infrastructures in health care, the strategy addresses the dilemma when the number of adopters is below critical mass, i.e. too low to ensure general benefits from the infrastructure. The focus of the bootstrapping approach is on how one can work in such a situation in order to establish a self-reinforcing growth process. It advises the selection of an appropriate starting point in order to create a platform that allows some action to be taken, given the existing constraints and opportunities.
The next step is to search the context for opportunities and then to expand this platform on the basis of these available opportunities. General principles within this model are to expand existing solutions rather than request new solutions (more users before more functionality), to experiment in shielded areas only, to learn from simple use areas before complex ones, and to identify usage areas with low cost and high gains for the prospective users. These principles help in sorting the immediate steps from the future steps, in choosing what to do first and last.

The benefit of this strategy lies in breaking down a task that seems impossible when considered as a whole. This is of relevance also with respect to handling and dealing with interdependencies during implementation, a task which an IT employee characterized as “eating an elephant”. If it is possible to plan organizational implementation in a way where a starting point has been carefully selected so that the dependencies extending beyond the project’s sphere of influence are minimized, and where the need to negotiate cross-site and cross-level are also minimized, then the greater the chance for successful implementation of this limited change.

If a starting point like this can be found where a limited change can be achieved, then a platform has been built from which to proceed. At this stage, some interdependencies have been uncovered and perhaps even sorted out. Ideally, the project team should have learnt from this process, and be in a better position to predict and prepare for new and “larger” (i.e. more far-reaching or comprehensive) interdependencies in the next rounds. On the contrary, if no such selection has been carried out, and the whole project (“the elephant”) is taken on, the more likely are delays and frustrations in the change process due to the couplings and dependencies of systems and procedures beyond the project site. It may not be possible to achieve this in a perfect or optimal way. For instance, there may be no area where there is not a need to coordinate change across locations. We have no reason to claim that the selection of a starting point or the planning of a sequence of steps in our case was not the most optimal strategy. However, even if the single optimal strategy cannot be defined, this way of thinking may effect a change in mindset. We believe that the project management should be oriented towards vigilance and detection and focused on learning to deal with interdependencies rather than insisting on meeting milestones and deliverables.

7 CONCLUDING REMARKS

The purpose of this paper was to illuminate a specific source of complexity associated with implementing IS that becomes an integrated part of an organizational information infrastructure. We have emphasized the role of complex interactions and tight couplings in such a process and described how a long and cumbersome process of dealing with such interdependencies delayed the project we studied. The challenges associated with the interdependencies had to be resolved in a manner which entailed sorting out the consequences of the couplings that were proposed, introduced or detected. It also involved negotiations with other actors, over whom the project did not have control. Finally, due to the nature of an organizational infrastructure, the solutions had to align multiple local changes with one another and coordinate local with overall (organization-wide) changes. We believe this phenomenon is understudied, yet significant. It constitutes a particularly challenging aspect of leveraging information infrastructures to achieve organizational change. Finally, we have sketched how a learning-oriented approach to deal with these multiple interdependencies and couplings could look like.

THE MEDIATING ROLE OF IT KNOWLEDGE INTEGRATION CAPABILITY IN THE RELATIONSHIP BETWEEN TEAM PERFORMANCE AND TEAM CLIMATE

Abstract

The purpose of our paper is twofold: on one hand we draw on the team climate literature to understand how IT knowledge integration capability can be promoted within team-based structures; on the other hand we rely on resource-based view framework for understanding how IT knowledge integration capability affects teams performance, in terms of effectiveness, and efficiency. We tested our research model on a sample of 410 members and leaders of 69 organizational work teams. Results show the critical role played by team climate for favouring IT knowledge integration capability, which in turn affects team outcomes.

1 INTRODUCTION

Organizational researchers and managers acknowledge the importance of teams to organizations (Hoegl and Gemuenden, 2001). In modern organizations, knowledge workers are becoming more and more important, and cooperation became completely immanent to the labouring activity itself. Productivity, wealth, and the creation of social surplus take the form of cooperative interactivity through linguistic, communicational, and affective networks. In mainstream literature terms, this means the increasing relevance of teams within modern organizations (Appelbaum and Batt, 1994; Argote and McGrath, 1993; Adler et al., 2008).

Researchers have developed several models and constructs in the attempt to analyze the degree to which team members interact for explaining their ability to accomplish complex tasks (i.e. creative, innovative, and knowledge-based task). Indeed, complex tasks are regularly conducted through teams, as teams represent the most immediate social entities through which individuals obtain resources (Faraj and Xiao, 2006; Hoegl et al. 2003). For example, Li and Zhang (2002) found that members’ integration facilitates innovative solutions in the product development domain, which relies on the ability to exchange, coordinate and aggregate individual contributions (Faraj and Sproull, 2000). Thus, the ability of team to integrate resources through the leverage of team processes represents a favourable condition for facing the complexity of their task. In order to cope with such complexity, team members should be able to exchange and integrate knowledge for obtaining positive performance (Garud and Kumaraswamy 2005; Gold et al. 2001; Lee and Choi 2003; Pfeffer and Sutton 1999; Wasko and Faraj 2005).

According to the resource-based view framework, knowledge represents one of key resources to obtain and transform other resources. The way through which team members rely on processes for favouring the creation, codification, and sharing of knowledge, has been recognized to positively affect performance (Gold et al. 2001). Despite the widely recognized importance of team capability to activate processes for integrating knowledge, the effectiveness of knowledge management process capability needs to come along with technological capability that supports and incorporates knowledge management processes (Burgelman 1994). While established rules and directives contribute to firm performance, proper IT support is required to maximize the effect of the rules and directives as the knowledge integration mechanism (Ray et al., 2004). IT as an organizational capability can facilitate
the process of transforming knowledge into action, and the effective exploitation of the rules and directives may depend upon a well-established technological infrastructure (Armour, 2001). Thus, the harmonious combination of knowledge management process capability and IT capability represents the effective configuration of resources and knowledge to determine team performance.

Moreover, according to previous literature pointing out that facilitating conditions have emerged as an important precursor to knowledge integration (Grant, 1996a), we believe that IT knowledge integration capability is affected by the existence of a team-level climate that favours the circulation of information among team members. Indeed, a positive team climate creates the types of team environments in that collaboration, team learning, and thus innovative activities are encouraged (Lumpkin and Dess 1996). In such environments, teams can integrate knowledge to reduce members isolation (Kanter 1983). Thus, a positive team climate may enhance an organizational performance by creating new knowledge (Ireland, Hitt and Sirmon 2003). Through developing a positive climate, teams are able to create a new knowledge and exploit it (Dess et al. 2003; Kazanjian, Drazin and Glynn 2001).

The remainder of this paper is structured as follows. First, we present constructs and hypotheses. Next we discuss the methodology, including data collection, and analyses. We conclude with a discussion of our results and implications for theory and practice.

2 THEORY AND HYPOTHESES

The first objective of this paper is to understand how IT knowledge integration capability can be promoted within team-based structures.

Following some previous researches (i.e. Grant 1996a,b), we name IT knowledge integration capability, a type of combinative capability (Kogut and Zander, 1992), which consists of knowledge management process capability, and technological capability. Knowledge management process capability is defined as the capability to capturing, storing, sharing, and using knowledge (Davenport and Prusak 1998; Bock et al., 2005). Technological capability is defined as the capability to leverage IT in order to obtain tangible and/or intangible benefits (Bharadwaj, 2000).

Extant literature in organizational behaviour domain proposed different types of teams, and analysed different team mechanism and properties (Cohen and Bailey, 1997; Barrick et al. 2007). Team climate plays a pivotal role because it refers to the creation and influence of social contexts (Bock et al., 2005) that influence team members’ behaviour. Climate represents a shared perception of the types of behaviours, practices, and procedures that are supported in a specific context (Schneider et al., 1998). According to Glomb and Liao (2003) team climate influences individual behaviour through social information processing mechanism (Salancik and Pfeffer, 1978), thus leveraging the way individuals think and feel about a certain aspect of their environment (i.e. specific team environment). In this study, we examine the relationship between two critical properties of team climate (autonomy and experimentation) and IT knowledge integration capability. We focus on these two dimensions of climate because they represent the salient aspects of organizational climate which have been outlined by scholars interested in understanding individuals’ knowledge sharing (Bock et al. 2005). Individuals tendency toward knowledge sharing is mostly influenced by those climate facets that can be traced back to a tolerance of well-reasoned failure (Leonard and Sensiper 1998), and a freedom to make decisions (Kirkman et al. 2004).

Teams vary in the degree to which they are characterized by an autonomy climate, or decision-making authority for their actions (Bruhn and Gibson, 2006). Autonomy climate may be defined as “the degree to which the task provides substantial freedom, independence, and discretion in scheduling the work and in determining the procedures to be used in carrying it out” (Hackman and Oldham, 1980, p. 79). Autonomy climate refers to freedom, independence, and discretion in the task of a team (Cordery et al., 1991; Hackman, 1987; Kirkman and Rosen, 1999; Langfred, 2000). Organizations with centralized decision-making decrease (1) collaborative processes within the team as
communication increasingly flows vertically rather than horizontally, and (2) team members’ willingness to fully contribute their knowledge to problem-solving processes. On the contrary, team members in teams with a high degree of autonomy climate are reliant upon themselves for task decisions, which will likely increase the sharing of information, the coordination of task activities horizontally within the team (Hoegl and Parboteeah, 2006), and knowledge creation (Zellmer-Bruhn and Gibson, 2006). Moreover, autonomy climate strongly influences team learning because members in autonomous teams are encouraged to develop new ideas and/or to adapt ideas developed in other parts of the organization to fit their particular local context (Zellmer-Bruhn and Gibson, 2006). IT users need to acquire and/or develop IT and task-related knowledge to be able to use technology effectively in order to gain the planned objectives (Attewell, 1992; Nelson et al., 1995; Sein et al., 1999; Lassila and Branchau, 1999; Rogers, 2003; Sharma and Yetton, 2007). Two dimensions characterize users’ knowledge: an individual one, and an inter-individual one. The inter-individual cognition (Sharma and Yetton, 2007) is based on a transactive memory system (Argote 2005; Liang et al. 1995) and the development of collaborative task knowledge (Kang and Santhanam 2003-04). According to Wegner et al. (1985), transactive memory develops when individuals use the memories of other individuals as external storage, and it consists of (1) knowledge contained in the memories of individual group members, and (2) knowledge relevant communication processes among group members. Sharma and Yetton (2007, p. 221) follows Kang and Santhanam in defining collaborative task knowledge as “an understanding of the interdependent relationships among all users’ work procedures, enabling users to assess the collective consequences of their individual ways of using a collaborative application in the context of a business process, coordinating across individuals and contributing to group performance”. Autonomy climate supports the creation of these two dimensions of the inter-individual cognition through the fostering of information sharing, collaboration, knowledge creation, and team learning. Therefore, autonomy climate may enhance the development of IT knowledge integration capability. Formally,

\[ \text{Hypothesis 1: Increasing autonomy climate at team level will have a positive impact on IT Knowledge Integration Capability.} \]

Teams vary not only in terms of autonomy climate, but also in terms of innovative behavior. Teams may be innovative in the use of knowledge and technology if they incorporate the rule of agreement (i.e. non blocking the ideas of others) as a norm of their climate. The norm of agreement is critical for the creation of an experimental climate in teams, which is defined as a climate that provides room for experimentation and is tolerant of “competent” mistakes (Vera and Crossan 2004). Low levels of room for experimentation and low tolerance for mistakes represent climate that pursue efficiency over effectiveness and exploitation over exploration (Crossan and Hurst 2003). In contrast, high levels of possibility to experiment and tolerance for error are not associated with blind risk taking and lack of discipline, but represent a climate that promotes action as opposed to reflection as a way to understand and deal with reality (Cunha et al. 1999) and where boundaries and minimal constraints are defined so that experimentation can occur (Vera and Crossan, 2005). When team members perceive their environment as interpersonally nonthreatening and tolerant of, or even supportive of, taking risks and trying new approaches, higher levels of psychological safety and engagement in innovative processes. This means that experimental climate supports (1) creation, and new combination of knowledge, and (2) change in the technology and/or in the way of doing things by users. Indeed, technology is an effective knowledge medium and relates to the transformation of experimentation to performance (Walsh and Ungson 1991). This aspect is also corroborated by recent research outlined that team-level climate may affect the degree of experimental behaviors performed in interacting with technology for integrating knowledge (Maruping et al. 2008) Formally,

\[ \text{Hypothesis 2: Increasing experimental climate at team level will have a positive impact on IT Knowledge Integration Capability.} \]

Previous research has emphasized the importance of team-interna processes, and it has recently analysed processes between teams (e.g. Hoegl et al., 2004), but it has overlooked the analysis of team capabilities (Tiwana and McLean, 2005). In particular, we know little about the role of technological
capabilities in influencing both team effectiveness and efficiency. Resource-based view literature in the IS field has analyzed the role of technological capabilities, and the link between these capabilities and performance (e.g., Bharadwaj, 2000; Wade and Hullan, 2004), but the main focus of these studies is the firm level. They have overlooked the role of technological capabilities at team level. The second objective of this paper is to understand the relationship between IT knowledge integration capability and team effectiveness, and efficiency.

Teams conduct knowledge-based complex tasks (e.g. new product development) (Faraj and Xiao, 2006; Hoegl et al. 2003). Therefore, IT knowledge process management capability may positively influence (1) output effectiveness because it supports the use of knowledge within the team (Faraj and Sproull, 2000), (2) efficiency because it supports the storing, and the sharing of knowledge enhancing the team members’ ability to exploit process and procedures (Faraj and Sproull, 2000). IT knowledge integration capability as a combinative capability may enhance these positive effects. Formally,

Hypothesis 3: Increasing IT Knowledge Integration Capability at team level will have a positive impact on team effectiveness.

Hypothesis 4: Increasing IT Knowledge Integration Capability at team level will have a positive impact on team efficiency.

3 METHOD

3.1 Study context

Data were collected in two large European companies in the retail and insurance industries which introduced a new communication technology - voice over IP (VoIP). The technology was introduced to manage all technology-mediated communications among individuals in an integrated manner. The technology was needed to support activities such as agenda sharing, information sharing, mobility management, and event coordination. In addition to offering more information that can be accessed and managed by users, this system embodied the convergence of different communication capabilities, enabling individuals to communicate with their colleagues. This is particularly relevant because individuals, through a unique platform, are allowed to choose among different communication channels that match their synchronicity needs (e.g., voice, instant messaging, conference call, and e-mail). In this particular case, while the use of the system was strongly encouraged, there was no policy in place for non-compliance and no actions were being taken as a result of the usage reports, suggesting that system use was voluntary. Data were collected using a survey methodology. The questionnaire was developed using a multi-stage iterative procedure. First, an initial set of items was constructed drawing upon prior work that measured the constructs adopted in our study (Langfred, 2005; Vera and Crossan, 2005; Chan et al. 1997; Pearce and Sims, 2002. Next, we conducted interviews with the IT managers responsible for the implementation project. This helped ensure that the questionnaire was appropriate for the organizational setting and the technology introduced. One week before the launch of the survey, CIOs at the participating organizations sent an e-mail memo explaining the importance of the study to all potential respondents. This procedure has been already adopted in previous studies (Teo et al. 2003).

Data were gathered through a web survey containing five-point Likert-type scales. To obtain more reliable ratings of the team-level constructs under consideration, multiple respondents from each team participated: the team leader and at least three team members. To ensure data validity, only teams returning at least three questionnaires (the team leader and two team members) were considered. Of a total of 810 individuals and 129 teams targeted for the survey, 410 usable surveys referring to 69 teams were completed, yielding response rates of 50.6% (individuals) and 53.4% (team). The teams were functional long term teams involved in the commercial processes of their organization.
3.2 Measures

In order to obtain reliable team-level ratings for the variables in the study and to avoid potential common source bias, we collected responses from multiple sources in each team, including the team leader. Because some of the data from this team-level study were collected from multiple individuals within each team, it was necessary to justify the aggregation of individual-level within-team ratings to team-level scores (Klein and Kozlowski 2000; Rousseau 1985). This included a one-way analysis of variance (ANOVA) based on team membership to test the between-group variation, and the computation of ICC (Interclass Correlation Index) for assessing the stability of the team-level means (Bliese 2000).

**Team autonomy climate.** We used a five-item scale adapted from Langfred (2005) which captures the shared perception of the degree of autonomy that team has in the decision making process. Results of a one-way ANOVA indicated significant between-team differences in ratings of team autonomy climate \((F = 1.44; p < .05)\). The ICC was 0.79 indicating stable team-level means for this construct. A team-level score for autonomy climate was computed by averaging within-team responses to the scale.

**Team experimental climate** was measured through a three-item scale derived from Vera and Crossan (2005) tapping the shared degree that experimentation is allowed within the team. Results of a one-way ANOVA indicated significant between-team differences in ratings of team experimental climate \((F = 2.01; p < .01)\). The ICC was 0.68 indicating stable team-level means for this construct. A team-level score for team experimental climate was computed by averaging within-team responses to the scale.

**IT Knowledge Integration Capability** was measured adopting five items from Chan et al. (1997) related to IT capability and 3 items from Gold et al. (2001) for assessing the knowledge-oriented facet of the construct. The scale had a reliability of .84. Results of a one-way ANOVA indicated significant between-team differences in ratings of IT Knowledge Integration Capability \((F = 2.13; p < .01)\). The ICC was 0.58 indicating stable team-level means for this construct. A team-level score for this construct was computed by averaging within-team responses to the scale.

**Team effectiveness** was measured through four items derived from the output effectiveness scale by Pearce and Sims (2002) which assesses the quality of the output delivered by the team. The scale had a reliability of .84. Results of a one-way ANOVA indicated significant between-team differences in ratings of team effectiveness \((F = 1.78; p < .01)\). The ICC was 0.63 indicating stable team-level means for this construct. A team-level score for effectiveness was computed by averaging within-team responses to the scale.

**Team efficiency** was measured adopting a two item scale developed for the study in order to assess whether the team delivers its output respecting the budget and the deadlines. The scale had a reliability of .84. Results of a one-way ANOVA indicated significant between-team differences in ratings of team efficiency \((F = 1.35; p < .05)\). The ICC was 0.84 indicating stable team-level means for this construct. A team-level score for efficiency was computed by averaging within-team responses to the scale.

**Controls.** Following Hoegl et al. (2003), we included team size as a control variable. Larger team sizes have been associated with both increased and decreased performance. Larger teams are argued to give team members access to a broader array of resources. However, larger teams also create greater coordination complexity, thereby hindering the ability of individuals to collaborate and perform effectively. Since the teams involved in our study are characterized by varying degrees of task interdependence in team members’ work, the behavior of each team member has an impact not only on the effectiveness of that individual, but also on the effectiveness of the team as a whole (Griffin et al. 2007). Thus, we included task interdependence as control variable. Interdependence was measured using a three-item scale adapted from Campion et al. (1993). This scale had a reliability of .67. A one-way ANOVA revealed significant between-team variation on individual
ratings of this scale (F = 1.75; p<.01). The ICC for task interdependence was 0.80. Tenure was measured through an interval scale with the following anchors: 1= less than 3 years; 2=3 -5 years; 3= 6 – 10 years; 4= more than 10 years.

4 ANALYSIS AND RESULTS

We adopted partial least square (PLS) method to analyze the data. PLS is a structural equation modeling technique which use a component based approach to evaluate the relationship within, and variance explained by a structural equation model. PLS is a technique that is increasingly being used in IS research because it requires minimal sample size and it places minimal demands on residual distributions (Chin, 1998; Fornell and Bookstein, 1982). According to Agarwal and Karahanna (2000) data analysis process was divided in two steps. During the first phase we established the psychometric validity of the adopted measures, while in the second we tested the hypotheses.

4.1 Measurement Model Assessment

The psychometric properties of the scales were assessed in terms of items loading, internal consistency, and discriminant validity. As can be seen from the factor analyses results reported in table 1 all items loaded respectfully on their corresponding factor (Fornell and Bookstein, 1982). In order to assess the discriminant validity the average variance extracted (AVE) should be higher than the interconstruct correlations. As indicated in table 2 all the constructs share more variance with their indicators than other constructs. Moreover, as depicted in table 2, Cronbach alpha and composite reliability for each construct exceeds 0.7, confirming the internal consistency. These results are consistent with previous studies (e.g. Karahanna et al., 2006; Tiwana and McLean, 2005) allowing us to conclude that the measures testing the model all display good psychometric properties. Table 2 reports also correlations, descriptive statistics, and ICC indexes.

4.2 Structural Model Assessment

According to Agarwal and Karahanna (2000), in a PLS analysis, “paths can be interpreted as standardized beta weights in a regression analysis”. As Figure 1 illustrates, team autonomy and experimental climate factors explain 19% of the variance in IT Knowledge Integration Capability, while IT Knowledge Integration Capability explains 13.4% of the variance in team effectiveness and 12.4% in team efficiency. Results provide support for hypothesis 1 stating a positive relationship between autonomy climate and IT Knowledge Integration Capability (coeff. = .23, p < .05). Team experimental climate has a positive effect on IT Knowledge Integration Capability, providing support to hypothesis 2 (coeff. = .27, p < .01). Hypothesis 3 and 4, which posit that IT Knowledge Integration Capability have a positive influence on effectiveness and efficiency are supported (coeff. = .35, p < .01 and coeff. = .38, p < .01, respectively). Since data collection at the same point in time and using the same instrument the potential for common method variance exists. We controlled for common method variance running a Harman’s one factor test, which demonstrated that common method variance was not a threat to our findings. Indeed: (1) the unrotated factor structure, explaining 69.6% of the variance, did not show a single factor; (2) the first factor did not account for all of the variance (38.9%) (Podsakoff and Organ 1986).

![Figure 1: PLS results. * p < .05; ** p < .01](image)

**5 DISCUSSION**

**5.1 Theoretical implications**

This research contributes to the literature on team climate, IT capability, and team performance in two ways.

First, our results show that team autonomy climate enhances the IT knowledge integration capability. This means that teams with high level of autonomy, in terms of freedom, independence, and discretion in scheduling the work and determining the procedures, may positively benefit the IT knowledge integration capability. Moreover, team experimental climate enhances the IT knowledge integration capability. Thus the existence of room for experimentation and tolerance of “competent” mistakes...
within the team, may positively influence the IT knowledge integration capability. Our paper goes beyond the traditional climate literature pointing out a direct effect of team level climate on team level capabilities. In particular, our research answers existing call for developing a better understanding of the contextual factors at the team level of analysis which may influence the way through which members exploit resources and technology for developing processes and procedures for acquisition, combination, creation, and sharing of knowledge (e.g. Tiwana and McLean, 2005). Thus, our examination of the drivers that affect IT knowledge integration capability represents an important step in overcoming the knowledge and capabilities at the team level of analysis.

Second, our results underscore the positive effect of IT knowledge integration capability on team performance (i.e. effectiveness, efficiency). Therefore, our results are worthy because we shed some light on the role of IT capabilities on team outcomes. Literature in the IS field has explored the role of IT capabilities, and the link between these capabilities and firm performance (e.g. Bharadwaj, 2000; Wade and Hullan, 2004), while scant research examined these issues at the team level. In particular we answer previous research calls that underscored a lack of knowledge about the link between IT capabilities and team performance (Tiwana and McLean, 2005).

5.2 Managerial implications

The results of this study have substantial implications for organizations that adopt technologies for supporting team activities. It has long been recognized that the introduction of new technologies is not enough for realizing gains in performance. Thus, to the degree that it facilitates the discovery of new sources of value for the technology, active experimentation and autonomy are desirable contextual factors.

Based on our findings about team climate, managers may consider creating a climate that is supportive for exploration and autonomy. Team structures that emphasize a tight integration of technology use into employee work practices. While previous research underscores the need to design team-based structures, our results point out that IT knowledge integration capability is influenced by a climate that facilitate information exchange and learning among team members.

5.3 Limitations and future research directions

As with any work our research has limitations that should be addressed in future studies. Because of the cross-sectional nature of the study we were unable to test for true causality, although causality is theoretically implied in some of the proposed relationships. A longitudinal study can provide some more relevant considerations and implications. Therefore, this study should be reiterated over time in order to catch the temporal effects of depicted variables. Moreover, we did not have access to the demographic data of non-respondents and were thus unable to verify the existence of any significant differences between respondents and non-respondents. Some issues for future research emerge from this study. Although the system we examined embodied characteristics that are common to other systems, future research should validate our results in other settings in order to increase the generalizability of our findings. Moreover, the results are based on the Italian context, suggesting the need for future research in other national and cultural settings.

5.4 Conclusion

In conclusion, the primary contribution of this work is the empirical validation of team level climate as factors influencing IT knowledge integration capability. From a theoretical perspective, a climate-based perspective provides new opportunities for extending the research on team capabilities related to
IT. Clearly, an understanding of the effect of IT knowledge integration capability on team performance is of significant importance to practitioners who are attempting to fully exploit the potential of new information technologies and team knowledge-related processes.

IT-ENABLED CHANGE INTO THE STRUCTURES OF HEALTH INFORMATION SYSTEMS IN AFRICA: A CASE STUDY IN KENYA

Bernardi, Roberta, Warwick Business School, University of Warwick, CV4 7AL, Coventry, UK, Roberta.Bernardi06@phd.wbs.ac.uk

Abstract

In the recent years most African countries have embarked on a series of reforms involving the decentralisation and also integration of health information systems in order to allow improved efficiency and effectiveness in the health care. However, although the discourse around these issues are reflected in global policy documents of almost twenty years ago, IS are still fragmented and weak at the lower levels of the health service. The paper takes a multivocal and multilevel institutionalist perspective to analyse the role of information technology in shaping these shortfalls between institutional accounts and enactments of reforms. Based on the case study of two divisions of the ministry of health in Kenya, it aims to better understand the change implications of information technology for the structures of a health information system in Africa. This is meant to improve the understanding of the way technology-mediated human interactions produce variance between planned organisational change envisaged in donor-driven reforms of the health care service and unplanned HIS structures emerging from the local institutionally-embedded usage of IT tools.

Keywords: Health information systems, IT artefact, Institutional theory, Developing countries
1 INTRODUCTION

Information technology is one of the key components in the implementation of health service reforms supported by international development partners. These reforms are meant to improve the performance of the health sector mainly through the decentralization and integration of health care. Health Information Systems constitute the main core for the implementation of these reforms. Firstly, decentralised information systems can provide decision makers at the lower levels with timely and accurate information for management and planning. Secondly, integrated health information can support coordinated and effective actions in health care delivery.

Still, there is evidence that public IT investments can lead to unexpected organisational impacts that are distant from the original plans or reform objectives, particularly, in developing countries (e.g., Ciborra 2005). Contradictions have been reported, for example, in the usage of IT in the implementation of New Public Management reforms (Hood 1991). Instead of reducing bureaucracies into flatter and more information efficient structures (Osborne et al. 1992), IT implementations within NPM have actually led to the fragmentation of information systems (Kimaro et al. 2005; Dunleavy et al. 2006) increasing, rather than reducing, complexity.

The divergent findings on the implications of IT in the implementation of public sector reforms (e.g., Ciborra 2005) raise the issue of the gap between the organisational impact of information technology as envisaged in formal restructuring plans and unplanned (or informal) practices or structures emerging from IT usage.

Likewise, although the political discourse on the decentralisation and integration of health information systems has engaged development policies for almost twenty years, health information systems are still fragmented and centralized, at least in Africa (Kimaro and Sahay 2007). Most research in this area has actually found that major differences across health information systems depend on competing rationalities underpinning donor-driven reforms, public administrators’ procedures and system users’ practices (Chilundo and Aanestad 2004), bearing strong connections with the “resource-deprived” environment (Kimaro and Sahay 2007). Yet, although past research in health information systems in Africa and other developing countries has clarified the mismatch between formal triggers of change (e.g., public sector reform policies) and informal constraints to change (e.g., professional roles, social expectations, IS users’ routines) (Kimaro and Sahay 2007), little is known about the role of the IT artefact in relation to this formal-informal divide.

The case study illustrated in this paper is meant to address this gap by answering the question of how the IT artefact influences the structures of health management information systems in an African country in relation to its institutional and resource-material environment. The research question rests onto the assumption that the institutional environment both shape and is shaped by users’ enactment of IT (Orlikowski and Barley 2001). The mutual relationship between the institutional environment and IT enactment also accounts of the influence of institutionally-embedded resources (Scott et al. 2000), including, not only financial and human resources but also the technical properties of the technology.

Thus, the proposed case study takes a multilevel and multivocal institutionalist perspective to analyse how new and old rules, norms, and cultural meanings influence technology innovation and the usage of IT in information processing within two national health information systems of the Ministry of Health in Kenya.

The theoretical perspective used is “multivocal” as it takes into consideration the complex interlinkages between varied rationalities and sets of meanings (Lounsbury 2007) underpinning the actions of different actors (e.g., international donor partners, national ministries, public employees, etc.) involved in the reforms of the health systems in Africa (Kimaro and Sahay 2007). In particular, the proposed perspective recognizes two main logics: the “New Public Management” (Hood 1991) embedded in imported reform models and the “Old Public Administration” (Lynn 2006) of traditional African bureaucracies. By considering institutions as enablers of “entrepreneurs action” under an
institutional entrepreneurship perspective (Dacin et al. 2002), the clash between different logics may cause the “translation” (Zilber 2006) of new imported practices into localised “hybrids” (Hood 2000) depending on the modalities of adaptation of the new model (e.g., New Public Management).

The frictions between multiple rationalities and processes of hybridizations can be better understood through the “multilevel” perspective which views the context of African Health Information Systems as characterized by three levels of action: the macro or policy level (e.g., formal policies), the meso or organisational level (e.g., management structures) and the user or agentic level (e.g., IS users’ routines). The three-level perspective allows to zoom in onto the main sets of meanings underlying international and national development policies at the macro level. It highlights how these are mediated or moderated (Dada 2006) by organization level structures, including for example, the influence of different professional norms (e.g., medical doctors, data managers, etc.), and, eventually, interpreted and enacted by institutionally embedded IT users at the micro-level.

In addition, the enactment of institutions at different levels is associated with the means enabling the mobilization of interpretive resources of the institutional environment (Sewell 1992). These means are represented by the technical features of the technology and also the physical and human resources available. In the first instance, the degree of “interpretive flexibility” or “malleability” of IT designs (Orlikowski 1992) influences may either facilitate or constrain new meanings and practices, thereby, reshaping the institutional order of the public health sector.

Under this perspective, the case study presented in this paper provides a historical longitudinal analysis of change opportunities (or constraints) enabled by the institutional environment and by the resource-material environment (IT technical features, human resources, information tools). This has been achieved by focusing upon changes into the information processing behaviour of IS users following the introduction of a specific technology. In particular, the analysis has evidenced the way they use the technology to process information by taking into account its technological properties and how they make sense of it (Orlikowski 2000; Davidson 2006) by drawing from rules, norms and beliefs of a specific institutional context (Powell et al. 1991; Barley et al. 1997).

The empirical lens adopted draws from the information processing view of organisations, whereby the designs of organisations is associated with their information needs (e.g., Galbraith 1977) and the information flows between the different parts of an organisation (Mintzberg 1979). The main assumption here is that changes in IT-enabled information processing practices reflect changes into the configuration of the organization.

Acknowledging the misalignment between formal policies and designs and unplanned or informal outcomes of their implementation (Piotti et al. 2006), the case study seeks to provide a more systematic understanding of the interplay between top-down pressures (e.g., donor-driven development policies) and bottom-up responses (e.g., data management practices). In particular, by explaining those institutional mechanisms giving rise to multiple rationalities and how these are enacted at different institutional levels, it will clarify the processes influencing the adoption and usage of IT in the restructuring of health information systems.

2 MULTIVOCAL AND MULTILEVEL INSTITUTIONALIST FRAMEWORK

The proposed theoretical framework is characterised by three levels of analysis: macro or policy level, meso or organisational level, and micro or agentic level (Figure 1). For each of these levels, different institutions have been classified under three major institutional pillars: regulative, normative, cultural-cognitive (Scott 2001). This classification allows to better understand what are the major institutional mechanisms influencing the encoding and enactment of typified behaviours by IT users. In particular, the framework views cultural cognitive institutions as informing all the others (Scott 2004).
Figure 1. Multilevel institutionalist framework

The macro or policy level focuses on the influence of different actors (e.g., Governments, donor agencies) in the diffusion of new public sector models and technologies (Ciborra et al. 2005). At this level the main institutional mechanisms are “legal and authority systems” including the international pressure carried through donor funding (regulative pillar), “Civil service norms” (normative pillar) (Scott 2001), and the two main sets of meanings (“cultural-cognitive pillar”) characterising the multivocality of the public sector in Africa: the New Public Management embodied in the reforms (Hood 1991), and the Old Public Administration (Lynn 2006) of local public service models (Table 1). Institutional logics at the macro level influence the institutional elements at the meso or organisational level encompassing governance and management systems, information processing mechanisms, human and technological capacity (regulative pillar), norms and legitimacies dictated by the professional field of the organisation (e.g., health) (normative pillar), patterns of typified information

Proceedings ECIS 2009
processing behaviours (or “scripts”) encoded in different institutional logics (NPM or OPA) (Barley, 1986) and influenced by the material properties of the IT tool (e.g., software source) and institutionally-embedded enactment of the IT tool (“IT-in-practice”, Orlikowski 2000) at the micro-level.

Table 1. Institutional logics of the New Public Management and Old Public Administration

At this level, IS users mobilise IT resources by drawing from this set of institutionalised patterns of information behaviour encoding institutions informed by either NPM or OPA institutions. Depending on how these are sensed (Weber and Glynn 2006), IT users build their perceptions and assumptions on information needs (e.g., uncertainty and equivocality reduction, Daft et al. 1981) and their choice of the best actions, processes and structures to meet them (Malhotra 2000). Hence, by grounding the information processing view of organisations within an institutionalist perspective, it is assumed that the information behaviour of individuals depends on how they legitimate their information needs over time under specific point-in-time institutional and technological pressures. This, in turn, influences their choice of which patterns of information behaviour or scripts to enact. Typified behaviours or scripts are viewed as encoded in policy or macro-institutional mechanisms, organisational structures, and technical features of the IT tools available. The revision of typified behaviours may destabilise the institutional order (Chreim, Williams et al. 2007) giving rise to hybrids that inform new organisational structures.

3 THE CASE STUDY OF TWO HEALTH INFORMATION SYSTEMS IN KENYA

3.1 Methodology

The case study consists of two units of analysis: the central Division of Health Management Information Systems (D1), and the Division of Vaccines and Immunisation (D2). The divisions represent two of the units of analysis of the case study of three health management information systems in Kenya including the HIV/AIDS information system of the National AIDS Programme. Data were collected during a field visit at the Ministry of Health in Kenya. The case study comprehends a sample of thirty-eight semi-structured interviews (one hour average each), 13 from the Division of Health Management Information Systems (D1); 11 from the Division of Vaccines and
Immunisation (D2), and the rest from the National AIDS Programme, which is not illustrated in this paper.

Staff members with the earliest date of deployment were selected in order to capture the longest longitudinal accounts possible. Moreover, the sample included not only health records officers, the direct users of the information system, but also medical management and technicians, i.e., the indirect users of the information system. The inclusion of different organisational roles into the sample of informants was part of a “comprehensive sampling” strategy (Miles & Huberman, 1994, p. 38) in order to have a more systemic view of the evolution of the information system and technological changes.

The questionnaire was structured according to the theoretical framework in Figure 1. Questions were asked regarding their main functions in the division, changes in their working practices, professional values, technological changes and institutional reforms. Interview data on public sector reforms were also triangulated with main policy documents of the Government of Kenya and Ministry of Health covering a period from 1990s up to date. Relevant international agencies’ policy and project documents were also retrieved online.

Data analysis was also framed within the theoretical framework of Figure 1. Interviews were first transcribed and coded in NVIVO 8. Starting from a pre-defined set of codes for each level (macro, meso, and micro) and pillar (regulative, normative, and cognitive), new codes were created along the process of data analysis (Miles & Huberman, 1994 p. 58). Time-series codes were also created starting from 1980 with a five-year interval. After coding each set of interviews for one division, codes were reviewed and similar codes were grouped under common categories (“pattern coding”, Miles & Huberman, 1994, p. 69). As a consequence, all data from the previous division had to be reviewed and analysed again to take into account the new concepts.

### 3.2 Overview of context

The two divisions have developed separate information systems, each characterized by different technological, organisational and policy histories that have affected their evolution. In the last two decades, the health care system in Kenya has gone through a series of public sector reforms mainly under the pressure of multilateral financial institutions such as the WB and the IMF (e.g., “Structural Adjustment Programmes”; “Poverty Reduction Strategy Paper”). In reaction to these reforms, the Ministry of Health issued the National Health Policy Framework (GOK 1994) followed by two major five-year implementation plans in 1999 and 2005 (MoH 1999; MoH 2005). The health sector reform had among its objectives the decentralisation of sector management to the lower levels of the health systems (e.g., districts) and the integration of the health service packages for a more cost-effective and accessible health care.

Thus, the implementation of the reform required the creation and strengthening of health management information systems at the provinces, districts, and health facilities. It is also supposed to involve the merging of health information systems scattered across the various vertical health programmes (e.g., HIV/AIDS) into the central health management information systems of the Ministry of Health.

It followed that in the 80s the Ministry started decentralising the local planning of the health care provision to the districts (GOK 1994) including the creation of health management information systems in district offices. However, apart from this, not much has been achieved in the implementation of the reforms. On the contrary, programmes have developed separate information systems exacerbating the lack of integration and coordination across programmes. This did also negatively affect the decentralisation of health information systems by overloading reporting systems of districts and health facilities.

Since 2005, however, the introduction of result-based management and monitoring and evaluation systems has given a new boost to the decentralisation and integration of health information systems (NSSSP II 2005-2010, MoH 2005). These reforms represent the apex of the restructuring of the public
sector under the logic of the NPM, marking the formal shift from a bureaucratic output-based to a managerial outcome-based approach. As a result, more emphasis has been put onto an integrated well functioning Health Management Information System at all levels. This is supposed to work as a key component of the monitoring and evaluation system of the health service.

3.3 Case study analysis

3.3.1 Division of Health Management Information Systems (D1)

The HMIS Division (D1) is responsible for the collection and analysis of routine health data (e.g., outpatient morbidity, inpatient morbidity and mortality, service utilization, hospital administrative statistics, etc.). Data are managed through Clarion a dos-based data base management system developed in the early 90s through donor assistance. However, given the low usability of the system and the lack of specialised assistance for maintenance, in 2004 most data were migrated to Excel for data analysis. Due to the low data storage capacity of Excel, the only data still stored in Clarion are the in-patients which need to be exported to Excel sheets for the analysis.

Thus, after more than fifteen years Clarion is still in place, despite the fact that health information officers in the division feel quite uncomfortable to work with an obsolete dos-based system that they consider unfriendly and cumbersome. Moreover, the technical features of Clarion (incompatible with Windows- and web-based platforms) have limited its diffusion in the health service and, consequently, its legitimization. This system could not be easily and cost-effectively adopted by the lower levels of the health system posing limitations to the decentralization of the division’s information processing structures. As a consequence, apart from a few districts sending their reports in Excel sheets, most data entry is still done at the central level enacting the OPA cultural-cognitive institution of “centralised information processing”.

This is mainly due to the lack of legitimacy of the division within the health system (“macro-normative”). In fact, the contradictory views over the nature of the mission and tasks of the division in the health system caused no little confusion in the governance arrangements of the division (meso-regulative) with serious implication for its financial support (macro-regulative): “we were under preventive and promotive, then I realised another time we were told no […] we should report to […] planning cause you provide information for planning […] that is why even when we asked for support we could not be supported”. It is only after the introduction of performance contracts with the public sector reforms in 2005 and the official recognition of HMIS as the Ministry’s Monitoring and Evaluation system that the division’s staff could rely on a stronger institutional back-up, a new governance structure with a clear mission legitimized by the top-ranks of the Ministry.

Since then, the management and staff’s decisions and actions have also been characterized by the logics of managerialism and accountability triggering the strengthening of its information processing capacity. Only recently have the provinces and districts been equipped with new IT tools, which could bring to a partial decentralization of its information processing structures. However, this has not happened with government funding, as one could have expected, but still with donor resources.

Hence, the formal acknowledgement of the role of HMIS by the government reforms has not been followed by a substantial legitimization of the division (“Rhetoric of change”). Its mission is still output-oriented and passive with respect to the new overall vision and mission of the Ministry of Health aiming towards a more efficient and inclusive health service The lack of support and legitimacy at the macro level and the absence of a strong and focused mission at the meso level hindered the entrepreneurship of health records and information officers and the medical leadership in their attempts to strengthen the information system.

Management and health information staff are still struggling to gain major legitimacy and attract more government support notwithstanding the more enabling policy environment. Under these circumstances, they have been unable to put into place technological improvements and coherent information processing mechanisms and procedures (e.g., different data entry processes per system)
that could have streamlined the division IS through a stronger integration across central and peripheral levels of the health information system. Hence, the information processing structures of the division are still centralised and cumbersome.

3.3.2 Division of Vaccines and Immunisation (D2)

Like in the division of HMIS (D1), in the Division of Vaccines and Immunisation (D2), computerisation happened in the early 90s with the adoption of CEIS (Computerised Epidemiological Information System), a dos-based system developed and implemented through donor assistance. Like Clarion, CEIS was very cumbersome to use especially because of the lack of programmers that could fix its bugs and upgrade it to accommodate new information requirements. However, towards the end of 2003 the division experienced a more radical technological shift with the upgrading of the old system into Epi-Info, a more user-friendly, self-sufficient Windows computerised system, compatible with a web-based working environment. This innovation enabled a major integration between the central information system and data management offices at the periphery.

This technological shift is the result of an institutional process that started in the 80s when the division was created under the international mandate of the World Health Organisations Expandable Programme on Immunisation (WHO 1989). Thus, based on the major legitimacy of its mission in the global health strategies (macro-normative), the division was supported by conspicuous donor funding. Informed by the OPA logic of “politicisation of service”, the exogenous pressures of donor funding triggered a series of actions and events at the micro level, that, by contrast, were mainly informed by the NPM logics of “accountability” and “customer-orientedness”.

One action in particular was the initiation of a performance-based grant programme of immunisation at the beginning of the year 2000. This constituted an incentive for the division to improve its routine monitoring systems to provide data evidence that could award them with further funding. Thus, under the NPM logic of “managerialism”, the management of the division engaged in a series of activities to streamline the information system. It started by asking support from international partners to design EPI-Info, a new Windows-based network system. By the end of 2003 EPI-Info was rolled out to the provincial offices which started performing data entry. In this way, the workload of processing information was more evenly distributed between the centre and the provincial offices (“partial decentralisation of information processing”). Later on, policy guidelines on data management were also introduced at all levels bringing more consistency in routine reporting.

Although the latest improvements have happened under the pressure and with the help of international partners, the need to attract donor funding does not seem to have been the major reason behind it. In the last decade, most donor funding has been diverted from immunisation to other international health priorities (e.g., HIV/AIDS). Hence, while in 1999 donor contribution to the routine immunisation system was 83% against the 17% from Government budget, in 2001 Government financing equalled 53% of total expenditures after the Government increased considerably its contributions to vaccines procurement (WHO 2001).

This means that besides the attractiveness of donor funding, the structural improvements in the health information system that followed the development and implementation of EPI-Info rested onto the new legitimation that immunisation and disease surveillance data acquired within the country. Aware of this, management sought as much support as they could to improve their monitoring and evaluation systems in order to provide evidence of the division’s achievements and needs to secure funding from the Government budget.

Hence, the Government ownership (and legitimacy) of national immunisation initiatives facilitated the “translation” (Zilber 2006) of the value of health information for planning instilled by international partners. In this way, the management of the division was facilitated with respect to other departments such as HMIS (D1) in the implementation of the Second National Health Sector Strategic Plan (2005-2010).
Hence, the logics of accountability and customer-orientedness have been the major triggers towards the adoption of a new computerised system for the restructuration of the health information system following the legitimacy of the division in the national health service. These logics survived the considerable withdrawal of donor contribution. In contrast, they were reinforced by the need to compete for the meagre government resources. The appropriation of these endogenous logics into the national immunisation services allowed a more consistent action of management towards an efficient and effective M&E system within the framework of the new reforms.

4 DISCUSSION OF FINDINGS

Findings show that the adoption of Information Technology has led to distinct institutional shifts and organisational outcomes. In the Division of Health Management Information System (D1) cultural-cognitive institutions informing central information processing still persist in contrast with the Division on Vaccines and Immunisation (D2) where the process of decentralisation of their information systems has been more effective. The different impact of the technology onto the structures of the health information systems of the two divisions is due to both institutional and the embedded material resource environment, namely, the technical properties of the technology and available human capabilities.

Although decentralisation policies started far back in the late 80s, the decentralisation of health care delivery has never been fully achieved. The case study shows how different approaches towards technological change and the usage of IT in the two divisions have actually produced opposite outcomes in the decentralisation of the structures of two health management information systems informed by the same policy environment.

In particular, in the first division the weakness of endogenous macro-policy institutions fails to translate the new logics of the NPM informing the reforms into the local setting. The mediator function of the meso-level institutions in maximising the benefits of IT-enabled change is thus hindered. The initiative of management and records personnel did not find the necessary support at the policy level lacking access to the resources necessary for the enactment of the new logics. Although the normative pressures at the meso level from the health records profession to improve the efficiency of the HIS might have identified the need for new IT systems and information processing practices, the lack of a viable institutional, and consequently, material resource environment has prevented these demands from being turned into a necessity and a clear response action.

In contrast, an increased commitment by the central Government in the provision of immunisation services brought about the necessary legitimacy of the Division of Vaccines and Immunisation (D2) in the national health system. The new legitimacy instilled a stronger motivation by management towards the enactment of imported logics informing donor-driven monitoring and evaluation systems into the local context. This motivated management towards the employment of information technology for the partial decentralisation of the information system. Management has been an important catalyst of change towards this direction by focusing on the provinces as the strategic layer of coordination of the health information system and by standardizing data collection practices. Hence, although donors were instrumental by providing the financial and technical resources necessary for the set up of the new computerised system (Epi-Info), the main trigger of the IT-enabled decentralisation of the information system came from endogenous pressure to acquire national legitimacy that would secure Government funding.

Although the alignment between political administrative, management and user levels (Kimaro & Sahay 2007) is important for attaining results, this alignment is easier to achieve when there is a strong support and legitimation from the political administrative level. Institutional forces at the macro-policy level are the main triggers of IT-enabled organisational change. This change is as much consistent and effective as the main cultural-cognitive institutions informing it are supported by endogenous institutions at the macro level.
Finally, further important considerations can also be drawn from the material resource environment, specifically, in relation to the technical features of the IT systems. Epi-Info (D2) and Clarion (D1) were both exogenous technologies of western origin introduced to improve efficiency (timeliness) and accuracy (completeness) of information (Health reports). However, this happened in two different and distant periods of time with different technological advancements. In the early 90s, the technical properties of information technologies did not enable easy networking and communication channels for the integration of information processing. Moreover, being Dos-based, its lower level of usability and user-friendliness implied high deployment costs to the data management offices at the periphery. Lastly, off-the-shelf data management packages were not as diffused as today (e.g., Excel) and the development and enhancement of integrated application suits for data storage and analysis, especially, with poor in-house capacity, was quite demanding. Given the technological advancements of the time, Clarion was among the best technologies to achieve “timeliness and completeness of reporting” by enabling fast data entry and increased data storage capacity at the central IS office.

Hence, although the institutional pressures and sources for change are more or less the same for both systems (donors want more efficient M&E system “accountability”) and such institutional pressures or mechanisms encode the same meanings (“cultural-cognitive institutions”) of change, the enactment of these meanings is influenced by material technological environments (entailing different technological properties) spanning across two different technological eras. Eventually, this gives rise to two different structural and institutional outcomes (centralisation vs. partial decentralisation) and of course performance outcomes.

Likewise, what is it that turns the users’ perceptions of Clarion as an efficient system of the 90s to an outdated and cumbersome system of the year 2000? Most likely, the trigger of a change of cognitive framing (Orlikowski et al. 1994; Davidson 2006) of Clarion has been the exposure towards more advanced technologies. This must have increased the awareness that there are more efficient ways of processing data through IT tools. Hence, it can be inferred that the major factor influencing the changes in the framing of Clarion has been the evolution of the technological environment and the availability of more advanced data analysis features. This has contributed to a more limited usage of Clarion and, on the other hand, a more frequent usage of Excel, which contributes to the enactment of different IT-enabled IP behaviours (“IT-in-use structures”, Orlikowski 2000) and also distribution of tasks.

5 CONCLUSIONS

The case study has shown that the impact of information technology onto the structures of a health information system in Africa is mainly influenced by the support of endogenous macro-level policy institutions and resources. These stimulate the enactment of exogenous cultural-cognitive institutions informing donor-driven reforms by management and key professions at the meso-organisational level towards the usage of technology for sustainable change. Moreover, the material resource-environment represented by the institutionally-embedded technical properties of IT and relevant human expertise is instrumental for the translation of exogenous logics informing change. Hence, the IT artefact can be used to reduce the gap between formal planned structures and informal routine or practices (Kimaro & Sahay 2007) of IT users, if new rationalities embedded in imported reform models are translated to the local context through stronger Government commitment at the macro/policy level. This can facilitate the task of management and key professional staff in their effort to leverage information technology for the realignment between policy discourses at the macro level and their enactment at the micro-level.

The material resource environment plays a considerable role in shaping the institutional forces underpinning IT innovation and usage. Donors’ resources are still instrumental in the transfer of new technologies and accountability systems to the health systems of countries like Kenya. In fact, decision makers within Governments are not familiar with the usage of information technology as powerful tools for planning and monitoring the health system. Moreover, specialised solutions such as
computerised epidemiological systems are more available from the global market than the local market.

Management and professionals at the meso level of the public administration can reduce the gap between global and local “technological frames” (Orlikowski and Guah 1994, Davidson 2006). Being more exposed to international experts, and new innovations, and building onto past experience of IT investments, they can master IT-enabled transformations for a sustainable and effective restructuring of the health information system.

Moreover, the technological environment, in terms of different technological properties, also contributes to the definition of institutional pressures and management and IT users enactments. Hence, expectations of structural changes and performance depend onto the opportunities offered by technological advancements. In the same way, the enactment of same logics (e.g., efficient data processing) can lead to different structural outcomes depending on the material properties of the technology and the influence of the material technological environment (e.g., dos-based systems are kept for centralised systems, while Windows- and Web-based technologies are introduced to decentralise systems). These considerations offer a contribution towards a better conceptualisation of the IT-artefact in the human enactment of information technology.

MICRO-EMANCIPATORY PRACTICES IN
INFORMATION SYSTEM DEVELOPMENT

Abstract

The paper revisits the notion of emancipation in Information System Development (ISD) that seems to have lost a battle against functionalist and managerialist approaches dominant in information system (IS) research and practice. Unlike functionalist and managerialist views, the emancipatory view of ISD, informed by Critical Theory, considers ISD as a site of organizational innovation, self-reflection and a struggle for humanization of work and liberation from different forms of domination. Critics of emancipatory project in IS and management literature question the very possibility of the emancipation and deplore its intellectualism, naivety and negativism. The purpose of this paper is to re-consider the notion of emancipatory ISD in the face of these criticisms and develop a more refined and nuanced view of micro-emancipation in ISD that is meaningful in practice. Informed by Alvesson and Willmott (1992, 1996) we explore, question, redefine and ground the micro-emancipatory ISD processes based on a longitudinal (15 year) study of a retail company. Our analysis and critical reflection demonstrate that micro-emancipatory ISD processes have real substance for the people involved, and that their meanings are neither fixed nor universal, but rather local, emergent, uncertain, and sometimes contradictory. This paper contributes an empirically grounded and practically relevant reconceptualization of micro-emancipatory ISD projects which reveals both its benefits and risks for all involved.

Keywords: Micro-emancipation, Information Systems Development (ISD), Emancipatory Practices in ISD, Emancipatory ISD
1 INTRODUCTION

An emancipatory approach to information systems development (ISD) was proposed to counteract an increasingly narrow and functionalist focus on organizational productivity and efficiency dominant in both the mainstream information systems (IS) research and IS practice. Informed and inspired by Critical Theory several prominent researchers exposed new forms of control and domination emerging through implementation of IS disguised under the ‘objective’, ‘impartial’ and ‘scientific’ ISD methodologies (Weizenbaum, 1976; Klein and Lyytinen, 1985; Lyytinen and Hirschheim, 1985, 1988; Lyytinen and Klein, 1985; Lyytinen, 1992; Myers and Young, 1997). An alternative view of IS as social communication systems that have a potential to freeing employees from ‘repressive social and ideological conditions and thereby contributing to the realization of human need’, was proposed by Hirschheim and Klein (1994, p. 87). They argued for an emancipatory ISD methodology that assumes a systematic and meaningful user involvement, open and non-distorted communication, and reasoned argumentation based on cooperation and mutual understanding among IS developers, managers and employees affected by the system.

However, emancipatory ISD ideas and approaches have been dismissed as unrealistic and naïve, incapable of addressing real-life power struggles or preventing colonizing effects of IS (Wilson, 1997). More broadly the emancipatory project of Critical Theory as such and its application in management (including IS) have been criticised by poststructuralists for implying a rationalist bias, for harbouring essentialist assumptions about unified, autonomous subjects and for imposing all-embracing frameworks or ‘metanarratives’ that reduce the complexity and heterogeneity of phenomena (Lyotard, 1984; Calas and Smircich, 1987).

While much of these criticisms, primarily from poststructuralist quarters, arise from a considerable misunderstanding of Critical Theory and its concept of emancipation – as demonstrated by Alvesson and Willmott (1996) – some are justified and worth heeding. Acknowledging the disillusionment with grand programme of emancipation, they propose a more modest concept of micro-emancipation that describes partial, temporary and precarious forms of liberation and resistance to oppressive organizational practices. Their proposal, however, has not been explored further in the literature. In the IS literature in particular, the emancipatory ideas and ideals seem to be forgotten and the whole debate about their meaning, reality, and relevance relegated to history.

In this paper we aim to revive the debate around the notion of emancipatory ISD. More specifically we aim to revise the concept of emancipatory ISD as proposed by Hirschheim and Klein (1994) and explore its relevance in the face of major criticisms in the literature. Inspired by the Alvesson and Willmott’s (1992, 1996) proposal for examining micro-emancipation projects we aim to develop a more refined and nuanced view of micro-emancipation in ISD that is meaningful in practice. While ISD projects are typically firmly driven by desired performance improvements (efficiency, effectiveness) we suggest they can also be seen as sites of organizational transformation where status quo is questioned and existing forms of control problematized and resisted, and where workplace conditions are challenged.

We achieve our aims by first presenting a short literature review and then a longitudinal study (15 years) of an IS development in a Belgian retail company. In the following section we trace and critically investigate the development practices of their most important IS (a corporate information dissemination and groupware system they call ISID. Based on this analysis we develop a framework that defines a refined and empirically grounded conception of micro-emancipatory ISD processes and practices. In the Conclusion we discussed its contribution and implications for the theory and practice of ISD.
2 EMANCIPATORY IS DEVELOPMENT IN THE LITERATURE

Emancipatory ideas in ISD have their origins in the Scandinavian participatory design approach and the socio-technical design movement in the UK in the 1960s. In response to the increasing use of information technologies (IT) serving an economic rationalist agenda at the expense of further bureaucratization and dehumanization of work, participatory design and socio-technical principles were based on humanist ideals, workers autonomy and workplace democracy. They argued for the use of technology to achieve both efficiency objectives and improved ‘quality of working life’ (Mumford and Weir, 1979; Bjerkins et al. 1987; Bodker et al., 1987; Bjerknes and Bratteteig, 1995; Mumford, 1983, 2000, 2006). Both these approaches assumed an underlying belief in technological progress and human knowledge and enthusiasm for computer applications that would replace boring, repetitive and dehumanizing jobs, increase job satisfaction and thereby eliminate workers’ alienation. Proliferation of projects that adopted and advanced participatory design in Norway, Sweden, Denmark – referred to as the collective resources approach – together with projects that adopted the socio-technical design in the UK, followed by other European countries, Canada and the USA, in the 1970s and early 1980s, raised hopes in the democratizing potential of IT.

However, their promises of humanization of work, workplace democracy and workers empowerment to make design and work-related choices were not long lived. The economic pressures in the late 1980s and 1990s and the raise in unemployed labour changed market and employment conditions leading to the revival of computer-aided neo-Taylorism (Moldaschl and Weber, 1998). The deployment of IS to cut costs, downsize workforce, increase managerial control, and achieve lean and efficient production based on standardized work processes, went counter to socio-technical and participatory design principles and practices. Socio-technical design, as Mumford (2006) conceded, ‘moved from success to failure’ as ‘[t]he attraction and validity of bureaucracy was seen as stronger and safer and the new humanistic approaches as over-risky’ (p. 321). Researchers are raising their critical voices against the narrow view of IS as a means of furthering economic rationalist agendas, the view that obscures repressive social conditions and ‘the continued destruction of the human potential’ (Asaro, 2000; Saravanamuthu, 2002; Howcroft and Wilson, 2003).

A distinctly critical approach to IS development was influenced by Critical Social Theory (e.g. Lyytinen and Hirschheim, 1985; Lyytinen and Klein, 1985; Cecez-Kecmanovic et al., 2002; Alvarez, 2008). Hirschheim and Klein formulated four conditions for an emancipatory IS development methodology (1994, pp. 87-88): 1) Providing support for an active process of individual and collective self-determination; 2) Providing support for critical self-reflection and associated self-transformation; 3) Inclusion of a broader set of institutional issues relating particularly to social justice, due processes and human freedom or more concretely in ISD to employees’ ethical needs, quality of work life, personal autonomy, and the linkage between participation and democracy; and 4) Inclusion of the principle for critical evaluation of claims or rational discourse during the systems development processes.

The emancipatory ideas in ISD and more broadly in management, however, have been criticised for neglecting the reality of business conditions, the pre-eminence of shareholders’ interests and robustness of organizational power structures. The alleged utopian nature of emancipatory projects was a reason for claiming their disconnection from reality and the mundane practices of management (Alvesson and Willmott, 1992). Furthermore, critical management studies and critical approaches to IS have been accused for being one-sided (anti-performative and anti-management), negativistic and unconstructive (Alvesson and Willmott, 1992). Moreover, Wilson (1997, p. 196) in response to Hirschheim and Klein (1994) questions their “arbitrary ideological position” and criticises the conditions for emancipatory ISD processes. Being suspicious of the real meaning and agenda of the humanistic approach he contends that an ISD process conceived of as a rational discourse that counteracts distorted communication, can be seen as a formula for totalizing discourses, that view organizations as homogeneous entities.
Empirical studies are called for to examine and respond to these claims and criticisms. In this paper we draw from a longitudinal case study of ISD with the aim to 1) revise the concept of emancipatory ISD as originally proposed by Hirschheim and Klein (1994), and 2) to develop a more refined and practice-based view of micro-emancipation in ISD (informed by Alvesson and Willmott, 1992, 1996) and discuss its relevance in the face of major criticisms in the literature.

3 RESEARCH SITE AND METHODOLOGY

Our motivation to study participatory and emancipatory IS developments initially came from practice. While conducting a longitudinal case study of informatization processes and organisational development in the Colruyt company (from 1993 to 2008) we observed unique practices of user participation in the development of IS with explicit democratic and emancipatory intent. Intrigued by these observations we decided to study more in-depth the meaning and nature of user participation as it emerged and continued throughout the company’s history. We focused on the Information System for Information Dissemination (ISID), which is a groupware and document management system that was developed by the company’s IT department. ISID’s development commenced in the early 1970s and it has been under continuous development ever since. ISID proved to be an essential component of participatory decision making and the cooperative culture that the company has been developing since its inception until today. It was therefore particularly intriguing to investigate how the Colruyt company actually developed ISID, how it attracted and engaged users and how users felt about their participation in the systems development and use. Given the criticisms and controversies found in the literature we were particularly interested in examining participatory and emancipatory ISD processes and theoretically explaining the controversies around non-emancipatory and emancipatory discourses and practices.

The Colruyt company was founded in Brussels, Belgium, in 1965 as a single food discount store - a revolutionary concept in Europe at that time. Selling its products 10% below prices charged by competitors, paying employees 10% above industry average wages, and realizing a 1% profit margin on sales remains the company’s business strategy (IS Manager, Interview 1993, 2000). Today, the Colruyt company is the third largest food retail chain that operates 205 food discount stores in Belgium and 45 stores in France with annual sales revenue of US $8 Billion (company Annual Report, 2007-2008).

Mr. Jo Colruyt’s (CEO until 1993) relied on Information Technology (IT) to support and innovate all business processes. IT was adopted not only to automate tasks and improve efficiency, but also, and more importantly, to support workers in their operations and work simplifications as well as participation in decision-making. Jo Colruyt recognized that IT affects people and influences social conditions of work. He stated: ‘Existing conditions, social structures, relations between individuals, and relations between social classes in a company change when new technologies are introduced’ (interview 1993). To enable workers to embrace IT and meaningfully contribute to company’s continuous innovation it invested heavily in staff training and education (e.g. in 2007/8 training and education budget was Euro 9.5 mil or 3.2% of after tax profit). Seminars were available on communication, self-actualization, self-empowerment, self-expression, decision-making and assertiveness.

Our longitudinal study of the Colruyt company started in 1993 when a co-author first visited company headquarters in Brussels to interview founder and then CEO, the late Jo Colruyt. Since then regular visits to company Headquarters involved informal discussions and formal interviews with employees and managers, and attending and observing official meetings in stores, warehouses and headquarters and observing the use of ISID. On-site audio taped interviews were conducted with Jo Colruyt, the former CEO of the company and his son Jef Colruyt who became CEO in 1994, the chief information officer, the marketing manager, middle level managers, IS personnel, workers in stores and warehouses, and union representatives. In total twenty five interviews were completed over the period 1993 until 2008 and ten company meetings attended. Semi-structured interviews were
conducted and later transcribed for further analysis. Data collection also included researcher’s observation notes, company documents, policy statements, work procedures and rules, meeting documents, most available via ISID, as well as company annual reports (1975, 1985, 1988, and 1990-2008), union reports, and newspaper articles.

Our interpretation of the nature, meaning and challenges of ISID development and use drew on the narratives of actors, employees, managers and IS specialists and the ways these individuals made sense of and reflected on events and on-going changes. The narratives and meaning making processes were an integral part of their social construction of reality, their social actions as well as social and cultural (re)production (Czarniawska, 1998). The narratives reflected what was important to these actors and what was problematic and challenging in ISID development. Furthermore, we analysed the documents created as part of ISID development, relevant for the company as a whole and communicated via ISID. We adopted thematic analysis that was informed by theoretical concerns and interrelated with the analysis of interviews.

For the analysis of empirical material collected during ISID development we adapted Alvesson and Willmott’s (1992, 1996) two-dimensional framework. This framework was applied as a guide and at the same time used for critical reflection that refined it. The framework proposes a distinction between the type of emancipatory project and the focus of its intent in order to enable a more refined analysis and understanding of emancipatory projects in practice. The type of emancipatory project may range from questioning, to incremental transformation or reformist, to utopian type. While questioning involves critiquing, challenging and at times resisting dominant forms of thinking and social arrangements, without proposing the desired (or the ideal), the utopian type advocates alternatives to existing conditions. The utopian element is important, as Alvesson and Willmott (1992, p. 450) explain, when participants envision alternative arrangements, social relations or ends. Between these two opposites, an incremental or reformist type of emancipation involves gradual change towards the desired forms or systems.

Concerning emancipatory intent a distinction is made between means, social relations and ends. The emancipation of means concerns distorted discourses and oppressive organizational practices that are assumed to be necessary to achieve organizational and managerial ends. The emancipation of ends, on the other hand, ‘is concerned with unfreezing institutionalized priorities and, thereby, opening up debate about the practical value of economic growth, consumption, the quality of life and so on’ (Alvesson and Willmott, 1992, p. 450). Finally, the focus on social relations draws attention to social and power structures, relations of domination and control, and the ways these limit autonomy, creativity, self-determination and self-realization.

The Alvesson and Willmott (1992, p.450) framework introduces analytical distinctions that are relevant for examining and clarifying the nature and scope of emancipatory ISD. Inspired by their work we adopted this framework in the analysis of practices during ISID development in the Colruyt company, which we present next.

4 EXPLORING EMANCIPATORY PRACTICES OF ISID DEVELOPMENT

To explore practices during ISID development and examine specific dimensions of the macroemancipatory framework as proposed by Alvesson and Willmott (1992, 1996) we shall follow the project of ISID development from its beginning in 1970 till 2008. We present our findings along these dimensions.

Questioning, challenging, and critiquing
ISID was initiated based on the criticism of existing processes, working conditions, and inefficiencies, made by both managers and employees. Employees were especially dissatisfied with poor access to information. In the 1960s and early 1970s company relied on face-to-face communication and workgroups (written records from group meetings were widely distributed) in an attempt to build a culture of open communication and free expression. However as the company grew it faced increasing problems with communication and information sharing among hundreds of its distributed employees. The first phase of ISID development in the 1970 started in response to criticism of poor information and lack of support for distributed groups of employees and various forms of participative decision making (meetings, workgroups) that could not rely any more on paper-based dissemination of information and reports. Although Colruyt was known as the first company in the 1970s to set up a computer system that store documents and disseminate them in printed form to its employees, employees did not considered it good enough for the cooperative work and decision making processes already established when the company was smaller and working face-to-face. Employees requested faster information channels, they criticised the lack of timely and relevant information they needed to competently and efficiently perform their jobs (in stores, warehouses, sales), coordinate their actions and take part in decision making.

In the second and third phase of ISID development narratives changed with the focus shifting toward more subtle issues such as equity in terms of rights to access to information. From the first ideas ISID provided unrestricted access to information to all employees. However, an incident of information misuse of (documents from ISID leaked by Union Stewart and misinterpreted in a TV program in 1984 with a significant damaged to Colruyt reputation) sparked a wide-ranging debate about the conflicting demands between completely open access to ISID and preserving confidentiality of sensitive information in the interest of all. If ISID was going to realize Colruyt principle of ‘access to information as a right’ for all employees, the question was on what bases this right could or should be curtailed? An anti-emancipatory step was taken – considered necessary but regrettable by the majority of employees – to restrict access to confidential information. Mr. Jo Colruyt was among those who preferred to train the community in responsible ISID use but he also realized that protecting confidential information was inevitable at a time:

> It will always remain a delicate balance between confidential ISID documents and a broad access to information. I prefer to keep the number of confidential documents small in relation to non-confidential documents. It appears useful to teach employees to use information judiciously and to instruct them in normative behaviour with respect to information. Employees have the right to a very broad range of information [stored in ISID]. (Jo Colruyt, 1984)

It was widely accepted by managers and workers that democratic rights and open access to information in ISID needed to be balanced against the risks of misuse and the harmful disclosure of confidential information outside the company. However, the views how to achieve this differed.

Questioning the means, namely, ISID development discourse and practices in addition to the ends to be achieved with ISID implied user-developer and worker-manager social and power relations. Open access by anyone to ISID led to equalization of power that some managers felt threatening and pockets of resistance surfaced more or less overtly. This ‘relational friction’ can be seen to arise from an inherent labour-capital conflict that lies in the foundation of any capitalist company. By supporting and enabling more effective management and control of processes and employees, IS often exacerbate this conflict. However, the Colruyt company’s distinct feature is its continuous effort to reveal and openly confront labour-capital conflict manifested in various relations and processes. By way of questioning, challenging, arguing, critiquing and requesting changes ISID development and implementation led to incremental transformation of discourses and practices (means), power relations and ends to which we turn next.

**Incremental changes and transformation**

Starting during the early 1970s ISID development impacted on and was impacted by changing relationships between users and developers as well as workers and managers. There was an awareness
among the workers that ‘having information means having power to act in an informed manner’. With IT training and with experience in ISID development and use, workers became increasingly aware of their role in the ISID development as part of their participative rights.

Furthermore, incremental changes were experienced in worker-manager relations. Due to access to ISID and workers’ informed participation in decision making, power relations became less hierarchical and more cooperative. However some managers resisted information sharing and devolution of power. Transformation occurred as part of culture change and personal development through training:

We have a culture of [personal] growth within the company. I myself have experienced these [culture and personal growth] at all managerial levels, it is evident, and you know this. I think that only individuals who can accept sharing information with subordinates and with others are promoted to managers. (Walter de Hertog, interview 2003)

Transformations towards sharing of information – primarily through ISID – and devolution of power were not without conflicts, but ultimately, the few managers who obstructed these processes retired.

An important question concerns the emancipatory transformation of ends, that is to say, the extent to which IS development and implementation contributed to the articulation/transformation of ends and their achievement. Transformation of ends was directed toward a more balanced articulation of economic versus social or humanist aims. The former CIO Marcel Lengeler and other employees mention ‘increasing individual performance’, ‘job improvement’, ‘commitment to hard work’, while at the same time emphasising ‘enhancement of job satisfaction’ and ‘enjoyment of work’. Similarly ISID is seen as a major contributor to both better company performance and community building. In fact the economic and social/humanist ends are often seen as conditioning and supporting each other. One employee, for instance, pointed out that ISID enabled him to enjoy ‘freedom to make decisions and to share responsibility within [his] company’. Furthermore, the value of workplace democracy and power decentralization enabled by ISID also is understood as contributing to organizational flexibility as well as its capacity to adjust to new situations as stated by Mr. Jo Colruyt:

Power decentralization has the enormous advantage of organizational flexibility to instantly adjust the organization to new situations. … To communicate [via ISID] means that as a group we are capable of greater achievements. Moreover, in this way we experience greater satisfaction from our work and experience the joy of an increased work engagement. (ISID document, April 1984)

The evidence shows that transformation of ends achieved through ISID involved a continuous struggle to balance personal and organisational achievements, personal performance and enjoyment of work, and to harmonize the Colruyt company’s economic prosperity with community building.

Utopian vision of ISID development

The ideal of open access to information was an important utopian element in the vision of the ISID development. When confronted with existing conditions and risks of leaking confidential information this ideal could not be sustained. Having such an ideal as a guiding vision for ISID however was and still is beneficial as it indicates a desired state of affairs and reminds company members how far or close they are from achieving it. It also counteracts tendencies to make further restrictions.

Furthermore, ISID development can be seen as a ‘rational discourse’ as defined by Habermas’ (1984) Theory of communicative action. Being very pragmatic Colruyt company members do not talk about the ideal of rational discourse but engage in it in practice. This was demonstrated during ISID development team meetings that one of the authors attended where participants showed excellent questioning skills, providing arguments and counter arguments, and conducting an open and well argued debate. The outcomes of ISID meetings were made public via ISID thus increasing company-wide awareness of its results and seeking responses and involvement by others.

The development of ISID can thus be seen as embracing a utopian vision of the company and its communication. Although in the early years (1970s) this vision seemed indeed quite utopian it was
nevertheless powerful and inspirational: it gave company members a sense of direction and purposefulness. Confronted with existing conditions, the vision stimulated thinking and debates thus enhancing emancipatory project. Importantly, employees maintained a critical attitude:

Of course not everything in the company comes up rosy, anyway this is the case everywhere else, how else would it be possible to maintain a critical spirit. (Claude Pardonche, 1984)

Similarly we can see a utopian element in the vision of the ISID development process as a rational discourse. Being very pragmatic Colruyt members do not talk about the ideal of rational discourse, which reminds us of the debate about Habermas’ (1984) ideal speech situation. Since early 1970s they have talked about and applied norms and rules regarding employee participation rights, fairness in social interaction and reasoned argumentation in all key problem solving activities and meetings. ISID development practices and discourses reflected these more general norms of broad participation, rational debate and argumentation.

Another powerful utopian vision in the course of the ISID development has been the vision of equality and symmetrical power relations, among managers and employees as well as among the users and developers. The vision of decentralisation of power that required decentralization of information was and remains to be a guiding principle in ISID development. For instance in the first stage of ISID development employees requested to be informed about company performance and current operational issues in order to be able to participate in decision making. Similarly the vision of ISID as social infrastructure and social arrangements to achieve individual and collective self-determination, power decentralization, and reduction of alienation and domination featured for instance early on in debates about the ways information is captured and distributed to all members, and later in discussions about the open access and necessary protective measures (sparked after Unions’ misuse of ISID documents).

An important utopian view of ISID focused on company ends. Ideally the development and use of ISID is seen as enrichment of professional and personal life of all members, contributing to democratic work environment, work enjoyment, individual and collective self-realization, and thereby freeing creative capacities of employees, opening up company opportunities and improving performance. The vision of ISID was essential to realize the company’s philosophy and to implement in practice its ideals, principles, and strategies.

The utopian vision of ISID and its role in determining and achieving company ends can be criticized, especially from a poststructuralist perspective, as totalizing, possibly excluding other voices. There is the risk, a poststructuralist would claim, that the utopian vision of participatory culture, open communication and the ideal of ISID development as rational discourse degenerates into ideology with anti-emancipatory implications. While such a risk cannot be excluded, our in depth analysis of micro-emancipatory events and situations (grounded in the narratives by actors, documents, ISID transcripts) suggests that the utopian element in ISID development stimulated critical thinking and opened up novel alternatives as envisaged by Alvesson and Willmott’s (1992):

The utopian element emerges when the current conditions are confronted with a new form of ideal, which aims at opening up consciousness for engagement with a broader repertoire of alternatives. Utopianism then represents alternative thinking rather then the suggestion of a ready-made, better alternative or the providing of courses of action. (p. 450)

The utopian vision of open communication inspired and opened up desirable models of ISID that drove its technological development. Rather then imposing a solution, the utopian vision released creative capacities of employees, motivating them to search, and continue searching, for innovative ways of communicating, working and decision making.
5 MICRO-EMANCIPATORY ISD FRAMEWORK

The above analysis reveals a large range of foci and approaches in ISD practices that potentially have emancipatory implications. These emancipatory implications do not necessarily correspond to grand views of liberation. Instead we identify numerous micro-emancipatory processes and practices that are situated, local and meaningful for the people involved. Macro-emancipatory processes are defined within the framework in Table 1, adapted from Alvesson and Willmott (1992).

Table 1. The ISD micro-emancipatory framework (adapted from Alvesson and Willmott, 1992)

First the object or focus of emancipatory change may range from the means to the ends:

- **Means** refer to discourses and practices of IS development and use that enable achievement of individual, group and organizational ends
- **Social relations** affected by IS development including those between developers and users, and workers and managers
- **Ends** supported and enabled by IS development include:
  - Individual performance and job satisfaction
  - Democratic workplace and participative decision-making
  - Organizational performance and community building

Each of these foci of emancipatory practices in the observed ISID development in Colruyt is examined in terms of the nature or type of emancipatory change, that is, whether or to what extent it involved:
• **Questioning, challenging and critiquing** current work and information practices as well as **arguing** and **requesting** new and higher quality of information, better access to information, user-developer and worker-manager power relations, articulation of ends, etc.

• **Incremental changes and transformation** of discourses and processes of ISD; worker-manager and user-developer social and power relations; and individual or organisational ends;

• **Utopian views and vision** of discourses and practices of ISD (means), social and power relations and the ends to be achieved with ISD.

These dimensions determine the ISD framework (Table 1) that analytically distinguishes 9 classes of micro-emancipatory changes. Based on our analysis we formulated a generic question to explore micro-emancipatory processes for each class. For instance, the question (second row, first column): *Has ISD questioned or problematized user-developer and worker-manager social and power relations?* is intended to focus attention on social and power relations in an organisation and how ISD questioned or challenged them. These questions may assist researchers to examine specific, local micro-emancipatory practices and investigate the meaning of emancipatory ISD.

### 6 THEORETICAL CONTRIBUTION AND LESSONS LEARNED

The paper contributes to the debate about the emancipator ISD practices. It revisits the concept of emancipatory ISD as originally proposed by Hirschheim and Klein (1994) and develops a more refined and practice-based view of micro-emancipation in ISD informed by Alvesson and Willmott (1992, 1996). Grounded in empirical data from the longitudinal case study of ISID development in the Colruyt company (1993-2008) the paper discusses and provides arguments for the micro-emancipatory ISD framework. The framework identifies classes of micro-emancipatory practices illustrated by examples from ISID development and use. The case analysis shows that micro-emancipatory practices are local, situated and meaningful for the people studied.

The proposed framework to study micro-emancipatory ISD practices grounded in empirical data in many ways responds to criticisms of emancipatory ideas in the literature. Chief among them is the charge that emancipator ISD neglect the reality of business conditions, the pre-eminence of shareholders’ interests and robustness of organizational power structures (Wilson, 1997). The alleged utopian nature of emancipatory projects was a reason for claiming their disconnection from reality and the mundane practices of management. The paper demonstrates the reality of emancipatory ISD practices and their meaning in context, however local or contentious they might appear. The company is both an industry leader in efficiency and in democratic social relations. The emancipatory ISID development in Colruyt reflects its participatory culture, devolved decision making, autonomy and responsibility of workgroups, as well as individual and collective strive for excellence and superior performance. There ISID development processes were equally driven by concerns for work improvement, efficiency, effectiveness, and sound technical solutions, as they were by improvement of working conditions, employees’ work satisfaction, individual and collective self-realization and community well-being.

Furthermore, increasing efficiency and effectiveness of business processes and overall company performance – seen as economic objectives – are not necessarily opposed to workers’ participation, their greater autonomy, responsibility and emancipation – perceived as social and humanist objectives in ISD. Achieving social and humanist objectives does not need to be at the expense of economic ones, as is widely assumed. Similarly, increasing levels of economic performance do not necessarily require increasing control, diminishing autonomy and stringent subordination. In fact in Colruyt by acquiring greater autonomy and responsibility and by increasing their participation in decision-making enabled and supported by ISID, employees became more innovative in simplifying work processes and more successful in increasing their efficiency and effectiveness. Participatory rights, access to information and empowerment of employees have been practiced as values of their own, which in turn became the drivers of the company economic prosperity. While facing tough economic conditions and
ever harsher competition, the Colruyt company has invested in ISID prospered and was continually expanding: it is the third largest food retail chain in Belgium with stores expending in France and Germany. The longitudinal study of ISID at Colruyt demonstrates not only the realism of the emancipatory ISD in practice but also confirms the reality of Hirschheim and Klein’s proposals:

It can be seen that emancipation produces positive consequences for effectiveness and efficiency concerns: stable, self-confident personalities are the pillars of a stress-resistant work force; individuals confidently expressing ideas is the bedrock of creativity to meet competitive demands; and only people accustomed to autonomous, responsible action can be expected to make initiative when things go wrong, which increases organization’s flexibility and capacity to deal with uncertainty (1994, p. 98)

Another major lesson from the Colruyt company perhaps is that in order to advance the emancipatory ISD, and make it more relevant for IS practice, one can use not only a humanist argument but an economic one as well. By adopting numerous micro-emancipatory practices in ISID development Colruyt continuously transformed its processes and practices leading to equalizing developer-user and manager-employee power relations. ISID development was part of the decentralization of decision making, increasing employees’ discretion and autonomy, and enhancement of workplace democracy. Importantly though the company’s emancipatory transformation produced commercial success. In almost every aspect of its performance – sales per store, sales per square meter or per employee; profit per employee or square meter, etc. – Colruyt shows superior results compared to other similar retail chains. This is despite additional costs of coordination and reaching agreement inevitable in decentralized management. Linking emancipatory ISD development practices with company business success and more broadly linking the practices of workplace democracy and employees participation in decision making (enabled and supported by ISID) to the company superior performance and commercial success, may be a story that would catch managers’ and IS practitioners’ attention.

By using an economic argument we may have some chance to draw managers’ and companies’ attention to the unrealized potential of the emancipatory ISD project and the dangers of neglecting it. We have to make it clear that we are not advocating here yet another form of instrumental use of humanist values. We aim to draw attention and raise consciousness about the micro-emancipatory practices as liberating, unleashing individual and collective creative potential for humane and more democratic forms of work and social relations as well as for company economics success. These results open up new space for further examination and critical assessment of micro-emancipatory ISD in practice.

Abstract

This paper provides an action research account of why and how UML use cases and socio-technical analysis were combined and used to support the development of an information system, using Multiview/WISDM as the framework of ideas. Significant learning points from, and the motivation for, the research is that a focus on task satisfaction and socio-technical evaluation, rather than on the broader concept of job satisfaction and a full, traditional socio-technical analysis, was more acceptable in practice as it related more clearly to the IS domain. The paper presents a socio-technical evaluation (STE) process, reflects on its application to a particular web-based project, and makes recommendations for its use in future ISD projects. The STE process consists of a task satisfaction survey (TSS), which draws on use cases as a template for investigating users’ perceptions of task efficiency, effectiveness, and enjoyment, supported by qualitative interviews in order to systematically identify, verify, and discuss the users’ problems and improvement proposals before and after IT implementation. The use cases constitute the context-specific, development-oriented link between the work system, systems development, and the STE process, which in turn helps ensure that the main goal of supporting and improving the work system through continuous development and deployment of an IT system is kept in mind.

Keywords: Socio-technical analysis, UML use cases, Action research, Task satisfaction
1 INTRODUCTION

The literature on information systems (IS) is very clear that the number of IS project failures are unacceptably high; the main reasons for this being 1) the failure to predict and manage the IS Development (ISD) process and the impacts and outcomes of introducing a new IS into an organization and 2) a lack of explicit concern for human and organizational aspects throughout the IS’s entire developmental and operational life cycle (Doherty & King, 2005). The lack of concern is often explained by a prevalence of a ‘hard’ mindset, and therefore a focus on processes, engineering oriented methods, and IT; that is a focus on technical development rather than socio-technical change (Clegg, 2000; Doherty & King, 2005; Mumford, 1997). Moreover, it is explained by limited use of socio-technical approaches outside of an academic context, among other reasons, because practitioners are unfamiliar with these approaches or because they find them too cumbersome, time-consuming, and ‘soft’ (Clegg, 2000; Doherty & King, 2005; Kautz & Pries-Heje, 2000; Mumford, 1997).

The aim of this paper is to develop, through action research, a pragmatic approach to socio-technical analysis of information systems that draws on and can be used alongside traditional, engineering based approaches to ISD. To this end, we suggest that focus be shifted from a full, traditional socio-technical analysis and its belonging concept of job satisfaction to a time and resource efficient socio-technical evaluation that emphasizes task satisfaction. The research contributes to ISD literature and practice with a socio-technical evaluation (STE) process, reflections on its application to a particular web-based IS project, and recommendations for its use in future ISD projects. The STE process consists of a task satisfaction survey (TSS), which uses UML use cases as its organizing structure, supported by qualitative interviews. The process is used both before and after IT implementation. The use cases provide the concrete, development-oriented connection between the particular work system, the IT system under development, and the content and outcome of the STE process.

The structure of the paper is as follows. In the next section we review the literature on traditional, engineering as well as socio-technical approaches to ISD. In the third section the research approach is described. Section four introduces the case organization and describes the action research intervention. In section five the organizational impact and the lessons learnt from the application of the STE process is discussed and implications for future projects drawn out. The final section provides a summary of the research and its main conclusions.

2 BACKGROUND

The number of formalized, engineering oriented ISD methods is vast. Many of these have been developed through a process of taking successful programming strategies and broadening them out into analysis and design. This was seen first with structured programming, which was expanded to structured analysis and design, and now with OO programming and OO analysis and design, where a convergence of ‘best of breed’ OO methods has led to development of the unified modelling language (UML) notation. The language has become widely accepted as a modelling standard for OO software development (Dobing & Parsons, 2006). It provides a number of techniques for OO analysis and design, i.e. for requirements specification and verification via use case, class, activity, collaboration, sequence, and statechart diagrams as well as use case narratives. The literature often prescribes that UML should be combined with use case-driven iterative and incremental programming.

Despite the predominance of traditional methods concerns have been voiced about their effectiveness and methods, such as ETHICS and Multiview, which combine a focus on the social and the technical have been proposed. ETHICS (Mumford & Weir, 1979; Mumford, 1983, 1995) - Effective Technical and Human Implementation of Computer-based Systems - aims to improve an organizational work system by increasing both job satisfaction and organizational efficiency and effectiveness. ETHICS provides a systematic, analytic approach for work design that prescribes thorough and well-informed
definition of both social and technical objectives and alternatives as well as evaluation of alternatives in accordance with goal fulfilment, costs, constraints, and resource consumption and emphasizes continuous user involvement throughout the project. It is assumed that high job satisfaction exists when there is a good ‘fit’ between the employees’ expectations and needs and the requirements of the job. The ‘fit’ can be measured via a questionnaire survey, such as Mumford’s (1983) 58 item questionnaire that addresses the overall job satisfaction as well as five areas: knowledge, psychological needs, efficiency, task structure, and ethics. For each of these areas, the ‘fit’ can be assessed and used as input for formulating design objectives.

Multiview (Avison & Wood-Harper, 1990) is a contingency method that incorporates a focus on both hard and soft aspects of ISD by drawing on and combining known hard and soft methods such as Structured Analysis (De Marco, 1979), Soft Systems Methodology (SSM) (Checkland, 1981; Checkland & Scholes, 1990), and ETHICS (Mumford & Weir, 1979; Mumford, 1983, 1995). Multiview has been continuously developed through action research to accommodate critique and lessons learnt as well as to address emerging application areas (e.g., web development) and new ISD methods (e.g., OO analysis and design via the Unified Modelling Language (UML)) (see, e.g. Avison et al., 1998 for an account of Multiview2 and Vidgen et al., 2002 for a description of Multiview/WISDM). However, despite these efforts an empirical study among former Multiview students turned IT professionals shows that there were only a few examples of direct adoption of the method, because it was considered too soft and time-consuming (Kautz & Pries-Heje, 2000).

A recent development that draws on socio-technical ideas is Alter’s (2006) work system method, which is a well described, rigorous, but non-technical approach for communicating about how current work systems operate and how they can be improved, with or without the use of IT. The work system method has much promise, but may come to suffer from the same barriers to method adoption and diffusion as ETHICS and Multiview, namely that it is developed in an academic context, that it advocates a systems concept that goes well beyond IT, and that it is perceived as a comprehensive method despite the author’s guidelines on how to use it in a flexible way.

In general, hard methods, such as Structured Analysis (SA) and Object-Oriented (OO) systems development, have had a major effect on teaching and practice, while soft approaches such as SSM and ETHICS have had much influence on the advancement of theoretical ideas and the ISD research agenda, but a much more modest impact on actual practice (Fitzgerald et al., 2002). It is very important to continue the development of, and teaching in, broad and wide-ranging hard and soft approaches, but there also seems to be a need for socio-technical methods and techniques that accept and build easily on the existing hard mind set, thereby allowing a more comfortable route to adoption of (some) concern for the social side, e.g. by supplementing the IS development and deployment processes with a socio-technical evaluation cycle.

3 RESEARCH APPROACH

The research presented in this paper came about as a part of a longitudinal action research (AR) project. The AR project was performed in collaboration with Zenith International, a company specializing in consultancy to the food and drinks industry. It concerned the development of a web-based IS, coined the Research Data Repository (RDR) for the benefit of Zenith’s market research department. The project was performed collaboratively by Zenith and the University of Bath within the Teaching Company Scheme (TCS, a government funded programme that promotes collaboration between industry and universities) and involved the active participation of academic researchers. Officially the project lasted from October 2001 to October 2003, and the IS was in operation when the project finished, but researcher involvement and intervention continued, albeit in a less formal and extensive manner, until April 2005.

A number of different types of AR exist (Baskerville & Wood-Harper, 1998). However, the defining features of all AR is intervention into and change in a practical problem situation for the purpose of 1)
solving the particular problem (problem solving cycle) and 2) contributing to the research literature with new knowledge (research cycle). The research presented in this paper aimed to fulfill this dual imperative (McKay & Marshall, 2001) by 1) improving Zenith’s internal report production process via development of a web-based IS and 2) creating new ways to understand, support, and improve ISD processes and method usage based on practical experience (Mathiassen, 2002).

Multiview/WISDM (MV) was chosen as the framework of ideas (Checkland, 1991) for guiding the research and problem solving cycles because it offers a structure for web-based ISD that facilitates the construction of a situation-specific method. Thus, MV allows for a research focus on process emergence and method usage as well as practical deployment of ISD methods for the purpose of problem solving. The MV framework does not introduce new methods and techniques. Instead it relies on pre-existing methods that are categorized in a method matrix.

The method matrix comprises a collection of formalized methods and techniques organized according to five different aspects of ISD. It aims to support a socio-technical approach by including methods that emphasize design and construction of technical artefacts as well as methods that address the human and organizational aspects of ISD (Vidgen, 2002). The archetypical methods in the matrix are SSM (Checkland, 1981; Checkland and Scholes, 1990) for organizational analysis, UML (Booch et al., 1999) for information analysis and technical design, ETHICS (Mumford, 1983, 1995) for work design, and web usability (Nielsen, 2000) for the human-computer interface. MV is not supported by a pre-specified process model. Instead the method authors suggest that the focus of attention changes during the process as the IS developers move in and out of the five aspects of the method matrix and that while one aspect might be the focus of attention at a particular time, the other aspects can – and should - still be present in the minds of the developers (Vidgen et al., 2002).

The research presented in this paper is qualitative in nature as we are concerned with questions of how and why, not how many or to what extent. Moreover, the number of people employed in the market research department (5-6 people) does not allow for quantitative analyses. Even though a questionnaire survey was used to collect pre- and post-implementation data about task satisfaction it was considered a qualitative technique relevant for getting a quick indication of employee perceptions and the results were analysed as qualitative data. However, in another setting, given a sufficient sample size, the survey approach could be used for conducting quantitative research and the questionnaire and its results could be submitted readily to statistical tests for reliability and validity.

Table 1: Data collection in RDR project

The empirical material is made up of interview transcripts, collected documents, and questionnaire survey data (see Table 1). To write the case description we have read and analysed the empirical data using a narrative-oriented approach, where we continuously asked “and then what happened?” (Pentland, 1999). Moreover, to gain a deeper, more nuanced understanding of the TSS findings we discuss the results in relation to the requirements specification from May-June 2002 and interview data from April 2005. The results of the analyses are presented below.
4 THE INTERVENTION

As described in Vidgen and Madsen (2003), the RDR project was undertaken as in-house development. The steering committee involved 6-8 people and the project team consisted of 3-4 people, with one full time developer and the others being involved in the actual development activities to varying degrees.

The setting for the RDR project was Zenith’s market research department, which consists of six full time employees, including the Market researcher director. Each year the department produces a number of market reports, with the two most important ones being the ‘Bottled Water’ and ‘Water Coolers’ reports. The reports are based on data gathered from as many companies as possible in a line of business, e.g., bottled water. The reports are then sold to companies in the drinks industry, such as manufacturers (who provided the original detail data), packagers, and distributors. From initiation to publication, each report takes around three to four months to produce. Each report is led by a single market researcher who gains a deep insight into the data and manages the structure of the report. A large volume of market data has to be collected, stored, processed and formatted. The Market researcher director explains the report production process in the following way: “For the 10-11 years the company has been going, we have produced company profiles in Excel format, we have linked each profile to overview tables and have created charts manually in PowerPoint…Charts then pasted from PowerPoint, pictures into Word and put it all together using these packages. Obviously, this is extremely time-consuming…” (interview, November 2002)

The requirements analysis established that “the main requirement for the new system can be encapsulated as ‘improving the report production process’.“ (requirements specification, June 2002). The four stages of report production are (Figure 1):

- Gathering and checking company profile data, approx. 50% of total report production time;
- Preparation of market summaries from company profiles, approx. 25% of total report production time;
- Analysis of markets and trends, approx. 20% of total report production time;
- Formatting the report for publication, approx. 5% of total report production time.

The requirements analysis showed that the key objectives of the RDR application were to: input and store company profiles in the database (stage 1), combine data from company profiles (stage 2) to form meaningful market analysis (stage 3), and automatically generate a formatted report from the database (stage 4).

From the outset the RDR project was conceived as an initiative that would have a major impact on the work practices in the market research department. An early idea was therefore to collect pre- and post-implementation data based on the generic ETHICS job satisfaction questionnaire (Mumford, 1983, 1995) in order to get an indication of the market researchers’ job satisfaction before and after the RDR application was put to use. Pre-implementation data would be used by the project team to formulate design objectives and guide the development. Post-implementation data would be used by the project team and other stakeholders, such as company management and the TCS representative, to get an understanding of changes in job satisfaction over time and therefore, whether the employees found the project to be a success or not.

Approval to administer the ETHICS job satisfaction questionnaire was sought from the market research director, who in turn asked the personnel director to review the questionnaire. Both directors found it difficult to see the association between the ETHICS questionnaire, the ISD process, and the RDR project. The personnel director was also concerned that the questionnaire was intruding into human resource territory and, furthermore, considered that the questions were somewhat naive, leading, and that more than half were phrased from a negative viewpoint. For example, ‘Senior management is out of touch with the way people feel’. The directors felt that the ETHICS questionnaire had the potential to increase
(and even create) tension between staff and management, undermine the organizational culture, and generate disquiet. At first these concerns came as a surprise for the project team. However, on reflection, the ETHICS job satisfaction questionnaire is a general purpose instrument that does not contain questions directly concerned with IS or ISD, and, clearly, its deployment was not perceived as a meaningful intervention in this situation. The generic ETHICS instrument was therefore abandoned. Instead the project team decided that a way of assessing job satisfaction that was grounded in the specific context of the RDR project was needed.

As a part of the requirements analysis, UML use cases had been developed to understand and document the current work system in a structured and comprehensible manner (Figure 1). After some consideration, it was decided to let the use case diagram form the template for the production of an RDR-specific questionnaire and to create a set of questions that could record user perceptions for each use case in the diagram. With MV as our framework of ideas we looked to the other methods in the method matrix for inspiration for formulating relevant questions. SSM’s (Checkland & Scholes, 1990) three E’s - efficacy, efficiency, and effectiveness - are used to judge the success of a systemic transformation. Efficacy is concerned with whether the system works: does the use case transformation of input to output take place? Efficiency considers the amount of resource needed to execute the use case; in this context market researcher time is the most precious resource. Effectiveness asks whether the use case contributes to the accomplishment of the larger business process, i.e., the production of a market research report. In addition to the three E’s we also ask about task enjoyment, which is related to ethicality and is one of two further “E” evaluations proposed by Checkland (the other being “elegance”). Thus, it was decided to maintain a focus on the market researchers’ satisfaction, not with their jobs in general, but with the particular tasks as well as with the report production process as a whole. Use case activity 5 (Figure 1) was excluded from the questionnaire as this activity is executed solely by the market research director. A set of five questions was therefore created for each of the use cases 1 to 4 in Figure 1:

• The use case activity is easy to do (individual business process efficacy);
• The use case activity takes up too much of my time (individual business process efficiency);
• The use case activity takes up too much of the total process time (business process efficiency);
• Spending more time on the use case activity would add value to the overall process (business process effectiveness);
• I enjoy the use case activity (task enjoyment).

Finally, an area for respondents to make open comments was included in the questionnaire.
4.1 Pre-Implementation

In July 2002, shortly after the requirements analysis, the pre-implementation TSS survey was conducted. The results of the survey and the implications for the future development of the RDR can be summarized as follows:

Use case 1: there was strong agreement that the task of gathering and checking company profiles is difficult, time consuming, and not very enjoyable. The RDR must improve the efficiency of this task;

Use case 2: feelings about producing market summaries was mixed, being given low and high scores;

Use case 3: users enjoyed analyzing markets and trends and the RDR must free up more time for this activity;

Use case 4: formatting the report for publication is time-consuming, unenjoyable, and error-prone. The RDR must automate this task as far as possible.

The overall business process: there was strong agreement that the process is thorough but that there are too many non-value adding tasks, i.e., company profiles and (use case 1) and report formatting (use case 2).
The results from the TSS were in line with the findings from the requirements analysis, which had already helped the project team understand the report production process and its deficiencies. Thus, the survey confirmed the project team’s understanding and helped establish confidence in the ‘correctness’ of the requirements specification within the project team and among the other members of the steering committee. Enjoyment and Efficiency objectives were explicated, discussed, and on the minds of the project team during development, but the requirements specification was not updated to include the TSS results.

4.2 Post-Implementation

In January through March 2004 the RDR was used for the first time to produce the report for the “UK Bottled Water” market and then again in March through April 2004 for the “UK Water Coolers” market. The UK Bottled Water and UK Water Coolers reports were produced for a second time in 2005. By April 2005 work had begun on producing further reports for among others West Europe Water Coolers and East Europe Water Coolers. In April 2005, the questionnaire was re-administered and used as a vehicle for discussing RDR use, challenges, and potential changes with the individual market researchers than had filled out the survey. The results from the survey and the interview sessions are summarized below.

**Use case 1**: The RDR has made the task of gathering and checking company profiles easier and less time consuming, but not much more enjoyable.

The interviews reveal a much more complex picture. In the first year (2004) much time was spent inputting, checking, and re-checking the quality of the historic data taken from the existing Excel files. Moreover, data inputting is, and has become even more laborious with RDR as it takes place via a cumbersome form-oriented interface with many drop-down menus and entry fields and as it is hard to get an on-screen overview. Suggestions for improvement are to allow for inputting and exporting of data into RDR via Excel and to develop an overview of what has already been inputted and what is missing for each company profile as well as a note facility for storing general and company specific facts and comments.

**Use case 2**: the RDR has improved the task of preparing market summaries from company profiles.

The market researchers have had to learn how to run the queries or they have to ask the Developer to extract the market summaries they need. Both ways, extracting the market summaries is much easier and they are better than before, because they are based on better and more data. However, developer intervention is not unproblematic, and the market researchers raised concerns about loss of ownership and the relationship between ownership and level of incentive (or satisfaction): “I feel very much like the whole process has been passed over to [IT support]… in the past, you did it from beginning to end... it was completely your baby. I feel like I have lost ownership on that, which in a way takes away some of the incentive …” (Market researcher, interview, April 2005)

**Use case 3**: “Analysis of markets and trends”, the questionnaire data is ambiguous and it cannot be concluded that the RDR application has freed up time for the task of analyzing markets and trends.

During the interviews, the market researchers explained that the RDR provides more - and more accurate - data and makes it easier to extract data for the purpose of analysis, but the IT system has not otherwise changed the way the analysis of markets and trends is carried out. Interpretation and writing are still the main activities and is done by the market researcher. However, both the Market research director and one of the Market researchers see much potential for the analysis of markets and trends over time as the database gets stronger. They explain that when there is about ten years worth of data for most companies in the database it will be possible to make really strong historic as well as trend analyses.

**Use case 4**: the RDR has made the task of formatting the report for publication easier, less time consuming, and more enjoyable.
Report formatting has become much easier as it is done more or less automatically, with some intervention from the Developer. The Market researchers explain that “well…you just press a button…[but] in my experience it still takes some time for the [Developer] to do some tweaking.” (Market researcher, interview, April 2005) and that “formatting a report for publication is easy. I mean, again, on that one certainly the profiles are ten times easier, a hundred times easier than what we used to do…” (Market researcher, interview, April 2005).

The overall business process: the RDR has automated the tasks of gathering and checking company profiles and formatting the report for publication, while maintaining a thorough process.

Again, the interview data reveals a much more complex picture. There are indeed time and efficiency savings being made as a result of the RDR. These are mainly related to the semi-automation of the preparation of market summaries from company profiles (use case 2) and the formatting of the report (use case 4). However, further development is needed to get efficiencies in data entry (use case 1). One of the Market researchers states that “…I think it is more a case at the moment that [the RDR] has changed the burden to different parts really… Inputting is the laborious part of it, where previously it was less so. That is disappointing, but on the flip side, extracting the data once it is in there…when you ran the queries, you had full confidence in that data.” (interview, April 2005).

The increase in thoroughness and competitive advantage are due in part to the improvement in data quality. The market researchers trust the database contents and the reports that are produced from the database. Broader data coverage of the markets is also reported.

The report production has been improved but there is more to do. The interviews reveal that improvement of data entry is the key objective for developing the RDR further, and that even though “there is a general sense of buy-in from the staff…you are never going to get 100% euphoria over everything anyway.” (Market research director, interview, April 2005). One of the Market researchers also state that “in general am I satisfied with our process of producing research reports? Not yet. I think it is difficult to get to that stage, where you are 100% happy with it.” (interview, April 2005).

5 DISCUSSION

The organizational impact of the RDR can be summarized as follows. The questionnaire results show that the ‘fit’ for the tasks of gathering and checking company profiles (stage 1) and formatting the report for publication (stage 4) had improved greatly. The interviews reveal that data inputting (stage 1) had become more cumbersome and onerous, while improvements were due to the building of a strong database (stage 1), easier data extraction to form market summaries (stage 2) and the final, formatted report (stage 4). Thus, the two data sources are somewhat contradictory and even though some tasks and sub-tasks have improved a lot, the burden seems to have shifted to other parts of the work process. This suggests that questionnaire data, whether interpreted as quantitative or qualitative data, is best used in conjunction with other in-depth, qualitative data collection techniques, such as interviews, to identify, verify, and discuss the users’ problems and ideas for solutions before and after IT implementation. Moreover, it means that it is difficult to assess whether the RDR is a success or not. We suggest that in this case - and perhaps more generally? - it is more accurate to talk about the IS’s successes and failures by focusing on how well it supports the different phases and tasks within the particular work system, here Zenith’s report production process. IS development is also better pictured as a sequence of interventions, where each intervention has both intended and unintended consequences as well as predictable and unpredictable outcomes. This goes for systems use too where, even without the intervention of IS developers, the system in use will drift over time as users find new ways of working and work-arounds.
In Figure 2 we illustrate systems use, development, and evaluation as a set of interlocking activities. First, requirements are extracted from the current work system (Use), transformed into an IS requirements specification in the form of UML use cases, and used as the basis for the IS design activity. At the same time, evaluation data collected via a survey and interviews, organized around the use case structure of the requirements specification, is elicited from users of the current system and used to evaluate user satisfaction with the current work system (STE). Then, an intervention (ISD) is made on the basis of improvements identified by the STE in conjunction with the specified as well as emerging requirements from the work system. The process then continues in cyclical fashion moving between evaluation and ISD ad infinitum. The work of ISD is never finished as each intervention “solves” one set of problems while introducing new ones, as we found with the Zenith case. Many organizations will take a pragmatic view about what constitutes a “good enough” solution and cease development. However, environment changes and drift happens and even if no additional ISD is planned the STE process could/should be conducted regularly to verify that the current work system and IT are indeed, or still, good enough.

The lessons learnt from the application of the STE process is that it was a powerful tool before implementation, for verifying and building confidence in the requirements specification within the project team and in relation to the steering committee and after implementation, for identifying areas for improvement and for a getting a nuanced understanding of systems success as each task is investigated, not just the broad picture. A particular strength of the approach is the integration with UML use cases which provide the concrete connection between socio-technical evaluation, IS development, and systems use. However, the TSS should be extended to include questions about the need for variety, challenge, discretion, and autonomy (Mumford, 1995) at least at the overall process level to get an indication of which social characteristics the market researchers value.

We conclude that in future projects it is necessary to increase the STE process’s concern for the human and organizational aspects further although continuing to recognize the need for parsimony and pragmatics if the approach is to be adopted by practitioners. We propose that this can be achieved with relatively few resources and by building on the prevailing technical way of working in practice, e.g., by:

- **Pre-implementation:** conducting a more comprehensive TSS that covers both technical and social task characteristics and combining it with other qualitative data collection techniques to identify, verify, and discuss technical and social system requirements. Both efficiency and enjoyment requirements could/should be documented in the requirements specification.

- **Post-implementation:** re-administering the TSS and conducting follow-up interviews at least once and preferably on a periodic basis, e.g. once a year, to assess systems success and drift.
and to continue to ‘grow’ the IT system (Truex et al., 1999) and the support it provides for the work system (Alter, 2006).

6 CONCLUSION

The ISD literature recognizes that many IS developers and stakeholders prefer technical rational ISD methods and either do not know the socio-technical approach or are likely to find it too ‘soft’ and time-consuming. A significant learning point, and motivation for, this research is also that in the case of the RDR project it was more meaningful to consider the constrained but more grounded, IS oriented term of task satisfaction rather than the broader concept of job satisfaction advocated by ‘traditional’ socio-technical analysis.

We therefore developed and deployed our own socio-technical approach consisting of a task satisfaction survey (TSS) and interviews to identify, verify, and discuss the users’ problems and ideas for improvement before and after IT implementation. We considered the approach a separate evaluation cycle that supplemented the development activities, and coined it the Socio-Technical Evaluation (STE) process. The STE process builds on the prevailing ‘hard’ mindset towards ISD by taking a task perspective and by using UML use cases as a template for structuring the TSS around a focus on the users’ perceptions of efficiency, effectiveness, and enjoyment of each use case as well as of the overall process and general level of satisfaction. Pre-implementation, the evaluation was instrumental in establishing confidence in the requirements specification within the project team and among the other stakeholders. Post-implementation it facilitated a nuanced understanding of project success, process shifts, and within-task changes as well as identification of areas in need of further IS development. However, too much emphasis was placed on technical characteristics related to the efficiency and effectiveness of tasks and processes, while social characteristics concerned with the variety, challenge, discretion, and autonomy of these activities to some extent were overlooked, both in the application of the STE process and in the design of the IT system.

We recommend that in future ISD projects an even greater concern for the human and organizational aspects of the work system is incorporated by: conducting a more comprehensive TSS that covers both technical and social task characteristics, including both efficiency and enjoyment objectives in the requirements specification, and re-administering the TSS and conducting follow-up interviews on a periodic basis to assess the success, drift, and improvement opportunities of the IT system as these change over time.

Abstract

Creativity-intensive processes such as the development of marketing campaigns or the production of visual effects increasingly find their way into the agenda of process managers. Such processes often comprise of both well-structured, transactional parts and creative parts that often cannot be specified in terms of their process flow, required resources, and outcome. Moreover, the processes’ high variability sets boundaries for the possible degree of automation. In this paper we introduce the concept of pockets of creativity as an analytic device which is hoped to support process managers in their efforts to identify and describe creative sections in business processes. We argue that this step of identifying and describing is imperative to successfully allocate resources, integrate creativity into the overall process, and introduce process automation for those parts that are well-structured and can actually be automated. Our argument rests in the examination of existent literature as well as in findings from exploratory case studies that were conducted in the film and visual effects industry in order to study processes that rely on creativity.

Keywords: Creativity Management, Business Process Management, Media Industry, Workflow
1 INTRODUCTION

Creative people and their practices play a prominent role in business processes as organizations seek to deploy the merits of business process management to more than just the set of transactional processes (Hall & Johnson 2009). Product development and marketing campaigns are just two examples of such creativity-intensive processes (Seidel & Rosemann & Becker 2008) that increasingly find their way into the agenda of process managers. Besides this, there are entire and quickly growing industries designed around creativity-intensive processes with the entertainment industry being the most prominent example of a creative industry.

To make the merits of business process management available, process modeling has emerged as an important enabler. Existing process modeling languages normally focus on modeling the process flow (e.g. Engels & Förster & Heckel & Thöne 2005). However, business processes that involve creativity are characterized by a high demand for flexibility. Whereas parts of processes in creative environments may be well-structured and easy to model, other parts may be not. For example, a visual effects production process includes tasks such as *receiving materials* where references or scans are received from different sources. Such tasks are well-structured and may even be automated. However, the same process also includes tasks such as *modeling or animation* which require the creativity of the involved artists, and generate creative products. Creative products are characterized by novelty and appropriateness and creativity can be described as the process that leads to the generation of such products (Woodman & Sawyer & Griffin 1993). Particularly two facets of creativity within business processes demand special attention: (a) Creative tasks/sub-processes usually do not have a predefined process structure and (b) creative tasks have outcomes that are – at the minimum to a certain extent – hard to predict (Seidel 2009, Seidel et al. 2008).

It may seem appropriate to view these creative sections as ‘black boxes’ as the underlying processes are complex and hard to predict. However, we argue that this approach would not be sufficient and leaves too much to the individual conducting the creative task. Based on the awareness that the more creative tasks have a significant impact on business processes we believe that it is necessary to create more transparency. We do not suggest to model and prescribe the process flow as in many cases this might prevent people from being creative. However, we propose to identify how creative tasks are characterized, how creative tasks can be supported and how they can best be integrated into the overall business process they are part of.

In this paper, we introduce the concept of *pockets of creativity* as a means to identify and describe parts of business processes that are characterized by creativity. The challenge is to identify what is actually known about a creative section within the business process. We propose a set of constraints that enable process managers to determine whether a process section is indeed creative and to then describe this section.

With this paper we make two primary contributions. First, we shed light on the characteristics of creativity from a business process management perspective and provide researchers with an analytic device that can guide further studies. The device is the result of a design process (Hevner & March & Park & Ram 2004) which is grounded in empirical data. Second, we introduce a means that process managers can use in order to identify and describe pockets of creativity in business processes in order to effectively manage creativity-intensive processes.

We proceed as follows. First, based on the awareness that creativity in business processes becomes manifest in high process variability (Seidel 2009, Seidel et al. 2008) we discuss recent work on variability in business processes and develop a framework that gives structure to our subsequent reasoning (section 2). We then briefly discuss an exploratory study of processes in the film and visual effects production (sections 3.1 and 3.2). Based on three key observations we introduce the concept of pockets of creativity as a means to denote creativity in business processes and relate the concept back to the framework of variability (section 3.3). We then describe an example from the film industry so as
to illustrate how such pockets of creativity can be identified in business processes (section 3.4). In a chapter on related work we link our work back to existent research (section 4). The paper concludes with a discussion of contributions and limitations and provides an outlook to our future research agenda (section 5).

2 FRAMEWORK OF VARIABILITY IN BUSINESS PROCESSES

Recent years have seen a number of studies concerned with variability within business processes. Much of this work has been carried out by scholars who focus on automation and implementation of business processes. In the following we explore some classification schema for process variability that originate from this discussion before we then introduce a framework, which rests in the argument of our colleagues.

Sadiq et al. (2005) identify three dimensions of change in workflow management. The first dimension is labeled dynamism and addresses a workflow’s ability to change when the related business process evolves. The second dimension is that of adaptability, which refers to change that does not affect the underlying business process but instances of such processes. In doing so, this dimension subsumes a workflow’s ability to react to exceptional circumstances, which may or may not be foreseen. The third dimension is that of flexibility which describes a workflow’s ability to execute based on only partially specified models. Thus, the complete specification of the model only becomes available at runtime.

Similarly, Weber et al. (2008) distinguish three different types of process flexibility: built-in flexibility, schema evolution, and ad-hoc changes. While built-in flexibility and schema evolution resemble Sadiq’s dynamism and flexibility dimensions of change, ad-hoc changes always occur on an instance level and, thus, have a meaning different from Sadiq’s adaptability dimension which addresses both foreseen variability at a schema level and unforeseen exceptions that have to be dealt with at an instance level.

Van der Aalst et al. (2005) classify process support systems according to the level of structure of the underlying processes. They distinguish support for unstructured processes, for ad-hoc processes, and for implicitly and explicitly structured processes. According to this framework, support for unstructured processes does not impose any control flow, whereas ad-hoc workflow management systems allow for the modification of workflow specifications during execution of workflow instances. Yet, an explicit process model is required for every workflow instance. Systems that support processes with implicit structure rely on process specifications that do not explicitly define every possible route within a process. In contrast to explicitly structured process specifications, such systems rely on the definition of restrictions and authorizations that merely set out boundaries for altering a process instance.

In the area of creativity-intensive processes (Seidel 2009, Seidel et al. 2008) we are faced with another level of variability which transcends the understanding of an exception as a "deviation from the ideal" (Klein & Dellarocas 2000) and also the notion of flexibility, that denotes last-minute lashing of control flow structures prior to instance execution (Sadiq et al. 2005, Weber et al. 2008). In creativity-intensive processes variability is deliberately injected as these processes rely on divergent thinking and exploration of various options (Runco 2007). Consequently, we advance that creativity is another dimension of change and extends the levels of process flexibility. In creativity-intensive processes, variability remains until a process terminates. The process is not straight-jacketed before execution – neither by explicitly defining every option at build time via a detailed workflow model, nor by deferring decisions as far as possible by providing a loosely specified, flexible workflow model. In a creativity-intensive process it is impossible to specify every decision in advance. Yet, it is not the case that creativity-intensive processes are not eligible for management. As various industry examples exemplify, such processes not only comprise of completely unstructured sections, but also contain sections that indeed may be specified explicitly. In consequence, also the creative parts of a process must heed restrictions and contextual conditions so as to fit into the overall process.
In the remainder of this paper we will apply a two-dimensional framework for addressing creativity in business processes that rests in the above discussion (cf. Figure 1). In order to expose how the occurrence of creativity in business processes relates to the introduced levels of variability, the first dimension distinguishes different points in time in the life cycle of a business process when variability may be eliminated. These are build-time, pre-run-time, and run-time. Although Sadiq et al. (2005) and van der Aalst et al (2005) refer to decision-making at run-time, we advocate to understand these eliminations of variability as to happen prior runtime: Processes or process fragments of these categories have to be explicitly specified before they can be executed. Therefore, merely unstructured and implicitly structured processes as specified by van der Aalst et al. (2005) and process fragments that bear creativity imply de-facto variability at run-time.

The second dimension depicts three key aspects of a business process. Besides the control flow aspect discussed above, there are other facets of a business process to be considered from the vantage point of a holistic perspective (v.d.Aalst et al. 2005, Weber et al. 2008). First, there are resources which actively conduct a business process or are applied or consumed within a process (Russel & v.d.Aalst & ter Hofstede 2006, Weber et al. 2008). Second, there is the process related object or product, which is altered in the course of a process (v.d.Aalst et al. 2005).

Figure 1: Variability in business processes
3 POCKETS OF CREATIVITY

3.1 A study of organizational creative processes

In an exploratory study on creativity in business processes Seidel (2009) and Seidel et al. (2008) investigated processes from the creative industries. The study aimed at getting an in-depth understanding of business processes that highly rely on creativity. Data was collected from three organizations from the field of film and visual effects production. These organizations are very much characterized by the creativity within their processes. Thus, organizations were selected, where “the process of interest is ‘transparently observable’” (Eisenhardt 1989, Pettigrew 1990). The study focused on so-called post-production (Clark & Sphor 1998) and visual effects (VFX) production processes. These processes usually start in parallel to the actual production of a film or TV commercial (the process of filming) and are carried out until the product is finally delivered. The processes that were investigated not only rely on creativity, but are also repetitive. For example, many VFX sequences have to be produced for a feature film. The sourcing strategy involved semi-structured interviews and the use of process modeling techniques. Table 1 provides an overview of case study organizations, interviewed people, and analyzed processes.

Table 1: Case studies and analyzed processes

In the following section we first discuss some major findings with regard to the nature of the processes that were studied (section 3.2) and then relate these findings to the above introduced framework (section 3.3) before an example case is provided where the application of the concept of pockets of creativity is further illustrated (section 3.4).

3.2 Study findings: process creativity versus product creativity

With regard to the main characteristics of creative sections within the analyzed business processes, three key observations could be made (Seidel 2009, Seidel et al. 2008):

1. In most cases the outcome of a creativity-intensive process is not entirely known in advance. Yet, often it is not the case that nothing is known about the creative product. Just think about a particular animation sequence for a film or a visual effect in the next Hollywood blockbuster. As a producer who needs that sequence to complete the film, you would certainly know the technical format and you might also know its length (not necessarily though). However, some aspects remain unknown until the process commenced. Particularly creative aspects (e.g. what characters occur in a particular sequence, or what do the characters look like etc.) are not known in advance.

2. Not only the process outcome is not known in advance, but also the actual process that leads to this outcome. Required process steps and iterations are not entirely predictable. For example, when producing a particular visual effect for a feature film, the organization does not
know what iterations are necessary for what process step (e.g. creating the skeleton, creating the surface, lighting). Also, required process steps may not even be known in advance as the product and its properties are further developed throughout the process. However, it is not the case that nothing is known about the process structure. For example, particular well-structured sub-processes such as review processes, or aspects of data management may be known in advance.

3. As required process steps and iterations are not entirely predictable, so are resources and involved people not known in advance. For example, within visual effects production processes in organization 2 (cf. Table 1), while the process is conducted, it may become necessary to involve further people with particular skill sets. Again, it is not the case that nothing is known about required resources. Certain resources that are required (e.g. a particular editing suite) may be known as well as resource restrictions (e.g. available time).

Based on these three observations, we propose to distinguish two facets of creativity, namely product creativity and process creativity. The study suggests that the primary reason for process creativity must be seen in product creativity; as certain features of the product are not known in advance it is hard or even impossible to predict what is needed to carry out the process. Product creativity refers to the outcome of a creative process— the creative product of which many aspects are not known in advance (supported by observation 1). If the characteristics of the output are clearly defined and there is no (intended) variance in the output, there is no product creativity. Process creativity refers to the process of creative thinking or the process of creative problem solving. Thus, it refers to the variable structure of the underlying process (supported by observation 2) as well as vague information about required resources (supported by observation 3). If the process is highly repeatable or its structure is at least pre-defined, there is no process creativity. This is usually not the case in processes that rely on creativity.

However, as has been indicated, even though there is a certain degree of unpredictability, processes in organizations undergo certain constraints regarding resources, product, and control flow: a product has to fulfill certain requirements (this is reinforced by the awareness that creative products are always purposeful) and the process is restricted by both the required resources and the availability of resources such as human resources, time, budget, and equipment and by dependencies between different process fragments. Consequently, we introduce three types of constraints that describe what elements of a pocket of creativity are known in advance: product constraints, control flow constraints, and resource constraints. When the process is carried out it must adhere to those constraints. Thus, these constraints limit the degree of freedom of a process due to business imperatives.

By specifying these constraints, that is, defining required and available resources as well as demanded characteristics of the output and required process steps, the process designer can (a) allocate resources as well as identify potential strategies or software tools in order to support a particular pocket of creativity and (b) to better plan for precedent and subsequent process steps. In a visual effects company, for example, the digital format of the deliverable of a creative task will be known so that the equipment that is used in subsequent tasks can be planned. However, knowing that certain characteristics are not known in advance, can also require the process designer to plan for subsequent process steps, such as review cycles to make sure that the (creative) product actually meets the requirements. Also, identifying the required resources of a pocket of creativity is of high importance as it is well-known that a lack of resources may even kill any creativity (Amabile 1998). At the same time, providing more than the required resources may not foster creativity. Yet, in many cases, the demand for certain resources might not be known in advance.

Table 2 provides an overview of the relationships between product creativity, process creativity, and the three types of constraints.

process and for subsequent sections of a process. Explicating characteristics of the product enables to define how the process can continue after a particular task. In pockets of creativity not all requirements to the product are specified in detail. That is, there is variance in the outcome of the process.

Table 2: Types of constraints in pockets of creativity

3.3 Relating the findings to the framework

Figure 2 highlights how the different aspects of creativity can be related to the above introduced framework and thus describes the main characteristic of pockets of creativity. Process creativity becomes manifest in variable control flow and variable resource requirements at run-time. That is, both control flow and resource requirements are not known before the process is actually executed. Product creativity becomes manifest in variable product specifics. That is, the actual characteristics of the product are not known in advance but evolve while the process is executed. The three types of constraints restrict the degree of variability.

Figure 2: Characteristics of pockets of creativity

Obviously, there are varying levels of both process creativity and product creativity. However, the identification of those tasks/processes that do not involve any process or product creativity at all, may allow organizations to automate these tasks without having to fear killing any creativity.
As the above described empirical research has shown, in many cases process and product creativity occur conjointly. Yet, the data suggests that product creativity can be seen as the primary reason for process creativity. This is particularly the case within industries such as the creative industries. However, it may also be possible that, in other industries such as banking or insurance, the output is predetermined (for example due to legal requirements and other compliance issues) but the process of how to achieve that output may be creative. Notably, it is arguable whether such processes may in fact be framed as being creative as they do not necessarily generate products that are characterized by both novelty and appropriateness.

3.4 Example Case

We use an exemplary creativity-intensive process from the film industry, the so-called post-production process, in order to exemplify the concept of pockets of creativity and its applicability. This retrospective analysis is a first step towards the evaluation of the proposed concept. Within the process of post-production there are several technical and creative elements. One highly creative element is the so-called Offline-Editing. Offline Editing is the stage within the process where different pieces of footage are put together by an editor so as to tell the film’s story. Offline Editing is a complex process that comprises of both well-structured and highly creative tasks. Table 3 provides an overview of product-based, process-based, and resource based constraints that apply for the pocket of creativity of Offline-Editing.

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Example Case</th>
</tr>
</thead>
<tbody>
<tr>
<td>Product constraints</td>
<td>The different output formats are known as well as the length of the sequences. This is prerequisite to continue the process and meet client requirements (e.g. the length of a TV commercial).</td>
</tr>
<tr>
<td>Control flow constraints</td>
<td>The process is highly creative and requires flexibility. Whereas the actual structure of the offline editing cannot be explicited in advance, the pocket of creativity involves well-structured sub-processes such as technical and creative reviews which have to be executed in a predefined order.</td>
</tr>
<tr>
<td>Resource constraints</td>
<td>Various constraints regarding time, budget, human resources, and equipment apply to this pocket of creativity. However, certain aspects are not known in advance. For example, the process may require the involvement of additional personal with certain expertise in offline-editing.</td>
</tr>
</tbody>
</table>

*Table 3: Exemplary constraints*

The offline edit is creative in nature: Only certain aspects of the outcome of the process are defined. The final product looks different each and every time the process is conducted. The final product is highly subjective as different people have differing understandings of aesthetics and creative quality (Firestien 1993). However, certain aspects of the product, such as format and length, may be known in advance. By explicating these characteristics of the creative product, it becomes possible to plan for subsequent process steps. For example, the format impacts on the equipment that is required to further proceed with the post-production process. The process-flow is not pre-determined. For example, the number of iterations through the creative tasks of offline-editing (rough cut) and offline editing (fine cut) are not known, or there may be need for communication in order to receive additional footage that can be used within offline editing. Even though there are resource-based constraints, such as time and budget, it is hard to predict what resources will actually be needed to carry out the task. For example, depending on client feedback it may be necessary to involve people with additional expertise in post-production into the process. Figure 3 depicts the pocket of creativity. Not that Figure 3 only presents a simplified, small part of the overall post-production process. The pocket of creativity comprises of two creative tasks and a well-structured sub-process.
Summarizing, by expatiating this pocket of creativity the process designer ensures that this creative section of the process can be supported and can also be integrated into the overall process. However, by determining what part is indeed a creative task that is not further broken down in terms of process flow, the designer avoids straight-jacketing of a creative process which might prevent creativity.

4 RELATED WORK

As has been indicated, it is not the case that there have not been attempts in order to support flexible business processes. In the following we provide an overview of the work of fellow colleagues who addressed the phenomenon of variability in business processes. In order to do so, we proceed from the more rigid approaches to the more flexible ones. Obviously, particularly the latter ones may be considered by organizations that seek to support creativity-intensive business processes.

Research on workflow evolution addresses the question of what to do when static workflows have to be adapted due to changes of the underlying business process (Casati & Ceri & Pernici & Pozzi 1996). The challenge is twofold: On the one hand, the process of modifying the existing workflow model has to be managed in order not to necessitate a complete reconstruction. On the other hand, running workflow instances must be adjusted according to the new workflow description. Existent techniques for workflow evolution provide support for occasional changes of business processes, which are generally structured and stable (Seidel & Adams & Ter Hofstede & Rosemann 2007). However, when general process blueprints are absent, there is no evolution to be managed.

Approaches towards exception handling have been discussed in order to handle such events that are not accounted for in the original process model, often referred to as exceptions. Allowing for all possible, and known, exceptions within the workflow model can quickly lead to workflow models that are hard to read and maintain. To tackle this problem, Russel et al. (2006) suggest the application of exception handling systems which separate the handling of exceptions from the main process model. Yet, an exception handler has to explicitly know about the exceptions it may handle. In consequence, such systems are incapable of dealing with flexible or even more so creative processes.

In order to allow for a higher degree of flexibility, Sadiq et al. (2005) introduce the concept of pockets of flexibility. They propose an approach to workflow modeling that enables the specification of loosely defined process sections within highly structured workflow models. These sections comprise a set of
workflow fragments and constraints, which restrict the control flows that are allowed between the fragments. For pockets of flexibility, prior to execution, the control flow is specified for every workflow instance (Sadiq & Sadiq & Orlowska 2001). This approach allows workflow processes to be tailored to individual instances in a so-called late instantiation fashion. But still, right before execution there has to be an explicit workflow model that describes process coordination. Thus, this approach is too rigid to handle creativity-intensive processes.

Note that all of the above mentioned approaches require the process designer to model the process flow in detail – at build-time for all workflow instances or right prior run-time to facilitate individual processes routing for every workflow occurrence. In response to this, over the last few years a new paradigm has emerged. The so-called case handling paradigm seeks to overcome the limitations of rigidity inherent in workflow systems by applying a data-driven approach. Van der Aalst et al. (2005) argue that most workflow systems do not reflect the way work is conducted in most non-manufacturing environments. For this reason, they propose to focuses on the whole case rather than the a single work item related to a task and to follow a data-centric approach rather than merely considering process-flow (v.d.Aalst & Berens 2001). The core features of the case handling paradigm are: provide all information available to avoid context-tunneling, decide on the activities to be executed on the basis of the information available rather than the activities executed before, separate the distribution of work from its authorization, extend the classical ‘execution’ role by additional types such as ‘skip’ and ‘redo’, and allow workers to view and modify process data outside the corresponding activities. The wide range of concepts that may be applied for specifying a case, ranging from explicitly describing the process flow to implicitly defining its structure by merely setting out post conditions related to data objects, may qualify the case handling paradigm – at least in some scenarios – for its application in creativity-intensive processes.

Groupware systems constitute a genre of IT systems that take away the focus from supporting business process coordination but promote cooperation between people. Consequently, these systems are capable of handling variability in business processes, as they do not rely on predefined process structure but foster interaction between people – a primary source of creativity (Gurteen 1998). Thus, van der Aalst et al. (2005) propose the application of groupware systems to support primarily unstructured processes.

5 CONCLUSION

In this paper we introduced an analytical framework that characterizes so-called pockets of creativity in business processes. The analytic framework we presented has been developed based on argument that rests in the examination of existent literature as well as on an empirical study on creativity-intensive processes. We suggested to distinguish between process-creativity and product-creativity and introduced three types of constraints: product constraints, control-flow constraints, and resource constraints. Those parts of a creativity-intensive process that are non-creative can be modeled and automated with conventional process modeling techniques and workflow systems. Those sections that have varying degrees of creativity however, are different: Whereas some parts may have enough structure and constraints to be supported by declarative approaches such as case handling, other parts do not have any structure at all. Here, groupware and knowledge-intensive applications can be means to facilitate creativity and enhance process performance.

It is hoped that process managers can apply these criteria in order to identify pockets of creativity in business processes so as to shed light on the relationships between well-structured and creative parts of business processes. It is further hoped that the explication of these relationships will enable to enhance process efficiency by optimizing and automating the well-structured non-creative tasks while not straight-jacketing the creative parts and, thus, compromising creativity.

This study has some limitations. Most notably, the three key observations that led to the notion of product creativity and process creativity as well as to the formulation of the three types of constraints are based on empirical studies with only three organizations from one particular industry. Thus, future
research must consider creativity-intensive processes from other domains. Future research will also focus on the exploration of strategies and IT systems that can be used in order to support such creativity-intensive processes, so as to ultimately enhance organizational efficiency and effectiveness. Moreover, one may question the practicality of the proposed approach as creativity must often deal with rigid structures and inflexibility. A response to this assertion may be the conduct of further studies in which the proposed approach is further applied and evaluated. Other aspects that have not been comprehensively covered in the present paper are the study’s impact on the business process lifecycle as well as the actual modeling notations/grammars that can be used to model the proposed constraints. In summary, it is hoped that the proposed approach can inform the development of a more comprehensive methodology.

Acknowledgments

This paper is the result of a collaborative research effort in the context of the research project ManKIP (Management of Creativity-intensive Processes, promotional reference 01FM07061) funded by the German Federal Ministry of Education and Research (BMBF) and the European Social Fund of the European Union and the ARC Centre of Excellence for Creative Industries and Innovation (CCI) (www.cci.edu.au) funded by the Australian Research Council. THE EFFECT OF INFORMATION AND COMMUNICATION TECHNOLOGIES, WORKPLACE RE-ORGANIZATION AND TRADE ON THE DEMAND FOR EMPLOYEES’ SKILLS: A COMPARATIVE ANALYSIS OF GREEK AND SWISS ENTERPRISES

Abstract

This paper aims at investigating empirically at the firm level the effect of the use of modern information and communication technologies (ICT), and also of two other factors, the adoption of new forms of workplace organization (which is regarded as a ‘complement’ of ICT), and trade (export) activities (a major characteristic of modern economy), on the demand for employees’ (vocational) education and skills. The study is based on firm-level data collected through a common questionnaire from firms’ samples of similar composition (concerning firm sizes and industries) in Greece and Switzerland; from these data econometric models of similar specification have been constructed for both countries. The results of multivariate analysis show that the intensive use of ICT correlates positively with the employment shares of high-educated personnel and negatively with the ones of the low-educated personnel. These findings are consistent with the hypothesis of ‘skill-biased technical change’. Further, the intensive use of “employee voice”-oriented organizational practices correlates positively with the employment shares of high-educated employees in both countries, and also negatively with the employment share of low-educated ones only for the Swiss firms. The results for the “work design” organizational practices are more ambiguous. Thus, there is only partial confirmation of the hypothesis of skilled-biased organizational change. Finally, we found some evidence in favour of the trade effect (export activities) only for the Swiss firms. Our results show both similarities and differences in the above aspects between Greece and Switzerland, and indicate that national context characteristics affect the relationship of the demand for employees’ (vocational) education and skills with ICT use, adoption of new forms of workplace organization and trade.

Keywords: labour(employees) skills (education) demand, labour(employees), information technology, workplace organization, trade

1 INTRODUCTION

Most of the research that has been conducted concerning the impact of information and communication technologies (ICT) on organizations has been focused mainly on their effects on organizational performance, processes and structure (e.g. Melville et al, 2004, Attaran 2004, Pearson and Saunders 2006, Albadvi et al 2007, Wan et al 2007); however, other aspects of the organizational impact of ICT, such as their effects on the demand for employees’ (vocational) education and skills, have not received much attention by the ICT researchers and practitioners, despite their high organizational and social importance. In the last 10 years there is a discussion about the observed shift of labour demand toward high-skilled personnel and its possible explanations (Machin and Van Reenen 1998, Berman et al 1998, Acemoglu 1998, Acemoglu 2002, Arvanitis 2005). One of the proposed explanations is based on the so-called ‘skill-biased technological change’-hypothesis, according to which the reason for the observed upskilling of labour force is the non-neutrality of technological change, which favours the use of skilled labour more than the use of other labour inputs; the basic reason for the most recent acceleration of technological change is the diffusion of ICT, which seem to have given new impetus to the substitution of low-skilled by high-skilled employees. However, this ‘technology’ hypothesis cannot explain the entire magnitude of the observed labour demand shift, so other possible alternative or complementary explanations have been proposed. One of them, highly associated with the introduction of ICT, is the introduction of new forms of workplace organization, such as team work, job rotation, decrease of hierarchical levels, decision decentralization (Caroli 2001); these new forms of workplace organization are regarded as a basic ‘complement’ of ICT (OECD 2003). Another alternative explanation that has been proposed (see e.g.
Wood 1995) is the internationalization of economic activities (trade), which is a major characteristic of modern economy.

The present study explores empirically the hypothesis that ICT and its basic complement, new organizational practices, are important determinants of the demand for labour of different educational levels, and further that the joint use of these two factors leads to a mutual strengthening of their impact on these labour demands. A third hypothesis refers to the influence of international trade (in this case: exports), which characterizes modern economy, on the composition of a firms’ workforce. This allows a comparison of the effects of ICT, with the ones of the new organizational practices and the trade. The analytical framework is that of a demand function for employees with different education levels (heterogeneous labour) at firm level. Also, taking into account that most of the research on the organizational impact of ICT has been conducted in a few large and highly developed countries, we have conducted a comparative empirical study of the above effects in Switzerland (a highly developed country) and in Greece (a country that does not belong to the highly developed ones, though it has made considerable economic progress in the last 15 years). Both the Greek and the Swiss part of this study are based on firm-level data collected through the same questionnaire and from samples of similar composition (concerning firm size classes and sectors), and also use the same variables and models specification, so they are comparable.

The study’s new contribution to empirical literature consists in: (a) taking into consideration not only ICT, but all three main factors forwarded in literature for explaining the shift of labour demand in favour of high-skilled labour, which allows a comparison of their effects; (b) investigating possible complementarities among all these three factors; (c) investigating the above effects in a very different national context from the ones in which most of the research on the organizational impact of ICT has been conducted: the national context of Greece (a country not belonging to the highly developed ones); (d) conducting a comparative study of the above effects between two countries, Switzerland and Greece, which are characterised by different levels of economic development.

The structure of this paper is as follows: In section 2 the conceptual framework and the research hypotheses of this study are presented. Section 3 contains a review of the relevant empirical literature. Then in section 4 the model specification and the data of both the Greek and the Swiss parts of the study are described. The results of the econometric estimates are presented and discussed for both countries in section 5. The final section 6 contains the main conclusions and some policy implications.

2 CONCEPTUAL BACKGROUND AND RESEARCH HYPOTHESES FORMULATION

The “Skill-Biased Technical Change”-Hypothesis: The Role of ICT. The shift toward more highly educated workers, which can be observed since the late sixties or possibly the early seventies in many OECD countries, appears to have accelerated in the last twenty years (see e.g. Berman et al. 1998; OECD 1998). While many factors have contributed to this increase most authors think that this effect is attributable primarily to skill-based technical change. The size, breadth and timing of the recent labour demand shift have led many observers to seek skill-biased technical change in the largest and most widespread new technology of the last years, ICT (see Bresnahan 1999; Bresnahan et al. 2002). On the one hand, high-skilled labour is a precondition for the use of ICT; for example, training in problem-solving, statistical process controls and computer skills can increase the benefits of ICT. On the other hand, highly computerized systems not only systematically substitute computer decision-making for human decision-making in routine work, but also produce a large quantity of data which needs high-skilled workers, managers and professionals to get adequately utilized. ICT capital (a) substitutes for workers performing cognitive and manual tasks that can be accomplished by following given rules and (b) complements workers in performing non-routine cognitive tasks concerning generalized problem-solving and complex communications (see Bresnahan 1999; Autor et al. 2003). Therefore our first research hypothesis is:

Hypothesis 1: There are considerable positive (negative) effects of ICT on the demand for high-educated (low-educated) employees.

The “Skill-Biased Organizational Change”-Hypothesis: The Role of New Forms of Workplace Organization. A further hypothesis put forward in the literature recently refers to the influence of the increasing diffusion and application of reorganization processes. The basic idea is that a gradual shift from rigid ‘Tayloristic’
organization (characterized by specialization by tasks) to ‘holistic’ organization (featuring job rotation, teams, integration of tasks and learning across tasks)” (Lindbeck and Snower 2000, p. 353) is taking place within firms, being an important characteristic of modern economies. The main elements of reorganization at the workplace level are (see Caroli 2001 for a survey of the literature on this subject): (a) decentralization of decision-making by delegation of relevant competences from management to lower hierarchy levels, increased involvement and autonomy of employees at the shop-floor level; (b) new working practices such as team-work (semi-autonomous work-teams, quality circles, etc.), job rotation, other forms of multi-tasking, multi-skilling, etc. Many authors seem to share the idea that changes in work organization towards more “holistic” structures, definitely require an upgrading of the skill content of most jobs related to these changes. Caroli (2001) presents a series of reasons for it. Current organizational changes increase employees’ responsibility for tasks and operations. This is not only the case for operatives but also for supervisors and technicians, whose roles, hence skills, are considerably modified by the new organizational practices. Thus, an important precondition for the successful implementation of most of these new organizational practices is the availability of a higher skilled (or higher educated) workforce. Therefore our second research hypothesis is:

Hypothesis 2: There are considerable positive (negative) effects of new forms of workplace organization on the demand for high-educated (low-educated) employees.

We tested this hypothesis for the two main new forms of workplace organization according to Black and Lynch (2002), which concern “work design” and “employee voice”, as explained in more detail in section 4. Therefore hypothesis 2 is analyzed into the following two sub-hypotheses:

Hypothesis 2.1: There are considerable positive (negative) effects of new forms of ‘work design’ on the demand for high-educated (low-educated) employees.

Hypothesis 2.2: There are considerable positive (negative) effects of new forms of workplace organization characterised with more ‘employee voice’ on the demand for high-educated (low-educated) employees.

The Trade Hypothesis: The Role of Trade. The main hypothesis is that the accelerated growth of world trade and foreign direct investment leads to a new international division of labour: the production of goods (and services) with a high content of low-skilled labour is dislocated to developing countries, while activities with a high content of high-skilled labour are concentrated in the developed countries (see e.g. Wood 2005); this results in a declining relative demand for high-skilled personnel and increasing relative demand for low-skilled personnel. Firms from developed countries with high wages (as compared to developing countries) can become internationally competitive by selling products and services with a high content of high-skilled labour. Therefore our third research hypothesis is:

Hypothesis 3: There are considerable positive (negative) effects of trade, especially exports, on the demand for high-educated (low-educated) employees.

Complementarities. The use of ICT, new forms of workplace organization and human capital build a “complementary system” of activities (Bresnahan et al. 2002, p. 341ff; Milgrom and Roberts 1995, p. 191ff.). According to Milgrom and Roberts (1990 p. 514) “the term ‘complement’ is used not only in the traditional sense of a specific relation between pairs of inputs but also in a broader sense as a relation among groups of activities”. Greenan and Guellec (1994) show in a theoretical paper that the relative efficiency of a centralized mode of firm organization in which knowledge is confined to specialized workers and a decentralized one in which every worker participates in learning depends on the technological level of the firm: “whereas the centralized style is more efficient when the technological level is low, the decentralized one becomes more efficient when the technological level is higher” (p. 173). Also, the exports result in a need for international competitiveness, so they necessitate higher use of ICT and new forms of workplace organization. Hence, our group of complementarity hypotheses are:

Hypothesis 4a: There is a positive (negative) interrelationship between technology and organization leading to a mutual strengthening of the effects of these two factors on the demand for high-educated and low-educated employees respectively (complementarity hypothesis a).

Hypothesis 4b: There is a positive (negative) interrelationship between technology and organization on the one hand and exports on the other hand leading to a mutual strengthening of the effects of these factors on the demand for high-educated and low-educated employees respectively (complementarity hypothesis b).
3 REVIEW OF PREVIOUS RELEVANT EMPIRICAL STUDIES

We concentrate here to empirical studies with a similar setting as our study, i.e. studies at the firm level that investigate the impact of at least one of the three factors ICT, organization and trade on the composition of labour demand. Table A.1 in the Appendix gives a summary of this literature. We can see that most of these studies have been conducted in highly developed countries (such as USA, Germany, UK, France, Italy, Norway, Switzerland, etc.). In most of the German studies have been found positive effects of both the ICT and the organizational factors on the share of the high-educated, mixed results for the middle-educated employees, while for the low-educated ones, in most studies negative effects of ICT have been found. Interaction terms for organization and technology were investigated in some cases, but no statistical significant effects could be identified. The studies in the USA and the U.K. demonstrate clearly the expected positive (negative) effects of ICT on the employment of high-educated (low-educated) employees, however the impact of new forms of organization is less clear than that of technology (but in most cases as expected). For French and Italian firms the influence of ICT on the employment shares of employees with different skills is less important than that of organization. Most studies could not find any discernible effects of ICT, but concerning the organizational factors there is a tendency for a positive impact for the high-educated and a negative one for the low-educated employees.

Concerning the trade effect there are only few studies taking it into account, together with ICT and/or organization, and their results are ambiguous. As we can see in the Appendix one of these studies that has been conducted by Kaiser (2001) based on German data has reached the conclusion that export activities exercise a negative influence on the employment share of skilled workers, but have no effect on the employment shares of academics and unskilled workers. Another study conducted by Maurin et al (2002) found a (partly) positive effect of trade on the employment of high-skilled employees of French enterprises. On the contrary a third one conducted by Salvanes and Forre (2003) found a positive effect of trade on the employment of low-skilled employees for a sample of Norwegian firms.

On the whole, the results of these studies show differences among countries, but should be viewed as indicative and not completely comparable, because some of the observed differences can be traced back to differences with respect to the sectors and industries covered in the studies, the specification of the organizational variables and the nature of the investigations (cross-sectional versus longitudinal approach). Further empirical research is required, including all these three factors proposed in the literature for explaining the shift of labour demand in favour of high-skilled labour (ICT, new forms of workplace organization and trade), and also covering countries of different levels of development based on similar samples, variables and models, so that comparisons can be made.

4 MODELS SPECIFICATION AND DATA

The analytical framework we adopted in this study is that of a demand function for employees with different education levels (heterogeneous labour) at firm level. In particular, we considered in this study three categories of employees: high-educated (employees with education at the tertiary level including universities, technical and business colleges), middle-educated (employees with a formal degree in vocational education) and low-educated (employees with some vocational education but without a formal degree or without any formal vocational education). The employment share for each of these categories was used as dependent variables (variables H_EDUC; M_EDUC; L_EDUC). For each of them we constructed one model; all these three models had the same independent variables, which are described in the following paragraphs. Table A.2 in the Appendix shows the definition of all the variables of these models.

As measures for technology input, particularly ICT input, we used the intensity of use of two important technologies, Internet (linking to the outside world) and Intranet (linking within the firm). The firms were asked to report the share of their employees using Internet and Intranet, not by a precise figure, but within a range of twenty percentage points (1% to 20%, 21% to 40% and so on). Based on these data we constructed two five-point ordinal variables for the intensity of use of Internet and Intranet respectively. In a further step we calculated a composite indicator for ICT by adding together the standardized values (with average 0 and standard deviation 1) of the two constituent variables for Internet and Intranet, which was used as independent variable measuring ICT use. We expect in general a positive correlation of this ICT variable with the employment share.
of high-educated employees, and a negative correlation with the share of low-educated employees; we have no a priori expectation for the relation between ICT variable and the employment share of middle-educated employees.

The measurement of the organizational inputs (extent of adopting new forms of workplace organization) is an issue still open to discussion, since there is not yet agreement among researchers on the exact definition of the ‘organizational capital’ (see Black and Lynch 2002 and Lev 2003 for a discussion of this matter). In order to choose variables for measuring the extent of changes and/or introduction and use of new organizational practices at the workplace level we draw on the definition offered by Black and Lynch (2002). They distinguished two components of organizational capital associated with innovations in “work design” and “employee voice”. The first component (work design) includes various modes of changing the occupational structure of the workplace, the number of levels of management within the firm, the existence and diffusion of job rotation, and job share arrangements. The second component (employee voice) is associated with new practices such as individual job enrichment schemes, employees having more decision competences, etc. So we constructed two corresponding composite variables for organization, one for “work design”-oriented organizational practices (ORG1) and a second one for “employee voice”-oriented organizational practices (ORG2), and used them as independent variables. The variable ORG1 is constructed as the sum of the standardized values of the following three variables: intensity of use of team-work (project groups, quality circles, semi-autonomous teams, etc.) (in a five-points Likert scale); intensity of use of job rotation (in a five-points Likert scale); decrease of the number of management levels (in a three-points scale) (see Table A.2 in the Appendix). The variable ORG2 is calculated as the sum of the standardized values of the following eight variables: decentralization-shift to employees of the competence to determine: work pace; the sequence of performing tasks; the way of performing tasks; to assign tasks; to solve emerging production problems; to contact customers; to solve problems emerging with customers (all these seven variables in a five-points Likert scale); and also overall shift of decision competences from managers to employees (in a three-points scale) (see Table A.2 in the Appendix). We expect an overall positive effect of organizational variables on the share of high-educated employees and a negative effect on the share of low-educated employees. We have no a priori expectations with respect to the middle-educated employees. The trade effect is measured in our specification by the export intensity (exports as a percentage of sales; variable EXPQ), which is also used as an independent variable.

We included in the above three models three more independent variables, which are related to workplace organization, but are not components of organizational capital per se. The first one is referring to the extent of incentive-based compensation (a dummy variable for the extent of applying employee compensation according to team-performance); the second variable measures labour flexibility (a dummy variable for the extent of using of part-time work) (both in a five-points Likert scale). With respect to the team-performance-based compensation variable the sign of the correlation to the dependent variable is not a priori clear for middle- and low-educated employees, but we expect that team compensation is considered as more adequate and/or is more often used for higher- than lower-qualified employees. The relation between part-time work and education level of the employees is in the empirical literature not clear and depends on the overall conditions of the labour market as well as its institutional framework. Further, we included two variables measuring the intensity of price competition (IPC) as well as non-price competition (INPC). In a recent paper Gersbach and Schmutzler (2006) postulate and derive theoretically two hypotheses about the market conditions under which industry-specific training is likely to occur: (a) concentration is high or competitive intensity is low, and (b) product differentiation is sufficiently strong. We consider the intensity of price competition as measured in this study as a proxy for ‘competitive intensity’ in the above theoretical context and the intensity of non-price competition as measured in this study as a proxy for ‘product differentiation’. Thus, according to hypothesis (a) intensive price competition would exercise a negative influence on training propensity; on the contrary, according to hypothesis (b) intensive non-price competition would have a positive effect on training propensity. Given that a firm’s training propensity is generally positively correlated to the demand for high-qualified employees we conclude that the above-mentioned hypotheses could be directly used as theoretical background for the two competition variables in our model. Finally, we use extensive controls for firm size and industry affiliation to account for firm- or industry-specific influences not taken explicitly into consideration. Additionally, in order to test our complementarity hypotheses 4a and 4b (section 2) we proceeded to a second estimation of the above three models (having H_EDUC, M_EDUC and L_EDUC as dependent variable respectively) with five additional interaction terms for the possible complementarities between ICT, ORG1, ORG2 and EXPQ.

The data used in the Swiss part of this study were collected in the course of a survey among Swiss enterprises, which was based on a disproportionately stratified (with respect to firm size) random sample of firms with at least 20 employees covering all relevant industries of the business sector as well as firm size classes (on the
whole 29 industries, and within each industry three industry-specific firm size classes with full coverage of the upper class of large firms); finally filled questionnaires were received from 1710 Swiss firms. The data used in the Greek part of the study were collected similarly through a survey among Greek enterprises, which was based on a ‘similar’ sample to the one of the Swiss part of the study (i.e. with the same proportions of firm size and industries classes), using the same questionnaire (translated in Greek); finally filled questionnaires were received from 281 Greek firms. In both parts of this study a non-response analysis was performed, which did not indicate any serious selectivity bias with respect to the use of ICT and new organizational practices (team-work, job rotation).

5 RESULTS

In Table 1 and Table 2 are shown the estimates of the models for the employment shares of the high-, middle- and low-educated employees in Greece and Switzerland respectively. For the Greek data we used OLS (Ordinary Least Squares) as estimation method; for the Swiss data we estimated a Tobit model in order to take into account the rather high number of observations with the value 0 in the dependent variables. We estimated these three model once without interaction terms (column 1, 3 and 5 in Table 1 and Table 2) and once again with interaction terms (column 2, 4 and 6 in Table 1 and Table 2). Since these results are only cross-section estimates, it is not possible to test directly the existence of causal relations between the dependent variables and the independent variables; nevertheless, some robust regularities come out, which if interpreted in view of our hypotheses 1 to 4 (see section 2) could possibly indicate the direction of causal links.

Technological Factors. From Table 1 we can see that for Greece the coefficient of the ICT variable is positive and statistically significant for the high-educated employees, and negative and statistically significant for the middle-educated employees as well as for the low-educated employees. For Switzerland the estimates for the ICT variable coefficient in Table 2 show clearly that the technological factors correlate positively with the share of high-educated employees and negatively with the share of low-educated employees; technology is not discernibly related to the employment share of the middle-educated employees. In sum, we found a positive effect of ICT on the shares of the high-educated and a negative effect on the share of low-educated employees for both countries. Both effects appear to be robust across all estimates. Thus, hypothesis 1 of “skill-biased technological change” receives strong support for both countries. This is the most important common finding.

Organizational Factors. From Table 1 we remark that the organizational variables appear to have only a weak influence on the composition of the workforce in Greek firms. We found a positive effect of ORG2 (employee voice) for high-educated employees and a negative one of ORG1 (work design) for the low-educated employees. From Table 2 we can see that organizational practices associated to the “work design” (variable ORG1) are positive correlated with the share of high-educated and negatively related to the share of middle-educated employees, while no effect is found for the low-educated employees. Thus, for Swiss firms practices such as team-work, job-rotation and flattening of the overall firm organization show the expected positive effect on the share of high-educated employees but a negative effect for the middle-educated employees. Significantly related to all three employment shares is the variable ORG2 measuring various dimensions of “employee voice”. We found positive effects of this variable on the shares of the high- and the middle-educated employees and a negative one for the low-educated employees. In sum, by comparing the two countries organizational factors seem to be much less important for Greek firms than for Swiss firms. Also, the decentralization of decision making, as it is measured by ORG2, shows a positive effect on the share of high-educated employee for both countries; this is the second common finding that provides some empirical evidence for the validity of hypothesis 2 of “skill-biased organizational change”. On the whole, the results for the organizational variables ORG1 and ORG2 are only partly in accordance with hypothesis 2.

Export activities Hypothesis 3 is of no relevance for the Greek firms: the export intensity does not have statistically significant effect on any of the three education-related employment shares (Table 1) On the contrary, the trade effect seems to be quite important for Swiss firms (Table), due to their much stronger exposure to the international competition than Greek firms, mainly in highly sophisticated sectors, such as pharmaceuticals, electronics/instruments, financial and other business services. The positive effect of export activities on the share of high-educated employees is in accordance with expectations, but not the positive effect for the low-educated. A possible explanation for the latter effect might be found in the fact that to the internationally competitive firms belong also enterprises, which use production techniques based on automation that can be operated by workers with low skills; so an increasing degree of production automation would lead to
an increase of the employment of low-educated employees at the cost of middle-educated employees that are typically involved in more traditional production techniques. The above results provide some evidence in favour of the trade effect (export activities) hypothesis 3 only for the Swiss firms.

Complementarity Effects. For the Greek firms we did not find any complementarity effects (Table 1); on the contrary, interesting complementarity effects were found for the Swiss firms (Table 2). The coefficient of the interaction term ICT*ORG1 is positive (and statistically significant) in the equation for the high-educated employees, significantly negative for the middle-educated employees and insignificantly negative for the low-educated employees. For ICT*ORG2 we found no effect for the high-educated employees, a negative effect for the middle-educated employees and, rather unexpectedly, a positive effect for the low-educated employees. Finally, there was a positive effect of the variable ICT*EXPQ for the high-educated employees. The result for ICT*ORG1 can be interpreted as a hint for the existence of complementarity of ICT and workplace organization, which means that besides the direct positive (negative) effects of ICT and new work design practices on the employment shares of high (low)-educated employees, there also exist indirect effects which can be traced back to the joint impact of these two factors on the employment shares. The positive effect of ICT*ORG2 with respect to low-educated employees is contrary to hypothesis 4a. On the whole, hypothesis 4a receives only partly support from these results. Finally, there is only little evidence in favour of hypothesis 4b: the interaction term EXPQ*ICT has a positive and statistically significant coefficient only in the equation for high-educated employees for Swiss firms.

Other Factors. Part-time work and team compensation are of no relevance for the Greek firms (Table 1). On the contrary, for the Swiss firms (Table 2) the variable for part-time work correlates negatively with the share of high-educated employees and the share of middle-educated employees, but positively with the share of low-educated employees. These results reflect the relative importance of various dimensions of quantitative labour flexibility for different employee categories; seemingly, part-time work is considered adequate primarily for low-educated employees. Further, compensation according to team-performance is not relevant for any of the three employee categories in both countries. With respect to the two dimensions of competition, for Greece (Table 1) we found a positive effect of the intensity of price competition (IPC) on the share of the low-educated employees, a positive effect of the intensity of non-price education (INPC) for the high-educated and a negative effect of the same variable for the low-educated are in accordance with theoretical expectation (hypotheses (a) and (b) in Gersbach and Schmutzler (2006). For the Swiss firms (Table 2) the competition effects are of considerably smaller importance; we could find only a negative effect of IPC on the share of high-educated employees, which is also in accordance to theoretical prediction.

6 CONCLUSIONS AND POLICY IMPLICATIONS

6.1 Conclusions

In sum, comparing the three examined factors, which have been proposed by the literature for explaining the shift of labour demand in favour of high-skilled labour, the technology (ICT) has been found to have a strong and robust effect on the demand for employees’ skills (a positive effect on the demand for high-qualified personnel, and a negative effect on the demand for low-qualified personnel) in both national contexts (i.e. in both a highly developed country, Switzerland, and a country not belonging to the highly developed ones, Greece). On the contrary, the new forms of workplace organization in Switzerland seem to have a strong effect on the demand for employees’ skills (its pattern of effects differs between new work design and employee voice practices, with both of them increasing the demand for high-qualified personnel), but in Greece this effect is much weaker; this indicates that in the context of Greece, a country not belonging to the highly developed ones, firms have not sufficiently learnt to adapt their personnel composition to new forms of workplace organization. Similarly, the export intensity in Switzerland has a strong effect on the composition of firms’ personnel (showing a pattern different from the ones found in the limited previous empirical literature on this topic (see section 3): increasing the shares of high-educated and low educated personnel, and decreasing the shares of middle-educated personnel); however, in Greece, a country with much lower export activity, and therefore a much lower exposure to the corresponding international competition, the export intensity does not affect the composition of firms’ personnel.

By comparing the results from the two countries, both similarities and differences in the above aspects can be identified. In Greek firms the main drivers of shift to high-qualified employees is the use of ICT and the decentralization of certain competences; also, the use of ICT is the main driver of reductions in the shares of middle-qualified and low-qualified personnel. On the contrary, in Swiss firms there is a wider range of significant drivers of shift to high-qualified employees: use of ICT, adoption of new work design practices, decentralization of certain competences, export activity, and also the interaction between ICT and new work design practices, as well as the interaction between ICT and export. Swiss firms seem to be able to take a maximum out of the potential of technology and decentralization through the combination of them with appropriate human skills; in order to remain internationally competitive, Swiss firms also tend to increase the skill content of their products. These results indicate that national context characteristics affect the relationship of the demand for employees’ (vocational) education and skills with ICT use, adoption of new forms of workplace organization and trade.

6.2 Policy Implications

The results of this study have significant implications for firms’ management and government policy. Firms’ management before making ICT investments, adopting new forms of workplace organization and intensifying their export activities, should adapt their personnel skills and probably composition. Also, government policy
makers have to pay special attention to the conditions favouring the formation and growth of required human capital in the economy; it is necessary to take into account the results of this study, which indicate that nearly all the examined factors (with very few exceptions) have a negative effect on the demand for middle-educated and low-educated personnel, which can result in increasing unemployment for these groups and therefore complex and multi-dimensional social problems. Therefore they should design appropriate policies for addressing this issue. In order to offer more employment perspectives to middle-educated persons government should promote and develop not only tertiary education, but also education institutions that produce this middle-skilled personnel. For instance, in Switzerland, the system of the “normal” vocational education (“Berufsfhehr”), which is one of the two pillars of the Swiss “dual” education system that produces middle-educated personnel, has to be (further) upgraded, especially with respect to the content of education. A more difficult problem is to offer more employment perspectives to low-educated persons. Additional education and/or vocational training is one way of addressing this problem, but it is not a way accessible for all involved persons, particularly not for older ones; for such cases social partners and policy makers have to co-ordinate efforts for specific solutions aiming at the social integration of this category of employees. Finally, taking into account our conclusion concerning the effect of national context characteristics on the above aspects, it should be noted that for designing our corresponding policies both at the firm and government level we cannot just ‘copy’ solutions from other countries; instead it is necessary to exploit the relevant knowledge of other countries, but in combination with a sound knowledge of the particular characteristics and specificities of our own national context.

Abstract

The international industry of engineering products and services is characterized by high complexity and competition. Corporations that expand globally have experienced that managing interdependent activities and business processes across several countries requires an effective deployment of advanced information technology. Whereas the literature has described implementation of global information systems as a means to coordinate and control the business processes, empirical studies have shown that introducing a large-scale information systems involves several managerial challenges when organizations are geographically dispersed. This paper studies deployment of a global enterprise system to support evolvement of global business processes. On the basis of a qualitative case study of a multinational corporation implementing an enterprise system across several geographical locations, we identify counteracting forces in the process of global standardization of IS and business processes and discuss how the organization try to manage these forces and challenges therein. The findings suggest that global business processes develop through diverse processes of learning and negotiation between local practices of use and infusion of the global enterprise system.

Keywords: Global business processes, Standardization, Enterprise systems, Multinational Corporation
1 INTRODUCTION

The supplier industry of engineering products and services is characterized by high international competition, and success increasingly depends on expanding the global reach of the organization. To support coordination and integration of global business processes and facilitate cross-border collaboration, western firms tend to deploy advanced information technology (Walsham 2001). The resulting business process network needs to evolve dynamically to adapt to continuously changing global and local business conditions. Several authors argue that the global enterprise should balance in a continuous learning and innovation between the local practices and global standardization (e.g. Begley & Boyd 2003).

We use the term global information systems to describe the development, use and management of information systems in a global context. During the last decade many organizations have implemented large-scale enterprise systems (ES), defined as modular information systems that cover key functions of a company and enable integration and coordination of business processes within the company and with business partners (Davenport 1998). Deployment of ES to support cross-border operations in multinational corporations (MNC) is particularly challenging and typically leads to significant changes in organization, technology and business processes (Biehl 2007). Whereas much of the literature has described implementation of global IS as a means to control the processes, empirical studies have shown that introduction of information systems in global organizations often has unintended consequences (Ciborra 2000) and may even lead to less control (Hanseth et al. 2001). Despite a large body of research on ES implementation and use, reviews of this literature show that the majority of these studies are conducted in a domestic context. Most studies attempting to capture differences between different cultures are limited to one or two countries (Moon 2007), and research studies involving a heterogeneous collection of applications and user communities are limited. There is thus a need for more studies on how ES can support cross-border collaboration on business processes. Also, more in-depth research on the effect of competitive environment, business strategy and strategies to resolve misfits in multinational ES environment is asked for (Sheu et al. 2004).

The tension between standardization and customization has been subject for several IS studies. There is an extensive body of research emphasizing the need to adapt to requirements of the local context of use (Davenport 1998). The need for standardization and coordination has been focused in IS management studies in organizations operating internationally (Lehmann & Gallupe 2005). The research question addressed in this paper is how a multinational corporation balances the forces for and against standardization in the process of global IS deployment. We draw upon findings from a qualitative case study in a multinational engineering enterprise headquartered in Northern Europe. The company is part of a global group of organizations providing advanced engineering and construction services and technology products worldwide. The paper explores the evolvement of a global ES that was successively introduced within the global company and its subsidiaries. The study illustrates that introducing and exploiting information systems in a global organization can be seen as a standardization effort, but is always embedded in local situated practices. We use the concept of dialectics of change from Van de Ven and Poole (1995) as a theoretical lens to guide the analysis of the changes and counteracting forces related to global standardization and local adaptation during implementation and post-implementation of the enterprise system.

The paper is structured as follows. The next section discusses the research foundation for global IS and business processes crossing national boundaries. Section three presents an overview of the case research setting, while section four introduces the research approach, data collection and analysis. Findings from the case study on global IS implementation based on analysis of counteracting forces of change are presented in section five. Concluding remarks and implications for further research are presented in the last section.
2 RELATED RESEARCH

This section provides a brief overview of research on IS deployment to support development of global business processes. Further, a theoretical lens for analyzing the process of development and change in organizations is presented.

Globalization of business processes implies that different organizational units need to be coordinated and integrated across geographical and organizational boundaries. Control and governance are core issues underlying IT strategies (Hanseth et al. 2001) and global IS research has traditionally focused on the potential of IS for control and coordination, global efficiency and transfer of learning (Lehmann & Gallupe 2005). However, deployment of large-scale, global IS is constrained by an evolving socio-technical installed base of information, systems, artifacts, organizational structures and practices (Rolland 2000). Establishing a global infrastructure plays an important role, by supporting global business processes and facilitating coordination and collaboration across time and space (Walsham 2001). An empirical study of a global IS infrastructure implemented in a maritime company found that it is necessary to strike a balance between global requirements and being local when designing large-scale IS. This study also illustrates the largely invisible costs to achieve a working solution, locally and globally (Rolland & Monteiro 2002).

A conceptual model for global IS suggested by Lehmann (2001) employs a two-dimensional typology consisting of a common core and local variations of the IS. The model suggests that it is impossible to support global organizations with a one-size-fits-all information system. Instead, there is a core of systems compulsory for all users and local systems to provide functionality specific for one or a group of regional subsidiaries. Lehmann and Gallupe (2005) characterize the implementation of a global IS as a territorial force field between the central/global and local, and a functional force field between business and IT.

![Force field dimensions surrounding a global information system](Source: Lehmann & Gallupe 2005, p. 170).

Enterprise systems represent one category of global IS to support cross-border operations. There have been an increasing number of research studies on ES implementation during the recent years (Lorenzo et al. 2008; Moon, 2007; Sheu et al. 2004). The fit between ES and business processes is regarded critical for
the success of ES implementation (Robey et al. 2002; Soh et al. 2003). Companies that implement ES should thus simultaneously change and improve their business processes to take advantage of new data, but most organizations find it demanding to make process change during implementation (Davenport 2004). ES deployment has been described as a means for increased coordination and control in global organizations by facilitating enterprise-wide integration of information across functional and geographical boundaries. Whereas introducing ES is challenging to any organization, multinational implementation adds new dimensions of complexity due to national, cultural, organizational, and technical differences (Markus et al. 2000; Sheu et al. 2004). Research studies find that changes such as introducing ES often has unintended side-effects in global organizations (Ciborra 2000). For example, a study by Hanseth et al. (2001) illustrates that implementing an ES system to enhance control over a global organization may just as well deliver less control from a managerial perspective.

The majority of previous studies on large-scale ES implementation have adopted a variance approach, typically describing critical success factors or value that companies generate from the ES implementation (e.g. Biehl 2007). Other studies apply a process perspective, focusing on how change develops over time in a sequence of stages (Markus et al. 2000). These stage models match the life cycle motor from Ven de Ven and Poole (1995), who presented four basic “motors” to explain processes of development and change in organizations; life cycle, teleology, dialectic and evolution. The dialectic motor emphasizes colliding forces or contradictory values that compete for domination or control. Organization theories that incorporate “logic of contradiction” have been valuable to explain change in organizations as the result of countering forces, those promoting organizational change and those opposing it. Robey et al. (2002) use the dialectic perspective in a comparative analysis of ES implementations in several industrial firms. In their view, the dialectical theory is valuable to situations where two or more parties have opposing views, values and power, while still working towards a common goal. In this paper, dialectics of change is used as a theoretical guidance to explore how global business processes and global IS develop and change during implementation and post-implementation of a global enterprise system. Introduction and development of global IS can be described as change processes, influenced by countering forces that promote standards and stability, and forces opposing global standardization but promoting local adaptation and innovation.

3 CASE OVERVIEW

The empirical study is conducted in ‘Eng-Construct’ (EC), a global group of organizations providing engineering and construction services and technology products worldwide. EC was established in 2004 after an organizational merger by two of the leading organizations within the industry. The multinational corporation headquartered in Northern Europe serves several industries, including oil and gas, and chemicals. It employs approximately 24,000 people in about 30 countries. TPS (‘Tech Product and Services’) is one of the companies within the EC group. TPS has been in the industry for more than thirty years and delivers high-tech engineering products for drilling rigs, both off-shore and land-based installation. The company has also a large, global support service network to support customers in different countries. During the recent years, the company has experienced a large international growth, which has increased the overall complexity of the organization and has now approximately 2500 employees located at the headquarters and regional offices and subsidiaries in Europe, Asia, Northern and Southern America. The products and services provided by TPS need to be competitive in the global market, leading to a continuous pressure on this and other companies within the EC group to work more effectively and efficiently without compromising on quality and safety. The core global processes of TPS are sales, procurement, supply chain management, engineering, customer service and after sales services.

The EC group initiated a global change program in 2004, aiming to coordinate and standardize strategic information systems and harmonize business processes across organizational and national boundaries. One
part of the program was deployment of global IS to harmonize business processes, globally and locally. An enterprise system, SAP, consisting of application areas or modules such as Finance, Payroll, Knowledge management, Supply chain management and Customer service, was implemented through several waves in companies and subsidiaries within the group. The EC group established a central, large-scale ES implementation project team, with IT/IS personnel from the central organization and a large number of external consultants and project managers. In 2005, TPS started the implementation of the global ES at the headquarters. Since then, it has been rolled-out successively in the subsidiaries over a period of three years, till summer 2008. Other central parts of the global IS are the new corporate Intranet, project system and collaboration applications. The global IS, consisting of global and local applications, serves to support development and improvement of the global business processes. Currently, several new initiatives are thus put into operation in parallel to enhance utilization and reaching the anticipated benefits of the global ES implementation, demonstrating the ongoing need for further improvement in global IS support. These projects address various process improvements related to for instance finance, engineering and supply chain.

4 RESEARCH METHOD

The applied research approach is an interpretive case study, assuming that people create and associate their own subjective meanings as they interact with the world around them. The specific context where the global IS is introduced, the particular business area, and characteristics of the multinational corporation are all considered important elements to focus (Walsham 1995). Previous empirical research on global IS is used to guide the research study, thus iteratively linking theory and data (Eisenhardt 2002).

The data reported in this study is part of a larger research study aiming to explore how global IS and business processes emerge in a global organization. The paper reports from twenty interviews conducted through two phases during fall 2007 and spring 2008. The first phase was a ‘screening’ consisting of three open interviews with functional managers within human relation (HR), IS/IT and global project management. The aim of these interviews, which lasted up to two hours, was to get more background information about the global company and the specific industry in which it operates, core business processes and strategy for deployment of global IS. Also, key informants for the next rounds of interviews were identified. During the second phase, seventeen interviews lasting from one to two hours were conducted. The interviews were semi-structured, and the informants were encouraged to talk freely about their experiences with and perceived outcome of the global ES implementation related to local and global business processes within their function area, challenges and expectations for future use. The interviews were conducted at the informant’s office or in a meeting room. One of the interviews was a group interview. The informants were managers from different business areas in Norway, UK and India, including HR, quality management, IT/IS, procurement and customer service. Also, global process owners, project managers and super users involved in the implementation at four different sites were interviewed. All interviews were recorded and transcribed. In addition, access was given to attend meetings and improvement workshops where notes were taken. Secondary materials such as process models and work-flow diagrams, collected during some of the interviews and on request, provided important contextual information on the process. The analysis of the empirical data proceeded in an iterative way between interpreting interview transcripts, secondary data and notes from meetings (Miles & Huberman 1994). Theory of dialectics of change was used as a ‘sensitizing device’ to analyze the findings from the empirical study.
5 FINDINGS

In this section we present some findings from the case study as counteracting forces for change towards global standardization and cooperation on global business processes.

5.1 ES strategy and motivation

Research on success factors of ERP has documented the need of a clear strategy and goals for implementation. Some of the informants from the headquarters explained that the main motivation for implementing the global ES was a need to replace an old legacy system that did not support international expansion in a satisfying way. According to one IS/IT manager, the new global ES was: “... a prerequisite for being able to manage a transformation from being a company with some international installations to becoming more global and handle the increasing number of projects and activities globally.” Another motivation for global standardization was that the company had been through processes of mergers, and there was a need for enhanced integration of operations. A common, global ES was expected to enable integration of work practices and information flow and integrate functionally oriented applications at different business units.

Informants at the local level, who typically were introduced to the implementation project at a later stage, asked for a more clear and articulated strategy from the group, pointing the direction for the change processes. One of the informants from the subsidiary emphasized the need of balancing between a global vision and local practices: “...there should be a global vision. And each business unit should try to support that global vision. And well, they may have some specific needs on their own, because their business may be slightly different. But it should still try to meet the global vision. And, again, if we step back down the process, our process owners need to make sure that the process meets both the global and the local needs”. The informants from the headquarters reported that there was a focus on communication and information during the first phases of implementation. However, the findings illustrate the need of continuous updated information during roll-out to subsidiaries and in post-implementation phase.

5.2 Towards global business processes

To support increasing international operations and expansion of the company TPS defined and implemented global business processes that should interconnect previous separate practices across various locations. Some of the managers stated deployment of a global ES was fundamental to manage and enhance global business processes such as customer service and supply chain management. The ES project manager said: “What we see, is that the quality is not better than how we manage to coordinate our activities, work in a similar way. Without a global IS infrastructure and routines, there are too many alternatives. By implementing enterprise systems such as SAP we get an opportunity to have a common terminology and interface.”

Some informants experienced that reaching consensus on business processes was challenging at some business areas and organizational units. Establishing the governance model with global business process owners and super users was reported as a critical factor in the process. Dedicated global process owners were appointed during roll-out to subsidiaries and these persons became central in process mapping and modelling and post-implementation activities to harmonize the global business processes. Their involvement as border-crossing facilitators was regarded essential for the success of the implementation, due to their knowledge about the processes and the business. One of the external project managers stated: “The global process owners are very important for establishing collaboration and development of global processes across geographical locations. The person has profound competence on the particular business process, but should also be a facilitator to ensure that the overall goals are achieved”. The global process owners filled the role as “translators” between the consultants, who knew how the enterprise system worked technically, and the key users, who had business and local process knowledge. One of the global
process owners emphasized that development and cultivation of global business processes will be an ongoing learning process: “a job that is started, but by no means completed. By now, it is established in to-be process models, but we still have a way to go…”.

5.3 Configuration of global ES

The aim was to implement an SAP industry solution. Some of the informants emphasized that this was one of the first times that the organization should adapt to a standard application. Still, a central part of ES implementation is technical configuration to customize the solution to the company needs. One manager at the headquarters said that the organization was not prepared on the dimension of the configuration job. The central project team, consisting mainly of consultants with a Scandinavian background, configured a “SAP light” version that was rolled out at subsidiaries. The configured version was thus very dependent of the consultants’ interpretation of the business needs, globally as well as locally. One of the key users from a subsidiary expressed concern with respect to the configuration and the role of the consultants and the central implementation team: “At the courses they presented: This is how SAP works. This is not correct, this is how they have configured it to work”. Training of super users on how the ES is configured is thus important for further use of the system.

Another important part of the ES configuration is definition of roles with access to functions and responsibilities, which proved to be a challenging task. The IT/IS manager emphasized that this will be an important, ongoing activity: “…there has been a walkthrough of the organization’s roles and functions, how we collaborate on business processes. And this deals not only with the system, it is a process that means you have to look at who is responsible for which tasks. And this in many respects has had an ‘upbringing’ effect on the company, centrally as well as locally, to relate to a more structured process”. Moreover, walkthrough of processes in the standard configured solution revealed local differences, e.g. in employee-management relationship.

Some of the informants raised serious concern with the central goal of providing ‘one-size-fits-all’ solution in a heterogeneous MNC. Particularly one manager at a smaller subsidiary emphasized large costs in implementing and learning a complex ES and few benefits for a smaller unit due to what he described as inflexibility in procedures and inability of the global system to adapt to specific local needs.

5.4 Knowledge sharing and learning

Experiences expressed by informants working with the customer service process illustrate the dialectics between old knowledge embedded in the process, “the way we have always worked”, and the new global ES. The process of learning required unlearning old ways of working, which can be challenging. Training is necessary to increase knowledge about the ES, which in turn is expected to enhance utilization and value realization from the ES investment. As commented by one of the global business owners: “In SAP, there is so much important information that could be utilized in a better way, for improved decision making - we do not utilize the potential of the system well enough yet”. There were examples that lack of ES knowledge resulted in “workarounds” where employees found their own way of solving the problems, which again resulted in different work practices. This was explained partly by a need for more training and exercises related to actual work processes. Another explanation was that implementation of “industry best practices” and corresponding routines had not yet been translated into local work practices. Also, knowledge sharing was mentioned as critical for learning and capability transfer. The project manager, for example stated: “One of the most important barriers to organizational learning is that there is not established well-functioning arenas for knowledge sharing. We certainly need to improve our ability and willingness to share knowledge between the organizational units and between headquarters and subsidiaries”.

Proceedings ECIS 2009
Process knowledge is critical for establishing global business processes. Some initiatives were mentioned as important to overcome lack of process knowledge. Especially at the last rollout in Asia, the global process owners and super users were actively involved at workshops where work processes and use of ES were modelled, discussed and ‘negotiated’. Also, written procedures and user guidelines such as “SAP for dummies” for the customer service process available from the Intranet were important for enhancing knowledge of global business processes and improving the processes. Development of e-learning program supporting classroom training is another initiative mentioned.

5.5 Cross-cultural and cross-functional communication

The core activities of the companies are often project driven, and there is a need for cross-border collaborative work. Several of the informants emphasized that cross-functional cooperation and communication is crucial for developing and maintaining global business processes. One of the super users described his as a coach for a team in which everyone has a particular role to play.

Cultural diversity was reported as an important factor in the case. Differences in national culture influenced the process, for example when discussing and modeling new business processes. One of the super users noted: “In our country, if someone disagrees he or she usually speaks out. This is not necessary the case in other cultures”. A cultural awareness initiative has been launched in the company for enhancing cross-cultural work. One line manager emphasized that an attitude to information sharing and collaboration cannot be taken for granted: "There are cultural differences, for example developing an understanding within the organization that we have to share work and knowledge between different countries, locations. That is a new situation for us”. Moreover, the implementation revealed important differences at the geographical locations. For example, some of the informants described that similar roles could have different authority across different locations, demonstrating that the organizational culture has an effect on definitions of roles.

Managing of the IT consultancy process was reported to be most challenging during the first rollout to smaller subsidiaries as the project team was not familiar with the subsidiary’s particular needs and the limited internal project resources. One informant at a subsidiary argued that a more global implementation team should have been established from project start-up.

5.6 Change processes on global and local level

During the implementation project the company experienced changes in roles and responsibilities. The global company has a heterogeneous work force regarding age, and professional and educational background. Technical skill and process knowledge were also critical factors that varied a lot between the different units and locations. The company was not prepared for this challenge, and one of the functional managers commented how the new global ES made work more transparent: “One of the outcomes of the change was that some of the employees became more clever to do their job, whereas others actually became less competent. Because writing skills etc. became more visible, now people had to do things by themselves. That was an important learning experience”. Job design, job enlargement and job simplification were activities during this process. An organizational change management (OCM) role was established at the local business units to ensure information, communication and training. The OCM and line managers played important roles in this phase.

At the group level a shared service model was established covering the functional areas of finance, human resources, payroll, time and travel administration. The findings show that this represented a major organizational change that had an effect on the employees’ and managers’ daily work. The HR manager explained how the new global ES and increased international focus need to be learned and cultivated in TPS, “a process that will take time in an organization, in which delivering engineering product and services has had a local focus with use of mainly locally developed applications. This is a new situation for us, going from being a locally managed organization with international projects, to becoming an international company”. Informants from the headquarters and subsidiaries expressed different
experiences with the shared service model. One informant at a smaller subsidiary expressed the view that the shared service model did not support the smaller units well enough.

After the last rollout in May 2008, the company experienced a need to go back and take a fresh look at the implementation and routines established at the head office in light of the experiences and discussions from the local rollouts. Areas such as training at different levels, further development of global business processes with updating of corresponding routines and guidelines were decided. Moreover, TPS has launched several initiatives aiming at continuous improvement of the global IS. One of the initiatives is the establishment of an improvement board. The main objective of the improvement board, which consists of line managers from the different functions and subsidiaries, is to prioritize changes to improve global business processes and global IS. Evaluation of the global ES through user surveys at different locations is another example of improvement initiatives.

6 DISCUSSION

In this section we discuss some main challenges and counteracting forces for change related to introducing a global ES in a multinational engineering enterprise. A global ES implementation could be characterized by forces at different levels (Lehmann & Gallupe 2005). In this paper the focus is on the global-local tension. From a central coordination point of view there was a need for standardization of modules, processes and routines. From a local standpoint the global IS should support the local needs and requirements. This tension could be described as a ‘territorial force field’ (Lehmann & Gallupe 2005). Table 1 summarizes key findings from the empirical study regarding counteracting forces promoting and opposing changes to globalization and standardization of IS and business processes. While some of the forces could be described at both the local and central level, the table shows where the force predominately occurred.

Table 1. Implementation of IS-Supported Business Processes: Promoting and Opposing Forces for Global Standardization at Local and Central Level

We discuss some of the main findings from the study, challenges that were encountered and initiatives to overcome these.

Deployment of global ES and business processes can be understood as a dialectic of learning and knowledge (Robey et al. 2002). The findings illustrate that there is a dialectic between existing
knowledge, embedded in business processes, routines and practices associated with legacy systems and manual routines, and new global business processes and routines supported by the global ES. Based on our findings, we suggest that lack of knowledge is a major barrier to overcome. At the individual, local level, the informants emphasized that there was a lack in knowledge of ES functionality, but also in process knowledge related to assimilation of new work processes. The case demonstrates that moving from being a company with international presence towards global integration is a learning journey by itself, for top managers, functional managers as well as employees. Configuration of a complex ES was another reported knowledge barrier. The ES was configured by the consultants in the project team and the organizations experienced that limited knowledge about the configuration was a limitation for understanding and further exploitation of the enterprise system.

Initiatives undertaken to overcome knowledge barriers are courses at different levels, focusing on practical use of the ES and how local practices are related to the overall global business process. E-learning programs and user guidelines are developed in supplement to classroom training for enhanced global services. The project team and consultants played an important role in bringing in new knowledge and distributing knowledge to different business units in TPS. However, the findings demonstrate that an active involvement of global process owners and super users with process knowledge in workshops and training at subsidiaries was necessary in this process.

Dialectics may also describe the tension between established, country-specific practices across the MNC and requirements for new, common work practices related to global business processes. The heterogeneity of TPS, consisting of geographically dispersed units of different sizes, activities and history, involves many different local practices based on functional areas of expertise. Thus, the findings demonstrate that development of global business processes could be characterized as iterative moulding and shaping processes to fit the needs of the organization. There is a need of infusing global strategies into local practices by communication of goals and strategies, as well as mapping local information and practices of use into global structures. Moreover, introduction of a global enterprise system does not necessarily imply that local practices become standardized across different business units, departments and cultures.

There are counteracting forces between a global ES promoting integration and standardization and the local need for differentiation. The findings illustrate that deployment of the global ES was regarded as a prerequisite for managing increasing global operations, but also adding complexity by introducing technical, organizational and business process changes (Markus & Tanis 2000) at the headquarters and subsidiaries. The system needs to be integrated with existing applications, physical networks, organization, culture and work practices (Hanseth & Lyytinen 2004), illustrating that information systems are always embedded in situated practice of use (Lehmann & Galupe 2005). During the period, the company has experienced a large growth, and the new system has to ‘align-in-action’ (Ciborra 1997) with the organization. The findings demonstrate that the need to align and integrate the global ES with the organization and business processes was regarded as particularly challenging and will be an ongoing process due to changes, for example in environmental conditions and mergers and acquisitions. While a stage model for IS implementation (e.g. Markus et al. 2000) seems appropriate for the first phases of the implementation, post-implementation could be characterized as gradual adoption of the ES, consisting of iterations of learning and improvements. Contrary to research treating implementation of ES as distinct stages, we find that implementation of global ES should adopt a long-term perspective and be regarded as long-time improvement and adaptation at different levels.

Establishment of a governance model with global process owners, super users and application managers was regarded essential in the case, both for consensus-making in discussions and modeling of business processes during rollout, ensuring ownership and further development of global IS and global business processes. The improvement board for prioritizing improvements across business units and functions was also reported as an important initiative. Evaluation of the global ES involves an increasing number of stakeholders as the ES is deployed globally.
Introducing a global IS to support global business processes has several implications that need to be discussed to find a balance between the global standards and local adaptation of global information systems and business processes. National and cultural differences such as government regulations, roles and authority need to be dealt with (Sheu et al. 2004). The need for communication of project goals and strategic guidelines seems to have been underestimated when rolling out at subsidiaries and in post-implementation phases of the enterprise system.

7 CONCLUSION AND IMPLICATIONS

In this study we have explored counteracting forces in change processes during deployment of an enterprise system in a MNC, in the context of global business process evolvement. The in-depth study is conducted in a company operating in the oil and gas industry, based on interpretations of informants from the corporate headquarters and three subsidiaries.

Our findings demonstrate the complexity of introducing a global ES into local work contexts, both at the headquarters and subsidiaries. The multinational company includes local sites and local practices of use. The case has illustrated that deployment of ES to support global business processes in a multinational enterprise can be described as a long-term learning process in which lack of functional ES knowledge and process knowledge related to assimilation of new work processes are major barriers to overcome. Standardization of IS and business processes implies that subsidiaries are often faced with changes imposed rather than designed. Our findings illustrate a need for infusing global strategies into local practices as well as mapping local information and practices of use into global structures. Global process owners and super users at local units and headquarters should play a critical role in these activities, which have been characterized by the informants as a continuous learning and negotiating process. Moreover, ownership and collaboration initiatives on global business processes are essential for value realization of the global ES, including ability and willingness to collaborate and share knowledge and capabilities across national and organizational boundaries.

The paper contributes to the body of global IS research by exploring deployment of enterprise systems in an organization that is geographically dispersed. By examining the phenomenon from the perspective of both headquarters and subsidiaries, the paper has explored counteracting forces at the territorial, functional and cultural levels and discussed how one multinational is dealing with these. These findings thus contribute both to research and practice. The case study explores one MNC in a particular industry over a limited period. The interpretive case study has raised several issues that should be considered in future research on global ES and business processes, and indicates the need for more in-depth research studies on how to improve the process of realizing the intended value of the global IS. The effect of the shared service model on heterogeneous units and processes of local involvement in development of global IS are examples of areas for further research.

michael.rohloff@wi.uni-potsdam.de

Abstract

Business Process Management is an important management practice for business transformation and organizational change. This paper presents a Business Process Management implementation approach in a large international company. It introduces a process management maturity assessment which was developed to assess the implementation of Business Process Management and the achievements. The maturity model is based on the assessment of nine categories which comprehensively cover all aspects which impact the success of Business Process Management. Some findings of the first assessment round are pinpointed to illustrate the benefits and best practice exchange as a result of the assessment.

Keywords: Business Process Management, Maturity Models, Process Implementation, Reference Modelling

1 INTRODUCTION AND RELATED WORK

Business Process Management (BPM) is a management practice which encompasses all activities of identification, definition, analysis, design, execution, monitoring & measurement, and continuous improvement of business processes. Consequently Business Process Management encompasses not only the analysis and modelling of business processes but also the organizational implementation, leadership and performance controlling (Becker et al. 2003, Schmelzer/ Sesselmann 2008, p. 7f.). Although it is a well-known and largely used practice there is an ongoing discussion on how to best implement Business Process Management. Due to the comprehensive nature of BPM a variety of different approaches exist (e.g. Business Process Reengineering (BPR); Continuous Process Improvement, Workflow Management, reference modelling and implementation of standard enterprise applications).

Facing the importance and vital role of Business Process Management for the transformation and organizational change of enterprises the question arises how different organizations perform in their development of Business Process Management. The notion of maturity has been proposed in other approaches to assess an organizations state in terms of implementing a specific program or the quality of a process.

A prominent and widely used model is the Capability Maturity Model developed by the Software Engineering Institute at Carnegie Mellon University (Paulk et al. 1993). This model was originally developed to assess the maturity of software development processes. Over the years it was extended to other domains. Today the Capability Maturity Model Integration is an approach for the assessment and improvement of product development processes in general. A number of additional maturity models were developed which cover other areas like the CMMI Acquisition Model (CMMI-AM) or the People Capability Maturity Model (P-CMM) for personal management and development to name a
few. Today, CMMI is widely used in practice to evaluate and to improve (software) development processes (CMMI; Ahern et al. 2004, Chrissis et al. 2006, Foegen et al. 2007, Hofman et al. 2007).

CMMI uses standardized question catalogues and evaluation criteria to assess an organizations product development process and to work out the strengths and weaknesses. It helps to define improvement measures and to plan the implementation in an organization. The CMMI introduces the concept of five maturity levels defined by special requirements that are cumulative.

In recent years a number of maturity models for Business Process Management have been proposed (BPMM; Fischer 2004, Lee et al. 2007, Rosemann et al. 2006, 2004, Rosemann/ de Bruin 2005, Smith/ Fingar 2004). Most of the models focus on only one dimension for measuring BPM maturity and very few applied studies are known. Exceptions are the Business Process Management Maturity Model (BPMM) of the OMG and the maturity model of Rosemann et al.

Rosemann et al. identified five factors which are perceived as covering and characterizing BPM (Rosemann et al. 2006, 2004, Rosemann/ de Bruin 2005, Hüffner 2007). In the progress of defining the model these factors have been restructured and renamed by Rosemann et al. and are finally defined as

- Strategic Alignment: Alignment of process management to strategic objectives
- Governance: Organizational implementation of BPM and responsibilities for assigned tasks
- Methods: Methods for all BPM relevant tasks
- Technology: Technologies e.g. I&C which support and enable BPM
- People: Competencies of people involved in BPM
- Culture: Common values towards BPM and process change

At the end of 2007 the Object Management Group (OMG) released the Business Process Management Maturity Model (BPMM). It is a model to assess the maturity of Business Process Management. The model is structured into five process area threads:

- Organizational Process Management: foundation and development of process management
- Organizational Business Management: planning, steering and resource allocation at enterprise level
- Domain Work Management: management of product and service deployment and delivery
- Domain Work Performance: product and service delivery and support
- Organizational Support: all supporting activities for controlling the core activities

BPMM defines objectives for each process area thread. This is supplemented by practices how to reach these objectives. Overall the BPMM offers a variety of recommendations for Business Process Management implementation. On the other hand it leaves some deficiencies in areas like process organization and process accountability. The important role of IT support for Business Process Management is not covered in this model.

This paper presents the implementation of Business Process Management in a large international company, undertaken as a corporate, company wide project within Siemens AG.

The next section outlines the objectives and the overall approach for implementing Business Process Management. It introduces a process framework including a reference process house and the overall structure and content of the BPM implementation process.

Section 3 gives an overview of the Business Process Management maturity model which was developed in order to assess and to derive improvement measures for the Business Process Management in the company. The assessment process and some results of the assessments are presented to illustrate some benefits of the approach.
2 IMPLEMENTATION OF BUSINESS PROCESS MANAGEMENT

2.1 The Business Process Management Initiative

Siemens is engaged in different business sectors with a very broad and diverse product and service spectrum. It is a global company with regional representations in more than 190 countries (for an overview see Feldmayer/ Seidenschwarz 2005, pp. 124 ff.). Over the years the process and IT landscape has developed differently in the respective business units and regions. With the Business Process Management activities a redesign, alignment and optimization of business processes and a better process standardization and utilization of synergies was intended.

A central element of the Business Process Management Initiative was the development of a Siemens Process Framework (SPF 2005) which consists of a reference process house (RPH) and common methods for process management across the company [Feldmayer/ Seidenschwarz 2005, p. 26, Schmelzer/ Sesselmann 2008, p. 241-252]. The initial company wide activities for process standardization started in 2000 with the E-Business initiative “Generic Business Processes”. The primary focus was on the definition of the Supply Chain Management processes based on the Supply Chain Operational Model (SCOR). In the following years the process activities where extended to the Customer Relationship Management and the Product Lifecycle Management. Finally, the activities were taken up and consolidated under the leadership of corporate CIO and the development of a comprehensive reference process house covering all business processes was accomplished (SPF 2005). The primary objective was to leverage synergies and cost potentials with a common organization and process coordination, and the definition of reference processes.

Reference models are increasingly used in industrial practice and leave the area of research (Becker/Delftmann 2007, Fettke and Loos 2007, see the overview in Brocke 2004, p. 393f., for reference modelling projects see RefMod). In practice reference models for processes have particular relevance (e.g. SCOR, Fettke et al. 2006, Scheer 1994). For the development of the Siemens Reference Process House the Supply Chain Operational Model (SCOR) was a fundamental basis.

The Siemens Process Framework (SPF, figure 1), with its binding set of principles and definitions for the overarching management of processes, provides the basis for a uniform implementation of process management within Siemens. The core component of the SPF is the Reference Process House (RPH). It contains the definitions of all Business, Management, and Support Processes down to the agreed level of detail. The Reference Process House is structured into the following process categories:

- Management Processes
- Customer Relationship Management (CRM) Processes
- Supply Chain Management (SCM) Processes
- Product Life Cycle Management (PLM) Processes
- Support Processes

These generic process definitions are fundamental to process standardization and provide a stable basis for process management. They are subject to the cascaded rollout and refinement in the business groups and regions. Incorporating process definitions, guidelines for documentation and modeling of processes, and a binding decision structure for process standardization, the Siemens Process Framework is the basis for:

- Configuration and design of specific business processes (e.g. CRM, PLM, SCM) and end-to-end business process chains
- Redesign of processes based on commonly defined standards for to-be processes
- Common language and common understanding of processes
- Realization of the saving potentials identified through
  - faster implementation of standard processes and alignment of applications
  - utilization of synergy effects
- Comprehensive benchmarking and best practice sharing.
The process management methods of the SPF represent a comprehensive set of tools, concepts, conventions, procedures, and guidelines which are needed for any implementation and operation of process management in the Siemens units. With the description of all roles and responsibilities required for effective process management the SPF provides a blueprint for the organization of process management in the respective business groups and regions. It ensures clear communication and decision processes.

Figure 1. Siemens Process Framework

The main objective of the introduction of Business Process Management is to increase the effectiveness and efficiency of all value creating processes of the organization. From an operational point of view, process management is about having defined processes, measuring their performance, and improving them incrementally as part of daily business. It is also about defining performance goals for processes “top-down”, based on benchmarking results or strategic goals derived from corporate initiatives, and performing major re-engineering activities on processes to close existing performance or cost gaps. Process standards and a common process framework are a fundamental basis for a systematic design and optimization of results, processes, and resources.

Most efficiency and effectiveness problems in an organization have their origin in non-mastered processes. A proper implementation leads to the mastery of processes with regard to lower non-conformance, as well as to high reliability and safety, and results in reduction of process costs, process cycle times, and improvement of quality. Process standardization affects the strategic levers operational excellence and active management of synergies and supports the vertical and horizontal strategies of Siemens. This is achieved by the cascaded definition and rollout approach of the Process Initiative based on the Reference Process House. The implementation of Business Process Management based on the Siemens Process Framework results in a number of benefits which where pursued with the Process Initiative.

- Establish a process management community within the business units and regions to coordinate and optimize local, regional, and headquarter process improvement initiatives.
- Provide a common reference framework for supporting &coordinating all process related projects
- Present a uniform appearance to customers and business partners through Siemens wide standardized process implementation.
- Provide standard service levels to the global customers.
- Enable best practice sharing across all business units and regions.
- Provide opportunity for shared services and an improved lean IT landscape through process standardization.
2.2 Process and implementation topics for Business Process Management

Experience shows that business transformations are often a consequence of good process management. Thus, the implementation of Business Process Management itself has to be organized as a business transformation program covering all relevant aspects of an organization’s development. These aspects have to be addressed by implementation topics which are dependent on each other with regard to their contents. All these issues are addressed by guidelines for BPM implementation (see Process Management Implementation Guide 2005). The following gives a short overview on the different implementation topics.

- **Process Management Organization**: Establish process management roles & bodies according to the Siemens Process Framework and assign the responsible persons.
- **Process Portfolio**: Select, assess, and prioritize the processes which have to be standardized and optimized.
- **Process Documentation & Standardization**: Develop consistent and organization-wide valid process definitions at least for the portfolio processes. Drive the standardization and alignment of business processes and the management and support processes. Establish a process house based on the Reference Process House with organization-wide binding and where necessary more detailed process definitions addressing at least the portfolio processes. Initiate process improvement initiatives for relevant processes of the process portfolio covering: visualization of as-is processes as required, derivation of improvement potentials & measures, design & implementation of to-be processes.
- **Process Performance Controlling**: Define key performance indicators (KPI) and metrics for the portfolio processes derived from business goals and strategies. Introduce a continuous KPI-based performance measurement and assessment for the processes.
- **Process Management Maturity Assessment**: Conduct process management maturity assessments of the organization. Derive & implement improvement measures. Repeat process management maturity the objectives assessments periodically.
- **Methods & Tools**: Provide standard methods and tools required for the operation of process management and according to the Siemens Process Framework guidelines (e.g. a RPH database and ARIS tools).
- **Communication**: Provide target group specific information about objectives, content, roles & responsibilities, and progress of process management to create awareness and support the implementation.
- **Qualification & Training**: Derive competency development measures for the persons involved in process management. Define and conduct target group specific qualification programs. Verify the success.
- **Target Setting & Incentives**: Check and amend target setting and incentive systems. Define process harmonization/standardization and process performance goals. Implement process target agreements, define related incentives.

Only if each of these topics are planned and implemented to a certain degree and in a coordinated way, the effects necessary for overall success are achieved. The overall maturity degree of a process management implementation is therefore directly linked to the maturity degree of each of the implementation topics (see next section). Of course, the business situation, the cultural environment, and the readiness of an organization are additional boundary conditions which have to be considered in the setup of the contents and the timeframe of the implementation program.

The process for process management is structured into the following generic process steps (compare Becker et al., Schmelzer/ Sesselmann 2008): Set Goals, Analyse, Define; Realize, and Review. The process is part of the support process “Process and Information Management” of the Reference Process House. All implementation topics need to be addressed in each of the 5 generic process management steps resulting in the overall structure and content of the BPM implementation process.
Figure 3 comprises the overall structure and the holistic view and comprehensive content of a BPM implementation process. All topics need to be addressed by a BPM maturity assessment.

### 3 A MATURITY MODEL FOR BPM

#### 3.1 Process Management Maturity Assessment (PMMA)

The assessment of the maturity of all activities related to Business Process Management is an essential element of the BPM implementation process. The so-called “Process Management Maturity Assessment (PMMA)” has its focus on the assessment of the organizational implementation of all Business Process Management activities. In contrast most maturity models solely focus on the performance assessment of a specific business process. The process performance of a business process is addressed as a separate category in the implementation process. In this respect the business process performance measurement is one category among others to be addressed in a BPM maturity assessment.

The Process Management Maturity Assessment provides a methodology for a structured analysis and objective assessment of the achieved implementation status of Business Process Management (process management maturity) and the compliance with the Siemens Process Framework (SPF) standards (Feldmayer/ Seidenschwartz 2005, pp. 107 f., Schmelzer/ Sesselmann 2008, pp. 337 f.). The major objective of the PMMA is the identification of need for action and derivation of measures for Business Process Management improvement, as well as the identification of requirements for further support. It serves as a driver for the process initiative. The following objectives are pursued with the PMMA approach:

- to assess the maturity of Business Process Management and the processes
- to monitor the advancement of the process initiative and to derive further fields of actions
- to reveal the potential for best practice sharing
- to motivate and increase the awareness for process management among the involved parties like management, process drivers, and users.

At the time of implementing the Process Initiative no holistic process management maturity model existed which would cover all relevant BPM implementation issues outlined in section 2. The BPMM model of the OGM and the maturity model of Rosemann et al. evolved in parallel to the own development of the Process Management Maturity Assessment (PMMA).

The PMMA follows the principle structure of the Capability Maturity Model Integration Method of the Software Engineering Institute at Carnegie Mellon University (CMMI) but provides a holistic assessment of all areas relevant for BPM based on a comprehensive set of criteria. As an indicator for process maturity, a five step model is applied in the same fashion as the CMMI model.
The PMMA consists of nine categories with one to three sub-categories each. The PMMA categories and sub-categories correspond to the implementation topics of the Process Management Implementation Guide (see section 2):

- Process Portfolio & Target Setting
- Process Documentation
- Process Performance Controlling
- Process Optimization
- Methods & Tools
- Process Management Organization
- Program Management, Qualification, Communication
- Data Management
- IT-Architecture

For every sub-category, each maturity level 1-5 is clearly defined in a to-be status by a set of criteria. These descriptions, as well as examples for questions and possible deliverables, are combined in worksheets. A tool based on MS-Office products was developed to support the assessment process.

Figure 3 outlines the five overall PMMA maturity levels which consolidate the detailed maturity levels of the categories.

<table>
<thead>
<tr>
<th>Maturity Level</th>
<th>Criteria Catalogue</th>
</tr>
</thead>
</table>
| 5 ———> “Optimizing” | - Processes are analyzed, optimized and adjusted to changes in market requirements systematically  
- Benchmarking and Best Practice Sharing are used continuously in order to identify improvement potential  
- Methods for mistake avoidance are used |
| 4 ———> “Quantitatively managed” | - Continuous measurement and adjustment of process performance (quality & quantity)  
- Process management is subject to a systematic maturity assessment (continuous PMMA)  
- Implementation controlling of initiatives with top+ degrees of implementation |
| 3 ———> “Defined” | - The process landscape is derived from systematically ascertained major components of the value chain, business strategy and binding internal/external guidelines.  
- In order to compile a process portfolio, a comprehensible assessment and prioritization of these processes is conducted  
- The systematically ascertained and strategically relevant processes incl. KPIs are documented according to the SFF in the reference process house of the GRDC, a KVP is established  
- Responsibilities for processes are established (roles, committees)  
- Rules and methods of the process management are defined and implemented |
| 2 ———> “Managed” | - Need for action identified/project manager entitled  
- Particular processes in the GRDC are harmonized/standardized  
- Deployment of process management as needed  
- Situation- and/or event-driven approach |
| 1 ———> “Initial” | - Processes are not defined – ad-hoc approach  
- Success depends on certain specialists  
- Schedule, quality and costs are not predictable |

Figure 3. Overall PMMA maturity level

For a sub-category all defined criteria of a maturity level must be met to achieve the respective level. The overall result of a PMMA will be stated in a maturity level grade (e.g. 3,2). The pre-decimal position states that 100% of all sub-categories fulfil the criteria of level 3 (bottleneck is the lowest value for a sub-category). The decimal place states the percentage of fulfilled sub-categories of the successive level (e.g. 20% of level 4). The achievement of a higher level (e.g. 5) in any sub-category is not reflected in the overall grade.

While the maturity levels of figure 3 document the overall assessment and consolidate the maturity assessment of the different categories, a more detailed look on each of the categories is provided by radar screens (see figure 6). Detailed criteria and a set of questions exist to assess the maturity level for each of the categories. Table 1 summarizes what needs to be accomplished for a maturity level 3 in each category.

### Table 1. PMMA categories and maturity level 3 achievements

In general, most CMMI based maturity models define five maturity levels and associate a higher level with a higher maturity and a better performing organization. Crawford (Crawford 2001) argues that this can be a misleading interpretation. An organization should aim for a particular maturity level in relation to its organizational strategies and objectives. A detailed view on the implications of the current maturity level based on the identified shortcomings and weaknesses is proposed in order to derive strategies for improvement.

### 3.2 Maturity Assessment: Initial study and findings

In addition to the workout of the PMMA, a qualification and training program was set up to build a pool of certified assessors who can conduct the PMMA. A roadmap was defined when to assess each organizational unit, eventually covering the entire organization. The PMMA is designed to be repeated once a year to track and drive the improvement.

Figure 5 outlines the execution steps for a PMMA: Between two and three days are required to prepare, conduct, and evaluate the PMMA. The PMMA will be conducted based on interviews with the head of the units, the Process Owners/Process Executives for the Business, Management & Support Processes, and the Process Framework Executive.

The initial assessment analyzed 14 organizational units from some business groups and regions.

The PMMA result can be documented in a radar chart showing the level achievement for each category. Moreover, with the help of PMMA highlights and lowlights for each category, suitable actions can be derived and initiated to improve the implementation status of Business Process Management (process management maturity).
The results for the analyzed units show an overall maturity level ranging below maturity level 3. Although all units participated in the Process Initiative and have implemented Business Process Management the figures show that it is quite some effort in terms of time, resources, and people involved to achieve organizational performance. Also, one has to keep in mind that due to the method of measurement the overall maturity level cannot be higher than the lowest maturity level in any category.

A more detailed view is provided by a radar chart showing the level of achievement for each category. Figure 6 shows the assessment for two selected units providing insights in strengths and shortcomings; e.g. one organizational unit is quite strong in Process Portfolio & Target Setting (level 4) and in Process Management Organization (level 5) and the other in Process Documentation (level 5).

Table 2. Strengths and weaknesses in the BPM categories
The assessment provides a detailed analysis which helps to identify strength and weaknesses and allows to compare the performance of organizations in a differentiated manner and provides a sound basis for best practice sharing. Table 2 summarizes some strengths and weaknesses for the different categories revealed across the assessed organizational units.

Organizations can learn from one another in terms of good and poor performance by understanding the performance of an organization and the underlying reasons. What proofed to be Best Practice can be adopted by other organizations in order to improve performance.

4 SUMMARY AND OUTLOOK

Business Process Management is an important management practice for business transformation and organizational change. This paper outlined the implementation of Business Process Management in a large international company, undertaken as a corporate, company wide project within Siemens AG.

The paper introduced a Process Management Maturity Assessment (PMMA) which was developed to assess the implementation of Business Process Management and the performance of organizations in this respect. The maturity model is based on the assessment of nine categories which comprehensively and entirely cover all aspects which impact the success of Business Process Management.

The proposed Process Management Maturity Assessment advances most of the maturity models which are based on a limited set of criteria. Only the Business Process Maturity Model of the OMG and the maturity model of Rosemann et al. cover also a broader range of BPM factors. Both were in progress of development at the time of PMMA development. All five factors of the Rosemann et al. model can be mapped to the nine categories of the PMMA. A detailed analysis of the underlying criteria and questions for assessment provided they are made public available would show the common ground, possible differences, and additions.

Since the PMMA is based on the principal structure of CMMI using defined maturity levels, structured questionnaires and work sheets, it is easy to use and an assessment for a respective organizational unit can be undertaken in a limited timeframe. A limitation of the CMMI approach is the consolidation of criteria to a single maturity level which may result in misleading interpretations. It is recommended using a detailed view on the assessment and maturity level of each of the nine categories in order to derive a more differentiated picture for improvement measures and best practice exchange, like it was outlined in the example from the business case.

The PMMA was developed to suit the BPM implementation approach which in parts, like the Siemens Process Framework, is company specific. However, the PMMA approach proved to cover all relevant factors for Business Process Management and can be adapted with little effort to a maturity model for general use. This could go in hand with a detailed cross check with the criteria and questions of the maturity model of Rosemann et al. and the Business Process Maturity Model of the OMG.

Overall experiences using PMMA for the assessments are promising in terms of acceptance, ease of use, and coverage of BPM impact factors. The PMMA fits into the overall BPM implementation process in the company and provides an important link to Business Process Management success.

Abstract

Despite business-to-government (B2G) electronic auction (e-auction) markets being a way for suppliers to create opportunities for market expansion and for trading activities, little has been done to understand the behaviour of suppliers participating in these markets. In this paper, we propose a framework to explain suppliers’ intention to participate, and the level of participation in B2G e-auction markets, which will be tested in the Thai B2G e-auction markets. Low supplier participation has been a major problem in the Thai e-auction markets. We posit that suppliers’ participation depends on organisational motivation, environmental uncertainty, and their capabilities. The conceptual framework draws from the Motivation-Ability Framework, Transaction Cost Theory, Institutional Theory, and Resource-Based Theory. It proposes that four key constructs - efficiency motive, legitimacy motive, environmental uncertainty, and organisational capabilities influence suppliers’ intention to participate as well as their participation level in B2G e-auction markets. The conceptual framework is developed by drawing on our understanding of the Thai electronic auction market as well as from extensive literature. We believe this framework may be useful to better understand the key reasons for suppliers to participate in B2G e-auction markets.

Keywords: Electronic auction markets, Business-to-Government (B2G), Suppliers’ participation.
1 INTRODUCTION

Business-to-Government (B2G)\(^1\) electronic markets can be considered as an inter-organisational information system with which participating buyers and sellers utilize electronic markets for a dynamic price-making mechanism (such as electronic auctions), as well as for the exchange of information related to price, product specification, and terms of the trade (Bakos 1991; Grewal & Comer & Mehta 2001). Electronic auction (e-auction) markets are increasingly being used in B2G electronic markets to procure goods and services for governments; they have been reported to yield significant price reductions and time saving for governments as well as to create opportunity for suppliers to penetrate new markets (Beall et al. 2003; Emiliani & Stec 2002; Smeltzer & Carr 2003).

The majority of research on e-auction markets is focused on developed countries, primarily in North America and Europe (Germer & Carter & Kaufmann 2004). There is very little empirical evidence on how B2G e-auction markets perform in the context of developing countries. Developing countries generally lack resources (e.g. skilled people, proper ICT infrastructure) and they also generally report slow economic progress (Jones 2007), compared with developed countries. Molla and Licker (2005) also support this assertion and further suggested that businesses in developing countries are faced with number of challenges (such as technological, financial, and legal infrastructure constraints) in their adoption of e-commerce. These are example barriers to the development and support for B2G e-auction markets. The literature also reports the need for transparency in e-government procurement, especially in developing countries (Rege 2001). Equity is generally promoted for developing countries (UN 2005). B2G e-markets can result in more equity in supplier participation (MacManus 2002) and therefore allow new suppliers to enter the marketplace using a competitive bidding process. For all the above reasons, this study which will be conducted in a developing country is particularly interesting. It will therefore increase our understanding of how B2G e-market will assist the Thai government in promoting the level of suppliers’ participation.

The Thai B2G e-auction markets have a number of characteristics that make them suitable for this study. Firstly, the study of B2G e-auction markets has become significantly important for the procurement of goods and services in South East Asian countries including Thailand (Jones 2007; Settoon & Wyld 2003). The Thai government shows commitment in promoting the B2G e-auction markets by making it mandatory for all Thai government agencies to procure goods and services through e-auction markets, whenever the procurement value is more than 2 million Baht (US$ 60,000). Secondly, the National Statistical Organization (NSO) of Thailand reported that the participation of suppliers in Thai B2G electronic markets is low. Only 0.3% of businesses participate in B2G e-markets compared to 85.3% in business-to-consumer (B2C) and 14.4% in business-to-business (B2B) electronic commerce (NSO 2007). Thirdly, primary researcher has full access to the Thai e-auction markets which makes this study possible.

Prior studies suggest that a sufficient number of qualified suppliers participating in B2G e-auction markets can lead to a competitive market environment (Beall et al. 2003; Elmaghraby 2005; Smeltzer & Carr 2003). Thus, the number of qualified suppliers plays a significant role for the success of e-auction markets. However, the effort to understand the behaviour of suppliers participating in B2G e-auction markets has been lacking. Prior research in this area has two main foci, both in terms of the type of electronic marketplaces (i.e. B2B electronic marketplaces) (Grewal et al. 2001; Son & Benbasat 2007) as well as the research approach (i.e. qualitative case studies). Qualitative case studies provide a rich picture of specific phenomenon within the chosen context (e.g. Emiliani & Stec 2005; Hackney & Jones & Lösch 2007; Soh & Markus & Goh 2006). However, the results do not allow us to generalize to other settings and they also do not allow us to quantitatively validate relationships between key constructs.

---

\(^1\) Business-to-Government is defined as “business activity that involves a business selling its products or services to the central, regional or local government” (source: http://business.govt.nz).
From a thorough review of the relevant literature, this study proposes a research framework with an objective to extend our understanding of the antecedents of suppliers participating in B2G e-auction markets by drawing from the relevant literature including these four theories: the Motivation-Ability Framework, Transaction Costs theory, Institution Theory, and Resource-Based Theory. Studies of B2G e-auction markets have been relatively rare so there is still a lack of a good understanding of how B2G e-auction markets work, especially from the suppliers’ perspective.

This study contributes to the literature in the following ways: Firstly, this study explicitly focuses on the linkage between B2G e-auction markets and supplier participation behaviour, which has not been done before. Secondly, this study conceptualizes supplier participation behaviour within the Motivation-Ability Framework, Transaction Costs Theory, Institutional Theory, and Resource-Based Theory, to extend our understanding of supplier behaviours in the B2G e-auction markets. Lastly, this study aims to fill a gap in the literature arising from a lack of research in the B2G e-auction markets environment.

2 LITERATURE REVIEW

This literature review is taken from diverse disciplines; marketing, economics, organisation management, strategic management, and information systems. We first introduce the electronic auction mechanism, then summarise four key theories important for this study, followed by a description of the Thai e-auction context, before stating the main research questions.

2.1 Electronic Auction

Electronic auction (e-auction) is defined as a market institution with an explicit set of rules determining resource allocation and prices on the basis of electronically submitted bids from market participants (Beall et al. 2003). The term “auction” is used to represent both selling auctions (bidding to buy) and purchasing auctions (offering to sell) (Kaufmann & Carter 2004). The literature in e-auctions is usually discussed in terms of selling auctions, rather than purchasing auction, for simplification (Kaufmann & Carter 2004). The four basic selling auction types were introduced by McAfee and McMillan (1987): (1) the English auction (ascending-bid auction), (2) the Dutch auction (descending-bid auction), (3) the first-price sealed-bid auction, and (4) the second-price sealed-bid (Vickrey) auction. In the same way, Kaufmann and Carter (2004) suggested that the four selling auction types have mirror images in the context of purchasing auction: (1) reverse English auction, (2) the reverse Dutch auction, (3) the first-price sealed-bid purchasing auction, and (4) the second-price sealed-bid purchasing auction. Moreover, the auction types can generally be defined as the following dimensions: the number of bidders, the number of bids per bidder, and the degree of visibility between bidders (Kaufmann & Carter 2004). For this study, we employ only the first-price sealed-bid purchasing auction (with descending prices, multiple permitted bids and almost full visibility) because it has been used in the Thai e-auction. Thus, the terms “e-auction” used hereafter refer to “the first-price sealed-bid purchasing e-auction”, which refers to the electronic competitive bidding between suppliers that drives prices down, or purchasing auctions from buyers.

2.2 B2G Electronic Auction Markets

This paper is confined to the context of a B2G e-auction market as it pertains to a situation with one buyer (government) and a group of sellers (Kaufmann & Carter 2004). In B2G e-auction markets, a government procuring agency invites pre-qualified suppliers who compete against each other to supply a specified good or service, thus driving down the price. Governments generally find the e-auction process attractive because of the tangible benefit of price reductions and the prospect of a reduced transaction cost (Beall et al. 2003; Hackney et al. 2007; Settoon & Wyld 2003). Similarly, suppliers can obtain benefits from opportunities to bid electronically for new business, to penetrate new markets, to create new low costs sales channels, to lower overall transaction costs for buyers in e-auction markets (Smeltzer & Carr 2003), and also to obtain benefit from auction process time.
reduction between bidding and winning the business (Smart & Harrison 2003). Sometimes the auction results are announced at the end of the event, or a day or two later versus weeks or months under traditional auction processes.

2.3 Relevant Theories

A number of relevant theories have been adopted for the theoretical development. These are explained in this section.

The Motivation-Ability framework was introduced by Merton (1957). It has also been applied in the marketing and strategic management literature to study organisation behaviour in terms of organisations’ movement towards online channel. For example, Grewal et al. (2001) employed the motivation-ability framework to investigate organisational participation in business-to-business (B2B) e-markets, they also developed the efficiency construct from transaction cost economics, the legitimacy construct from the institutional theory, as well as the learning and IT capabilities from the Strategic Management literature. Son and Benbasat (2007) extend Grewal et al.’s (2001) work by identifying the salient factors rooted in efficiency motive and legitimacy motive, which affect organisation buyer’s adoption and use of B2B e-marketplaces.

According to Transaction Cost Economics (TCE), all economic activity revolves around a transaction, which is simply some form of exchange of a good or service between two or more economic actors. To optimize the exchange, an appropriate governance structures must be matched to the nature of the transaction (Williamson 1999). Consequently, transactions may be divided into production and coordination costs (Malone & Yates & Benjamin 1987). Coase (1937) proposed that the use of price mechanisms generates cost such as searching for prices, reaching an agreement and enforcing the commitments. In this research, transaction costs represent coordination costs, which consist of operational costs and contractual costs among economic actors in the market. If transaction costs are high, no or little economic activity from suppliers is likely to occur. Bakos (1991) pointed out that information technology would reduce transaction costs, thereby enabling the emergence of more efficiently organised electronic markets.

The Institutional Theory has been used to study organisations. Institutional environments are important for organisational structure and action (Son & Benbasat 2007; Teo & Wei & Benbasat 2003). The key idea behind institutionalization is that organisational action reflects a pattern of doing things that evolves over time and becomes legitimated within organisation and an environment (Eisenhardt 1988). DiMaggio and Powell (1983) suggested three types of isomorphic pressures - mimetic, coercive, and normative – that cause an organisation to have the same form with their environment (e.g. competitors or government/buyer). Mimetic pressures may cause an organisation to imitate the actions of other structurally equivalent, whereas coercive and normative pressures operate through interconnected relations (DiMaggio & Powell 1983).

The Resource Based View (RBV) of the firm suggests that organisations compete and create value on the basis of resources that are unique, rare, valuable, and not easily imitable or substitutable (Barney 1991). Competencies develop when such resources are combined to create specific organisational ability (Day 1994). Peteraf (1993) also proposed a resource-based model of the theoretical conditions which underlie competitive advantage, namely resource heterogeneity, ex post limits to competition, imperfect resource mobility, and ex ante limits to competition. Hall (1993) suggested the sources of sustainable competitive advantage as being two types of capability differential; namely, capabilities based on assets and capabilities based on competencies.

2.4 The Thai B2G E-Auction Markets

The Thai e-auction markets were introduced by the Thai government in 2002. The Thai B2G e-auction markets are highly decentralized. There is no central procuring authority or control agency, there is no purchasing department or the associated purchasing staff. Each of the Thai government agencies can
procure the goods, services through e-auction markets provided by third-party providers of e-auctions. However, the Prime Minister’s Office (PMO) has authority to issue and update regulations that stipulate procurement procedures and standardized contracts in order to enforce all government procuring agencies and public enterprise to deploy transaction through e-auction markets. Given the authority of the different government administration units in mandating the strict electronic procurement practices of the Thai government, it leaves suppliers no choice but to comply with the set rules and regulations if they wish to expand their business to the government sectors.

The Thai government procuring agencies in B2G e-auction markets face a major problem pertaining to too few suppliers participating in these markets - this could result in a non-competitive electronic auction environment (NSO 2007). Smeltzer and Carr (2003) have suggested that at least four or five suppliers are needed to begin the bid process. Whereas, Elmaghraby (2005) argues that more bidders is not always better. These different views notwithstanding, it is important to understand the suppliers’ behaviour to participate in the Thai B2G e-auction markets in order to facilitate these markets’ success and to make these markets more competitive. Thus, the aims of this research are 1) to investigate the factors that influence suppliers’ intention to participate and the level of participation in the Thai B2G e-auction markets and 2) to examine differential effect of the four groups of factors in participation intention and participation level. The main research questions to be addressed are:

1. What types of precursor factors motivate suppliers’ intention to participate, and to increase their level of participation in B2G e-auction markets?
2. Do these key factors play different roles in explaining suppliers’ intention to participate and participation level?

3 FRAMEWORK DEVELOPMENT

In this section, we describe the theoretical development of a framework for explaining the factors that directly influence suppliers’ participation in B2G e-auction markets. We theorise that suppliers’ participation in a B2G e-auction market depends on a supplier’s motivation and their capabilities. The literature on e-commerce also suggested that environmental uncertainty is inherent in e-markets (Lee & Clark 1997). We propose that four main constructs: efficiency motive, legitimacy motive, environmental uncertainty, and supplier capabilities - influence suppliers’ participation (dependent variable) in B2G e-auction markets. Components of the proposed model (Figure 1) are explained below. While we recognise that independent variables may be interdependent to one another, the purpose of the current framework is an initial attempt to find the immediate antecedents of the dependent variable.

3.1 Supplier Participation

In e-auction markets, suppliers’ participation can be classified into two groups; transaction intention and the level of participation (i.e. exploration, trial, commitment, and passive stage). A supplier firm can only be in one stage at any point in time (Grewal et al. 2001).

3.1.1 Transaction Intention

In the technology acceptance model and e-commerce literature, transaction intention is likely to influence future transaction behaviour (Davis 1989; Son & Benbasat 2007; Teo et al. 2003). Behavioural intention refer to the motivational factors that reflect how people are willing to try to undertake a behaviour (Ajzen 1991). In transaction intention period, suppliers will face higher levels of uncertainty related to evaluating the pros and cons of doing business through the B2G electronic auction market (Son & Benbasat 2007).
3.1.2 The level of Participation

To deal with the varying levels of supplier activities in B2G e-auction markets, the participation level can be classified into the exploration stage, the trial stage, the commitment stage, and passive stage (Grewal et al. 2001; Son & Benbasat 2007). In the **exploration stage**, the supplier has been registered in the B2G e-auction market but has not yet begun to conduct trading activities through the e-auction market. In the **trial stage**, the supplier will have conducted several transactions through a B2G e-auction market, but supplier is still evaluating the pros and cons of this means of doing business. In the **commitment stage**, the supplier has made a full commitment because trading through a B2G e-auction market has become an important part of its operations. In the **passive stage**, the supplier has considered not doing business or terminated conducting business in the B2G e-auction market.

Figure 1 shows the proposed research framework for B2G e-auction markets.

---

### Figure 1. Research Framework for B2G E-Auction Markets.

3.2 Efficiency Motive

Organisations participating in e-commerce would be more tended to obtain both efficiency and effectiveness benefits (Bakos 1991). An e-market can reduce coordination costs, which include setting up a relationship, search costs, and transaction costs, between the buyers and the sellers (Bakos 1991). We draw from the Transaction Cost Theory to study the economic organisation of how suppliers seek to minimize transaction costs (Williamson 1981). Arguments for the move to e-markets were based on expected reduction in the transaction costs between buyers and sellers (Bakos 1991; Williamson 1981, 1999). Malone et al. (1987) proposed that information technology, by reducing the transaction costs of market-based coordination, will lead to increased use of market-based governance structures (such as B2G) than hierarchy-based governance structures (such as EDI). An organisation would choose one of these structures that best fits its economic efficiency rationale. Malone et al. (1987) provide two characteristics of products (i.e. asset specificity and product description complexity) which can influence an organisation to select one of governance structures between electronic markets and electronic hierarchies that minimize their total cost. This research also proposes additional variables that could potentially influence organisation decisions to participate in the e-auction markets; namely, market transaction costs, market transparency, and auction process cycle time.

Proceedings ECIS 2009
3.2.1 Product Characteristics

Hackney et al. (2007) suggest that not all products are equally suitable for procuring through e-auction markets. Hur et al. (2007) also support this assertion and further suggest that not all products are auction-suitable and the commodities are most suitable for e-auction markets. The type of products directly impact on its specificity (Hackney et al. 2007) and product description complexity (Malone et al. 1987). Malone et al. (1987) proposed two characteristics of products (i.e. asset specificity and product description complexity) that influence suppliers to participate in a B2G electronic auction market. Asset specificity is the extent to which specialised investments are needed to support an exchange (Williamson 1981) or cannot be easily utilized by other firms (Malone et al. 1987). If products in the e-auction market have high asset specificity, suppliers tend not to participate in this market. Product description complexity refers to the amount of information necessary to describe the attributes of a product (Malone et al. 1987; Son & Benbasat 2007). If complex products are difficult to translate into unambiguous product description, suppliers tend not to participate in a B2G e-auction market.

Proposition 1: Product characteristics (high asset specificity and high complexity) in a B2G e-auction market will negatively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

3.2.2 Market Transaction Costs

E-markets offer facilities to support communicating information about price and production characteristics, and conducting transactions between buyers and sellers (Bakos 1991). E-markets can also help to reduce transaction costs that occur between buyers and suppliers (Bakos 1991). Market transaction costs is defined as the coordination costs involved in using an outside markets, comprising operational costs and contractual costs (Gurbaxani & Whang 1991). Operational costs refer to the costs for accessing market information and process transaction such as search costs and communication costs. Contractual costs refer to the costs of establishing and maintaining contractual relationships with outside parties, including costs of writing contracts and costs of enforcing contracts. We propose that the transaction costs that occur in B2G e-auction markets will negatively influence suppliers’ intention to participate and the level of participation.

Proposition 2: High market transaction costs in a B2G e-auction market will negatively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

3.2.3 Market Transparency

Auction Market transparency is defined by Madhavan (2000) as “the ability of market participants to observe information about the trading process”. Suppliers can make decisions to participate in trading through e-auction markets based on the available information regarding trading rule, price as well as information on the transaction process (Granados & Gupta & Kaufmann 2006). More transparency in e-auction markets would help suppliers to reduce the information processing costs and opportunity costs of obtaining information about auction price and auction process.

Proposition 3: More information transparency in a B2G e-auction market will positively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

3.2.4 Auction Process Cycle Time

The use of traditional processes for government buying goods and service can consume several weeks or months (Beall et al. 2003; MacManus 1991). On the other hand, the use of e-auction markets can decrease auction process cycle times (Emiliani & Stec 2005), which are condensed into a period of a few hours (Beall et al. 2003). The cycle time reduction in B2G e-auction markets can benefit suppliers in that suppliers would be better able to plan production scheduling because time is reduced between bidding and winning the business (Beall et al. 2003), and suppliers also save costs in terms of a
reduction in negotiation time (Smeltzer & Carr 2003). We propose that the longer the auction process cycle time, the less willing suppliers are to participate in a B2G e-auction market.

Proposition 4: The longer auction process cycle time in a B2G e-auction market will negatively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

3.3 Legitimacy Motive

Much of the institutional literature emphasises that organisational structures and processes tend to become isomorphic with the accepted norms for organisations of particular types (DiMaggio & Powell 1983). According to RBV theory, isomorphism is often used as a mechanism for reducing uncertainty by organisations by adopting innovations (DiMaggio & Powell 1983). For example, Son and Benbasat (2007) studied how legitimacy-oriented factors, which are mimetic pressures, coercive pressure, and normative pressures, influence organisational buyers’ adoption and use of B2B e-marketplaces. They found that two isomorphic processes; mimetic and normative pressures have significant effects on adoption intent, but not on participation level. While, coercive pressures did not significantly explain either adoption intent or the level of participation.

3.3.1 Mimetic Pressures

As with Teo et al. (2003), we focus on two specific types of mimetic pressure: participation among competitors and perceived success of participated competitors. Participation among competitors refers to the participation level of competitors participating in B2G e-auction market. Whereas, perceived success of participated competitors refer to suppliers often closely monitoring their competitor to identify successful practices and imitate their actions to achieve similar benefits.

Proposition 5: Mimetic pressures in a B2G e-auction market will positively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

3.3.2 Coercive Pressures

Coercive pressures is defined by DiMaggio and Powell (1983, p. 150) as “both formal and informal pressures exerted on organisations by other organisations upon which they are dependent and by cultural expectations in the society within which organisation function”. These pressures may take several forms, such as force, threats, persuasion, and invitation (DiMaggio & Powell 1983). For example, the government is one of the largest customers of the supplier, and the supplier’s well being may very much depend on whether it is being awarded the contract from the government. Thus, the purchasing volume from government can dominate a supplier firm’s need to participate in B2G e-auction markets. We propose the effect of the perceived dominance of government procuring agencies on the supplier’s intention to participate and the level of participation in a B2G e-auction market.

Proposition 6: Coercive pressures in a B2G e-auction market will positively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

3.3.3 Normative Pressures

Normative pressures implies that strategic processes taken by organisations are subject to the values and norms shared among members of their social network (DiMaggio & Powell 1983). Normative pressures from participation in professional and trade associations may promote transactions through a B2G e-auction market. We posit that the effect of supplier participated in professional and trade associations on the supplier’s intention to participate and the level of participation in a B2G e-auction market.

Proposition 7: Normative pressures in a B2G electronic auction market will positively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.
3.4 Environmental Uncertainty

Organisational theories have suggested that organisations must adapt their environment to remain viable in business (Duncan 1972). The literature on the relationship between organisation and environment shows the link between these two variables. For example, Karimi, et al. (2004) show that managerial decision-making tasks are affected by rapid changes that occur in organisational task environments and that when confronted with environmental uncertainty. Lee and Clark (1997) also claimed that environmental uncertainty is inherent in e-markets. The literature has identified many different environment dimensions, three factors are viewed as particularly important (Kabadayi & Eyuboglu & Thomas 2007; Karimi et al. 2004; Newkirk & Lederer 2006) and have been included in a majority of e-commerce studies. They are dynamism, complexity, and hostility. This is also consistent with Duncan’s work (Duncan 1972), which identifies dynamism and complexity as major sources of environmental uncertainty. Dynamism refers to the rate and unpredictability of environmental change. It is especially challenging for suppliers who need to participate in B2G e-auction markets. Researchers have measured dynamism in terms of the frequency of environmental change and the unpredictability of market factors (Homburg & Workman & Krohmer 1999; Kabadayi et al. 2007). Complexity refers to the number and diversity of competitors, suppliers, buyers, and other environmental actors that firm decision makers need to consider in formulating their strategies (Duncan 1972; Kabadayi et al. 2007). Hostility represents the availability of resources and the degree of competition (Newkirk & Lederer 2006) in e-auction markets. Hostility can be measured in terms of the threats to the supplier’s firm posed by labor and material scarcity, intense competition in price, and product differentiation (Karimi et al. 2004; Newkirk & Lederer 2006).

Proposition 8: High environmental uncertainty in a B2G e-auction market will negatively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

3.5 Supplier Capabilities

This construct is mainly drawn from Resources-Based View Theory (RBV). In the strategic management literature, there is growing evidence that competitive advantage often depends on the firm’s deployment of capabilities (Barney 1991; Day 1994; Wade & Hulland 2004). Thus, firm’s capabilities enable a firm to compete more effectively in the marketplace (Day 1994). Coyne (1986) suggests that not only do the product and/or delivery system attributes need to be important to customers, a capability differential need to be significant for enduring sustainability. Suppliers with greater efficiency can develop sustainable competitive advantage by using this capability to reduce costs and develop a cost leadership position in their industry (Burney 1991; Porter 1985). Hall (1993) suggests that two types of supplier capabilities – capabilities based on assets and capabilities based on competencies - could influence supplier to gain competitive advantage in markets.

3.5.1 Capabilities based on Assets

We propose two sub-constructs that can influence suppliers to participate in B2G e-auction markets. Economics of scale and excess production capacity would be used as sources for suppliers’ competitive advantage in B2G e-auction markets (Elmaghraby 2005). Cost leadership refers to a supplier can gain sales by offering product and/or services at a price that is low than that of competitors as well as pursuing economies of scale in production. Suppliers can produce goods at low cost only if they produce in large quantities. For example, the government provides a large purchasing volume through a B2G e-auction markets which induces a supplier, who has economies of scale (i.e. cost for producing a second unit is less than cost for producing the first unit) to supply goods or services at a small cost than its competitors. Excess supply capacity infers a supplier may differ in its supply capacity. Excess supply capability can be used to supply products and services as supplier’s competitive advantage in order to pursue additional business (Elmaghraby 2005; Smeltzer & Carr 2003). If excess capacity exists in the supply base, a supplier can allocate this valuable resource in an
e-auction market (Jap 2002). For instance, when supplier’s excessive capacity exists, supplier tend to participate in a B2G e-auction market.

**Proposition 9:** Capabilities based on assets of supplier will positively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

### 3.5.2 Capabilities based on Competencies

Hall (1993) proposed two types of capabilities based on competencies which can be the sources of sustainable competitive advantage, namely, functional capability (i.e. top management’s IT self-efficacy) and cultural capability (i.e. total quality management). In the context of B2G e-auction markets, **top management’s IT self-efficacy** refers to the perceptions of the owner and/or CEO of supplier to use IT in the accomplishment of a task (Bandura 1986; Compeau & Higgins 1995). This definition is based on the concept of self-efficacy defined as “people’s judgments of their capabilities to organise and execute courses of action required to attain designated types of performances. It is concerned not with the skills one has but with judgments of what one can do with whatever skills one possesses” (Bandura 1986, p.391). For example, top management can use his/her ability to manipulate e-auction system provided by third-party providers of e-auctions. Hulland et al. (2007) also found that the organisation which had a strong IT skill capability was positively influenced to commit to the online channel. **Total quality management (TQM)** refers to the continuous improvement of work processes to enhance the organisation’s ability to deliver high-quality product or services in a cost-effective manner (Beer 2003). Supplier’s firms that implement TQM are better positioned to gain through lowered costs and improved customers’ satisfaction (Beer 2003). In addition, Powell (1995) found that TQM can produce economic value; and it can also be used as a potential source of sustainable competitive advantage for suppliers’ firm.
