Despite IS being predominantly treated as a source rather than a tool for ORM, the body of literature that explores ORM in IS provides the reference points that are necessary to understand the desirable properties of ORIS. Based on extensive analysis of both the ORM and IS literature, Wolf (2005, p. 104) suggests a list of criteria to assess the potential of existing approaches to manage IS risks: 1. “comprehensiveness” as sufficient coverage of all stages of the risk management process; 2. “life cycle coverage” as the ability to “address the risks of the system life cycle”; and 3. “IS risk sensitivity” as the “coverage of IS risk categories” that are reflected in the BCBS (2006, p.144) definition of OR: “the risk of loss resulting from inadequate or failed internal processes, people and systems, or from external events [emphasis added]”. In this paper we adopt this widely accepted definition of OR. This paper’s aim to explore issues of OR representation at the Requirements Definition stage of the ORIS development life cycle limits the first two criteria introduced by Wolf (2005). In this paper we are focusing on: 1) the stages of the risk management process that are directly related to the representation of OR, i.e.: risk identification, risk analysis and risk evaluation; and 2) the Requirements Definition stage of the ORIS development life cycle. The third criterion introduced by Wolf (2005) is addressed fully in this paper.

The Revised Basel II Framework (BCBS 2006) provides the major source of methodological guidelines and regulatory requirements for organizations that plan to transfer to an ORIS. It primarily provides regulatory requirements and high-level managerial guidelines for the banking sector. Hence, more than 50% of organisations that adopt an ORIS are banking institutions that have to meet Basel II regulatory requirements as part of their ORM strategy (Chartis Research Ltd 2008). This justifies exploration of the methodological implications suggested by the BCBS (2006) as part of the Requirements Definition stage of ORISs. The Revised Basel II Framework (BCBS 2006) suggests three methods for calculating operational risk capital charges. The Advanced Measurement Approach (AMA) is considered to be the most risk sensitive and sophisticated of these approaches (Flores et al. 2006). The organisations that adopt this OR measurement approach considerably minimise their capital allocation charges. A recent global market survey of 318 banks and insurance companies reveals that 52% of respondents aim to adopt the AMA approach as their ORM system by 2011 (Chartis Research Ltd 2008).

In order to be able to adopt the AMA approach the organisation is required to meet a set of “Standards” set up by the BCBS (2006, pp.142-152): “General Standards”, “Qualitative Standards” and “Quantitative Standards”. The first two sets of standards refer to the organisation of the ORM function in a bank, whereas “Quantitative Standards” refer to the methodological requirements for OR representation and assessment. Column 1 of Table 1 represents a full list of the “Detailed Criteria”, (a)-(f) (BCBS 2006, pp. 151-152) that have been interpreted in a more concise form by Scandizzo (2007, p. 56). The “Criteria” are part of the “Quantitative Standards” for the AMA introduced by the BCBS (2006). Column 2 represents the research evidence that supports the “Detailed Criteria” contained in column 1. Based on the outputs of columns 1 and 2, column 3 provides the set of desirable properties that aim to address the issues of OR representation and assessment. Finally, column 4 suggests a list of references that support the arguments and desirable properties in columns 2 and 3.

The first desirable property is related to the need to provide greater crossover between different OR assessment methods including: a) different degrees of subjectivity in relation to the object of the research; and b) different types of reasoning that underlie different methods of OR assessment (for example, subjective approaches that allow educated guesses such as scenario analysis vs. data-driven approaches based on statistical analysis of operational loss data) (Mestchian et al., 2005; Scandizzo 2007). Interestingly, both regulators (BCBS 2006) and practitioners (Breden 2007, p.193; Mestchian et al. 2005) call for the crossover between loss data and scenario-based approaches. The second desirable property is driven by the BCBS (2006) requirement to cover both expected and unexpected losses as
well as the major drivers that underpin ORs. This property calls for understanding of the complex nature of causality that underlies operational loss events (Lewis 2003; Holmes 2003).

Finally, the third desirable property relates to adopting a mode of logical inference that would aggregate the results of different OR assessment methods. This implies the ability to assess and represent the heterogeneous nature of OR by adopting, if necessary, a range OR assessment methods based on opposed modes of logical inference. This categorisation of OR assessments methods has been used by Scandizzo (2007) who distinguished between proactive (ex ante) and reactive (ex post) methods for OR assessment. The adoption of this desirable property would assure “soundness” (BCBS 2006, p.150) and rigour when weighting and aggregating the results of different OR assessment methods.

Table 1. Desirable properties for OR representation and assessment

The next section discusses how the two ontological/epistemological positions that dominate the IS and general risk literature support these desirable properties.

### 3. THE RELEVANCE OF DOMINANT PHILOSOPHICAL PARADIGMS IN SUPPORTING OR REPRESENTATION

This section explores the extent to which the ontological/epistemological positions, which are part of the dominant philosophical paradigms adopted in the context of IS and Risk Analysis research, support the set of desirable properties for OR assessment suggested in Section 2.
The OR literature (Moosa 2008; Flores et al. 2007) raised concern about the lack of methodological assistance provided by the BCBS (2006) to meet Basel II requirements. Specifically these concerns were related to the “Detailed Criteria” for AMA adoption. This questions the effectiveness of the resulting capital allocation models (Jarrow 2008). Contributing to this concern, we note that the description of the nature of OR provided by the Revised Basel II Framework (BCBS 2006) does not go beyond specifying a set of possible “major drivers of operational risk” (ibid, p.151). The same is true when it comes to specifying the ways knowledge about OR can be built (cf Detailed Criterion (e) of Quantitative Standards). Herein, we argue that the lack of ontological (which refers to the nature of the real world phenomena) and epistemological (which refers to the nature of knowledge about the real world phenomena) foundations in representing OR questions the “soundness” of the results of OR assessment required by the BCBS (2006, p.150). Consequently, a consistent ontological and epistemological position is required to support the properties throughout the Requirements Definition stage of the ORISs development life cycle.

The ontological and epistemological status of OR has been taken for granted in OR research. Moreover, research on ontology and epistemology of OR has been almost exclusively undertaken within the research domain of Risk Analysis (cf Rosa 1998; Klinke and Renn 2002), a multidisciplinary approach to assess risks related to complex socio-technical systems. Thus, we demonstrate the lack of explicit ontological/epistemological grounding for OR in Figure 1 by using a dashed line. This dashed line represents the integrated ORIS and subsequent ontological/epistemological position, which is in line with the aim of this paper.

Unsurprisingly the dominant philosophical paradigms discussed in the Risk Analysis literature (cf Rosa 1998; Klinke and Renn 2002) correspond to the paradigms widely discussed in the context of IS research (Becker and Niehaves 2007; Lee and Baskerville 2003; Walsham 2006; Kanellis and Papadopoulos 2009): positivism and interpretivism/constructivism (herein, the elements of the interpretivism/constructivism tandem are distinguished according to Becker and Niehaves (2007)). In assessing positivist and interpretivist/constructivist philosophical paradigms this research focuses on two major aspects of Kuhn’s (1970) definition of a paradigm; namely, ontology (that refers to) and epistemology (that refers to the nature of knowledge about the real world).

![Figure 1. Ontological/epistemological support for representing the OR phenomenon as part of the Requirements Definition phase of the ORIS development life cycle](image_url)

### 3.1 Addressing Desirable Property 1: “A non-contradictory multimethod OR assessment”

The positivist ontology supports the view that reality exists separately from the human mind. Epistemologically, positivists claim that the empirical knowledge accumulated through perceptual experience can provide objective knowledge about the real world (Becker and Niehaves 2007). Grounded in empirical methods, positivism provides limited justification for OR multimethod research because the value-free observation of the objective reality is considered to be the only valid approach to acquire knowledge about the object of the research. Thus, it excludes values and normative...
judgements from the OR assessment process or at least undermine their importance. The epistemological position adopted by positivism is not able to address the role of the social values in the knowledge building process. This is a serious limitation for a realistic OR assessment as the critical analysis of social values is the essential component of such OR assessment methods such as scenario analysis (Scandizzo 2005, 2007; Marais 2005; Cooke and Rohleder 2005).

The ability of constructivist/interpretivist paradigm to support this desirable property is also limited by its ontological position, associated with “‘internal’ or ‘subjective’” realism. It represents reality as an intersubjective or a personal construction (Walsham 1995 in Smith 2006). By equalising “subjective meaning” and “objective reality” (Lee and Baskerville 2003, p. 230), interpretivists/constructivists claim that “risk assessments constitute mental constructions that can be checked at best against standards of consistency...” (Klinke and Renn 2002, p. 1073). By: a) emphasizing the perception of OR as a key component of OR assessment and rejecting; or b) strongly undermining the value of data-driven methods, the interpretivist/constructivist position run the risk of biased OR perception. And this may finally lead to a wrong OR estimation (Rosa 1998).

3.2 Addressing Desirable Property 2: “Understanding of the complex nature of causal mechanisms that underlie OR losses, both expected and unexpected”

Causation in the positivist tradition is built on a number of conditions first introduced by David Hume. According to Cook and Campbell (1979, p.10) “the most important and the most positivistic” of these conditions is the condition of ‘constant conjunction’ (ibid). The latter, also known as the “uniformity of nature assumption” (Lee and Baskerville 2003 p.225) or “perfect regularities” condition (Anderson and Vastag 2004, p. 93), implies a “regularity of constantly conjoined pairs of events (Effect = f(Cause))” (ibid). This is only possible under a closed system assumption where the relationships between components are determined and constant (Blanskar 1978, 1979). The criticism of the ‘constant conjunction’ assumption brought by the positivist tradition relates to the claim that “high correlations demonstrate or are synonymous with causation” (Cook and Campbell 1979, p.10). This “den[i][es] … all conceptual status to unobserved phenomena” and is characterised as “logically inadequate” (ibid).

Focusing on the consistent description of events and behaviours under study rather than on uncovering universal laws (Lee and Baskerville 2003) constructivists/intepretivists emphasize the multidimensionality of factors that constitute the concept of risk (Rosa 1998). At the same time, while accepting that causes of risks are triggered by the interplay of diverse unspecified factors, it reduces the ontological reality of OR causes to the realm of the socially constructed epistemology (ibid). Another point of critique is introduced by Lee and Baskerville (2003). They argue that constructivism (same as positivism) adopts the ‘uniformity of nature assumption’ when presenting research outcomes and generalizing from them. In the context of OR - which is the product of the non-uniform interrelationship between the actors and the components of the inherently open socio-technical systems (Marais 2005; Cooke and Rohleder 2005) - the “uniformity of nature assumption” is not tenable. This said, both positivism and constructivism fail to represent the complexity of the causal dimension of OR.

3.3 Addressing Desirable Property 3: “Adoption of a mode of logical inference that assures consistency and rigour when aggregating the results of multimethod OR assessment”

The above discussion of how positivism and constructivism/interpretivism address the two desirable properties for OR assessment introduced in Table 1 demonstrates that each paradigm focuses on opposite poles of the dichotomous nature of risk. Epistemologically they co-exist as competing and even antagonist perspectives of risk (Klinke and Renn 2002; Rosa 1998). Due to the incommensurability of the ontological assumptions adopted by constructivism and positivism, the conceptual grounding for integrating knowledge supported by both perspectives is still missing (cf Rosa 1998; Downward and Mearman 2007). As both paradigms fail to appropriately support the multimethod OR research and uncover the complexity of OR causality, neither provide a consistent reasoning for rigorously aggregating the results of the multimethod OR assessment.

Proceedings ECIS 2009
In summary, Klinke and Renn’s (2002, p.1076) representation of risk as both a “social construction and representation of reality” proves to be appropriate in the context of addressing the set of desirable properties for supporting OR representation introduced in Table 1. In the next section Critical Realism (CR) is introduced and its ability to address the abovementioned issue is reviewed.

4. CRITICAL REALIST SUPPORT FOR OR REPRESENTATION

Critical Realism (CR) is a philosophy of science that is most commonly associated with the work of Roy Bhaskar (1978, 1979). Introduced as a direct critique of positivism, as well as a postmodern philosophical paradigms including constructivism, CR provides a well-established philosophy of science that strongly emphasises the primacy of ontology over epistemology (Bhaskar 1979). CR comes with an idea that the “reality is both intransitive (existing independently of humans) and stratified” (Mingers 2000, p. 1261). The ‘stratified’ CR ontology divides reality into three distinct ‘domains of being’ (Bhaskar 1979) that are commonly referred to as the domains of ‘real’, ‘actual’ and ‘empirical’ (Danemark 2002; Mingers 2000, 2006). The ‘real’ domain consists of underlying structures and generative mechanisms. Their relations trigger patterns of events and behaviours that reside in the ontological domain of ‘actual’ and represent all events and behaviours produced by causal structures and generative mechanisms even though they are ontologically separated from them. The domain of ‘empirical’ is made up of events that are actually experienced or observed by humans. On the epistemological level, CR aims to provide causal explanations about the limited empirical-based knowledge of events and behaviours. This section explores how the basic ontological/epistemological premises adopted by CR can help address the desirable properties defined in Table 1 that are not fully met by the constructivist/interpretivist and positivist paradigms discussed in Section 3.

4.1 Ontology-driven support for multimethod OR assessment

Critical realists claim that the strengths as well as the limitations of research methods are driven by, but also limited by the ontological position that methods are tied to (Downward and Mearman, 2007). This is in line with Kuhn’s (1970) representation of paradigms as constructs that relate particular research methods to the corresponding ontological, epistemological and other philosophical assumptions. The CR ontological/epistemological position addresses the first desirable property introduced in Section 2 (“A non-contradictory multimethod OR assessment ”): by a) representing an ontologically stratified view of reality as well as the objects of the research inquiry that are components of this reality; and b) claiming that the way reality is constructed determines the way knowledge about reality is obtained and generated (Bhaskar 1979; Mingers 2000; Danermark et al. 2002).

After Rosa (1998) and Klinke and Renn (2002), CR denies the ontological assumption that confines the phenomenon of OR to human perceptions and social construction alone. Hence, OR can neither be reduced to the “objective outcomes [that are] monetary in nature and easily traceable to entities in the general ledger account” (Breden 2007 p 179), nor to objective outcomes in terms of injuries, fatalities etc (Klinke and Renn 2002). As an object of social reality, the phenomenon of OR comprises components that correspond to ontological domains of ‘real’ (OR causal structures and mechanisms), ‘actual’ (the population of all possible operational loss events invoked as a result of causal powers (Bhaskar 1979) of the OR generative mechanisms) and ‘empirical’ (i.e. data accumulated in operational loss event databases). In order to assure rigour and “soundness” (BCBS 2006, p.150) of OR assessment, these ontologically distinct components of OR have to be addressed by multiple research methods that are able to target these research domains (cf Downward and Mearman 2007).

For example, the analysis of internal and external operational loss event data is mostly concerned with the ‘empirical’ component of ORs; and both ‘scenario analysis’ and analysis of ‘factors reflecting business environment and internal control systems’ (BCBS 2004, p.147) aim at uncovering OR at the real ontological domain where the underlying generative mechanisms and structures reside. Understanding that these major OR assessment methodological approaches focus on different
ontological aspects of OR provides additional motivation for combining these approaches, but also allows these approaches to be combined in a non-competitive way by distinguishing the ontological aspects of OR that they target.

4.2 Overcoming reductionism in representing the OR causality

In this subsection the second desirable property, “Understanding of the complex nature of causal mechanisms that underlie OR losses, both expected and unexpected”, is addressed based on the CR understanding of causal mechanisms. These ontologically separated objects generate patterns of events and behaviours that are both perceived/experienced and not.

As mentioned in Section 3, the ontological/epistemological position acquired by the positivist paradigm reduces the representation of causality to ‘perfect regularities’ that was first introduced by David Hume. It does not account though for “imperfect regularities” that may represent an empirical trace for a “genuine causal relation” (Anderson and Vastag 2004, p.93). According to CR the root-cause of the biased representation of causality suggested by both positivism and constructivism relates to the blurring of the ontological and epistemological dimensions. CR represents the object of research as an emerging property of an open system. Thus, CR denies the artificial closure of socio-technical systems that do not correspond to the nature of reality that is emergent and complex. The socio-technical reality being part of the real world is also represented as an open system. Hence, according to CR, the causality underlying the concept of OR is not necessarily a reflection of the succession of distinct causes and effects but rather an emergent property of the complex interplay between the agency and technical components of an open socio-technical system. Taken from this perspective, “[c]ause thus has an ontological depth” (Downward and Mearman 2007, p. 88). Causality underlying the concept of OR is thus the product of an interplay of the complex interrelations between agent’s values and the components of the operational environment that are grounded in the ontological domain of ‘real’.

The ontology-driven position of CR on the nature of causality is in line with the discussion in OR research. Thus, Holmes (2003, p. 84) when providing a “reality check” of “measuring operational risk”, concluded that major operational risk losses cannot be predicted by operational loss data-driven approaches to OR assessment. These are typically characterised as “descriptive and backward-looking, with limited intuition about how key features could create a risk event” (ibid, p. 85). The reason such losses cannot be predicted is because the causal structures that underlie major operational loss events are complex (Diegardt 2007; Marais 2005) and cannot be reduced to the individual OR “drivers” specified by the BCBS (2006, p.150). Rather they represent the complex relationships of these drivers “all acting in combination” (Holmes 2003, p. 84; Wolf 2005). Thus, the ability to understand the nature of complexity underlying OR causes is the key to proactive and more effective assessment and management of ORs (Scandizzo 2005).

4.3 Enabling the exploration of OR causality based on multimethod OR assessment

In this subsection the third desirable property, “Adoption of a mode of logical inference that assures consistency and rigour when aggregating the results of multimethod OR assessment”, is addressed by the retroductive mode of logical inference espoused by CR. This allows knowledge about the OR generative mechanisms and structures to be acquired, based on the limited empirical data.

The retroductive mode of logical inference is an ampliative (synthetic) mode of “inference from effects to explanatory structures” (Hartwig 2007 p. 257). It was first introduced by Charles Peirce as abduction however at the later stage of his research career he used both terms, abduction and retroduction, interchangeably (Lizska 1996). Retroduction aims to obtain knowledge about “what properties are required for a phenomenon to exist” (Danermark et al. 2002, p.206) and as such has been incorporated as part of the CR epistemological apparatus (Downward and Mearman 2007).

In the context of OR assessment, the retroductive process of elicitation of real causes of ORs (that account for both perfect and imperfect regularities) starts by classifying the empirical
events/phenomena (Resolution) and representing them in a theoretically significant way (Redescription) (Mingers 2000). Based on these empirically viable results, a 'creative model' of the possible OR generative mechanism(s) is built. Herein the reasoning moves from the acquired operational loss event data to the postulation of the OR underlying generative mechanism(s), which if it (they) existed would causally enact the operational risk events the given empirical data (Retroduction) (Mingers 2000; Downward and Mearman 2007; Danermark et al. 2002). Here the concept of emergence, which is “the methodologically significant consequence of the stratification of reality” (Danermark 2002, p. 61) plays a role. It allows to “isolate causal mechanisms downwards through strata” to understand the new non-reducible properties and mechanisms that are added to each stratum (ibid). Next, the existence of OR generative mechanism(s) is demonstrated by: firstly, isolating the hypothetical generative mechanism; and secondly, eliminating alternative hypotheses (Elimination). This is followed by identifying a correct OR causal structure in the model under review (Identification).

The adoption of the retroductive mode of logical inference enables the integration of the OR assessment approaches into a unified inquiry about the underlying causes of ORs based on the accumulated empirical data on operational loss events. In contrast to inductive inferential logic that is used by data-driven OR approaches, retroduction discovers new causal connections between the components of the inherently open socio-technical system. Importantly, the outcomes of the retroductive causal inference are not necessarily built on initial premises. This makes retroduction the only mode of logical inference that is able to produce new knowledge (Danermark et al. 2002; Downward and Mearman 2007). Given the incompleteness of the operational loss event databases in organisations (Scandizzo 2005) and the tendency of operational loss data to lose its relevance with the changes of socio-technical environment (Holmes 2004) - without this type of causal inference the understanding of the generative mechanisms underlying ORs would be less structured and more failure-prone.

In this section the basic CR ontological and epistemological assumptions proved to address the aggregated set of desirable properties built in Table 1. Hence, CR proved to be a viable alternative to positivist and constructivist paradigms in supporting the representation of the OR phenomenon at the Requirements Definition phase of the ORIS development life cycle. In the next section we illustrate these findings by extending a conceptual model of an ORIS with a view that supports evaluation of the regulatory capital required under the revised Basel II Accord (BCBS 2006).

5. ILLUSTRATION AND DISCUSSION

Today more than 50% of ORISs developed globally are integrated in the banking sector and thus are driven by Basel II (BCBS 2006) regulatory requirements (Chartis Research Ltd 2008). As the practice of wrong estimation of regulatory capital for OR coverage under the BCBS is still a norm rather than an exception (Jarrow 2008; Moosa 2008), the realistic estimation of OR losses and the application of these estimates to calculate subsequent economic capital is one of the ORIS priorities (Flores et al. 2006). At the same time, based on OR research, a better understanding of the inherent causes of operational failures provides a proactive and more reliable approach for evaluating ORs, as well as for building possible OR scenarios (Scandizzo 2005, 2007; Marais 2005). The identification of inherent causes of empirically gathered operational losses means it is possible to prevent certain major operational failures (Cooke and Rohlender (2005) and/or allocate an appropriate level of economic resources to assure continuity of business processes and sustainability of organizations.

Through exploration of the issues related to designing ORISs in the banking sector, Flores et al. (2006, p. 385) developed a conceptual model that depicted ORIS “calibration” role in OR regulatory capital estimation under AMA (the core of their model is depicted on the right hand side of Fig. 2). The model introduced by Flores et al. (2006) demonstrates that an ORIS potentially faces the danger of under- and overvaluation of the OR regulatory capital requirements due to the inability to appropriately represent and assess “Real Operational Risk” as opposed to “Estimated Operational Risk”. 

Proceedings ECIS 2009
Risk” (ibid p. 385). Thus, the undervaluation of OR by an ORIS is characterized in Flores et al.’s (2006, p. 385) conceptual model as: “the “entity systematically fails to cover risk fully. High possibility of system disruption”. In the case of overvaluation the “entity systematically covers risks with unnecessarily high capital charge. This prevents valuable financial leverage and damages competitive position”.

Thereby, we argue that the ramifications of adopting the CR ontology/epistemology presented in this paper can contribute to solving the issue of discrepancy between “Real Operational Risk” and “Estimated Operational Risk” brought by Flores et al. (2006) (cf Fig. 2). By doing so it contributes to a more effective capital coverage of ORs.

Figure 2  Informing OR assessment and OR regulatory capital estimation results through the retroductive mode of logical inference enabled by CR ontological stratification

As discussed in Section 4, the CR stratified ontology provides a basis for multimethod OR assessment. Further, the retroductive mode of inference espoused by CR provides the necessary epistemological tools to effectively hypothesise the nature of the causal mechanisms that underlie operational loss event data. It has been demonstrated that the empirical operational loss event data can provide access to the intransitive domain of ‘real’ through the ontological domain of ‘empirical’, which is a subset of the ‘actual’ ontological domain. This is represented as step 1 in the process of informing OR assessment and OR regulatory capital estimation results through the retroductive mode of logical inference in Figure 2. The enquiry about the real causes of ORs based on the empirical data was made possible by the adoption of the retroductive inference mode, which is espoused by CR as part of its epistemological apparatus (Downward Mearman 2007) (step 2). Processing operational loss event data with the view of understanding underlying causal mechanisms of ORs is represented as a separate conceptual block that is enabled by Critical Realist retroductive inference (step 3). It should be noted, however, that like Flores et al. (2006) we treat the hypothetical ORIS as a black box (step 4). Therefore, the question of how an ORIS should be designed in order to process the OR scenarios and their causal underpinning enabled by CR retroductive reasoning are outside the scope of this paper. This point is demonstrated by the question mark between the outcome of the CR retroduction and ORIS. Next, the OR assessment results are informed: a) by the empirical operational loss event data that is accumulated in the ORIS (Step 5); and b) by results of the retroductive process that provides better understanding of causal structures that underlie the data about historical OR losses (Step 6). And finally, the amount of OR regulatory capital is calculated (step 7).

Therefore, the ontological/epistemological support provided by Critical Realism helps address the “dilemma” between the full coverage of OR exposures and unnecessary OR capital charge (Flores et al. 2006, p. 385) through a better understanding of OR causes underlying the available historical data on operational losses. From the systems development perspective, it has been demonstrated how
critical realist ontological and epistemological position supports rigorous and consistent representation of the OR phenomenon at the Requirements Definition stage of the ORISs development life cycle.

In this section we extended the Operational Risk-Aware Information System (ORIS) conceptual model of Flores et al. (2006) and illustrated how a Critical Realist ontological/epistemological position supports an ORIS by reporting on the outcomes of OR regulatory capital evaluation in accordance with the requirements of the Revised Basel II Accord (BCBS 2006).

6. CONCLUSIONS AND FUTURE DIRECTIONS

In this paper we set out to address two main research gaps that hinder risk-sensitive approaches to Operational Risk (OR) by Operational Risk-Aware Information Systems (ORISs). The first concerned the lack of explicit ontological/epistemological positioning for representing OR. The second was the lack of understanding about how OR should be explored in a non-contradictory manner as a representational phenomenon forming part of the core of an ORIS.

We have addressed these research gaps by demonstrating how the ontological/epistemological position of the Critical Realist philosophy of science assists: 1) in representing the phenomenon of OR as part of the real system tracked by an ORIS; and 2) at the Requirement Definition stage of the ORIS development life cycle by taking into consideration more informed decisions. In doing so the paper demonstrates how the retroductive mode of logical inference brought by the Critical Realist epistemology informs ORIS in the discovery of OR causal mechanisms under the conditions of limited operational loss event data.

The research is limited by focusing only on the Requirements Definition phase of the systems development life cycle and on the risk assessment stage of the risk management process without covering risk treatment, monitoring and communication (cf AS/NZS 4360:2004). For simplicity the research took a black box approach in representing ORIS, focusing on how its representational properties may be supported by the Critical Realist ontological/epistemological position, and so left the question of how ORIS components should be designed to further research. Future research may include addressing these limitations as well as empirical evaluation of the model suggested in Figure 2.

Abstract

In this paper, we present a systematic literature review in the field of IT Outsourcing with a focus on risk management. The source material of the review consists of 97 high quality journal articles published in 18 journals between 2001 and September 2008. Besides an analysis of related work, this review provides an overview of applied research methods and theories in the field of IT Outsourcing. The articles are then analyzed from a risk management point of view to highlight key risk factors and their specific impact on IT Outsourcing. Identified risk factors are further analyzed in order to assign each risk factor to the phases of a typical IT Outsourcing process (life-cycle). The results of the review show that empirical research is the most applied method and that action research and reference modelling have not been used at all so far. Furthermore, elements of a research agenda are discussed in order to determine further steps to the construction of a reference model for risk management in IT Outsourcing. This paper mainly aims at an audience of experienced researchers in the field of IT Outsourcing who are looking for research ideas and at junior scientists (e.g. PhD students) entering this emerging field of research.

Keywords: IT Outsourcing, Risk Management, Systematic Literature Review, Research Agenda.
1 INTRODUCTION

IT Outsourcing has been one of the most discussed phenomena of the recent years (King & Torkzadeh 2008, p. 205). Considering the high growth rates that are being projected for this industry, the relevance of IT Outsourcing is strongly increasing. A cross-European study conducted by Ernst & Young in 2008 demonstrates the general significance of IT Outsourcing. According to this survey, 68% of all European companies have outsourced their IT at least partially. Seeing that, each company should implement a risk management system for IT Outsourcing to reach the business objectives. This can only be achieved by considering main risks and required safeguards (Bahli & Rivard 2003). A generally growing interest in this topic is also mirrored by its presence in major scientific research journals. For example, MIS Quarterly released a special issue dedicated to the topic of offshore outsourcing in June 2008. The field of risk management has been investigated by scientists from 1988 to 2000 (cf. Dibbern et al. 2004, pp. 34-38, 54). Dibbern et al. identified articles with a focus on topics of risk management in IT Outsourcing, ranging from 1994 to 1999. In our review we continue this work and analyze articles ranging from 2001 to 2008. The objective of this article is to provide an overview of the current research status on risk management in IT Outsourcing as it presents itself in international high quality journals. By means of a systematic literature review, an analysis of past, present and future research on IT Outsourcing and risk management in IT Outsourcing is presented.

Generally, the term ‘outsourcing’ applies to the transfer of business units/ functions to external service providers (Dibbern et al. 2004, pp. 9-10, Lee et al. 2000). In IT Outsourcing, this transfer process is limited to the realm of IT, where it can encompass a wide range of measures – from hiring an external software developer to delegating the management of a company’s complete data processing center to external service providers. The reasons for IT Outsourcing can be put down to a general shift in business strategies. The former diversification strategy aiming at risk distribution that used to be predominant until quite recently has now been replaced by a focus on the company’s core competencies. IT is usually not regarded as a core competency and is therefore frequently outsourced by companies. In the course of the IT Outsourcing transaction, economies of scale and external expert knowledge contribute to a more efficient realization and administration of IT. A second reason for IT Outsourcing lies in the current discussion about the incalculable value contribution of IT (Levina & Ross 2003, p. 332). Executive managers often regard the costs of IT as overhead costs which should be reduced to a minimum. In summary, IT Outsourcing can be regarded as a make-or-buy-decision in the context of IT management.

The paper is structured as follows: section 2 starts with a discussion of the applied research method (systematic literature review), the underlying review process and related work. The results of the systematic literature review are presented in section 3, which starts by presenting different classifications (e.g. research methods applied, theories applied and research topics) of the analyzed articles and ends with a systematic analysis of risk factors. Section 4 takes a critical look at the overall results and provides a summary of findings and recommendations for further research activities in the field of risk management in IT Outsourcing. An outlook on future research trends is also given.

2 RESEARCH METHODOLOGY AND FRAMEWORK OF ANALYSIS

2.1 Systematic Literature Review and Analyzed Journals

Considering the increasing number of books, journals, conferences and workshops, the application of a systematic literature review has become indispensable (Fettke 2006, p. 257). In a systematic literature review, relevant work and current findings are analysed with regard to a particular research question. The objective is to describe, summarize, assess, appraise, resolve or to integrate selected primary research results. The focus of the analysis can be set on methodology, theory, content or other aspects. Webster and Watson (2002) show a more content-oriented approach to writing a review article. In
their opinion, the main motivation for a research article should always lie in the additional benefit it has for the research community. Every figure and evaluation should increase the research community's knowledge. The thematic scope of the article should also be clearly defined. In addition, a methodology or model should be developed that further research could be based on. Finally, a review should imply conclusions relevant for other researchers and managers alike. To improve the quality of the analyses, both authors of this paper were involved in reviewing and coding the analyzed articles. The inter-rater reliability was good (inter-rater percentage agreement: > 90% in all analyses). The limitations of a systematic literature review lie in the paper selection and categorization process, which requires some judgment calls. However, we tried to minimize this risk by following a proven course of action for the creation of a literature review (Swanson & Ramiller 1993). The restriction of the source material to high quality articles leads to reliable results about the state of the art of IT Outsourcing.

The analyzed journals and the number of published articles regarding IT Outsourcing are shown in Figure 1. The selection of journals is relied on the journal ranking list published by WKWI (2008). This list has a wide acceptance among researchers. It declares 23 information systems journals as high quality journals. Figure 1 shows that the journals “Communications of the ACM”, “Information & Management” and “MIS Quarterly” make up a large part with 14, 10 and 14 published articles on IT Outsourcing. The analyzed time period spans 8 years, from 2001 to September 2008, because a review article by Dibbern et al. 2004 analyzed articles dating from 1988 to the year 2000. Amongst others, they analyzed papers on risk management in IT Outsourcing (Dibbern et al. 2004, pp. 34-38, 54). The work of Gonzales et al. 2005 spans a time period from 1988 to 2005 but does not analyze the topic of risk management in detail. The search for relevant articles was conducted as follows: As a first step, a matching list of pre-defined key words was applied to the search engine of each journal or to publisher independent journal data bases like EBSCO (Business Source Complete, EconLit (full text)) or Science Direct.

![Figure 1. Total number of articles per journal.](image)

To achieve extensive search results the following key words were used: Cloud Computing, Offshoring, Nearshoring, Outsourcing, IT Outsourcing, Sourcing, Application Outsourcing, Contracting Out, On-demand Computing, Application Service Provider, Software as a Service, Software on demand, Netsourcing, Internet as a platform, Utility Computing, Service Industry, Service Engineering, Service Outsourcing, IT Service Provider, Business Service Provider, Commerce Service Provider, Storage Service Provider, Vertical Service Provider, Full Service Provider and Managed Service Provider. The inclusion of many synonyms and/or semantically very similar expressions led to more exhaustive search results. The overall results were first saved in a list. In a second step, each article was checked for its relevance to the topic of IT Outsourcing by reading the respective abstract. The selected 97 articles were then analyzed by using the method of a systematic literature review.
Following Swanson & Ramiller 1993 we studied each paper’s abstract, introduction, discussion section and conclusion to classify the paper according to its research method, theoretical lens and research topic.

2.2 Related Work

In order to determine the research status it is necessary to evaluate former literature reviews about IT Outsourcing. In total, the authors found 5 different review articles dealing with IT Outsourcing (cf. Table 1).

| Title, Journal, Year, Authors | Information Technology Outsourcing in Australia – a literature review, Information Management & Computer Security, 2001, Christina Costa (Costa 2001) |
| Period, Publications reviewed | Period not explicitly named; Articles, books, surveys |
| Research objective(s) | analysis of economic and technical considerations regarding IT Outsourcing: e.g. success factors of IT Outsourcing arrangements |
| Review method | not explicitly described |
| Results | an overview of: cost reduction, technical considerations and relevance of core activities |

| Research objective(s) | framework for cataloging literature about IT Outsourcing: research foci, theoretical perspective, definition of the methodologies utilized to conduct the analysis, areas of consensus and suggestions for future research |
| Review method | search of journals by using “outsourc$” as search phrase; reading of abstract, introduction, discussion section and conclusion of articles to determine their research focus, theoretical foundation and methodology |
| Results | IT Outsourcing research is dynamic and vibrant: growing research synergy, healthy exchange between researchers; early research analyses: why, what function and how to outsource IT systems or services; recent research analyses: relationships and psychological aspects |

| Title, Journal, Year, Authors | Information systems outsourcing: A literature analysis, Information & Management, 2006, Reyes Gonzalez, Jose Gascoa, Juan Llopisa (Gonzalez, Gascoa & Llopisa 2006) |
| Period, Publications reviewed | 1988-2005, 131 articles ("prestigious” journals [10] as well as management and business journals [8]) |
| Research objective(s) | identification of main topics, most frequently applied methodologies, survey of authors and countries contributing to IT Outsourcing, suggestions to improve research on IT Outsourcing |
| Review method | search for several terms in the ABI database; and manual search in indices of the journals |
| Results | progressive growth of the topic, empirical research is often conducted (especially field studies), examples of new topics: computer staff and job threat |

| Title, Journal, Year, Authors | Why 'Nearshore' means that Distance matters, Communications of the ACM, 2007, Erran Carmel, Pamela Abbott (Carmel & Abbott 2007) |
| Period, Publications reviewed | 1998-2006, 150 textual sources: journal/magazine (45%), promotional (23%), web-based texts (22%), consulting articles (7%), and academic texts (3%) |
| Research objective(s) | categorization of publications into nearshoring location, dimensions of the nearshoring construct and evidence for the assertion of difference between near- and offshore |
| Review method | critical, systematic, and qualitative content analytical method; inductively derived coding categories which can be used as a basis for the analysis and can then be applied deductively to the textual sources |
| Results | “nearshore” has become a convenient label; locational and geographical differences will continue to play a role; distance is viewed as multi-dimensional (e.g. physical meters and time zones) |

| Period, Publications reviewed | June 2008, 43 articles submitted to MISQ for a special issue on IS Offshore Outsourcing (solely empirical research) |
| Research objective(s) | presentation of a representative extract from research that is being conducted on the topic of IS offshore outsourcing |
| Review method | extraction of research question(s), definition of offshoring (if given), context of the study, theoretical perspective(s), vendor countries, sample frame, general research method, analysis method, findings |
| Results | research regarding offshoring is still in nascent phase; research is still mainly qualitative and/or exploratory |

Table 1: Related Work.
Table 1 categorizes all reviews in chronological order and summarizes their research objectives, review methods and results. The specific difference of our article from the 5 indentified review articles (cf. table1) is:

- Only papers in high quality journals are analyzed. Specific analyses of the current research status and the articles’ theoretical perspective are conducted.
- In particular, risk management articles on IT Outsourcing are categorized and in-depth analyzed.

3 ANALYSIS OF RESULTS

3.1 Distribution of Articles over time

Figure 2 illustrates the development of practical, empirical and other (i.e. non-empirical and non-practical) articles over the last eight years. An article was counted as practitioner article if at least one of the contributing authors had a distinctly practical orientation that was outlined in the author information. In the years 2003 and 2008 an especially high number of articles on IT Outsourcing was published. Generally, the number of articles has grown during the time period discussed, reaching its peak in 2008. The number of published scientific articles follows the same pattern. The number of articles with empirical approaches, which amount to 31% of all papers published in the covered time span of 8 years, also shows an upward trend. However, the application frequency of the empirical research method has declined from 50% in the year 2001, to 20% in 2004 and 26% in 2008. The application of empirical methods can generally be regarded as a sign of scientific progress, because this research approach validates previously developed models, methods and concepts, sharpens the research area and contributes to its long-term establishment (Webster & Watson 2002, p. xiii). Finally, the fact that IT Outsourcing is a concept developed in practice (Dibbern et al. 2004, p. 9) explains the existence of a (small) number of practitioners who contribute occasionally to scientific research articles.

![Figure 2. Total Number of Articles per Year during the Period from 2001 to September 2008.](image)

3.2 Research Methods

The research methods that are commonly applied in IT Outsourcing are listed in Figure 3. Due to the distribution of articles to more than one research method the overall number is higher than 97. This also applies generally to the following analyses. A spectrum of IS research methods that we have applied is shown in Wilde and Hess 2007. The analysis shows that empirical research methods dominate the area of IT Outsourcing. The high number of conducted case studies underlines the strong practical component of IT Outsourcing. Formal models as well as trend and development analyses were included in the category of formal argumentative-deductive research. The authors realized that in most cases the hypotheses of empirical analyses were not based on pre-developed models, concepts or methods, but rather on general aspects of IT Outsourcing to keep track of changing demands.
Furthermore, one should note that in spite of numerous new models being developed, their practical implementation by means of empirical methods or case studies (including an iterative improvement process) is mostly either incomplete or does not happen at all. The three review articles identified in our systematic literature review are complemented by two more articles in Table 1. These were identified by means of an unsystematic review of literature conducted with search engines like EBSCO, Science Direct, etc. Furthermore, compared to explorative research, other methods are clearly underrepresented in this research area. But also previously unused research methods like action research or reference modeling should be applied in order to gain new insights. Action research aims to solve current practical problems while expanding scientific knowledge by using an iterative research process that both researchers and research subjects benefit from (Baskerville & Myers 2004). A generic reference model represents a class of domains; e.g. the development or improvement of processes, systems and organizational demands in certain fields (Fettke & Loos 2003). For the reference modeling approach BITKOM recommended the development of a reference model that supports the realization and implementation of IT Outsourcing.

![Figure 3. Research Methods Applied in IT Outsourcing.](image)

### 3.3 Theories Applied

Figure 4 illustrates the different theories applied in the 97 analyzed articles. The data shows that IT Outsourcing researchers strongly tend to base their approach on the transaction costs and agency theory. Other theories like incomplete contract theory or psychological contract theory are not very frequently utilized. The transaction cost theory is applicable because it deals with asset specificity, overall cost advantage, the threat of opportunistic vendor behaviour, and the complexity of the transaction (Bahli & Rivard 2003).

![Figure 4. Theories applied in IT Outsourcing research.](image)

Agency theory deals with principal-agent conflicts, information asymmetry and goal incongruence between an agent (the external vendor) and a principal (the client). Obviously, researchers in this area are still mainly relying on theories which have already been applied before, but they have also started to test other theories for their applicability to IT Outsourcing. This shows that the research area of IT...
Outsourcing is vivid, because both established and new theories play a role in it. As a result of a future literature review, a list of new theories to be established would be desirable. Furthermore, the application of multi-theoretical approaches could be especially identified.

3.4 Risk Management in IT Outsourcing

Main phases of risk management are context analysis (1), risk identification (2), risk analysis (3), risk evaluation (4), risk treatment (5), monitoring and review (6) and communication and continuous improvement of risk strategy (7). Since at least two companies are involved in an IT Outsourcing process, the range of risk factors expands and new risks could appear which are yet unknown to client companies. Furthermore, due to an increase in national and international regulations and quasi-standards (e.g. SOX, EuroSOX, Basel I, ITIL, Cobit, etc.) the risks that companies are facing grow and risk management for IT Outsourcing is explicitly demanded by suppliers, clients and states. To identify the topics of the articles we first chose an inductive approach and generated a topic list by reading each article. In a second step we aligned our list with the categorization by Gonzales et al. 2006. Figure 5 presents the results and illustrates the topics that IT Outsourcing articles are dealing with. It shows that risk management presently takes a relatively weak position. Apart from the chosen topic of risk management other articles address domains like quality issues or the project management of IT Outsourcing, but these issues are secondary if the IT Outsourcing arrangement is not successful because main risks and required safeguards are disregarded (Bahli & Rivard 2003). In total, 11 articles which deal with risk management in IT Outsourcing have been identified and examined in detail.

Figure 5. Distribution of Articles by Topics.

Figure 6 illustrates the distribution of research methods applied in the articles. Besides empirical research, formal, argumentative deductive analysis is often used to validate theoretical concepts and to formulate formal models for risk management functions.

Figure 6. Scope of Analysis for Risk Management in IT Outsourcing.

For prototyping and reviewing, Figure 6 indicates a research gap. The method of prototyping could be applied in the development and implementation of software for IT Outsourcing decisions and for facilitating IT Outsourcing (e.g. Service-oriented Architectures).

Table 3: Risk Factors in IT Outsourcing.

The risk factors listed in Table 3 were extracted from the analyzed 97 articles and were assigned to one of the five categories (economical, organizational, legal, technical or psychological). The three most frequently mentioned and therefore most discussed risk factors are Quality Inferior to...
Anticipation and Lack of Privacy/Data Security. A total of 23 different risk factors have been identified.

The risk factors listed in table 3 have specific effects and macro effects on the IT Outsourcing process. Figure 7 illustrates this causal relationship. The effects range from budget overrun (wrong cost expectations) to bad financial/economic performance. Every mentioned risk factor can trigger any of the possible effects, which in return may lead to macro effects. Macro effects are classified as one of four IT Outsourcing failure levels: IT Outsourcing process failure (the process/project is not completed within the time and budget); expectation failure (IT services and new processes do not match user and company expectations); interaction failure (users’ attitudes towards outsourced IT services are negative); and correspondence failure (there is a discrepancy between IT Outsourcing process, performed service and the planned objectives).

Figure 7. Risk Factors, Effects and Macro Effects (cf. Aloini et al. 2007, p. 553).

Figure 8 exemplifies a typical IT Outsourcing process (Georgius & Heinzl 2005) with risk factors assigned to the individual process steps. The process is initiated by the customer and ends with the expiration or renegotiation of the contract. The risk factors are taken from table 3. The Information Security Forum reported in 2008 that many companies only accounted for their potential IT risks after the outsourcing process had been completed. This makes it all the more necessary to develop, implement and establish risk methods and concepts for IT Outsourcing. As a guideline, the distribution of risks along a typical outsourcing process can be useful for risk prevention in IT Outsourcing.

Figure 8. Risk Factors in a Typical Outsourcing Process (cf. Georgius & Heinzl 2005, p. 5).
4 OUTLOOK ON FORTHCOMING RESEARCH

4.1 Current Trends in IT Outsourcing Research

A trend clearly indicated by the analysis is the special focus that researchers placed on offshore outsourcing in the year 2008. It is also apparent that IT Outsourcing is not location dependent any more, which creates new tasks and challenges. Two factors for this development are certainly the globalization of IT and the improvement of ICT. The total number of papers on IT offshore outsourcing has continuously increased, ranging from 0 in the year 2001 to 1 in the years 2002 to 2004 and 10 in the year 2008. Indirect requests for research by several ‘Calls for Papers’ have influenced this development as well (e.g. MIS Quarterly, June 2008). Other current developments show that IT Outsourcing is strongly influenced by trends like cloud computing or the software as a service model. The notion of “cloud computing” has been especially dominant in journals aimed at readers with a practical background. Cloud computing could cause major changes in IT business in the near future; several providers like Amazon, Salesforce and Google are already offering IT services via the internet which are processed by the “cloud” (Hayes 2008, p. 10). Along with the increasing spread of these concepts and technologies, new fields of activity entailing new risk factors emerge and require a new design of risk management in IT Outsourcing (e.g. Buyya et al. 2008, p. 5).

4.2 Elements of a Research Agenda

Looking at the research results in Table 3 we noticed that a stronger focus on performance measurement seems to be needed to support the progress of ongoing research (Rustagi et al. 2008, pp.127-128). Another gap which was discovered while assigning the risks to the steps of the outsourcing process in Figure 8 is the small number of risks in the last process step. However, more risk factors that need to be considered may be identified through more detailed examination. Also, it became apparent that the risks and benefits of multi vendor sourcing are not well known yet (e.g. Sia et al. 2008). Furthermore, none of the analyzed articles applied the method of reference modeling. To the authors’ knowledge, no reference model for risk management in IT Outsourcing has been published to date. Risk management is not popular compared to other research topics in IT Outsourcing, but it is necessary for companies. Therefore, a proposed research agenda illustrated in Figure 9 includes the development of a reference model for risk management in IT Outsourcing which is based on best practices. Cooperating business partners could then implement such a reference model, which could be continuously improved by means of iterative loops. Figure 9 illustrates one way of constructing such a reference model for risk management in IT Outsourcing by applying the presented research methods. Already existing models, as e.g. the „eSourcing Capability Model for Client Organizations” (Hefley et al. 2006) or the COBIT framework could support these specific steps. In a next step, a comparison of the presented results with methods and theories of general IT risk management could strengthen the research agenda and is therefore projected by the authors.

Figure 9. Elements of a Research Agenda.

Abstract

What is the role of control in maintaining trust in outsourcing relationships? Although the literature is quite rich on conceptualizing the relationship between control and trust in inter-organizational relationships, there exist quite sparse quantitative works which help to evaluate the models developed. In this paper, we analyze data from 156 IT outsourcing relationships of German banks in order to get insights into the actual relationships between different modes of control and the level of relational trust in these relationships. Additionally, we examine the role of service quality (measured in terms of reliability and responsiveness) in this context. The results show that trust is positively related with most modes of control, and that there is indicative evidence that control supports trust in high-service quality situations while it leads to a reduction of trust in relationships suffering from bad service quality (cycle of trust vs. distrust).

Keywords: Trust, Control, IT Outsourcing, Relationship Management, PLS, Survey
1 MOTIVATION

Although there exists a quite mature strand of research on how to manage an IT outsourcing relationship, only a few works have actually empirically studied the field of relational governance in this context. Among them are both quite early and fundamental works like (Grover et al. 1996; Lee and Kim 1999), which evaluate the role of relationship determinants on outsourcing success, and younger works, such as (Goles and Chin 2005) which develops a measurement model for relationship quality in IT outsourcing. Nevertheless, works have seldom trickled down the outsourcing governance determinants to a level on which direct and usable implications for the management of outsourcing relationships can be identified. For example, what are the control mechanisms and items that actually impact relationship quality dimensions like commitment and trust? By focusing on a particular aspect of this research strand, this paper wants to contribute both to a deeper and more managerial understanding of the relationship between control and trust in outsourcing relationships. There is a quite rich literature on conceptualizing the relationships between control and trust in inter-organizational relationships (IOR); nevertheless, there is not much quantitative research found that empirically evaluates these concepts and theories in IOR, in general, and in IT outsourcing relationships, in particular. One of these works is (Langfield-Smith and Smith 2003) which investigates the impact of control mechanisms from a transaction cost economics perspective by conducting a single case study. Further, the existing literature that has investigated the interrelationship between control and trust has derived contradicting findings, up to now. While some researchers found control to be positively related with trust, others suggest negative interrelations (Das and Teng 2001; Langfield-Smith and Smith 2003).

In order to contribute to this important strand of research, we want to answer the following research question: What is the relationship between trust and different managerial control mechanisms in outsourcing relationships? How does the level of service quality, in terms of reliability and responsiveness, affect this relationship?

The remainder of this paper is structured as follows: section 2 introduces related work and develops our research hypotheses. Section 3 outlines the chosen approach and gives an overview about our sample while section 4 empirically evaluates the proposed hypotheses. Section 5 discusses the results and derives implications for research and management before section 6 concludes the paper.

2 RESEARCH MODEL

Previous literature has highlighted the shortcomings of solely considering contractual issues for assessing the quality of IT outsourcing arrangements, as those contracts concluded at the beginning of an outsourcing relationship do not comprise all future eventualities and thus are inherently incomplete (Hart 1988; Macneil 1980). Consequently, researchers have shed light on the importance of a good cooperative relationship being another relevant facet of outsourcing management (Klepper 1995; Lacity and Willcocks 1995; McFarlan and Nolan 1995). In a first empirical investigation, Grover et al. (1996) have addressed this extended view of an outsourcing relationship by factors like trust and commitment which reduce threats from opportunistic behavior, help to better integrate partners and to reduce formal contracting. Other authors suggested incorporating additional aspects or dimensions aiming at a better and more comprehensive understanding of outsourcing relationship quality. For a good overview and summary on this as well as an empirical validation, see (Goles and Chin 2005).

Although it is difficult to capture and to measure, inter-firm trust has shown to be a fundamental dimension of relationship quality (Kanter 1994; Ring and Van de Ven 1994). Trust has been defined as “the firm’s belief that another company will perform actions that will result in positive outcomes for the firm, as well as not take unexpected actions that would result in negative outcomes for the firm” (Anderson and Narus 1990). Since the early 1990s, there have been numerous works which defined trust as a multi-dimensional concept (Das and Teng 2001). One of the most popular conceptualizations distinguishes between competence trust and relational trust (Anderson and Narus 1990; Das and Teng...
2001) – or “concern a partner’s ability to perform according to agreements (competence trust), or his intentions to do so (goodwill trust)” (Nooteboom 1996, 990, p. 990). Others have proposed a distinction between the need for trust and the actual level of trust (Gallivan and Depledge 2003). In this work we focus on the latter one.

The outsourcing literature moreover has shown the importance of trust for maintaining and managing an ongoing outsourcing relationship and tested its contribution to outsourcing success in numerous qualitative and quantitative works (Goo and Nam 2007; Grover et al. 1996; Kern 1997; Langfield-Smith and Smith 2003; Saherwal 1999; Willcocks and Kern 1998). In this study, we investigate the relationship, and thus trust, between client and vendor from the client’s perspective.

One of the antecedents of low outsourcing risk, high service quality, and success in IT outsourcing is monitoring the provider (“control”). In general, control is related to comparing as-is and to-be in order to reach the goals set by the firm through corrective actions, where deviations appear. However, since esp. in the area of IS, outcomes and corrective actions are not always clear ex ante, a broader view on control has been discussed (Kirsch 1997; Lee et al. 2008). Osterloh and Weibel (2006) differ between the control object, the point in time, and the control direction. The control object itself can then be examined in several ways. First, process control or behavioral control involves controlling process execution and also monitoring the employees’ behavior (Ouchi and Maguire 1975). Second, result control or outcome control traditionally is the comparison of as-is and to-be (Das and Teng 2001). Both behavioral and outcome control represent formal modes of control and thus can be characterized as a performance evaluation strategy (Eisenhardt 1985). Third, social control adheres to the compliance of codes and values (Ouchi 1979), is known as an informal mode of control, and can e.g. be assessed at different levels like group (clan control) and individual (self control) level (Kirsch 1997). Control can be conducted in an ongoing manner during an arrangement (feed forward controls) or at its end (feed-back control). In both cases, directed controls implemented to check for determined behaviors and performance standards, and undirected controls like e.g. early warning systems are possible. In general, the mode of control that is appropriate and therefore should be implemented is dependent on the context and the available information, e.g. it makes sense to implement outcome control when outcomes are measurable (Kirsch 1997).

In short term, it might be attractive from an outsourcing firm’s point of view to achieve a high level of control. This helps to identify variations and to initiate retaliatory action as early as possible, thus avoiding escalations (Zaheer and Venkatraman 1995). When viable controls are agreed upon in the outsourcing contract, this can have positive effects in a twofold way. While the service receiver can monitor the quantity and quality of the service, the service provider can substantiate that the delivered services meet the standards as determined in the contract (Langfield-Smith and Smith 2003). Thus, control can also be viewed positively from a vendor’s perspective.

However, accounting for elements like trust as described above when intending to build a long-term relationship, too much of control can result in undesired effects within a work relationship and destroy trust (Lorange and Roos 1992). The occurrence of such effects does not reflect the original goals of the controlling party and reasons can be found in an employee’s strive for relative independence. This can lead to a vicious circle as described by Argyris (1952) in a way that more control causes a decrease of satisfaction, causes less willingness to perform, causes less efficiency, causes more control, and so on. This is confirmed by Das and Teng (2001) who argue that formal control will undermine trust since it takes autonomy and independence away from the controlled partner firm. Considering this, one central issue for managers of outsourcing relationships would be to choose the right or optimal level of control, both from an organizational point of view (control mechanisms and systems) and a social point of view. In doing so, the benefits (reduced incentives for opportunistic behavior) and the costs (e.g. reduction of trust level) of control have to be balanced carefully.

Nevertheless, as already outlined, control can also have positive impacts in building and sustaining trust because specifying performance goals and controlling that they are achieved helps to motivate people who do their job well (Sitkin 1995) and because control reduces relational risks and thus facili-
tates trust and collaboration (Coletti et al. 2005). More control and certainty can lead to greater satisfaction, better conflict avoiding, cost reduction, and the development of trust in buyer/seller relationships (Marcolin and McLellan 1998). Moreover, Das and Teng propose a positive relationship by reversing the causality: “goodwill trust and competence trust will enhance the effectiveness of all control modes (behaviour, output, and social) in an alliance” (Das and Teng 2001, 265, p. 265). In their conceptual work on strategic B2B alliances, they argue that result controls will have a negative effect on trust while social controls lead to a higher level of trust. This is in line with findings that people who aim at building trustful relationships tend to avoid formal controls (McEvily et al. 2003).

Summarizing the different lines of argumentation, we hypothesize the different modes of control to be either positively, negatively, or concavely (reverse-U shaped) associated with the level of trust.

**H1a:** Control will be negatively related with the client’s trust in the vendor.

**H1b:** Control will be positively related with the client’s trust in the vendor.

**H1c:** There will be a concave relationship between control and the client’s trust in the vendor.

Furthermore, literature has discussed the existence of cycles of trust and distrust (Ring 1996) or spiraling effects (Marcolin 2002) when considering positive and negative impacts of control. A cycle of trust does appear if control is used to credit the provider for high performance. Good results from controlling the provider lead to increasing trust. By contrast, if the provider does not deliver high service quality, the reverse effect will appear: trust is destroyed by the cycle of distrust, since the client firm increases the control level and may find more deficiencies. Correspondingly, Sabherwal (1999) showed in a case study that good performance in an outsourcing relationship arises from a balance between trust and structural control, while the opposite will occur when an inappropriate structure comes together with a specific type of trust (over or under control).

This high interdependence between trust, control, and service quality as contingency variable leads to our second hypothesis.

**H2:** High service quality will lead to a cycle of the client’s trust in the vendor, while low service quality will lead to a cycle of distrust.

3  METHODOLOGY

3.1  Unit of Analysis and Approach

In our study, we surveyed the relationship of the 1,000 largest German banks to their IT service provider who is responsible for providing the primary loans system (i.e. operating and maintaining the IS used to grant and manage private construction loans and mortgages). The data were collected between April and October 2008.

In Germany, all banks belong to one of three sectors: while commercial banks are mostly independent when selecting an IT service provider, public savings banks and cooperatives both have joint IT service firm subsidiaries within their sectors. Moreover, particularly banks that belong to one of the latter two sectors show very ancient IT outsourcing relationships (cf. Table 1).

</tbody>
</table>

**Table 1.** Distribution of bank types in the overall population and in the sample
All banks have been initially contacted via phone in order to identify the appropriate person (Chief Information Officer or other IT manager, responsible for managing the relationship to the IT provider) and to ensure that the relevant IT system is not provided by an in-house unit. If it turned out that the bank was not engaged in outsourcing, it was dropped from the list of addressees and been replaced by the next largest one. Only 52 banks out of the initially largest 1,000 stated to have the operations of the loans system provided in-house. All other managers received the questionnaire (via mail, fax, or e-mail, depending on their preferences). After two reminders (paper-based and call-based) we eventually received 169 usable questionnaires (response rate = 16.9%).

For testing the basic relationship between trust and control (H1) we will provide both a regression analysis and a group comparison which allows us for a very simple but robust identification of a change in the relationship (such as concave relation which turns from an increasing relationship to an decreasing relationship at a certain degree of control). The second hypothesis is tested by hierarchical regression-based moderator tests and group comparisons.

3.2 Measurement

All of our constructs were measured by multi-item scales in order to increase reliability. The particularities are explained in the following and the indicators are listed in Table 7 in the appendix.

Control: To better understand the impact of control, we distinguish two of the three dimensions as discussed in the literature review above but more strongly dedicate them to the application domain in order to test for control action items: First, performance reports delivered from the IT service provider to the bank (CONTROL_REP) represent formal result control mechanisms (output control). Second, actions conducted by the provider firm itself (CONTROL_PROV) are examined, such as employee satisfaction surveys on the client side (output control). Third, detailed activity monitoring done by the client itself (CONTROL_BANK) represent the third dimension (behavioral control).

Trust (TRUST): We focus on the concept of relational trust. This construct was measured by reflective indicators derived from (Goles and Chin 2005; Kettinger and Lee 1995; Parasuraman et al. 1988).

Service quality: For capturing service quality, SERVQUAL (Parasuraman et al. 1988) has become one of the most commonly used measurement instruments both in Marketing Sciences but also in Information Systems (e.g., IS-SERVQUAL (Kettinger and Lee 1994)). From this instrument, we take reliability (i.e., ability to perform service dependably and accurately; SQ_reliability) (Grover et al. 1996; Lee and Kim 1999) and responsiveness (flexible reaction to problems and changing demands from client side; SQ_responsiveness). Especially, responsiveness often shows to be a critical facet of service quality when asking vendor managers.

To be able to conduct group comparisons and hierarchical regression analyses, we applied confirmatory factor analysis (CFA; principal component analysis, in particular) to achieve construct scores from the multi-item measures.

4 RESULTS

In this section, the proposed hypotheses are empirically tested, as described above. However, first of all we evaluate the measurement model in order to ensure reliability and validity of the scales used.

4.1 Validation of the Measurement Models

All of our tests are based on reflectively measured constructs. We deleted all cases which showed a missing value in any of the items used. This resulted in a reduced sample of 156 data sets.

Measurement instruments have to be analyzed regarding content validity, indicator reliability, and construct validity. Content validity examines the degree to which the supposed meaning of a construct
is reflected by its measures (Boudreau et al. 2001). Content validity was ensured by developing questions for indicators from preceding research as well as by performing pre-tests to check for ambiguities. The findings from the pre-tests were incorporated into the questionnaire after adaptation or elimination of single questions. For ensuring *indicator reliability*, loadings should be significant and above 0.7 (Hulland 1999) which is fulfilled by all our indicators (cf. Table 8 in the Appendix).

For ensuring *convergent validity* as an aspect of *construct validity*, composite reliability has to be above .7 (Nunnally 1978) and the Average Variance Extracted (AVE) should be above .5 (Chin 1998). Table 9 in the Appendix shows that all of our constructs fulfill this requirement. Finally, *discriminant validity* represents the extent to which the items of a latent variable differ from items of other latent variables in the same model (Hulland 1999). As Table 10 in the Appendix shows all inter-correlations between the latent variables are lower than the square root of the AVE (shown in the shaded cells).

The presence of *common method bias* was tested both by Harman’s single factor test and by integrating a common method factor into a PLS model consisting of all constructs only being related to their items and to the common method factor, as suggested by (Podsakoff et al. 2003) and e.g. executed by (Liang et al. 2007). The largest component of a CFA, capturing all indicators, explained 30.7% of the overall variance. Since we have only three basic constructs, this is acceptably low. Moreover, the common method factor did not count for substantial explanations of the theoretical constructs (most paths in the PLS model even showed to be completely insignificant). Finally, we added two theoretically unrelated marker variables which showed no significant correlation with any indicator used.

### 4.2 Examining the Relationship between Trust and Control (H1)

We tested hypotheses 1a-c, representing the interrelationship between control and trust within IT outsourcing arrangements, both by a multivariate regression analysis (TRUST = β₁ * CONTROL_REP + β₂ * CONTROL_BANK + β₃ * CONTROL_PROV) and a group comparison approach.

<table>
<thead>

<td>-.127</td>
<td>.207*</td>
<td>.280 (.265)</td>
</tr>
</tbody>
</table>

*Table 2. Regression results (* = significant at p<.01)*

While the linear regression test showed a significantly positive relationship between output control (by reports and provider-initiated control) and trust, and no significant (linear) relationship between behavioral control and trust (Table 2), we chose a group comparison approach in order to test for a concave relationship (H1c) or at least a tendency towards it. For each control measure, we ordered the banks by the respective level of the control measure and split the sample into three groups (with the split being at the terciles, leading to sub-groups consisting of 52 data sets each). For each of the three control measures, we compared the level of trust between the three sub-groups specified on the level of control (Mann-Whitney test). A comparison of the mean values of trust based on the control values separated into three groups may help to uncover a concave relationship (i.e., moderate controls lead to a high trust level, while less or (too) much control leads to a lower trust level).

<table>
<thead>

<td>2.29</td>
<td>2.28</td>
<td>2.77</td>
<td>.902</td>
<td>.026</td>
</tr>
</tbody>
</table>

*Table 3. Mean values of control dimensions related to level of trust and significance of difference (based on Mann-Whitney test)*
As the data in Table 3 show, the mean values in all dimensions and for the overall control construct (combining all seven control indicators) increase with the level of control. Although not all differences between the control subgroups in each control dimension are significant, a concave relationship can be screened out. A more detailed analysis within the control subgroups by again dividing the high-control group into three equally large sub-groups (again based on the level of control) did not reveal any additional insights.

Thus, we can partially accept H1b and will discard H1a+c. Moreover, detailed results show that (1) the more detailed and customer-comprehensible the performance reports generated by the IT service provider, the higher is the level of trust by the bank; (2) the provider’s activities in conducting employee satisfaction surveys at the client as well as in providing evidence for IT trainings of its own employees at least partly increase the level of trust reported by the bank; (3) behavioral control by the bank is slightly positively but insignificantly related with the level of trust.

4.3 Testing the Role of Service Quality as a Differentiator (H2)

Hypothesis 2 proposes the role of service quality to affect the relationship between control and trust. The higher the service quality, the more complementary rather than substitutive would the relationship between control and trust be. Since the described cycle of trust or distrust represents a temporal and furthermore reciprocal phenomenon, we cannot sufficiently validate it by cross-sectional data. Nevertheless, we tried different approaches in order to get at least indicative evidence for its existence.

First, we did a simple group comparison between outsourcing relationships showing high vs. low service quality. Since we measured service quality along two dimensions, we formed different groups based on both measures, as well. In order to achieve discriminant validity, we defined the two groups based on the lowest and highest third, omitting the mid-level third. Following our hypothesis, we would expect a negative relationship between trust and control in the low-SQ third while a positive relationship should appear in the high-SQ third. The following table shows the regression results for trust = β₀ + β₁ * CONTROL_REP + β₂ * CONTROL_PROV + β₃ * CONTROL_BANK + residual.

Table 4. Relationship between control and trust in low vs. high SQ groups (levels of significance: ***: p<.01, **: p<.05, *: p<.1)

The proposed situation appears only in one case (CONTROL_BANK, SQ-reliability). In two other cases (CONTROL_PROV), at least the impact shows an insignificant trend in the expected direction, thus being higher in the high-SQ group than in the low-SQ group. However, in half of the combinations, a reverse result is detected.

Second, we apply a moderator test based on hierarchical regression consisting of the three CONTROL variables, the two SQ variables, and the six resulting interaction terms. Confirming the hypothesis would require positive interaction effects. The results are presented in Table 5.

Again, the analysis uncovers some contra-intuitive results: some of the interaction effects are significantly or insignificantly negative instead of being positive. Moreover, graphical data analyses showed that at high levels of SQ, the relationship between control and trust becomes actually negative (not displayed).

Table 5. Moderator tests for service quality moderating the impact of control on trust (levels of significance: ***: p<.01, **: p<.05, *: p<.1)

Finally, we combined the first and the second approach. We did a similar moderator test with a reversed regression function, now using SQ as dependent variable and the interaction of control and trust as determinant. These regression tests were conducted within the low and the high SQ groups instead of on the overall sample. Confirming H2 would be reflected by a complementary relationship (i.e. a positive interaction effect) in the high-SQ sub-sample, and a substitutive relationship (negative interaction effect) in the low-SQ sub-sample.

Because we found multicollinearity problems during this analysis (VIFs up to 50), we followed the regression approach proposed by (Lance 1988) and successfully applied in other studies (e.g. (Prabhu et al. 2005; Tiwana et al. 2007)): we tested the following regression function: \( SQ = \beta_0 + \beta_1 * CONTROL + \beta_2 * TRUST + \beta_3 * dXX + residual \)

This approach prevents inflation of the regression coefficients resulting from multicollinearity. We did this procedure for all combinations of \( CONTROL = \{rep, prov, bank\} \) and \( SQ = \{reliability, responsiveness\} \) within the low and high service quality sub groups. The following table shows the results.

Table 6. Interaction tests for control and trust showing different effects on SQ at different levels of SQ

---

1 In order to increase reliability during the regression analyses, we did not choose the terciles with low and with high service quality as group separators but used the lower and the higher half in order to have larger sub-samples for the regression calculations. Nevertheless, using the terciles does not lead to structural differences in the results displayed by Table 6; path coefficient differences show to be even larger, but the smaller samples do not enable successful tests of significance.
Interestingly, now a major proportion of the results supports our proposition. Although the path coefficients are mainly insignificant, due to the small data samples, the differences between both groups are significant in all cases (based on a bootstrapping with 500 samples). Comparing the groups, there is usually a negative relationship in the group with low SQ, while it is positive or at least less negative in the high SQ group.

5 DISCUSSION AND LIMITATIONS

While many of the conceptual and few of the empirical works (Das and Teng 1998; Das and Teng 2001; Grundei 2006; Kale et al. 2000; Langfield-Smith and Smith 2003) argue for a negative relationship between control and trust, our work found mainly a positive relationship. This can at least partially be ascribed to the characteristics of our control items. Particularly, the provider-based control items, such as employee surveys or proving IT training certificates, are more or less directly reasoned in promoting a good relationship. Thus, this dimension is very likely to lead to a positive relationship.

Further, the control reports construct was measured in a more qualitative way, which also will contribute to a positive relationship. By contrast, the bank-driven control showed no correlation with the level of trust in the relationship and rather turned into a negative path when service quality was introduced as a moderator. A reason that can be directly extracted from the different service quality dimensions is that bank-driven control does not necessarily drive reliability (that would be the most obvious relation) but rather the responsiveness by the provider, which usually indicates commitment and in turn significantly drives trust in the relationship. The negative residual direct relationship then can be explained by reversing the link. Above, we discussed the reciprocal relation between trust and control, which can be uncovered here. The negative residual path simply indicates the reverse argument that a less trustful relationship will lead to more control actions by the bank itself. Nevertheless, most of our results quite strongly and impressively showed that there are no significantly negative relations between control and trust. This indicates that there is no over-control in our sample and that the finance industry and their IT providers are used to high levels of control being a natural and “healthy” part of their business.

Interestingly, there is no correlation between bank-driven control and service reliability, and moreover, provider-driven control in both models has a significant positive effect on trust, but is not related to higher service quality. This again underlines that the primary reasoning may lie in maintaining the relationship by these issues, rather than actually increasing operational service quality.

Contra-intuitively, the basic tests of service quality moderating the relationship between control and trust showed to be negative instead of being positive, as proposed. This represents a substitutive relationship between service quality and control regarding the achievement of a trustful relationship. In case of high service quality, the need and impact of control is less than otherwise. Nevertheless, in case of high service quality, control, at least as measured by the control action items in this paper, can even better interact with the creation of trust in order to achieve a successful outsourcing partnership (cycle of trust, as indicatively confirmed at the end of section 4.3).

This leads to our implications for management: our results clearly showed the positive impact of several control action items, both the provider and the client firm can apply. Providers that set up mechanisms that fulfill social control (such as surveying satisfaction of client employees or proving training certificates for own personnel) will increase and maintain trust. Nevertheless, the client should be aware that these measures will eventually turn into an increase in service quality and not only in relationship quality (dazzling effect). Further, the client has to be aware of the cycle of distrust. Good relationship quality which is oriented towards a long-term partnership requires sensitivity and sometimes forbearance in order to support the provider during difficult situations. Otherwise, control will just worsen and maybe destroy the outsourcing relationship with high costs on both sides.

Of course, there are a number of limitations that have to be considered when interpreting the results: (1) we investigated IT outsourcing relationships restricted to the German Banking Industry; (2) our findings are based on data from only one point in time, and collected from one person in each bank,
thus inhibiting the assessment of time effects (and, the cycle of trust/distrust, in particular) and incorporating subjectivity; (3) we are aware that parts of our measurement model may be subject to being too tightly bound to the application domain. Although this might be a weakness for rigorously testing theory on the relationship of trust and control, it will improve the trade-off between the results providing valid findings while being directly applicable by managers who maintain outsourcing relationships. Also, through adopting indicators from prior research and in-depth case studies, we can assume our measurement model to be appropriate; (4) we have not tested for any contingency factors, yet. Besides e.g. firm size or strategy, in particular the duration of the relationship could have an impact. Although we suppose the relationship age not to have an effect in our data since, as shown above, most arrangements have lasted more than ten years, further investigations will include such tests. Also, we concentrated on one specific information system to avoid noteworthy contingency effects, which could e.g. result when different outsourcing scenarios (e.g. characterized by various degrees of complexity) are examined and thus trust is more or less important with respect to distinct scenarios; (5) trust has only been measured as relational trust, neglecting other dimensions such as competence trust, in particular.

6 CONCLUSION

Based on data of IT outsourcing relationships between 156 German banks and their IT service providers, and on the literature that has dealt with the coherence of control and trust in inter-organizational collaboration, this paper investigated the relationship between control and trust, and also included service quality as a moderator. We could show that different types of control do differently affect the level of trust in IT outsourcing arrangements. While control reports and provider-driven controls proved to have a positive effect, bank-driven controls did not correlate with trust and furthermore showed a negative effect when considering the level of service quality. Quite surprisingly, the interaction effects of service quality and control turned out to be negatively related with trust. However, comparing high-service quality situations with those showing low service quality, we could indicatively validate the hypothesis that there may exist cycles of trust/distrust. Finally, by splitting control into different dimensions, we did a first step to generating more concrete implications for provider managers that can help determining the right level of control.

In a next step, we will incorporate different contingency variables and a richer concept of trust, as noted in the limitations, in order to take the true complexity of outsourcing relationships better into account. Moreover, we intend to collect periodical data from selected firms in order to get longitudinal data for more adequately testing the proposed inter-temporal effects. Ultimately, we hope to contribute both to a better scientific understanding of the complexities between control and trust and to a statistically validated managerial set of control action items which helps outsourcing relationship managers to achieve and maintain sustainable and successful IT outsourcing partnerships.

THE ICT CONVERGENCE DISCOURSE IN THE INFORMATION SYSTEMS LITERATURE – A SECOND-ORDER OBSERVATION

Herzhoff, Jan, London School of Economics and Political Science, Houghton Street, London, WC2A 2AE, UK, j.d.herzhoff@lse.ac.uk

Abstract

The idea of ICT Convergence is used by many practitioners and observers - such as economists, politicians, journalists, and academics - as an important descriptor for technological change. However, a review of previous work in this field suggests that, despite more than 30 years of research on ICT Convergence, the theoretical basis of the concept of convergence is still under-researched. In particular in the IS literature, the concept has been either relegated to the sidelines or taken for granted without further reflection. Therefore, a systematic analysis of the idea of ICT Convergence from an IS perspective is needed.

This paper aims to explore how the discourse of convergence is being shaped in the IS literature. In order to address this question, 317 articles published in ten leading IS journals from 1998 to 2008 have been examined. This study has been built around a Grounded Theory approach informed by Niklas Luhmann’s Theory of Distinction.

The findings show that convergence cannot be viewed as a single concept. Five archetypes of “convergence communication” are identified, and a conceptualization of ICT Convergence as a double process between alignment and interoperability is suggested. The main limitation of this paper is the focus on leading IS journals.

Keywords: Convergence, Luhmann, Theory of Distinction, Literature Review, Discourse Analysis
1 INTRODUCTION

"Convergence may be the most expensive word in history. It has cost people billions." —David Geffen, co-founder of DreamWorks, 2002

The idea of the convergence of information and communication technologies (ICT Convergence) has been accorded tremendous importance by practitioners and academics alike when describing the process of technological change through digitalisation. Many organizations have used the concept to justify large investments (Lind, 2004) or to solicit funds for entrepreneurial endeavours (Knox, 2003a). But convergence is also seen as one of the driving forces for the development of new information infrastructures and services, and is therefore important to understand from a systems design perspective (Lyytinen & Yoo, 2002).

ICT Convergence is not a new concept. It has been intensively discussed in the academic literature for more than 30 years and has established itself in all major disciplines adjacent to information systems, such as computer science, management, new media, or economics. However, despite the apparent maturity of this research area (Lind, 2004; Farber and Baran, 1977), there is no generally accepted definition of ICT Convergence (Nyström, 2007); instead Appelgren (2004:246) argues that "there seem to be as many definitions of convergence as there are authors discussing the topic".

Furthermore, many authors agree that the idea of convergence lacks a systematic theoretical analysis (see Hacklin, 2007; Nyström, 2007). The diffusion of new converged services like IPTV (the convergence of TV and the Internet) or mobile Internet (the convergence of mobile telephony networks and the Internet) is still very slow in many countries. It is, therefore, crucial to provide a more systematic analysis and more robust theoretical underpinning of this important phenomenon in order to inform future design and regulatory recommendations. This paper argues that because of its close link to technological change, it is highly relevant for the information systems community to engage in this multidisciplinary debate and to offer an own perspective.

Schütz (1962) suggests distinguishing between first-level and second-level constructs. A theory can be built explaining whether an observed phenomenon is a “war dance, a bartender trade, or the reception of a friendly ambassador” (Schütz, 1962 p. 54); or it can be investigated how the observed persons understand the dance. In Luhmann’s terms (2002), focusing less on the constructs than on the process of observation, either the dancers themselves (first-order observation) or how the dancers themselves understand the dance (second-order observation) can be observed. As this study is interested in how IS scholars describe convergence, the primary focus is therefore not the phenomenon of convergence itself; but on the perspective of a second-order observer (Luhmann, 2002). Therefore, at this point a definition of ICT Convergence will not be committed to upfront. This definition should instead emerge from second-order observation.

The purpose of this paper is, therefore, to provide a taxonomy based on a systematic second-order analysis of how the idea of convergence has been constructed and used in the IS literature. Based on the taxonomy, this study aims to analyse in particular what constitutes a particular form of convergence communication, namely "ICT Convergence", from an IS perspective.

The organization of this paper is as follows: The literature review provides an overview about the existing literature on ICT Convergence from both first and second-order perspectives. Next, the paper presents its analytical approach based on the work by Niklas Luhmann and gives a brief account on the applied methodology. Finally, five archetypes of convergence communication in the IS literature will be presented and analyzed based on Luhmann's form and differentiation analysis.

The research scope of this paper is limited to the conceptualisation of convergence communication, in particular ICT Convergence communication, in ten leading IS journals and therefore disregards lower-ranked journals, conference papers and books. However, an initial review of other related IS journals and conference papers has not indicated any significant differences to the results presented in this paper.
2 LITERATURE REVIEW

The following literature review draws the distinction between first-order and second-order research on ICT Convergence. The first-order research deals directly with the underlying phenomenon of convergence, its drivers and consequences. The second-order research, on the other hand, deals with how the idea of convergence has been constructed by the observers of the phenomenon.

2.1 First-order analysis of ICT Convergence

ICT Convergence has been studied from many different perspectives and may be seen as a truly multidisciplinary research topic. This review focuses on the key works in the fields of management, computer science, new media, and information systems.

Computer Science Perspective: The meaning of ICT Convergence, in the context of digitalization, has already been envisioned by H. E. Vaughan of Bell Labs in 1959 as integrated communications that can provide flexibility for new services. There are manifold debates on convergence from the perspective of computer science. Messerschmidt (1996) identifies nine key debates related to convergence in the Computer Science literature: (1) best effort versus Quality of Service (QoS), (2) scalability, (3) terminal and network coordination, (4) connection versus wireless, (5) control architecture, (6) interconnection versus interoperability, (7) embedded computing versus general-purpose computing, (8) heterogeneity, and (9) architecture and complexity management. In particular, the design issues pertaining to increased conflicts or “tussles” through convergence and how to better control networks are of primary concern (see, e.g., Clark et al., 2005).

Management Perspective: The term “technical convergence” was coined four years later in 1963 by Rosenberg, who studied the American machine tool industry of the 18th century. According to Hacklin (2007), the key debates revolve around how an organization should respond to convergence, which may be viewed in the larger context of how organizations respond to innovations or market disruptions not originated by them. The debates have proceeded on two levels of analysis: at the firm level and at the industry-level. The management literature, drawing upon Rosenberg, began to incorporate the concept of convergence into the study of strategic management, building analytical tools and offering recommendations on how companies should react to technical convergence (Pennings & Puranam, 2001). Researchers also debate how to conceptualise convergence itself. Is it an endpoint or a process? If it is a process, how can this process be described? However, only a few scholars have attempted to describe convergence and craft a theory. One of the first serious attempts to do so from a management perspective was undertaken by Greenstein and Khanna (1997)—who distinguish between convergence of substitutes, which entails one domain competing with another, and complementary convergence, which entails two different fields coming together. Stieglitz (2002) refines the model by introducing a second dimension, that of product orientation versus technology orientation. However, each of these conceptualisations focuses only on industry-convergence, taking technological aspects for granted. The latest major work on convergence from a management perspective was conducted by Hacklin (2007), who interprets convergence as a species of technological change. He suggests analysing it as a process that originates in convergences of knowledge, technology, and applications, leading eventually to industrial convergence.

New Media Perspective: Convergence is one of the many terms proposed to describe technological change through digitalisation in the media literature. Other competing terms offered in the 1970s include "comunications" (A. Oettinger) and "telematique" (Nora & Minc). However, "convergence" eventually triumphed as the dominant label for this form of technological change, and became the term to be deployed in both the management literature and the popular media. It was further popularised by Nicolas Negroponte’s famous figure of three overlapping circles, a highly static conceptualization that assumes that convergence is an end-stage. Ithiel de Sola Pool's book Technologies of Freedom (1983) uses the term to describe the convergence of different modes of communication. Henry Jenkins (2001) built upon de Sola Pool’s findings and systematises the concept of convergence by splitting it into five...
different processes: namely, technical and economic convergence, which together lead to global, cultural, and organic convergence. Jenkins (2006) argues in particular for a wider understanding of convergence and coined the term “convergence culture”.

**IS Perspective:** Only a few articles in the core IS literature deal with the concept of convergence explicitly—all, without exception, on mobile computing and information infrastructures. Lyytinen and Yoo (2002) briefly address convergence in their discussion of the drivers of a nomadic information environment. They see convergence, mobility, and mass scale as driving development for both information infrastructures and services. Convergence is defined as the “digital processing of all forms of data […] across different carriers […] with multiple devices….” (p. 379). Finally, they note that open standards are essential to convergence. Nielsen (2004) sees convergence as a “process bringing together different and heterogeneous actors as well as markets and technologies, a process not only bringing synergies but also challenges.” He argues that in particular conflicting interests might emerge from these convergence processes.

Jansen and Nielsen (2005) investigate the convergence of UMTS and WiFi infrastructures in Norway. They suggest conceptualising convergence as a form of co-evolution, pointing out that the convergence of these two infrastructures is by no means inevitable. Tilson (2008) addresses several convergence instances in the mobile and television industry. He uses actor-network-theory to ”explain convergence, the explosion in the number of interfaces requiring standardization, and other industry and standardization changes observed in the case studies” (p. 17).

### 2.2 Second-order analysis

Several studies over the last five years discuss convergence from a second-order perspective, i.e. analyzing or reflecting on the idea of convergence instead of describing the underlying phenomenon. Knox (2003b) analyses the idea of convergence from an anthropological perspective, considering how it has been mobilised in the development of new media in Manchester. She points out that convergence is used by both observers of new media (economists, academics, politicians, civil servants) and its practitioners (Knox, 2003a). Further, Knox argues that the articulation of the term often manifests a ”calculated performance" in which ”the lack of experience by these companies is self-replicated in as much as they are required to seek out novelty and new ways of working” (p. 47). Furthermore, she suggests seeing convergence not only as a singular description of a process but rather as a descriptor of change “which has gained its predominance from the fact that it cannot be pinned down to a single process, a single model, from the fact therefore of its own reproduction” (p. 120).

In a study of the usage of the term convergence in published newspaper articles between 1990 and 2004, Lind (2004) finds that the idea of convergence is often used to justify mergers and acquisitions, and also to flag impending change early in the redefinition of a market. In a study of how business and IT managers in the Finnish telecommunications and media sector perceive convergence, Nyström (2007) stresses the need for a better description of what convergence is and what it is not. Hacklin (2007) argues for the importance of a better understanding of how the term is used in the literature.

The main shortcoming of the existing body of second-order literature on ICT Convergence is, with the exception of the work by Knox (2003b) and Nyström (2008), that it has not moved further below the surface to enrich the understanding of the idea of convergence. Since the most prominent meaning of convergence has emerged in information and communication technologies (Hacklin, 2007), it is fruitful to engage in this discussion, particularly in relation to information systems.

### 2.3 Key findings

The review shows that most first-order observations in various academic disciplines take the concept of ICT Convergence for granted. Furthermore, the IS literature lacks a systematic second-order analysis of ICT Convergence. Finally, there is evidence that the concept has been diluted which makes an analysis of the distinctions of what constitutes convergence and what does not necessary.
Therefore, the expected theoretical contributions of this paper are threefold. First, this research aims to provide an initial second-order taxonomy on convergence from an IS perspective. The paper aims to show that convergence has been used in information systems in several different contexts, but only very superficially in the context of technological change. Second, this paper expects to improve the theoretical understanding of ICT Convergence from an information systems perspective. Third, it aims to contribute second-order observations to the debate on the conceptualization of ICT Convergence and also to push the analysis deeper than previous studies.

3 ANALYTICAL STRATEGIES – THEORIES OF DISTINCTION

One interesting aspect of all previous attempts to investigate the idea of convergence from a second-order perspective (with the exception of Hannah Knox’s approach using Callon’s analysis of framing and externality) is the lack of an analytical strategy as a guide for data collection and analysis. Andersen (1999) uses the notion of analytical strategies to describe the aspects involved in making an analysis from a constructivist point of departure. By doing so, he intends to emphasize that a second-order observation is not a method to be deployed in order to get closer to the truth about an object. Instead, the social perceptions of objects are to be analyzed.

Niklas Luhmann’s General Theory of Social Systems is one of the grand theories in the social sciences (Lee, 2000). Although there are many different ways to access Luhmann, this study has chosen the Spencer-Brownian route to the Theory of Distinction (Andersen, 2003, p. 64). To draw on Spencer Brown’s Law of Form (1969), the basis of form analysis is observation, which consists of two components, distinction and indication. Whenever something is observed, a distinction is made between the inner side and the outer side by choosing or “marking” the inner side as the unit of analysis. There is always something left to be “unsaid,” which is the residual category (Demetis & Angell, 2007). According to Luhmann, every researcher has to decide how he or she will observe the object of study (Luhmann, 2002). Any choice of distinction is contingent and hence open for criticism. Luhmann (2002) suggests looking instead at how the object draws the distinction between itself and its environment. Thus, this research is interested in how the authors of the texts make their own distinctions on convergence.

The approach applied by this paper uses two types of discursive analytical strategies in the data analysis, both based on the work by Niklas Luhmann: form analysis and a sub-form of systems analysis known as differentiation analysis (Andersen, 2003). Form analysis provides the foundation of the data analysis and focuses on the following question: Which distinction allows the observer to see the environment in terms of convergence, or, more specifically, which is the unmarked side of the difference when communication indicates convergence? Form analysis is not an end in itself, but it leads to the question of how social systems cope with—or, in Luhmann’s language, “de-paradoxify”—the paradoxes upon which their communication structure is built (Andersen, 2003: 101). In the analysis of how IS researchers apply the concept of convergence, this paper also applies differentiation analysis to identify distinct forms of “convergence communication”. The guiding distinction for this analysis is similarity/difference. This paper uses differentiation analysis to observe the functional differentiation between different types of convergence to build a taxonomy of convergence.

4 METHODOLOGY

The methodology is primarily influenced by the Grounded Theory approach, which has been used successfully in previous studies (Jones, 2004; Orlikowski & Iacono, 2001). This approach to analyzing IS journal papers uses a kind of content analysis in which categories are developed solely on the basis of the findings from the data and not imposed from the outside (Agar, 1980). However, it differs from the traditional content analysis since the categories were not pre-defined but have emerged during the data analysis.
This study follows the Corbin and Strauss (1990) version of Grounded Theory, but differs from their strict approach in two distinct ways. First, the data selection is based on corpus construction (Bauer and Aarts, 2000) instead of theoretical sampling. Second, the focus is not only on the core category but also on the core distinction using Luhmann’s Theory of Distinction as additional analytical strategy in the analysis of the findings.

Corpus construction (Bauer & Aarts, 2000) has the advantage of offering a vocabulary that is independent of sampling logic and that overcomes the shortcomings of theoretical sampling, as suggested by Strauss and Corbin (1990), such as multiplication of sampling methods. The goal is to select “incidents” of a phenomenon, not to sample a population (Bauer & Aarts, 2000). Barthes (1967) suggests selecting a data corpus based on relevance, homogeneity, and synchronicity. By keeping the focus on information systems relevance was ensured whereas homogeneity of the corpus was achieved by taking only journal articles into consideration. Finally, synchronicity has been maintained by focusing on journal articles that were published between 1998 and 2008.

This study focuses only on the leading academic IS journals. Ten IS journals (MIS Quarterly, Information Systems Research, Journal of MIS, Journal of the AIS, Information & Organization, European Journal of Information Systems, Journal of Strategic Information Systems, Information Systems Journal, Information & Management, Decision Support Systems) have been drawn upon based on the ranking from Louisiana State University, since it distinguishes among management, practitioners’, and “pure” IS journals. The selected journals also appear frequently in the top ten rankings in recent studies (see e.g. Rainer & Miller, 2005 or Peffers & Tang, 2003). The decision to focus on this body of literature and to exclude other journals, conference papers, etc., is driven by relevance and resource constraints. The primary aim here is to see how the highly relevant concept of convergence is treated and used in the mainstream IS journals.

A full text search has been conducted on the term "convergence" using Business Source Premier, Sweetwise, and ScienceDirect. The search has not been limited to "ICT Convergence" to achieve a broad understanding of convergence communication and to increase the variety of the findings. The only exception for the analysis period between 1998 and 2008 is the Journal of the AIS which has only been published in 1999. This timeframe has been selected to cover an extended period, but at the same time benefits from the easy data access to conduct a full-text search. For most of the journals, no electronic versions are available before 1998. Based on the search results, a corpus of 341 journal articles has been constructed and imported into the software package Atlas.ti. 24 articles which used the term “convergence” only in the bibliography have been excluded and the final corpus comprised of 317 articles.

The approach of informing Grounded Theory with the Theory of Distinction is new, especially in the IS field, but has already proven valuable in other domains of social sciences (Gibson et al., 2005). Theory of Distinction has been used as an analytical strategy to sharpen the perception of differences in the data analysis (Andersen, 2003). It is consistent with Grounded Theory in several ways. Firstly, both are interested in the emergence of meaning and focus on what has been communicated and how it has been organized. However, they differ in one distinct aspect: traditional Grounded Theory searches for the core category, whereas the Theory of Distinction is concerned with the “guiding distinction” (Gibson et al., 2005).

5. FINDINGS

Each article has been searched for the term “convergence,” and the relevant paragraphs have been coded by repeatedly asking what it means in this instance, in what context it is used, and what distinctions are made by the authors of these articles. Based on the context codes, six categories of contexts have been identified in which the authors used convergence. Three contexts are closely related to the research process itself, and three were related to the phenomenon under study.

The findings suggest that the IS community uses the concept of convergence to describe (I) research streams and theoretical concepts coming together; (II) quality criteria in methodology sections; and
The processing of quantitative and qualitative data analysis. The topical contexts can be broadly separated into (IV) decision-making; (V) technological change; and (VI) other contexts.

Table 2 illustrates the different sub-themes and the number of occurrences in the data corpus. One interesting aspect of this data is that convergence in the context of technological change has only 48 occurrences, which account for less than 15% of the articles (total = 317). In the next step, some initial concepts have been identified with their properties and their dimensions, and the data accordingly coded. These insights and the method of constant comparisons have been used to construct a first set of categories. Based on the analysis, the five identified categories or conceptualizations of convergence are: alignment, recombination, optimization, interoperability and correspondence. The category labels are rooted in the data. In the following paragraphs, all five views on convergence identified in the course of the analysis of the data corpus are presented.

**Convergence as Alignment:** In the IS literature, the concept of alignment is primarily used in the context of decision-making. In the data corpus two sub-forms are identified: one based on building up shared models between social systems and the other one on finalizing the decision-making process. In both cases, a change in both converging elements is anticipated in order to reach some sort of consensus. IT has more of a support role in the form of group or decision-support systems. Both sub-forms have an iterative process understanding of convergence. Convergence as decision-making is intended to increase focus and efficiency whereas convergence as building up shared mental models aims towards incremental change in individual accuracy.

**Convergence as Correspondence:** Convergence as correspondence focuses on similarities among concepts and highlights correlations or equality between them. It is used in the context of aligning research findings with existing research or in the process of triangulation. The converging elements are not anticipated to change, but are conceptualised in a stable state. Therefore, convergence is not seen as a process but as an end stage. The process is folded into one dimension and is not iterative:

Convergence as Recombination: Convergence as recombination deals with the mixing of elements, often resulting in innovation. It is used in the context of bringing together different concepts, for example, in the form of research streams, different functionalities, or media in the context of technological change. This view focuses on the mix and the outcome and does not account for an iterative process. It assumes no change in the converging elements themselves, as observed in the case of alignment, but instead results in the creation of a new element:

The industry has experienced the introduction of nearly twenty competing products [...] convergence of functionality of hand-held devices, palm devices, small phones, and car communication systems within a short time span of about 2 years. (Ramesh & Tiwana, 1999).

Convergence as Optimization: Convergence as optimization has been found mainly in the data analysis sections of the articles. An optimization problem is at hand and is analysed in different ways (e.g., genetic algorithms) to achieve a convergence to the optimal solution. This special form of convergence assumes that there is only one element that changes to a (predefined) ideal stage. It has a strong process view, and number of iterations and rate of convergence are important properties.

Convergence as Interoperability: The interoperability view on convergence is mainly found in the context of technological change, mainly in relationship to system integration and the network organization. Both deal with the detailed technical links between two or more elements moving together. While the integration form sees convergence more as a driver for efficiency, the network organizational form points out that it is set up through standards which are again a result of a negotiation or alignment process among players.

6 DATA ANALYSIS AND DISCUSSION

From the findings so far, three points can be highlighted. Firstly, the concept of convergence as technological change is relegated to the sidelines in the leading IS journals. It has a very small number of occurrences and is primarily picked up within the themes of mobility and network organisation. Secondly, convergence can be conceptualized based on the IS literature in five archetypes: convergence as alignment, interoperability, optimization, recombination, and correspondence. Thirdly, convergence communication in the context of technological change has been primarily described through convergence as interoperability and alignment and, on some occasions, through recombination. In the following differentiation analysis, the differences and the linkages among these five categories are investigated, specifically focusing on the idea of ICT Convergence. In the final step, a form analysis is conducted to identify the overall guiding distinction drawn by the authors in the context of technological change which shapes ICT Convergence communication in the IS field.

6.1 Differentiation Analysis of ICT Convergence

If the differences among the five categories are analyzed, it is observed that the categories mainly differ in the relations of the converging elements (see figure 1). The key distinction between alignment and recombination is that alignment is not about “mixing” media or functionalities. Instead, it deals with streamlining existing ideas, interests and opinions, i.e. agreement on standards. At the same time, the main distinction between alignment and interoperability is that interoperability builds detailed technical bridges or gateways among the converging elements, i.e. web services. Correspondence is a special case, assuming that the converging elements are the same, while optimization differs from the
other four conceptualizations because it assumes that there is only one element which moves towards an ideal state or optimum.

In the light of these findings, ICT Convergence is seen as a socio-technical complex (Bauer, 2002) that is observed by a very heterogeneous field of observers. The ICT Convergence complex develops parallel to other established systems that constitute its environment. Any particular observing system might be in focus, depending on the observer and his or her research question, letting the other system move into the background. Based on the observations made so far, the observers in the context of technological change observe convergence as a socio-technical process where both elements mutually constitute each other. A good example of this can be found in a definition quoted by Pawlowski & Robey (2004) from Susan Leigh Star et al. (1997, p. 4):

*Star et al. defined convergence as 'the double process by which information artifacts and social worlds are fitted to each other and come together...a process of mutual constitution.'*

While the focus of ICT Convergence in IS seems to revolve around this double process of alignment and interoperability, other forms of ICT Convergence communication cannot be ruled out. In fact, from a design perspective it might be very useful to closely examine the other three forms and, in particular, their distinctions.

### 6.2 Form Analysis of ICT Convergence

What is the guiding distinction that indicates convergence? According to Luhmann (1991, pp. 15-16), there are three ways to make distinctions. Firstly, a distinction can be made without specifying the other side of the distinction (e.g., convergence/no convergence). Secondly, a distinction can be made to restrict the other side of the distinction (e.g., convergence/divergence). Luhmann refers to the first category as objects and to the second category as concepts. Finally, there is a special kind of concept in which a distinction is made by copying it to the inside or outside of the concept itself. Luhmann calls these concepts, which can re-enter themselves, as second-order concepts (he gives an example of government and opposition, where government can itself have a deciding fraction and an opposition).

In the following section the forms of all five types of convergence are analyzed to identify the prevailing guiding distinction.

**Convergence as alignment:** Many authors make the distinction between convergence as a concept and divergence as its counter-concept. While the other side of the distinction of convergence through building shared models is the revelation of biases and conflict, divergence is seen in decision-making as part of the brainstorming phase which seeks creativity and opens up the option space. In the case of the double process of alignment and interoperability, convergence is observed as alignment becoming a second-order concept, which re-enters itself in convergence as interoperability.

**Convergence as interoperability:** Most authors do not make any explicit distinction except in the context of network organization where the other side of the distinction indicates the traditional form of closed systems.

**Convergence as recombination:** Similar to interoperability, most authors use it as an object without any clear distinction. Interestingly, recombination has a strong relation to innovation and therefore seems to be closer to the counter-concept of alignment. On the other hand, it leads to new forms which may question the existing beliefs, bringing in diversity and may result in divergence. The other side of the distinction is, in this case, a form of separation, i.e., a concentration on a specific concept, functionality, or medium (see for e.g. the original Blackberry or iPod).

**Convergence as optimization:** Here, many authors see any divergence from the optimum or ideal stage as main difference. Although this type of convergence communication has not been used explicitly in the context of technological change in the data corpus, some convergence rhetoric is based upon the belief of convergence as an ideal (e.g. discussion on ubiquitous computing). However, from a design perspective it may become problematic if the other side of the distinction is forgotten, namely that there are other alternatives as well. A similar point has been raised by Jansen and Nielsen (2005).
Convergence as correspondence: The other side of the distinction is difference. This view on convergence blends out differences and constructs an artificial sameness between two different elements. It might be helpful from a design perspective to remain sensitive to these differences.

6.3 Discussion

In most cases, the IS researchers in the data corpus use convergence as an object without any clear distinction from its environment. Some other researchers set it explicitly against a counter-concept (this was primarily divergence), and therefore fulfill the criterion of a concept according to Luhmann. Finally, some authors used convergence as alignment as a second-order concept. The first type of distinction is not very helpful; it is a distinction between convergence and everything else. It therefore offers a form, but not a conceptualization of convergence.

So what does making the distinction between convergence and divergence tell us? The unity of the distinction between convergence and divergence could be described as "mutual dependencies between elements." Jansen and Nielsen’s (2005) theory of convergence is based on a similar distinction. They call the unity "co-evolution." This indicates that convergence itself is not inevitable and that there might be other trajectories to follow. The first finding from the form analysis is that convergence itself is taken for granted and that the possibility of divergence is mostly ignored or seen as undesirable. Therefore, the relationship between convergence and divergence seems to be asymmetrical.

The second finding is that convergence is not absolute but relative to the observer. For example, ICT Convergence between mobile telephony networks and the internet may be increasing interoperability, but at the same time decreasing alignment between the actors (e.g. increasing conflicting interests). If the distinction between convergence and divergence is more closely analyzed, it can be observed that the same process can be convergence for some observers and divergence for others. The interoperability between different information infrastructures may be convergence from an infrastructure provider but divergence – in terms of increasing option space or choice – for the user. These contradictions in the guiding distinctions between convergence/divergence reveal a paradox.

Convergence becomes divergence, divergence becomes convergence – it all depends upon the observer.

According to Luhmann, two possible ways exist to deal with this paradox (Luhmann, 1991, p. 118). The first one is to replace the paradox with a new distinction; the second one is to observe it from a second-order observation and to question why more and more communication in society deals with convergence. One advantage of keeping the convergence/divergence distinction is that it puts emphasis on referentiality; it depends on the observer to determine whether something is convergence or is divergence. If this distinction is kept it is now possible to observe how the paradox unfolds. How does society deal with it? What mechanisms does it establish? Answers to these questions need to be sought to understand better the implications for design and regulatory challenges.

7 CONCLUSION, LIMITATIONS AND FUTURE RESEARCH

The idea of ICT Convergence has existed for more than 30 years and has gained tremendous importance in both practice and academia over these past decades. However, as this paper has shown, convergence has been relegated to the sidelines in IS and has, at best, been taken for granted. The purpose of this paper has been to offer a systematic analysis of how IS researchers see the general idea of convergence and, more specifically, the convergence of ICT.

The analysis of 317 articles from ten of the top IS journals is based on a grounded theory approach informed by Luhmann's Theory of Distinction. From this analysis five types of convergence communications in IS are identified. Besides the contribution to the multidisciplinary literature of second-order analysis of ICT Convergence and to the IS literature in general, this paper aims to contribute to the emerging literature which applies Luhmann’s concepts to empirical problems in particular in Information Systems (see, e.g., Kallinikos, 2006; Demetis & Angell, 2007).
Furthermore, this study offers two methodological contributions. Firstly, to the author’s knowledge this is the first study in IS, which links Grounded Theory with Luhmann’s Theory of Distinction. This approach is very helpful for the analysis because it enables the author to look not only at similarities, but also at differences. Secondly, critics of discourse analysis point out the problem that studies applying this method give only imprecise and implicit suggestions regarding how to carry out discourse analysis (Flick, 2002). Therefore, the author suggests using Luhmann’s discursive analytical strategies (Andersen, 2003) as possible guidance for discourse analysis.

Finally, the contribution to practice is to provide for regulatory and design decisions on convergence an alternative path for understanding convergence, which might encourage a less superficial and more thoughtful discussion, changing taken-for-granted assumptions on convergence itself.

The main limitation of this paper is the explicit focus on the main-stream IS journals. The primary limitation of this approach is that it does not take books, conference proceedings, working papers, or articles in other IS-related journals into account. This decision was made to keep the focus primarily on the main body of IS research and because of time constraints. Future research might consider a wider analysis of IS research, including other IS journals, conference papers, or books. Furthermore, an empirical study would be valuable to observe how practitioners attempt to deal with the convergence paradox. Finally, it might be interesting to find out why the concept of convergence has been relegated to the sidelines in the mainstream IS literature.

Abstract

Web 2.0 thinking and technologies create a number of new opportunities to conduct research broadly labeled as Research 2.0. Research 2.0 is a growing area of academic and commercial interest, which includes research undertaken in online research communities. This research in progress paper explores the practice of online research communities using a case study example operated by the commercial market research company Virtual Surveys Limited (VSL) in the UK on behalf of their client United Biscuits UK Ltd.

The preliminary findings are based on VSL and academics working together to improve the online research community participants’ response rate and the quality of contributions. Data collected for this study is based on meetings, participant observation, and a pilot survey of United Biscuits online research community (snackrs.com) members.

Using the responses of 112 snackrs.com community members, a preliminary typology of motivational factors is proposed. This can be used to refine the recruitment and development of activities in an online research community. Also, a model for supporting online research communities to ensure longitudinal engagement based on an adaptation of Salmon’s (2004) 5 Stage Model for e-moderation is proposed, extending the 5 stages to 7 – adding the stages of selection and disengagement

Keywords: Research 2.0, Online Research Communities, online communities
1 INTRODUCTION

In recent years there has been an exponential growth of user generated content of the web, facilitated by the emergence of the phenomenon of Web 2.0 (NetRating., 2006). The market research industry has embraced Web 2.0 tools as mechanisms for supporting their data collection activities, indeed the industry has recently started using the phrase ‘Research 2.0’ to cover a range of research methods utilising Web 2.0 tools and environments (Oxley, 2006). To reflect the market research profession’s interest in the area, the Market Research Society conference, held in December 2007, was dedicated to Research 2.0. Three particular drivers for Research 2.0 are the observation of a) declining response rates to both online and offline surveys and polls, b) users increasingly checking and posting online reviews of products, companies and services that they interact with and c) that online research offers potential costs savings of about 40% compared to traditional survey research (Stafford and Gonier, 2007). The market research environment is changing, with users not only supplying answers but also increasingly posing questions and taking a more proactive role in shaping the areas of research (Comley, 2008). The interactivity that is demanded by users and offered by Web 2.0 tools such as discussion boards, wikis and blogs (O’Reilly, 2005) can be utilised in Research 2.0 environments to provide market researchers with an opportunity to gain richer insights and a tighter relationship with their interviewees and hence provide their clients with potentially richer data. Market research companies have used online polls for several years to collect quantitative data, but the development of bespoke online panels using community tools such as discussion forums, blogs or social networks to collect qualitative data are a more recent but rapidly expanding phenomena with in excess of 1000 bespoke research panels currently being run online (Harmon, 2005). The lead companies in this area are internationals such as the GfK Group and Communispace in the US and Virtual Surveys in the UK (Comley, 2008). Online research communities (ORCs) are typically closed communities where interaction is based on an agenda prompted by the researcher or moderator. These bespoke communities may vary in size but response rates are usually higher than the open ‘naturally occurring’ online communities (NOOCs). Due to the emerging nature of this type of research inevitably there are issues such as the validity of findings (Stafford and Gonier, 2007) and the consequential maintenance of such communities (Comley, 2008).

This paper reports on an interpretive investigation in collaboration with Virtual Survey Limited (VSL) on the use of Research 2.0 techniques in one online research community they run on behalf of United Biscuits UK Ltd. Specifically, the research adopts a case study approach and aims to explore the motivations behind contributor engagement within online research communities and to identify appropriate stimuli to increase long-term contributor interaction. To accomplish this aim we draw on online communities engagement literature and e-moderation models. Afterwards, we briefly outline details of the initial findings. A preliminary typology of motivational factors based on Snacks.com is proposed and discussed in relation to the literature. This typology has been created to aid understanding of the complex mix of extrinsic and intrinsic motivational factors that contribute to participants’ rationales for engagement in online research communities. This work contributes to the management of online research communities by providing a more detailed understand of why certain members participate in such communities. It also provides guidance for online research community facilitators to assist them in supporting and encouraging those activities that increase participation in online research communities. The observations are discussed in relation to the 5 Stage Model for e-moderation (Salmon, 2004).
2 ONLINE COMMUNITIES

Naturally Occurring Online Communities (NOOCs). When developing NOOCs there are a number of key issues to be considered. According to Wenger, a community consists of three basic elements: firstly the notion of joint enterprise, that the participants share identifiable and common goals; secondly that the participants mutually engage, that they learn and undertake activities together; and thirdly that the participants have a shared repertoire, a set of communal resources that have developed as part of their engagement (Wenger, 1998). Furthermore, trust between community members is a key enabler of community contributions (Ardichvili, Page, and Wentling, 2003). For example, contributors may hesitate to contribute out of fear of criticism, contributors may deliberately or subconsciously provide misleading contributions, they may doubt the importance of their contribution, provide inaccurate contributions or doubt that their potential contributions could be relevant to a specific discussion. Indeed, to remove identified barriers, there is a need to develop various types of trust models, for example knowledge-based or institution-based. The literature also identifies a range of intrinsic and extrinsic motivation factors that influence participants in NOOCs (Nov, 2007). For example, a range of reasons were identified regarding why individuals shared, or failed to share, or engaged with other members of an online community including: self-esteem boosting, altruism, conformist considerations and the moderation processes (McLure and Faraj, 2000). Moreover, others suggest that intrinsic motivators such as a feeling of belonging or the notion of meaningful contribution are much more powerful enablers than extrinsic motivators such as monetary reward (Brandtzæg and Heim, 2008; Nov, 2007). The online activity of participants in NOOCs also provides insight into the success or otherwise of the community. For example, according to Dwyer et al (2004) there are two distinct categories of online behaviour, firstly information seeking as illustrated by passive access and secondly viewing and social engagement as illustrated by participants who undertake active contribution (Dwyer, Zhang, and Hiltz, 2004). The information seeker type implies that the members are interested in updating their own knowledge in relation to a specific area of interest. Hence membership is sustained by the quality of information provided and how it is organised and presented and the speed with which it is updated. The information seeker category reaffirms that it is not sufficient to measure the success of an online community on the active members only. For example, ‘lurkers’, those members who read the community contributions but do not post messages, can be argued to be an important element to community success. Indeed, the approximate percentage of lurkers per online community can be as high as 90% (Mason, 1999). When considering the social engagement category, the social engagement type implies a desire to develop social engagement through the community. Therefore, supporting interpersonal relationships and encouraging social engagement can be argued to be a key objective in developing successful online communities. In fact, social engagement may directly influence contributors’ satisfaction levels and the degree and quality of contact and collaboration with other community members. The role of the moderator is also shown to be critical to the success of NOOCs. For example, Ardichvili et al (2003) suggest that community moderators have to create the right conditions for content generation and dissemination. This aim can be achieved by promoting conditions for an open exchange of ideas and information, creating time and space for dialogue exchange and supporting innovative thinking. However, numerous authors question the notion of the ‘managed’ community arguing that Communities of Practice do not respond well to being managed “outside management efforts may throttle an otherwise thriving Community of Practice” (Ardichvili et al., 2003). Finally, there are a number of Human Computer Interaction (HCI) issues which, it is argued, affect user participation in online communities (Preece et al., 2007). Issues include contributor conceptualisation of the structure and rationale of the online environment, whether an environment is expressive or persuasive and whether an online environment adheres to various usability heuristics.

Online Research Communities (ORCs). Whilst the above literature review gives a rich insight into the key research issues for NOOCs there are key features of ORCs that differentiate them from the more traditional online communities. NOOCs tend to connect people with common interests, in ORCs
the community is closed and members are selected based on specified profiles, whilst these profiles tend to be of people with a common interest (for example frequent flyers) there are also occasions when the research dictates that the participants should be from outside of the niche. NOOCs tend to attract people who are passionate about the subject; whilst this may be the case in ORCs, the aim is to ensure that the participating body represents a broader view of users rather than only brand advocates. The nature of NOOCs means that the community is usually discovered via word of mouth or serendipity, in the case of ORCs, which are closed communities; recruitment to the community is targeted and strictly controlled. This means that NOOCs may have a much larger membership base than ORCs, although engagement in ORCs tends to be much higher. Furthermore, in NOOCs the agenda is self-evident, the community usually has a ‘cause’, whereas in ORCs the agenda is clearly communicated at the recruitment stage, the subject matter is usually dictated by the moderator, which frequently means that there is no shared agenda beyond answering direct questions from the moderator and therefore there are limited opportunities for the users to coalesce. Therefore, whilst in NOOCs, user interaction is usually peer-to-peer, in ORCs there is a tendency for participants to simply respond to the moderator with limited interaction between peers. This reliance on the moderator is also evident in the reluctance in ORCs, unlike NOOCs, for members to self-police; rather participants rely on the moderator to act as mediator and monitor. Furthermore, due to the ‘managed’ nature of ORCs where both moderators and clients are actively ‘listening’ and analysing responses, there is debate on whether some contributions are genuine or whether responses are tailored in an attempt to influence client decisions or attract extrinsic motivators (prizes, payments etc). Note that it is recognised that the incentive scheme has to balance the timeliness, appeal and instant gratification to the participant (Stafford and Gonier, 2007). Finally, whilst initial participant engagement within ORCs may be challenging, primarily due to the fact that the recruited participants may not be as familiar with Research 2.0 tools as those who engage in NOOCs, the evidence suggests that levels of engagement in ORCs are typically much higher than NOOCs (proportion of NOOC forum members who engage <5%, proportion of ORC members who engage 50-70% (Comley, 2008)). A summary of the main differences between the ORCs and NOOCs is presented in table 1.

2.1 Longitudinal Participation in Online Research Communities

In order to develop a model for supporting ORCs to ensure longitudinal engagement, this research has used Salmon’s 5 Stage Model for e-moderation as a foundation. The 5 Stage Model offers practical advice on the use of online communication (Chowcat, 2005; Moule, 2007). This model is based on several years of action research on online conferencing in the Open University UK (Salmon, 2004). Whilst this model was developed with learning communities in mind, it has since been used in a number of other ways to structure online communication processes (Lynch, Heinze, and Scott, 2009). We therefore feel that the model offers a starting point in discussing online research communities.
This model of online community building and facilitation describes a five-stage process mapping the different stages of engaging participants using online communication technology. In the figure demonstrating the model, the level of engagement is indicated by the interactivity column (far right hand side) and the darkness of the colour. For example, stage 4 “Knowledge Construction” is the most interactive of all the stages, this is indicated by the black colour (the amount of interactivity measure on the interactivity column). The development starts from stage 1 “Access and motivation” and progresses up to stage 5 “Development” indicated by the arrowed “learning” line on the left hand side of the model. Each of the stages is subdivided into two triangles representing the roles of the e-moderator and the technical support staff. These roles vary at each stage.

The first stage of the 5 Stage Model is concerned with accessing the system, when participants are issued with access information by the technical support and welcomed by the e-moderator. The second stage focuses on online socialisation of the participants in the community; they are encouraged to familiarise themselves with the environment and socialise with others. The information exchange stage puts more emphasis on interaction and engages participants with the materials. The final two stages are where the participants should already be familiar with their environment and thus are able to proceed with knowledge construction and development. The model is based on a sequential principle that there are certain steps that have to be mastered before higher-level steps can be undertaken. The underlying principle is to use activities to make participants interact with each other and the e-moderator, rather than simply and passively accessing information such as handouts and presentation material. The model assumes that the participants will need to learn how to use the system’s technology and functionality over time.

This 5 Stage Model has resonance with theories about group work, particularly, the working stages such as ‘forming, storming, norming, performing and adjourning’ (Tuckman and Jensen, 1977). These similarities are particularly visible in the interactivity scale of the 5 Stage Model. The 5 Stage Model indicates that the interactivity is reduced at the final stage as is the case with group working stages of Tuckman and Jensen. The purpose of the 5 Stage Model is to address online communication and group work within the constructivist pedagogy (Salmon, 2004). This highlights some of the main benefits of the model such as simplicity (Moule, 2007), grounded in practice, reflects constructivist pedagogy, clarity, and provision of a good navigation tool for facilitators (Chowcat, 2005). However, there are also some disadvantages in the 5 Stage Model, such as the exclusion of other pedagogies and e-learning approaches (Moule, 2007). The model prescribes a course structure, ignores rhythms of participation, isolates e-learning from other learning and finally it is not a model for e-learning per se (Chowcat, 2005), which is an advantage for our investigation into ORCs

3 INTERPRETIVE CASE STUDY RESEARCH DESIGN

The research presented in this paper adopts an interpretive stance. Using an interpretive case study approach (Oates, 2006; Walsham, 2006; Yin, 1994), the research aims to explore the motivations behind contributor engagement within online research communities and to identify appropriate stimuli to increase long-term contributor interaction. The researchers involved in the study area are the authors and members of Virtual Surveys Ltd management team who include individuals with over 25 years experience of running market research studies in commercial settings. The academic researchers are experienced in the field of information systems development, knowledge management, online community moderation and are from an Information Systems background.

The ORC being studied is managed by Virtual Surveys Ltd (VSL) on behalf of United Biscuits UK Ltd (UB). There are two other communities examined in this research, but for the benefit of richness of discussion only the UB community will be described to discuss the preliminary analysis – that is the snackrs.com community. Guided by Myers’ (1997) assertion that interpretive research should present multiple viewpoints of those involved and their different perspectives, the communities were observed over a six-week period and the observations and interpretations made by the researchers were presented back to VSL management for potential improvements to be discussed and incorporated back
into subsequent data collection scenarios. The researchers were actively involved in community membership and were able to create their own posts and reply to other community members. This allowed first hand experience of interaction in the community and provided the researchers with the same level of exposure to email prompts and alerts as any other community member would experience. The presence of the researchers made any major impact on the community members, as members are already accustomed to being observed by a) the actual market research company and b) by the client company stakeholders such as UB.

Since the communities are operated by a commercial market research organisation, this research is undertaken under their strict in-house ethical approval guidelines. Before the start of this research, approval was also gained from stakeholders within the individual online research community client organisations such as United Biscuits. The reconciliation of commercial and academic interests has at times posed certain challenges that impact on the richness of the data reported, for example we are not able to report exact community member numbers. However, collaboration with a market research company also has its benefits such as the ability to use cutting edge market research technology and being allowed access to professional market researchers; for example VSL facilitated the online survey design and creation.

3.1 The United Biscuit Community

The United Biscuits community has approximately 1000 (c. 700 female, c. 300 male) members. Each online research community employs a range of Research 2.0 functionalities including voting polls, discussion forums, virtual focus groups, blog environments and functionality to allow community members to upload personal details, photos, videos and create friendship networks (see Figure 1 for a screenshot example). Each community has a dedicated moderator who posts email requests to members to contribute to the ORC on a specific topic of interest to the client on approximately a twice-weekly basis. The participants are not offered monetary reward for engaging with the online research communities however all respondents in the United Biscuit community are are offered free snacks and gain additional rewards based on ‘quality’ discussion forum contributions. VSL typically release a market research survey and then supply responses to the client within a one-week period. Responses to query requests sent by email to the ORC typically start within minutes of posting a notification of a new query to participants, peak within 24 hours, with no significant additional responses after a one-week period. As is demonstrated by the speed of responses within these commercial ORCs, the volume of data generated within a short period of time means that a longitudinal study was not a prerequisite for gaining a meaningful dataset. Response rates on given topics are on average 2% of the total community with approximately 10 to 45 responses per request. One of the issues of community management is that the majority of community memberships are inactive - for example in snackrs.com over 500 users have not posted a single contribution. Figure 1 is a screen shot taken from the snackrs.com online research forum. This screen shot illustrates that the community website has a conventional navigation bar on the left hand side of the web page and some high level navigation items at the top and bottom. The discussion forums are listed by topics and participants are given some high level information on the number of new topics, number of posts and when the last post was added.
In order to undertake this research study, data was sourced from a number of locations and stakeholders. The data sources influence decisions on potential online research community improvements. This provides an incremental improvement to the community that is continuously studied and reviewed by the research team. The decisions on implementation of any issues rest with the staff of VSL. The initial reflections, which are reported in this research in progress paper, are based on the two academic authors of this paper becoming participants in the research communities for a six-week period. The findings were discussed with the VSL staff and community improvements were initiated. A detailed discussion of these findings is the subject of this research in progress paper. At the beginning of this research a snapshot of all the communities was made which tracks all members, their profiles and number of posts to the community. The data collection and analysis is based on seven stages, extending the 5 Stage Model to include ‘Selection Stage’ and ‘Disengagement Stage’. The ‘Selection Stage’ was used to probe if there are any particular variables that determined individuals’ activities in the community. The ‘Disengagement Stage’ was included to determine any common variables that might have contributed to community members withdrawing.

4 PRELIMINARY DATA DISCUSSION

4.1 United Biscuits Community Typology

In order to improve the levels of engagement, it was perceived as important to identify the motivators for community members to take part in the community. Therefore, the first stage of the research consisted of a detailed analysis of the responses provided by 112 members of the United Biscuits community (known as snackrs.com) in response to the question ‘What are the best things about being a member of this community?’ Because qualitative data analysis is an open and iterative process, categorisation resulted in the emergence or induction of a rich categorisation as the categories were ‘extended’, ‘filled in’, ‘bridged’ and ‘surfaced’ (Lincoln and Guba, 1985). The initial analysis of the responses to the above question indicated that the rationale for participant interaction in the online research communities could be subdivided into seven motivational factors, of concern is the limited number of quotes that appear to suggest that participants are seeking social engagement. Examples of responses against typology type are presented in table 2. Note that some participants provided several responses. This means that someone can be classified as, for example, both information seeker and social engagement seeker at the same time. The typology is provisional and the types will be further refined as the research progresses. A summary of the types analysis and their potential tendencies as identified in the literature is provided in table 3. It is important to note that these are ideal case scenarios and there may be situations that will not conform to these tendencies.
Table 2: Preliminary typology of motivational factors based on Snacks.com

As we can see from this preliminary analysis there is a complex mix of intrinsic and extrinsic motivational factors that contribute to participants’ engaging in online research communities. The typology does not suggest that one member will fit necessarily into a single one of the motivational types, for example some statements of members included several reasons that they felt were their motivators to participate in the online community activities. Yet there were also some individuals who only identified one reason for participation. Since these types are based on individual member’s contributions it is not possible for them to place the entire community into one type, however, the more members of a community that subscribe to one particular motivator, the more this motivator could be used as the main source of activities generation and community management. For example, if the majority of snackrs.com identify with “Freebie seekers” this would mean that the product samples are important to them and stopping this activity could reduce their engagement in the community, on the other hand if samples were sent more frequently they might be tempted to participate more.

4.2 Tendencies of motivational factors

The preliminary typology is further explored in Table 3 in relation to the literature in order to provide insight into the reasons behind participants’ engagement in these communities. The first identified type is the Social Engagement Seeker, these individuals are characterised by comments that indicate interest in interaction with other ORC members. For example, these people might be there because they want to see what others have to say and how they can interact with those interested in a common topic. These individuals highlight the community elements of joint enterprise and collaboration as proposed by Wenger (1998). They are stimulated by intrinsic motivators which contribute to their feelings of belonging to a community, such participant types are more likely to trust others in the community and are likely to be active participants (McLure and Faraj, 2000). Considering the 5 stage model of engagement, this participant type will require minimal support at the initial access stage. They are predisposed to socialise, however the quality of the information provision and critical
reflection as they move to the knowledge construction and development stages may need significant moderator support in order to ensure that a valuable contribution from them is achieved.

*Table 3: Tendencies of the motivational factors*

The second identified type is the Power Seeker, these individuals are characterised by comments indicating a desire to have some influence, usually with the ORC sponsor (e.g. UB). These participants may have a very specific reason for engagement in the community. These individuals have a limited sense of community and, when considering the 5 stage model of engagement, whilst providing detailed knowledge, constructive dialogue may be so topic focused that their contribution to the collection of wider research data may be limited, effectively there may be a need to find mechanisms to move them back to the early socialisation stage of the model if their contributions cease to be useful or of benefit to the development of the wider community.

The third identified type is the Freebie Seeker, these individuals were motivated to join the ORC in order to gain the extrinsic rewards on offer. Logically, the expectation was that the snackrs.com community would have the highest proportion of non-contributing freebie seekers as in this community all registered members of the community were provided with occasional free samples regardless of their level of engagement in the community. However, this community has a low proportion of non-contributing members. As this research progresses, further investigation will be undertaken regarding whether the free samples act as a stimuli for engagement in the community. Considering the 5 stage model, snackrs.com members were also active in terms of knowledge construction and development – there was a great tendency to interact and debate with community development activities occurring, for example a lively informal competition concerned with posting photographs of Halloween activities. This activity was only very loosely related to the research issue (Halloween packaged sweets) yet stimulated co-construction of participant views on the subject. For future work there is a clear need to more fully understand the influence of extrinsic motivators on ORC contributions.

The fourth and sixth identified types are concerned with information gathering – the Information Seeker and the Information Hungry, these individuals are characterised by comments indicating a desire to learn and gain new information. The differentiating factor between the two types is that the Information Hungry specifically want to gain some form of ‘edge’ so that they aware of new developments first. As with Power Seekers, these individuals tended to have limited sense of community and, when considering the 5 stage model of engagement, whilst they may make some attempts at socialising, they tend to move to simple poll responses rather than towards generating useful co-constructed knowledge. Mechanisms need to be established to ensure that they are drawn into socialising and ultimately moved towards community development.
The fifth identified type is the Hobbyists, these individuals are characterised by having a genuine commitment to the ORC topic area and may make ideal participants. The danger is that they become overbearing within the community, consider for example the participant in snackrs.com who had made 243 posts. When considering this participant type against the 5 stage model of engagement the challenge is to ensure that these types become pivotal members rather than bland information providers, their contribution needs to encourage rather than overwhelm other participants. Finally, the seventh identified type is the Geek, these individuals are characterised by having an interest in the technology rather than the topic. Close attention needs to be maintained on their contribution, for example geeks are interested in the technological use of the forum and how it advances their abilities to interact online with other members. For example, the opportunity to upload their own photographs and video content created a technological challenge that some members appeared to enjoy.

4.3 Relevance of the 5 stage model to ORCs

The 5 stage model was developed for educational settings where students are primarily motivated by gaining knowledge and understanding, the moderators role is primarily to assess students’ activities and facilitate their knowledge development. This is a major differentiator with market research communities, where, as identified in our motivational typology above, the motivators for the community members vary. This leads us to re-consider the 5 stages of the model proposed by Salmon (2004). A stage which is not within the control of the educators, but is of primary concern for a commercial online research community, is the motivating factors that influence members’ enrolment in such communities. For example, if a member is displaying “Freebie seeker” characteristics does the community benefit from their presence? Although we are aware that several factors might influence an individual’s contribution and participation, a stage of member selection needs to be added to the existing 5 stage model. This stage would appear before the access and motivation stage and would comprise “Screening” the participants and their intentions. Also, it would be beneficial to highlight the key values of communities at the second stage of the model such as the “Access and Motivation” stage. Practically, this could be implemented by providing a simplified terms and conditions of the site use that highlights the need for expected interaction levels.

Another stage which was not necessarily applicable to the 5 stage model is where participants withdraw their participation. Other processes in educational settings would manage this stage, however, in ORCs it is not practical and could be done much more easily with an exit survey so that data could be captured to establish any trends regarding why members are leaving. This can feed into the recruitment and community management process to identify trends and patterns of members disengaging because perhaps their initial rationale for engaging in the online research community was not being satisfied. This leaves us with an expansion of the five stage model to seven stages, one prior to the engagement “Screening” and one after the community engagement has failed and a member withdraws - this could be referred to as “Disengagement”. Although these stages are already in place in practice in ORCs, the online research community creators tend to focus on the selection of correct sample groups rather than necessarily considering their motivational factors, which we feel are as important to the members’ existence as fitting the right market research segment or participant profile.

Based on our observations, the current interaction of community members tends to be centred around the third stage of the original 5 stage model of “Information giving and receiving”. There is little social interaction between members and where interaction happens, it is primarily between moderators and members, where moderators are trying to clarify the findings for the research brief. Having said that, there are special activities that are designed to be “fun” and to bond community members, but these are not as popular with participants as some research focused discussions. The ideal stage of “Knowledge construction and development”, where participants take over the initiative for product development say by initiating a new biscuit design or packaging for existing biscuits, does not happen in the studied community. This, to some extent, questions the notion of the Web 2.0 phenomena – the technology is there for members to take over the initiative, but they are not stepping over the barrier...
and tend to be more driven by the prompts of moderators and their research agenda. This requires further investigations.

5 CONCLUSIONS AND RECOMMENDATIONS

The current research-in-progress paper has outlined the initial findings of our research study. At this stage it is not possible to recommend firm action in order to improve the engagement of online research community members. However, we are able to provide a preliminary typology based on users’ beliefs. This can be used for by VSL for identification of future online community member types, recruitment, development of incentives and interfaces to suit certain kinds of behaviour. For example, to encourage ‘Social Engagement Seeker’ type of behaviour, more ‘fun’ activities could perhaps be introduced to facilitate community building and not necessarily focus on the core community purpose. This would allow members to get to know each other and allow those who entered the community at a later stage to catch up and see the “human side of interaction”.

The research to date has begun to suggest a profile of an ‘idealised’ ORC participant who would: exhibit community elements, trust the community, have intrinsic motivators and be an active participant. Those individuals who would fit this ideal profile are ‘Social Engagement Seekers’ and ‘Hobbyists’. However, there are drawbacks to such idealised participants. For example, the ‘Social Engagement Seeker’ is primarily motivated by interactions with others hence they could potentially contribute too many off-topic conversations that may not necessarily be of interest to the client. On the other hand the participants who are less engaged in online research communities are those that exhibit no community membership, have no trust in community, are motivated by extrinsic rewards and are passive, for example the ‘Freebie Seeker’. Arguably, there is a need for only active members of the community, who contribute to the discussions, however, those that answer polls and surveys are important to the research company when they are trying to establish a view on a specific topic that can be generalised.

The above conclusions contribute primarily to the online research communities’ moderation literature and secondarily to the moderation of general online communities. The preliminary typology requires further refinement and this is a research direction that we are taking, however, other studies in other communities would benefit this process and allow us to better understand the moderation of online communities. We feel that the 5 Stage e-moderation model is a useful guiding point for the discussion of all online research communities and not only those in educational settings where they were initially developed. However, unlike in educational settings, participants cannot be selected by the educators, in market research settings the participant selection and retention process is crucial and we propose to add these additional “Screening” and “Disengagement” stages to the 5 stage model – making it a seven stage model for online market research communities.

Future work will be based on face-to-face interviews with senior VSL management, online research community system developers and the online research community moderators who are VSL employees. The community members’ views will also be elicited through an online survey created specifically to stimulate discussion on community improvement. Additionally, telephone interviews with a sample of participant community members will be undertaken. Google analytics data (for example times of website access, frequency of contribution, pages viewed, length of engagement on the page) will also be used to provide quantitative data on general participants’ engagement patterns. Finally, participant profiles will be further reviewed.

THE NOTION OF LIFEWORLD APPLIED TO INFORMATION SYSTEMS RESEARCH

Andrew Basden, IRIS, University of Salford, Salford, M5 4WT, U.K.
sbs@basden.demon.co.uk

This paper is dedicated to Heinz Klein, one of our most incisive thinkers whose depth and breadth in IS research is legendary, because it was he who inspired this paper and encouraged me to develop these ideas.

ABSTRACT

Much IS research brings a priori theoretical constructs to its domain of study, and this can generate distorted outcomes. To avoid this danger, IS research should be 'lifeworld-oriented'. Characteristics of the lifeworld are drawn from philosophy and applied to examples of IS research. Surprisingly, both positivist and critical research can be both theorizing and lifeworld-oriented, though in different ways. A proposal is then made for 'lifeworld-oriented IS research', which, by taking into account the lifeworlds of both researcher and researched, can make IS research richer and more relevant.

Keywords Information systems research, lifeworld, diversity and coherence, meaning and norms, background shared knowledge.

1 INTRODUCTION

Geoff Walsham's [2001] work Making a World of Difference: IT in a Global Context, provides an insightful discussion of information systems (IS) use, by individuals, groups, organisations and society. He says his whole professional interest may be encapsulated in the question "Are we making a better world with IT?" [p.251]. With a 'basket of conceptual tools', he identifies ways to make a difference.

But in one case study Walsham's analysis becomes uncharacteristically cavalier. ComCo, a company that produced plotters, had a team of engineers to maintain them, but then outsourced the plotter business. The engineers became agents. The company had an IT system, Traveller, to enable them to communicate. Walsham cites stories from three engineers, called Gary, Keith and Neil. Neil saw his job as fixing machines, not answering customers' questions, and subverted the Traveller system. Keith used the system, and ComCo itself, to further his own goals (setting up his own company). Now listen to the story of Gary [p.68-69]:

"Gary thought that his work had been helped a great deal by the use of the remote Traveller system. ... However, because of the limited memory of Traveller, which restricted the data that could be held on it regarding past jobs, Gary kept his own manual log book with details of work done and other comments that he believed might be useful in the future. Gary thought of himself as closely associated with Comco even though he was not an employee any more. ... In some cases, where agents attacked Comco's policies, he took the side of Comco, and he was keen on recommending ways to improve work practices and reduce costs for Comco. Gary regarded customer relations as a key part of his responsibility as a Comco agent. For example, rather than relying on Comco to supply the right parts for all repairs, he kept his own stock of commonly used spare parts in the boot of his car and at his home."
These snippets ring true as 'everyday' experience. But now listen to Walsham's interpretation of this [p.91]:

"Gary was able to draw on his deep knowledge of plotters to leverage power over Comco who placed high value on his expertise."

There is nothing in the entire story, however, to suggest Gary sought to 'leverage power over Comco'. On the contrary, Gary seems to have exhibited a very different attitude, loyalty to both Comco and customers and self-giving generosity. (If the original sources from which this case study is drawn (a Ph.D. thesis and an internal report) were more nuanced in their discussion, Walsham does not say.)

To make the interpretation Walsham used Foucault's notion of power-knowledge as a 'lens' through which to examine this case. It seems this lens has distorted his view. Use of a lens focuses on certain aspects of the situation being studied, and implies "(It is valid to suppose that) life/reality is like this." The very act of focusing can blind the researcher to other aspects that are just as relevant. This often leads to simplistic explanations [Goldkuhl 2002] and, as here, distortion.

The alternative is research oriented to everyday life, or what philosophers call the lifeworld. The lifeworld attitude in research takes things "as they give themselves to us" [Husserl 1954/1970,p.156]. Husserl proposed a 'principle of principles', that we should let the lifeworld present itself to us, rather than approaching it with a priori theoretical constructs. But what does this mean? It does not mean we can find an 'objective' interpretation; it means we should take a certain attitude in research.

Since Husserl turned a philosophical spotlight on the lifeworld other thinkers have discussed it, sometimes under other names, including 'natural', 'everyday', 'self-evident', 'pre-theoretical' and 'naive' (without negative connotations). The aim of this article is to examine the notion of lifeworld, use this to evaluate examples of IS research, and propose the notion of lifeworld-oriented IS research (LOISR).

2 LIFEWORLD

The lifeworld and everyday life are closely connected, with the lifeworld being the background knowledge that is employed in everyday life. 'Everyday' includes not only home life but also work and even the activity of scientific research, and here designates an attitude rather than a social role. The lifeworld attitude is one that is open to the 'everyday' in whatever role we are playing, in contrast to what may be called the theorizing attitude, which is not.

2.1 How to Approach Understanding Lifeworld and Everyday Life

One way to understand the lifeworld and how to conduct LOISR might be to find an ontology of the things of everyday life. Goldkuhl [2002] offers one:

- Humans
- Human inner worlds (both individualised and intersubjective)
- Human actions (intervention, interpretation, reflection)
- Symbolic objects (signs)
- Artefacts (artificially made material objects and their processes)
- Natural environment (objects and processes).

Not only is this richer than the comparable ontologies of Hartmann [1952] and Bunge [1979], and more geared to everyday life, but it also allows things to exist in several 'realms' simultaneously. For example a business strategy exists as intersubjective inner world, as symbols, and as human actions. Moreover, Goldkuhl suggests that in addition to making such distinctions, scientific conceptualisation also depends on language, understood as Wittgenstinian language games. That is Goldkuhl's theory of how to provide a scientific conceptualisation of everyday life.
Though Goldkuhl's insights are valuable (they are used below), using them as a starting point smuggles a theorizing attitude into study of the lifeworld. It might distort, because it has no grounds for differentiating, for example, fun, justice, love and faith. This is not what is wanted. Instead of beginning with commitment to an ontology, it is preferable to take a lifeworld attitude to understanding both the lifeworld and theoretical thought. The Dutch philosopher, Dooyeweerd [1955/1984], is one thinker who attempted this and pieces of his thought will be employed, along with that of others, to draw together some characteristics of everyday life and lifeworld. (For a systematic introduction to Dooyeweerd see Clouser [2005] or Basden [2008].) These differentiate a lifeworld or everyday attitude from a theorizing one. This is not necessarily a complete picture; pointers are given to further reading.

2.2 Diversity of Everyday Life and Lifeworld

The first thing that strikes us when we take a lifeworld attitude, Dooyeweerd [1955/1984,1,p.3] suggested, is the diversity of aspects or facets of life that we experience, and that these aspects relate to each other. Gadamer also referred to diversity, as a "wealth of modes" [1977,p.191]. Dooyeweerd suggested these include: quantity, space, movement, energy, life, feeling, distinction, formation, expression, sociality, frugality, harmony and beauty, justice, self-giving and faith, but made clear that such lists are every tentative. In the example above, because Walsham focused on formative aspect of power, he was unable to see that of generosity (self-giving). Gary's story exhibits other aspects too, in the records, resources and loyalty, all interwoven with that of generosity.

Each aspect is a sphere of meaning and law, which is irreducibly different from that of other aspects (e.g. self-giving cannot be reduced to formation). It is this irreducibility that gives everyday life its diversity. Yet the aspects are not wholly independent of each other, for example one often needs to form plans when being generous, and in volume II of [1955/1984], Dooyeweerd discussed at length the relationships each aspect has with others. There is a coherence among the aspects that is important when understanding why theory can be problematic, below.

Reflecting on diversity with a lifeworld attitude involves distinguishing the aspects of what is concretely experienced. This makes ontology important. The lifeworld rejects the nominalist theory, prevalent in much IS research, that ontology can be explained away by epistemology, but it does recognise that ontologies are not 'truth'. Unfortunately, the way ontology has been undertaken over the past 2,000 years (e.g. metaphysics, substance concepts, naïve realism, critical realism, systems theory) all impose prior theories about what the world must be like. The lifeworld attitude is not bound by any of these. Things seem to "give themselves to us" in a multi-levelled manner as Goldkuhl [2002] pointed out: consider a sculpture; it is both a piece of marble and a work of art. Schutz and Luckmann [1973] spoke of 'stratification' of the lifeworld. To take account of such stratification while undertaking research, it can be useful to employ a ready-made ontology, and this is where Goldkuhl's [2002] ontology is useful. We might be cautious however, given its origin in theory of scientific conceptualisation. It might be better to employ an ontology whose origin lies more in the lifeworld itself, such as Maslow's [1943] famous set of needs, especially since it includes strata not found in Goldkuhl. But Maslow omitted some found in Goldkuhl.

Sometimes those being studied have their own ontologies. These should not be obliterated by the researcher's prior ontology, nor should they be accepted uncritically. Critical respect for them is needed and one way to achieve this is to use an ontology based on types of meaning rather than types of thing, such as Dooyeweerd's suite of aspects above. Dooyeweerd's suite is not only more comprehensive than others but it emerged from a lifeworld attitude and allows, like Goldkuhl's, for multi-existing. To say something 'exists' in several realms is constituted in it exhibiting several aspects. The sculpture example above is his; it exhibits at least the physical and aesthetic spheres, as he discussed in depth [1955/1984,III,p.110-127].
2.3 Lifeworld as Background

Heidegger [1927/1962] emphasised that the human being is immersed in the world, 'thrown' into it, and that is the lifeworld attitude. In everyday life we "live within" the world, so the knowledge of it that we make use of and rely on as we do so (viz. the lifeworld) must have a background character. "To live is always to live-in-certainty-of-the-world" wrote Husserl [1954/1970,p.142]; in everyday living we place reliance on our lifeworld knowledge. To Husserl, the lifeworld is intuitive knowledge, 'pregiven', taken for granted [1954/1970,p.109]. "By this taken-for-grantedness," say Schutz and Luckmann [1973,p.3-4], who developed his thought, "we designate everything which we experience as unquestionable". It has a 'tacit dimension' [Polanyi, 1967].

In a theoretical attitude, by contrast, we adopt a role of detached observers of the world, distancing ourselves from what is known, questioning what is taken for granted and trying to make aspects explicit. As a result, "The lifeworld ... dissolves ... before our eyes as soon as we try to take it up piece by piece," [Habermas, in Honneth, Knodler-Bunte and Windmann 1981,p.16]. Research involves being an observer and a reflective thinker, but lifeworld-oriented observation and reflection abates the detachment, is sensitive to diversity, and is orientated to action and living rather than pure thinking.

2.4 The Lifeworld, Theory and Critical Stance

What place might theory play in LOISR? Gregor [2006] differentiates five kinds of theory in ISR, used for analysing, explaining, predicting, explaining and predicting, and for design and action. The first, which addresses the question "What is?", is the most basic and is necessary for the development of the other types, because it provides a lens through which they see the world. So LOISR is concerned with the quality of that lens.

If we accept Husserl's 'principle of principles', that we should not come with a priori theory, how can we make use of theory as input to research? Dooyeweerd [1955/1984,III,p.31] argued that "Naive experience may be deepened through ... scientific knowledge, but cannot be destroyed by it." Theory may be brought in at the start of research as long as it deepens without narrowing or causing undue distortion.

The challenge is to minimise such distortion and the 'dissolving' of the lifeworld "as we take it up piece by piece". Using transcendental critique, Dooyeweerd [1955/1984] argued that theoretical thinking necessarily pulls aspects apart, disrupting our view of their mutual interweaving, and Clouser [2005] explains this as high levels of abstraction away from reality, so that we focus exclusively on one aspect and try to ignore its relationship with others. There are two mitigations. One is that the aspects actually remain interwoven even though we do this, so we can always look for inter-aspect relationships, especially those of dependency and analogy [Basden 2008,p.71-72]. The other is what Clouser calls lower abstraction, in which we are aware of the distinctions among aspects (e.g. the beauty vs. the cost of a rose) but do not abstract them away from the types of things that exhibit them. Both Dooyeweerd and Clouser argue that the full operation of theorizing involves not just analytical distinctions and language (as Goldkuhl [2002] claims) but also faith commitments to deep presuppositions about the nature of reality. So theory can never be 'objective'.

2.5 Meaning and Normativity

What is it that is taken for granted? Some of our background knowledge is of relational facts (in Walsham's example, Gary is agent of ComCo). A considerable amount of the lifeworld, however, is meaning (for example, what it is to be an agent) and norms (what we conceive as good and bad, for example that the majority of Gary's day-time activity should be devoted to work for ComCo). Husserl's main concern, a 'crisis' in the European sciences, was loss of meaning and of "norms upon
which man relies" [1954/1970, p.6-7]. Habermas [1987] too acknowledged the lifeworld's meaning and normativity, though his concern was apparent loss of meaning in modern life in general.

Modern thinking has fundamental problems with meaning and normativity because Hume and Kant divorced them from existence (or process), and since that time much Western thinking has presupposed that 'facts' may be studied apart from 'values'. Ethics is relegated to something personal and optional. But the lifeworld knows nothing of the supposed divorce. Husserl sought "truths that are destined to be norms" [1954/1970,p.303], for example "the genuine judge, true honor, true courage and justice" - though it is debated whether he found a way to them. Dooyeweerd, however, might have found a way, because he rejected the Kantian-Humean presuppositions and grounded existence in meaning and law [1955/1984,I,p.4], in the way described above: to be a judge, qua judge, cannot be divorced from the normative notion of justice. However, he sharply differentiated between deep normativity, which transcends us, and norms that are concrete expressions of this, which are usually socially constructed.

2.6 The Social Aspect of the Lifeworld

The lifeworld is shared with others: when "thinking together, valuing, planning, acting together" [Husserl 1954/1970,p.109], we cannot do so successfully unless what is meaningful and normative to one is so to others in largely the same way. The lifeworld has an important social aspect and a strong (though weakly-understood) link with culture and world-view.

This makes language an important issue, as stressed by Goldkubl [2002] and Hirschhein, Klein & Lytytinen [1996]. Shared meanings enable us to understand what the other is saying, and language enables shared meanings and norms to develop. Habermas [1987] argued that this occurs when we critique the truthfulness, sincerity or appropriateness of each others' statements.

There are "highly different lifeworlds in which highly different things pass as unquestioningly self-evident" [Gadamer 1977,p.189] - e.g. those of engineers and judges, right- and left-wingers, adults and children. A person will live in several lifeworlds (a judge may be a left-winger), and some overlap. Some encompass others, e.g. left- and right-wing are mainly within the lifeworld of the Western world-view.

How can there be understanding across different lifeworlds? This question is important in cross-cultural considerations in the Internet age. If all lifeworld meaning is socially constructed via language, it is possible in principle for there to be two lifeworlds that have almost no meaning or normativity in common. As alluded to above, Dooyeweerd [1955/1984] believed socially constructed norms and meanings to be concrete expressions of more fundamental meaning and normativity that transcends humanity. It is this that makes human living possible, including social construction itself, and of which there are distinct yet interrelated spheres or aspects, and which account for multi-existence. These aspects, therefore, are common to all lifeworlds. Dooyeweerd argued that the kernel meanings of aspects can never be grasped by theoretical thought but may be grasped intuitively (e.g. that of justice). If Dooyeweerd is correct, then there might be two sides to the lifeworld: kernel meanings that are intuitively graspable across cultures, and specific meanings that are socially constructed within specific cultures [Basden & Klein 2008]. There are hints of this in Husserl [1954/1970,p.144] when he differentiated "objects ... as substrates of their properties" from "manners of appearance, or manners of givenness".

3 IS RESEARCH AND THE LIFEWORLD

To illustrate these points, how characteristics of the lifeworld have been recognised (or not) in two examples of IS research will now be examined - one that is positivist, which involves quantitative model-testing, and one that is critical, which recognises social structures around IS. Interpretive research, design research and research into frameworks for understanding a field must be left to
another time. It might be expected that a positivist stance would kill any lifeworld orientation and that research from a critical perspective is more lifeworld oriented, but some surprises are in store.

3.1 Research that Involves Quantitative Model Testing

Robert, Dennis & Ahuja [2008] examined the hypothesis that social capital (of three types: structural, relational and cognitive) assists integration of knowledge in a team, which in turn enhances performance of the team, and that this effect is more marked when lean digital environments (LDE) such as synchronous text messaging are used, than in face-to-face communication. They statistically tested this by asking 46 teams of junior-level business school students in the USA to undertake a task both face-to-face and via LDE. The task was to select applicants for university places. Each member of the team was given some information known only to themselves, and the degree to which this was shared and used by others was measured, to achieve a score for knowledge integration. To give teams the chance to build social capital, they had worked together for 6-9 weeks prior to the task and expected to continue working together for another month afterwards. Social capital was measured by questionnaire just before the task. The statistically significant results were: knowledge integration positively relates to team performance, both relational and cognitive capital enhance knowledge integration, and both structural and cognitive capital have more effect on LDE than on face-to-face working. Implications for both research and practice are discussed.

Since this research exhibits a positivist flavour, it is no surprise to find very little lifeworld orientation in the way it is carried out: abstracting certain variables away from the world, reducing social capital to three of its aspects, and relying too heavily on language-mediated information (questionnaires). Abstraction causes problems when the results are used in everyday life, in that a team manager might read them as saying "For good teamwork, the one thing to get right is knowledge integration" and ignore other contributors to team performance, of which there are many. Whereas researchers might have the background knowledge that other relevant constructs were omitted, the team manager might not.

There is just a little lifeworld-orientation in the execution of the research, in that time is given for social capital (not unlike lifeworld) to build up, though this was only a few weeks. Also, the links between social capital and knowledge integration recognise something of lifeworld diversity, in that nine factors are tested. Sadly, all but one of these come from other theory rather than the lifeworld itself, and their operationalisation as questions deemed precise enough to act as metrics robs them of much of their lifeworld meaning. Trust, for example, was reduced to "Given my teammates previous performance I see no reason to doubt their competence and preparation for another team task." Validity of constructs is discussed only in statistical terms and not in terms of their meaningfulness in the domain.

The rest of the paper, however, is more lifeworld oriented. The introduction shows the research to be motivated by a number of lifeworld characteristics, including "larger pools of expertise" (diverse, shared knowledge), "failure to integrate all available information and knowledge" (a concern that presupposes coherence), "knowledge is inherently rooted in ..." (background knowledge). The development of the conceptual apparatus, of what constitutes the three types of social capital, recognises diversity of factors meaningful to teamwork, not only the nine measured but also ones like 'attitude'. (Why were not all measured?) At the end of the paper we find a return to some lifeworld themes, including whether studying students might not be fully representative of real life - though their USA, business school culture is not questioned.

Thus, though the carrying out of the research lacks most lifeworld characteristics, the research itself is situated in the lifeworld. This is not uncommon in better quality positivist research into IS use.
3.2 Critical Social Research

Critical IS research can be more lifeworld-oriented because of its innate normativity. Adam [1998] makes a detailed critical-feminist study of how artificial intelligence (AI) is ‘inscribed’ with masculinity and asks what a ‘feminine’ artificial intelligence would look like. Her approach expresses a number of lifeworld concerns. The ‘masculine’ world view may be characterised as elevating certain aspects of life, especially those of economics, logic and technology. ‘Female’ thinking is more diverse, she says, focusing instead on bodily, sensitive, caring and even aesthetic aspects. ‘Non-Cartesian’ ways of knowing including intuition are emphasised. Adam’s book is normative, in being a call for reinstatement of these lifeworld characteristics in AI and IS research.

However, Adam et al.’s [2006] paper, which portrays critical-feminist approaches to understanding the place of women in the IT industry, is rather different. Against Husserl’s ‘principle of principles’, the authors [p.1], "draw upon the theoretical constructs of the gender and technology literature to theorize the relationship between gender and technical skill and how this impacts conceptions of gender identity.” The conceptual apparatus they employ is constructed from theories: of gender and technology, of power and silence in organisations, of links between masculinity and skill, and that women can take three strategies to working in IT: not to enter, to leave, or to become an ‘it’. The bodily, sensitive, caring, aesthetic aspects in Adam [1998] play little part.

In the data collection, however, much more of a lifeworld attitude is found. The interviews gave respondents freedom to express whatever was meaningful to them; in some, "the flood gates opened". Five of the authors had themselves worked in the IT industry and so could engage with the lifeworld of their respondents. To "let ... respondents speak directly" they quoted their words. Despite the quotations having been heavily selected to support the prior theories, a variety of allusions to background issues come through that are meaningful in the lifeworld.

In the interpretation and discussion this lifeworld orientation evaporates. The intention seems to be to show that the research has satisfied five elements of a theory about what critical research is. While there may a place for that kind of discussion, the research has perhaps missed an opportunity that a full lifeworld approach could offer.

Thus critical IS research might exhibit more or fewer lifeworld characteristics. It is not unusual for critical researchers to situate their research, not in the lifeworld of the researched, but in the debates going on in their own community. This might be why the earlier example drawn from Walsham’s [2001] work likewise exhibits a lifeworld orientation to data collection that is lost in the interpretation stage.

3.3 Comparison

To say that critical research is more lifeworld-oriented than positivist research is oversimplified. A more nuanced picture is revealed here by comparing the patterns of lifeworld and theorizing attitudes displayed by these two examples. In Robert et al. [2008] (positivist) data collection was theorizing but contextualization exhibits lifeworld characteristics, whereas in Adam et al. [2006] (critical) the pattern was reversed, and data collection was sensitive to the lifeworld but its contextualisation exhibits theorizing attitudes. Though the critical stance acknowledges normativity, there can be a danger that it imposes its own a priori norm (emancipation or power) on the situation being researched.

4 LIFEWORLD-ORIENTED INFORMATION SYSTEMS RESEARCH

How, then, can we undertake or recognise lifeworld-oriented information systems research (LOISR)? This paper will venture one definition: ISR is lifeworld-oriented to the extent that all relevant
lifeworlds are respected and taken into account. Two lifeworlds will be briefly considered, those of researcher and researched. (Other lifeworlds, such as of research funding bodies, need separate treatment.)

4.1 The Lifeworld of Researcher

Some lifeworld characteristics will be implemented by following good research practice. Things like courtesy to the researched, not misrepresenting what they tell us, not misusing literature, writing clearly, ensuring good argument, and so on are part of the normativity and meaning of research learned during research apprenticeship. It is the meaningfulness of doing research that makes it fulfilling, the diversity that makes it exciting, and the coherence that enables a project's integrity within the wider research context. All such characteristics of good research relate to the lifeworld of the researcher, though often taken for granted.

Research by its nature involves theorizing. So how can this be integrated with a lifeworld attitude? If Dooyeweerd and Clouser are correct that the human process of theorizing involves abstracting an aspect away from its companions, then some integration is possible. Researchers can bring a theory to the research as long as they remember that while it focuses on one aspect there are others that are important and can impinge on it. Also Clouser's [2005] idea of lower abstraction, in which the aspect is linked with the entity that exhibits it, can ensure appropriate interpretation of research. For example Straub, Limayem & Karahanna-Evaristo [1995] seemed to demonstrate the cross-cultural capability of the Technology Acceptance Model by testing it among Japanese, American and Swiss users - but closer inspection reveals that these were all people of one type, sharing one lifeworld: airline employees.

4.2 The Lifeworld of the Researched

The lifeworld of that which is being researched challenges IS research in a number of ways. It often differs markedly from that of the researcher, so different things are meaningful and normative in each. In LOISR the researcher needs to obtain an immanent, sensitive understanding that does justice to the researched's lifeworld. To do so requires attention to each of the characteristics of the lifeworld, including its diversity, its background nature, its meaning and normativity, and its social aspects.

Diversity of the studied domain challenges IS research in at least two ways. First, it extends beyond what the researcher may be looking for and the stated purpose of the research, so the research must be designed to allow flexible response when unexpected issues or aspects are discovered. Glaser & Strauss' [1967] grounded theory approach was motivated by this. Second, it can extend beyond the known purposes of the researched. In business and government for example overt aims of efficiency, profit or accountability might mix with hidden agendas or pressures. LOISR therefore must be sensitively critical of the researched (this is Klein & Myers' [1999] Principle of Suspicion). IS applications in leisure, social networking and the home exacerbate these challenges.

Walsham's [2001] 'basket of tools' can go some way to meeting both challenges, since each tool might disclose a different aspect - but the whole basket should be used, not just Foucault's notion of power! Another approach is to use an ontology like that offered by Goldkuhl [2002], but there are dangers in this. (1) The ontology might be used to justify the researcher's prior choice of issue rather than stimulating self-criticality and ensuring all categories are given their due. (2) The ontology can be imposed on the researched, whose own ontologies (often informal) are suppressed or explained away.

The author of this paper has found aspectual analysis to be the most useful way of meeting the challenges of diversity. This employs a meaning-based ontology like that of Dooyeweerd, because it more naturally avows unexpected variety. There are many variants [Basden 2008], but at root they all rely on providing a set of ways in which things can be meaningful and good or bad, which are
intuitively grasped by researcher and researched alike and which transcend the purposes of both, so that both are stimulated to consider matters often taken for granted.

That we ‘live within’ the lifeworld means that the context, especially the social and historical context, of the researched must be thoroughly investigated. This is Klein & Myers’ [1999] Principle of Contextualization. It also has implications for design research, having been used by Winograd & Flores [1986] to promote a new approach to IS design that aims at what Polanyi [1967] calls a proximal relationship with the IT tool.

The background nature of the lifeworld challenges LOISR to find ways to explicate the tacit and avoid giving undue priority to the easily-explicit. Because of the limitations of language, the researcher should treat carefully anything mediated by language, including questionnaires, statements of purpose made by the researched, explanations and justifications, discussions, written reports, academic papers and the like. ‘Reading between the lines’ is important in all these, and should be given more priority than it currently is. Knowledge elicitation techniques can be useful because they can probe beneath verbal expressions of knowledge to differentiate understanding (which might be intuitive) from context-dependent knowledge, problem-solving intent and illocutionary intention [Attarwala & Basden 1985, Ngwenyama & Klein 1994, Basden & Klein 2008]. Especially serious is when whole spheres of meaning are overlooked in the interaction between researcher and researched, the spheres of justice, self-giving and faith in particular. Using an ontology based on meaning, such as Dooyeweerd's aspects, as a checklist can help here [Basden 2008], but more sophisticated is Winfield's [2000] multi-aspectual knowledge elicitation (MAKE) technique, which allows the researched to surface aspects in ways that are natural and meaningful to them.

The background nature of the lifeworld also has implications for design research, having been used by Winograd & Flores [1986] to promote a new approach to IS design that aims at what Polanyi [1967] calls a proximal relationship with the IT tool.

The importance of meaning and normativity implies that LOISR will not be content to study entities, structures, processes or causalities, but will give due regard to meaning and normativity. This is recognised in principle by action research, and some insights from it might be useful to LOISR. Critical ISR can be useful because of its normative thrust, but is in danger of imposing its own a priori norm of emancipation or empowerment rather than being sensitive to norms of those being researched.

The social nature of the lifeworld implies not only paying attention to the social relationships pertaining to the researched, but also taking account of the social processes of lifeworld formation, as Robert et al. [2008] above did. It can also affect data modelling, as Hirschheim, Klein & Lyytinen [1996] show. Whereas fact-based approaches assume that relationships between entities is sufficient to model all reality, what they call the rule-based approach recognises that aspects of language and sociality are also important, not just to conceptualise the domain (as Goldkuhl [2002] stresses) but in its very constitution. That language and action cannot be divorced led to the Language Action Perspective, the potential of which for ethnographic analysis is discussed by Klein & Huynh [1999]. This begins to recognise the inter-aspect coherence discussed by Dooyeweerd [1955/1984] and if he is correct we must bring other post-social aspects in too, especially those of faith (loyalty, in Gary's case) and self-giving (generosity).

This brings us back to the original challenge of connecting the lifeworlds of researcher and researched. Klein & Myers [1999] warn that the very data is socially constructed through their interaction. If the two lifeworlds are too similar, this fact can be overlooked, so the researcher should always be questioning their own assumptions. Where the lifeworlds differ another problem emerges, that of multiple interpretations. In both cases, the researcher might let the kernel meanings of the entire range of aspects shed light on the researched area and the researcher's assumptions alike. If their kernel meaning and normativity are intuitively-grasable across lifeworlds, they might offer both critique and mutual understanding, whether the background knowledge of concrete things, norms and meanings is similar or different. This approach has yet to be widely explored, but the author has found it offers a
way by which the researcher can immanently understand the lifeworld of the researched whether he agrees with their concrete norms or not.

5 CONCLUSION

This paper has proposed a new direction for IS research: lifeworld-oriented IS research (LOISR). It has suggested that a theorizing attitude in IS research can be problematic because it narrows the researcher's view and diverts attention away from issues that may be important in the lifeworld of IS use. LOISR takes full account of the lifeworlds of both researched and researcher (and others). To understand this, characteristics of the lifeworld have been discussed, which LOISR should respect: diversity, background character, meaning, normativity and social aspect. Though a number of these characteristics may be detected in extant research methods, they have not previously been put together in the way outlined here.

LOISR does not preclude theorizing, but rather provides a context in which it takes place. If the role of theorizing is to carve out an aspect to deepen our knowledge, theorizing research might be valid when those working in a field are still exploring its inner structure. When a field moves towards maturity then researchers should increasingly recognise the links with all other aspects, and thus move towards LOISR.

The reader might have noticed the number of references to Dooyeweerd. Whereas Husserl introduced the notion of lifeworld, Dooyeweerd is, arguably, the best philosopher of everyday life to date. He was open to issues in a different way because he held presuppositions very different from those that have informed Western thinking for 2,500 years [Basden 2008 ch. II].

An examination of two examples of IS research surprised us: positivist research can exhibit lifeworld characteristics in its contextualisation while critical research can be theorizing. This implies that each stage of ISR needs separate attention, with different benefits arising in each. A lifeworld-oriented (L-O) motivation for the research can widen its appeal, a L-O set of concepts and issues can be easier for readers to understand and trust, a L-O research method yields richer findings, L-O interpretation generates a more faithful picture of the domain, and a L-O discussion makes the conclusions more robust and more widely applicable.

LOISR might also enhance the experience of those engaged in IS research. Respecting the researched's lifeworld with sensitive explication and treatment can make them more favourable towards the research, even when their knowledge is subjected to critique. Researchers are likely to find the activity of research more rewarding and interesting because it is richer and invites fascination. Referring to intuitively-grasped kernel meanings can help researcher and researched understand each other better.

LOISR is a new idea, so it may be too early to know what its drawbacks might be. It could require more effort, especially in handling a wider range of factors and in explication of tacit knowledge. Unless care is taken, research could become characterized by a broad, shallow collecting of an ill-conceived plethora of pieces of information. Attention to the relationships between aspects might help to avert this danger. A number of questions remain, which deserve further consideration. Are all the insights about the lifeworld equally important? Is the above a complete list? Are the insights consistent, given the variety of philosophers from which they have been drawn? Almost certainly there is much yet to be discovered about the lifeworld.

In Richardson & Howcroft [2006] it is suggested that the researcher should not be seen as a mirror, who reflects reality-as-it-is (the positivist, objectivist assumption), but should be seen as a lens or spotlight, which focuses on one part of it, drawing attention to what others might have overlooked (the critical assumption). But perhaps a more apt metaphor for the lifeworld-oriented researcher is a lamp, which makes many types of thing visible. The colour of the light, and what is looked at, are controlled by the researcher, but the lamp nevertheless allows things to present themselves, not only to the
researcher but to all who care to look, including those who live among them. This is the hope of lifeworld-oriented information systems research.

Abstract

Managers spend much of their time communicating and use an ever-larger range of communication tools for the purpose. Empirical studies have shown that while ICT tools extend communication opportunities, they do not replace other means of communication. Instead, managers use a set of communication tools in which traditional media coexist alongside ICT tools.

In addition, studying the use of just one medium fails to give us a full picture of managerial communication. To gain a better understanding, we need to examine how a range of different means of communication are used.

To this end, we conducted a case study in a car manufacturing company with data mainly collected through interviews with 36 managers. Our analysis of the data showed that managers use a set of communication tools that form superposed layers, each new ICT being layered over the existing media.

Far from being the result of individual-level rational use, this layering process is socially constructed by the different users depending on their context. Our study identified three forms of layering, namely “subject to constraint”, “planned and emergent”, or “chosen”. We argue that these differences in the layering process can help explain disparities in the outcomes of ICT adoption between organisations.

Keywords: Napoleon effect, Layering process, electronic mail, case study.

Managers spend a large part of their time communicating, and the range of communication tools they use is growing (Te’eni, 2001). However, they are also short of time and need to manage “time famine” (Perlow, 1999, p.57). As information and communication technology (ICT) applications should enable them to reduce traditional lag time in theory, the use of such tools appears to be a crucial factor for managers’ success. In addition, companies have invested massively in ICT applications in the hope of benefiting from their communication capacities (Watson-Manheim and Bélanger, 2007). Their outcomes, however, differ significantly between organisations.

The growing use of ICT applications raises the question of whether or not they replace traditional means of communication (face-to-face, meetings, telephone, etc.). Several studies have explored the issue from a perspective of both complementarity and substitution (Crawford, 1982; Culnan and Markus, 1987; King and Xia, 1997). The results, however, have been contradictory. In contrast, the co-existence of different means of communication that form superposed piles has been noted (Boukef Charki and Kalika, 2006). There is a layering process through which each new ICT tool is layered over the existing media. Kalika (2002) proposed the concept of the ‘Napoleon effect’ to describe this layering process. In baking terms, a Napoleon (also known as a cream slice or millefeuille) is a cake in which pastry, cream or custard, and fondant icing are stacked in layers. A Napoleon is therefore made...
up of a number of layers of different ingredients. The Napoleon effect refers to the superposition of different layers of media. As all media coexist, each new medium is superimposed over the existing ones and thus form the Napoleon effect.

In this paper, we have attempted to further our understanding of the Napoleon effect by examining the use of e-mail, meetings and telephone. Fast becoming ubiquitous (Rice & Gattiker, 2001; Van den Hooff et al., 2005), electronic mail is used to communicate quickly and instantly without worrying about the availability of the recipient (Straub & Karahanna, 1998). Communicating electronically therefore allows greater time management flexibility and would appear to entail fewer constraints than meetings or phone calls. Studying the use of e-mail in comparison with meetings and phone calls is therefore of interest to both academics and managers.

We begin by discussing our theoretical development and describe our research methodology. We then present and discuss our results. The paper concludes with our contributions and areas for further research.

1 THEORETICAL DEVELOPMENT

Comparing the uses of new ICT media and traditional ones is a fertile research area (Watson-Manheim and Bélanger, 2007). We first point out the shift from studying a single medium choice to the management of a set of communication media. We then discuss how the layering process perspective can bridge the gap between existing theories.

1.1 From a choice of medium to management of a set of communication media

Several theories have been put forward to explain how and when a medium is used. Theories on media use are often either single medium theories or multiple media use theories. Most of these theories focus on a single medium choice (media information richness theory, channel expansion theory); few have looked into multiplicity of media use. These theories have been formulated only recently and are not yet well documented.

1.1.1 Single medium choice theories

Single medium theories focus on why a medium is used. Different theories, among them information richness theory, have attempted to account for the choice of medium. This theory provides a rational choice explanation with respect to the individual’s choice of medium (Daft and Lengel, 1984; 1986). Its conclusions have been called into question by many researchers, however. Initially formulated for traditional communication, its application to ICT applications such as e-mail is controversial. In addition, information richness theory offers little explanation of e-mail use (Van den Hooff, 2005). Indeed, the ability of the medium to overcome temporal and spatial constraints and the individual user’s experience with e-mail are often more influential in the choices made. In addition, e-mail use may be motivated by the need to overcome spatial and temporal constraints without concern for the content of the message and its ambiguity (Dimmick et al., 2000; Van den Hooff et al., 2005). While proximity fosters face-to-face communication (Fiol and O'Connor, 2005), e-mail use is often justified by distance (Rice and Aydin, 1991; Straub and Karahanna, 1998). The choice of medium conveys a symbolic meaning, independent of its objective features.

In an extension of information richness theory, the symbolic interactionist perspective (Trevino et al., 1987; 1990) integrates situational constraints and symbolic considerations. At the same time, channel expansion theory (Carlson and Zmud, 1999) highlights the importance of experience. These extensions have improved our understanding of e-mail use while remaining rational choice theories made at individual level. However, these theories cannot explain the fact that two groups with the same context differ in their use of means of communication (Zack and McKenney, 1995).

Fulk et al. (1990) make the assumption that both sense-making and behavior are subject to social influence. Choice of medium relies on a subjective rationality influenced by colleagues’ behavior,
experience, and group standards. This means that e-mail may be used even if there is no correlation between the communication content and the objective characteristics of the medium. This choice may be considered rational by group norms of communication even though it does not correspond to the effectiveness criteria identified by information richness theory (Fulk, 1993). Markus (1994) shows that social definitions relating to e-mail use can be different from those envisaged by information richness theory. Users conform to social standards in determining the behavior to adopt, which implies that their personal choice is limited.

Thus, single medium choice theories have provided different explanations for the choice of medium. Medium use is explained not only by contingency factors but also by situational factors and social influence. Besides, many studies have demonstrated the complementarity of these factors (Wijayanayake and Higa, 1999; Webster and Trevino, 1995; Trevino et al., 2000; Kraut et al., 1998; Van den Hooff et al., 2005).

Still, users are not confronted with the exclusive choice of just one medium, but rather with managing a set of communication means. In this sense, Dennis et al. (2008) argued that communication performance will be improved when individuals use a variety of media to perform a task rather than a single medium. Moreover, studying the use of a single medium cannot give us full understanding of users’ communication. So, recent research has looked into the use of an array of communication media.

1.1.2 Multiple media use theories

Since managers use a range of communication tools, we focus on multiple media usage (Bélanger and Watson-Manheim, 2006; Massey and Montoya-Weiss, 2006; Watson-Manheim and Bélanger, 2007; Lee et al., 2007). Multiple media use theories focus on the management of an array of communication media to accomplish a specific task. The studies that have investigated multiple media use are summarized below (table 1).

</table>

Table 1. Summary of multiple media use studies

For a specific task, users can either use a single medium at a time or multiple media simultaneously (Massey and Montoya-Weiss, 2006; Bélanger and Watson-Manheim, 2006; Lee et al., 2007), sequentially (Bélanger and Watson-Manheim, 2006; Lee et al., 2007), and repetitively (Bélanger and Watson-Manheim, 2006; Lee et al., 2007). In addition, Bélanger and Watson-Manheim (2006) show
that users can combine different ICTs to send the same message which can be either sequential or concurrent.

Given the overwhelming range of communication media available in the workplace and the possible combinations of media (Lee et al., 2007), one wonders how users manage. Multiple media use enables “message clarity” but also leads to redundancy (Lee et al., 2007). This multiplication of media raises overload issues (Bélanger and Watson-Manheim, 2006), since individuals must cope with the escalation of incoming messages. This processing effort needed to deal with the messages or signals is described as communication load which will lead to information overload (Jones et al., 2004). Information overload occurs when not all communication input can be processed and used (Jones et al., 2004).

Information overload is a managerial issue, as the growing use of ICT tools does not obviate the need for more traditional media. Instead, we observe an accumulation of means of communication that can be likened to the layering typical of a napoleon or millefeuille (Kalika et al. 2007; 2008). In other words, as the number of layers increases, the napoleon becomes too much of a mouthful. We thus need to focus not only on multiple media use but also on the coexistence of different media.

1.2 The layering process perspective

The growing use of ICT applications raises the question of whether or not they replace traditional means of communication. Belanger and Watson-Manheim (2006) point out that substitution does not explain the observed media use. Instead, they note innovative media use combinations. Since media coexist, it is necessary to transcend the complementarity and substitution dichotomy. To do so, we propose the layering process perspective as new lenses to examine media use accumulation.

Table 2 compares the layering process perspective to single medium choice theories and multiple media use.

Table 2. Comparison of the layering process perspective to single medium choice theories and multiple media use

We argue that by exploring the layering process we can improve our understanding of how different media coexist and thus address information overload.

We posit that there is a process by which new media are layered over existing media. Layers of media thus overlap. The added media may or may not modify those already present. We can thus expect to identify different forms of layering depending on how the added layer changes patterns in the usage of
extant media. When the added medium is superimposed on existing layers without being mixed in with them, media accumulation is the result. In other words, as the layering process does not reshape the design of previous layers and does not reduce the existing media use, the napoleon effect is more pronounced, and the resulting concoction becomes, so to speak, harder to swallow. By contrast, when the previous layers are redesigned, the napoleon effect is less pronounced. Since the added layer is mixed in, the napoleon is, as it was, easily ‘eaten’. The array of available media is better managed.

In addition, as managers use a range of communication means, we need to focus on multiple media usage (Massey and Montoya-Weiss, 2006; Watson-Manheim and Bélanger, 2007). Indeed, managers are not confronted with the exclusive choice of just one medium but rather with managing a set of communication means. To improve our understanding of managers’ communication, we focused not only on e-mail use but also on how different media are used.

We demonstrated that the fit between the task and the medium are not the only explanations for the choice of medium. This means that we need to consider situational factors, social influence and the emergent properties of the medium. Moreover, a focus on the use of just one medium is obviously unable to encompass all the complexity of managerial communication. We can improve our understanding by examining how different sets of communication tools are used and we therefore propose the Napoleon effect as a framework for studying media use.

We argue that by exploring the Napoleon effect, we can better understand how managers use different communication media. Their use is explained not only by contingency factors but also by situational factors as well as social influence and the emergent properties of the media. This leads us to expect that the layering process of the new media will vary according to the context, which is characterised by task, organizational environment and the group’s internal system (Desanctis and Poole, 1994). We posit that there is not just one Napoleon effect but several, depending on the context.

Our paper aims to study the Napoleon effect in different contexts. We therefore pose the following research question: how does the Napoleon effect differ between managers in relation to their specific contexts?

2 RESEARCH METHOD

To improve our understanding of the layering process that is intrinsic to the adoption of a new medium in different contexts, we conducted a case study in a French car manufacturing company (Eisenhardt, 1989).

2.1 Research sites

Given that multiple cases facilitate comparisons (Eisenhardt and Graebner, 2007), we conducted a multi-site case study that focused on three departments in the company. According to Miles and Huberman (1994), inter-site analyses allow for enhanced comprehension and clearer explanations of the phenomenon under study, while multiple cases provide grounded empirical findings (Eisenhardt and Graebner, 2007). In addition, the more the number of contexts studied, the greater the validity of the research (Lee, 1989). The importance of case selection was highlighted by Eisenhardt (1989) and we therefore selected three departments which differ with respect to the task carried out and the context of ICT use. While promoting the use of ICT tools is a key concern in the company as a whole, we identified certain differences and characteristic features with respect to each of the three departments studied:

Department 1
Department 1 is a strategic department in the company, dealing with car design and engineering. The work is highly interdependent and requires the involvement of numerous collaborators. A great deal of communication is needed to coordinate both inside and between the different units. In this sense, managers work in an open space and units are co-located.
E-mail is the main ICT tool used by the managers. Disparities were noted between the managers, however, depending on their hierarchical level. Senior managers appeared reluctant to use e-mail and needed the assistance of their secretary to process and print their e-mails.

- "... I followed suit like many of the people here...I was not a pioneer...I had to use it (e-mail) and I used it..."
- "...I can’t always be sitting in front of my computer to read my e-mails, I need my secretary’s help to print them..."

**Department 2**

Two main tasks are carried out in this department, namely the design and sale of parts and accessories. The managers work in an open space.

Department 2 is a pilot department in ICT use.

- "... (name of company) launched a BtoE project and we volunteered to be a pilot department..." (head of department 2).

The e-management project aims to promote new managerial practices through the use of ICT.

- "... we were interested in an experiment which allows us go beyond administrative productivity gains to define new ways of working and new practices." (head of department 2).

The head of the department initiated this project which involves all the local department managers. The e-management project aims to improve coordination mechanisms and define rules to improve e-mail use. Table 1 summarises the characteristics of these objectives.

<table>

<td>The e-management project aims to improve the use of e-mail. Some rules have been adopted to reduce e-mail overload including reducing the mailing list and avoiding the use of CC.</td>
</tr>
</tbody>
</table>

Table 3: Objectives of the e-management project

While the e-management project is not limited to ICT use, it aims to improve coordination through ICT use.

**Department 3**

The managers in this department deal with internal and external corporate communication. E-mail is the main ICT tool used by managers to coordinate the widely dispersed networks so as to manage temporal and geographical constraints.

The characteristics of the three departments studied are summarized at table 4.
2.2 Data collection

Our case study led us to combine several sources of data (Eisenhardt, 1989; Eisenhardt and Graebner, 2007). In addition to interviews, we had access to internal documents and took part in meetings. The meetings were particularly useful in helping us understand the company context as well as that of each department studied. We systematically took notes during the meetings and analysed them later. This mix of methods and sources of data collection enabled us to ensure the internal validity of our research (Miles and Huberman, 1994).

We used diverse data collection methods, but our main sources of analysis were semi-structured interviews (Myers, 1997; Myers and Newman, 2007). We conducted thirty-six in-depth interviews that each lasted one hour on average. Particular emphasis was laid on (1) the work setting, (2) the ICT used to carry out the work, and (3) ICT use vs. traditional media.

2.3 Data analysis

All our interviews, apart from one, were recorded and fully transcribed. We first analysed the media used by each manager, and then in each department. Finally, we compared the differences between the three departments.

Media use analysis
For each manager, we firstly analysed the use of different communication means and then built a media choice matrix.

Intra-case analyses
As recommended by Eisenhardt (1989), we drew up a full description of the characteristics of each department’s context. After analysing the different aspects separately (use and choice), we attempted
to establish links between them. We progressively drew up summaries in which we formulated our
cconclusions in line with our theoretical framework. For each department studied, we built an intra-
department matrix to describe the media use. Our familiarisation with the characteristics of each
department made the inter-department comparison easier (Eisenhardt, 1989).

**Inter-cases analyses**
The inter-department matrix compares the differences and similarities between the three departments
studied as suggested by Eisenhardt (1989). We also highlighted the specificities of each department.
Our conclusions were formulated through successive iterations between theory and our empirical
results. Our interpretations were honed through an analysis of internal documents and the notes taken
during the meetings.
Finally, in order to ensure the plausibility of our findings, our results and our own interpretations were
presented within the company and communicated to the participants.

3 RESULTS

Meetings remain the company’s favourite coordination mechanism, although the number of meetings
is a key issue. Managers frequently complain about meeting overload and its impact on their agenda.

- "... unfortunately, meetings are a disease, a disease of (the name of the company), it’s a well-
  known fact ...".

E-mail is the main ICT tool used by the managers. It extends communication opportunities as it allows
managers to surmount temporal and space constraints.

- "it allows us to dialogue easily with people all over the world whatever the time or the day,
it’s no longer an issue...

Despite its growing use, e-mail has not replaced the need for other communication means. This means
that managers use a set of communication tools in which e-mail is used in addition to meetings and the
telephone but does not supplement them. Rather, it leads to the superposition of different
communication means whereby different media are layered and thus form the Napoleon effect.
Disparities were observed between the three departments in their use of the different communication
means, however. A detailed description of media use in each department is presented below.

3.1 Department 1

E-mail use is tracked through an external memory, which enables the history of the exchanges to be
traced. This is particularly useful with respect to the number of people involved and the strategic tasks
carried out in this department for the company (car design and engineering).

- "... we need to keep track of the information...to keep tabs on the threads...".

E-mail use can reduce face-to-face but not the number of meetings. The managers interviewed often
complained about meeting overload. This problem is accentuated by the impression that many of the
meetings are unjustified.

- "...We spend a lot of time in meetings...I’m sure that 80% of them are unnecessary...

The number of meetings is accounted for by both coordination needs and communication norms.

Indeed, car design and engineering necessitate the involvement of several managers from different
units of this department.

- “...it is a complex product... and it needs the contribution of managers from design,
purchasing, manufacturing, logistics units, etc, ... they all have to work together, and this is
not simple...

Thus, e-mail does not seem to fit the requirements of coordination constraints at this department,
In addition, meetings are privileged coordination means in the department. In this sense, the culture of the company is described as “tribal” encouraging meetings.

- “...a lot of meetings are useless...nothing really happens... no decisions were made...if meetings are more decision-oriented, we will make fewer...”

It turns out that even though meetings are required to insure coordination between different units of the department, the higher number of meetings is an issue in this department. Managers suffer from meetings overload.

E-mail overload is also an issue in this department, so managers have taken to using the telephone instead.

- “to avoid this problem (e-mail overload), we prefer to use the telephone...so that we can have an answer immediately...rather than send an e-mail and increase overload...we place more emphasis on the phone...”

In short, both e-mail overload and the resistance of senior managers to e-mail use are constraints in the use of this medium. More particularly, problems related to e-mail overload reinforce the need for phone calls. Thus, in this case, we do not only observe an accumulation of different layers of media but also an increase of telephone layer. The outcome of this layering process is constrained by the problems of e-mail use and coordination needs in this department. As e-mail layer fails to reshape the existing ones, the Napoleon effect becomes then more pronounced.

3.2 Department 2

While meetings are considered the main means of coordination in the company, managers in this department say there has been an improvement, with less time spent in meetings and a reduction in their number. Meetings have also become more decision-oriented.

- "... it was the nature of the meetings that we wanted to change...”
- “...we ask for a meeting when there is a complex problem which requires that we meet to discuss about the issues”.

This improvement is in line with the aims of the e-management project. However, contrary to the hoped-for outcomes, e-mail is used with colleagues situated in the same open space at the expense of face-to-face. In fact, e-mail is used to communicate with colleagues who are working close by in order to avoid disturbing them.

- "... it’s something that really amazes me, we’re in an open space, and very often you don’t hear any voices, just click, click, click... the noise of fingers on the mouse... it’s obvious that e-mail has replaced face-to-face...”.
- “... we use e-mail heavily everywhere in the company and even in meetings. We use it even more than the telephone. As we are overloaded, we cannot see each other very often, we use e-mail instead...it is rather funny as it conveys closeness...”

Indeed, proximity is perceived as hindering oral communication.

- “moreover, in open space one hears all... if everyone starts to speaking...it quickly becomes cacophony”

We also noted a reduction in phone calls eventhough they are still preferred when there is an emergency and there is a need for interactivity.

In this department then, the use of e-mail has led to improvements in meetings but also a reduction in face-to-face contact. E-mail use in this case reshaped the design of previous layers. Unlike the previous department, the layering process of e-mail layer over the existing ones manages to tighten them. The napoleon effect is then less pronounced than it is the case in department 1.
Although the first outcome of this layering process was planned (meetings are reduced and are better managed), the second (face-to-face reduction) is emergent and even goes against the spirit of the e-management project.

3.3 Department 3

While e-mail is the main ICT tool used by all the department’s managers, we noted that phone calls and face-to-face communication is preferred.

Phone calls are considered to convey greater proximity. They are also often preferred when managers communicate with their international network.

- "... the telephone because it confers a certain degree of proximity and is more friendly..."

This preference for the telephone may be explained by the nature of the tasks carried out, which require greater sensitivity with respect to the relational. In addition, managers prefer face-to-face contact when communicating with co-located workers in the same open space. However, the superposition of the different means of communication has not led to a reduction in the number of meetings, which is considered to be even higher.

- “(meeting) is an issue in the company, there is a mania of meetings...”

In conclusion, it appears that in spite of the growing use of e-mail, phone calls and face-to-face are still preferred. E-mail use does not reshape the design of the existing layers.

We summarize the layering process at each department at table 5.

Table 5. Comparison of the layering process between the studied departments

4 DISCUSSION

Managers use a set of communication tools in which both traditional and new media coexist. Our analysis shows that the use of ICT, in our case e-mail, extends the choices available to managers without completely replacing traditional media. All available media form superposed piles or the so-called Napoleon effect. However, we noted some differences in the layering process between the departments studied. Three forms of the Napoleon effect were identified in this study depending on the context. We first analyse the differences in context and then focus on the characteristics of the different forms of Napoleon effect.
4.1 **Differences in the context of each department**

The differences between the three departments studied depended on the characteristics of the departments’ activities, the communication norms and the context of ICT use (Desanctis and Poole, 1994; Markus and Robey, 1988; Robey and Sahai, 1996).

4.1.1 **Characteristics of the departments’ activities**

The three departments differ mainly with respect to the activities carried out, namely car-design (department 1), sales (department 2) and internal and external communication (department 3). Each department therefore has different coordination needs (Lawrence and Lorsch, 1967) and so differs with respect to its use of communication means. In particular, we noted that the large number of interlocutors and the complexity of the manufactured product led to a high prevalence of meetings in department 1. In parallel, the function of department 3 (communication) leads managers to prefer direct communication and this would explain why e-mail has not replaced the telephone. E-mail use therefore effectively appears to be explained by task-related activities (Yoo and Alavi, 2001). In this sense, Germonprez and Zigurs (2009) emphasized the need to consider the fit between the technology and the task. Put it differently, the fit between media used and the task that department undertake explains how the layering process takes place.

4.1.2 **Communication norms**

Along with Hill et al. (2009) we emphasized the importance of communication norms in explaining media use. Moreover, our analysis of e-mail use enabled us to highlight shared practices and communication norms in each of the three contexts studied. We noted, in particular, that meetings remain a privileged means of coordination in department 1, while e-mail is used when communicating with co-located colleagues in department 2, and there is a preference for direct contact in department 3. E-mail use can reinforce or support the emergence of new practices and communication norms that we identified through our analysis of meetings and direct contacts.

The Meeting layer: hard to be removed

Meetings are formal routines (Dosi et al., 2005) through which information is exchanged at different hierarchical levels. In addition to institutional meetings that are planned throughout the year, meetings can either be programmed or not. The number of meetings is a major issue in the company and all the managers interviewed complained about meeting overload. Improvements have been observed in department 2, however. Meetings are better managed and focus more on decision-making. This is largely due to the e-management project, which aims to improve working methods through ICT use. The involvement of local management in the project has helped achieve this objective. The layering process is not spontaneous in this case but has instead resulted from the management’s determination to change working methods. Along with Kalika et al. (2008), we emphasized the “involvement of management” effect through the case of the department 2. Local management was in this case successful at influencing the layering process.

E-mail use can either or not reshapes meetings layer depending on the case. Nevertheless, in all the cases, it can not remove the need for meetings and the result is an accumulation of media. Indeed, even if e-mail is used for a broad range of tasks (Van den Hooff, 2005), it can not remove the need for face-to-face communications. It turns out that while the objective features of e-mail explain the layering process, it fails to explain differences the way it happens. We demonstrated that when the e-mail layer is added, the layering process over meeting can have several forms. These differences are explained by the specificity of each context.

The direct contact layer: beyond the apparent contradiction

An analysis of the use of e-mail in departments 2 and 3 indicates that proximity may be interpreted differently. Indeed, whereas proximity is regarded as a threat to face-to-face communication and
phone calls in department 2, it facilitates face-to-face in department 3. Differences in interpreting proximity are explained by the shared practices and communication norms specific to each context.
- In department 2, managers use e-mail instead of oral communication (face-to-face and phone calls) to avoid disturbing their interlocutors and co-workers.
- In department 3, managers are more sensitive to relational aspects and thus prefer face-to-face communication and phone calls to e-mail use.

The choice of medium depends on the significance users assign to their behaviour, which would either reinforce or support the emergence of new communication norms (Feldman, 1984; Germonprez and Zigurs, 2009). E-mail use does not modify communication norms in department 3 but it does contribute to the emergence of new norms in department 2. Managers prefer to use e-mail even with co-located colleagues. To put it differently, the layering process of e-mail over direct contacts can either or not reshape the design of previous layers.

4.1.3 Context of ICT use

While ICT use is a key concern in the company, differences can also be identified between the three departments with respect to the context of ICT use.
- The managers in department 1 need their secretaries to help them process their e-mails, making this form of communication more problematic as a substitution for other forms. In addition, senior managers are reluctant to use e-mail and tend to use the telephone to overcome e-mail overload.
- Department 2 is a pilot site in ICT use. The e-management project aims to improve working methods by promoting ICT tools. Local management is also highly involved in this project.
- E-mail is the main ICT tool used by all the managers in department 3.

In other words, differences in ICT context explain the specificity of e-mail use in each department and thus e-mail layering over the existing layers.

4.2 Different forms of layering process

In our study, we identified different forms of the layering process that depended on the context of each department, analysing the characteristics of task-based contexts, communication norms and the context of ICT use. We concluded that previous media layering can provide insight into the way a new medium will be layered over the existing ones. The use of a new medium can either reinforce or reshape old layers. Users make sense of the added layer taking into account the opportunities and the constraints of their context. The layering process is then far from being a result of an individual rationale choice.

At the same time, we demonstrated that local managers can influence the layering process. They act as sense-givers (Maitlis, 2005) and thus may redesign the layering process. However, this may happen in way that is contrary to the e-management project objectives and may even go against the spirit of the media (Desanctis and Poole, 1994). It turns out that while the layering process can be reshaped by local management, it can also be interpreted and negotiated by managers depending on their particular objectives (Lamb and Kling, 2003). This interpretation may be different from what is initially expected by local managers. Users reshape the layering process through their interaction through the media and with each other. Thus, while the layering process is rooted in the context of media use (the fit between media and tasks, communication norms and the context of ICT use), we demonstrated that the layering process results also from the negotiation of the sense making of users and sense giving of local managers.

To summarise, whereas the layering process is reshaped by previous layering of media, it is also planned and emergent. The layering process is hence socially constructed. We can expect to identify a large number of layering processes in line with the sense local managers attach to the new medium and the sense understood by individual users, taking into account the layering patterns of existing media. We highlighted three forms of layering patterns in this study:
- The meeting is the main coordination mode and it is difficult to substitute this by electronic communication because of the constraints of the departments’ activities and traditional communication norms. In addition, both e-mail overload and the reluctance of senior managers to use e-mail can explain its non-substitution for meetings and phone calls. Because of these constraints, the use of e-mail does not appear to change how the previous layers are used, but instead tends to strengthen them. We posit that the layering process of different media is subject to specific constraints, and in this case the Napoleon effect is seen to be subject to constraints.

- E-mail use leads to improvements in meetings which are subsequently better managed. In addition, e-mail is preferred to face-to-face communication and phone calls. While it can lead to new communication opportunities, the use of e-mail with co-located colleagues goes against the spirit of the “e-management” project. In this case, e-mail use changes how previous layers were designed. The process of layering is therefore thought through in that it is planned within the frame of the e-management project but is also emergent. The Napoleon effect thus appears to be both planned and emergent.

- Despite the growing use of e-mail, phone calls and face-to-face communication are preferred. Both the characteristics of the task carried out and the communication norms encourage direct interaction at the expense of electronic exchanges. In this case, e-mail use does not change how previous layers are designed. The Napoleon effect may consequently be said to be chosen.

5 CONCLUSIONS

In spite of the limitations of subjective measurements (managers’ perception), which exclude objective factors such as the variation in the number of meetings and phone calls (Limayem et al., 1997), we identified both theoretical and managerial contributions. The focus on the Napoleon effect enabled us to improve our understanding not only of the choice of medium but also of media use. It provided us with greater insight for understanding how different means of communication are used by studying the layering process that underlies their adoption and use. However, different forms of layering process can be identified, and our study ascertained three forms in particular, i.e. the Napoleon effect may either be subject to constraints, planned and emergent or chosen, depending on the context. We demonstrated that the Napoleon effect depends on both the sense-making of users and the sense-giving of local managers. The layering process is thus interpreted and negotiated by users (Lamb and Kling, 2003), which can either be in line with or go against the spirit of the media (Desanctis and Poole, 1994). The Napoleon effect is the result of a negotiated use of the media, depending on the design of previous layers. This negotiation can either modify or reinforce the existing media layering. Far from being the result of rational use at individual-level, the Napoleon effect is in fact socially constructed by the different users depending on their context. This can explain the disparities between organisations when they adopt a new medium. As we pointed out earlier, the use of a new medium can have different and even contradictory effects depending on the context.

We also demonstrated that the layering process can improve working methods. In this case, it necessitates the involvement of management and a rethinking of the coordination mechanisms. This may provide solutions to companies aiming to improve their use of communication means.

Our study was conducted on a set of communication means that included e-mail, meetings or face-to-face and phone calls. Future studies could examine a more diversified set of communication means. In addition, our focus on the Napoleon effect is static. Further research could examine the Napoleon effect at different points in time. A future line of research could be to analyse how the Napoleon effect would evolve with the introduction of new ICT tools such as mobile technology.

Abstract

Social Networking Sites (SNS) are one of the most popular business models on the Internet at the moment. At the same time, Social Networking is increasingly interesting as a topic of research in Information Systems. Drawing on existing research in the field, in this paper we propose to distinguish ISN (Internet Social Networking) as a phenomenon from its concrete manifestations in the various SNSs in the marketplace. On the basis of this distinction we take to the classification of SNSs grounded in real-life marketplace variety. In doing so, we identify seven different classes of SNSs. We argue that a typology of SNSs is useful for shaping our understanding of the diverse nature of ISN as existing in concrete manifestations. Most importantly, our classification makes accessible existing research for conceptually sound meta-analysis research. In order to fully grasp the phenomenon of ISN we also propose to include in the definition web sites that feature only certain aspects of ISN, while networking is not their core feature. Using our classification we discuss future research directions.

Keywords: Social Networking (e.g. Facebook, second life), Web 2.0, Virtual community, Computer-mediated communication (CMC).
1 INTRODUCTION

Social Networking is not a new phenomenon. But with the rise and widespread diffusion of the Internet and its enabling technologies, the topic has gained significant momentum over the past years. Since the emergence of the first web sites that supported the creating and inter-linking of user profiles in the late 1990s (Boyd & Ellison, 2007) social network sites have mushroomed. Today, Social Network Sites (SNSs) are among the most frequently visited sites on the Internet. In popular traffic statistics, SNSs consistently rank among the top sites just behind the ubiquitous search engines (Alexa.com, 2008). Social network sites such as MySpace (www.myspace.com) or Facebook (www.facebook.com) account for more than one hundred million members (Schonfeld, 2008; Zuckerberg, 2008). Moreover, various new, smaller and more specialised SNSs have emerged over the past few years, further signifying the success of this new business model (Costa, 2008; Green, 2008). Also, a new industry is currently developing around the phenomenon; some providers deliver technologies (like www.elgg.org) or even full services (like www.ning.com) that enable web site providers to integrate their own social network services, which essentially makes possible and drives the emergence of a plethora of new specialised SNSs. Consequently, thousands of SNSs have been created over the last year alone, providing a networking-space for smaller communities, which are for example characterised by geographical proximity or special interests.

At the same time as SNSs have emerged on the Internet, the phenomenon has gained increasing attention from the scientific community. As a consequence, a considerable body of research on SNSs has been created (Boyd & Ellison, 2007). Studies have researched different social network sites (e.g. Choi, 2006; Schaefer, 2008), have focused on different aspects of Social Networking on the Internet (e.g. Ellison & Steinfield & Lampe, 2007) and shaped our understanding of the specifics of SNSs (e.g. Donath & Boyd, 2004; Kreps, 2008), such as impression management (profiling) (e.g. Lampe & Ellison & Steinfield, 2007; Rosen, 2007), privacy issues (e.g. Govani & Pashley, 2005; Gross & Acquisti, 2005) or the proliferation of special interest networks (e.g. Mellins, 2008; Pledger & Howard & Thomas & Reitberger, 2008). However, in doing so, existing research is most often quite focused: studies are either limited on researching a single SNS (most often Facebook) or they concentrate on one or few aspects of Social Networking. Few studies have carried out comparisons across cases. Mostly, these are limited to three (e.g. Ahn & Han & Kwak & Moon & Jeong, 2007; Dwyer & Hiltz & Passerini, 2007) or two cases (e.g. Ahn et al., 2007; Kumar & Novak & Tomkins, 2006). Some studies also compare users with none-users of SNSs (e.g. Hargittai, 2007; Ofcom, 2008).

While a lot of empirical work has been carried out in the field, few efforts have been made to align or integrate existing research findings. Research to date remains rather scattered, not only across various studies, but also across communities. This limits its impact in providing a better understanding of the general phenomenon of Social Networking on the Internet. At this point in time, more research is needed that takes stock of what has been achieved so far and that also tries to elicit general streams of understanding from the existing body of work by comparing the findings of existing research.

Against this backdrop, we argue that we need to develop a more differentiated conceptual understanding of Social Networking on the Internet. More specifically, we propose to distinguish between the phenomenon of Internet Social Networking (ISN) and its concrete manifestations in existing Social Network Sites (SNS). We argue that current definitions do not provide a differentiated enough understanding, which however is necessary to fully grasp the phenomenon and the variety of manifestations in the respective web sites (Beer, 2008). For example, if we want to draw conclusions from comparing the findings of existing studies, we need to understand the variations in the underlying manifestations of the phenomenon as influenced by the concrete SNSs. Today, even though similarities can be found in the findings of studies based on specific SNSs, these results can not be readily compared or generalised (Hargittai, 2007). Essentially, such comparisons are problematic without a good conceptual understanding of the existing diversity in manifestations of ISN across different SNS. For example, we would expect that user behaviour, and thus the proliferation and role
of phenomena such as user profiling, turns out quite differently on SNSs like LinkedIn (a business-related SNS) when compared to Facebook (a SNS with a focus on students).

Henceforth, we propose that we need to derive a conceptual understanding of the existing variation in manifestations of ISN across different types of SNSs. Essentially, by identifying different types of SNSs we are able to take into account the various SNS characteristics in setting up future research studies. Therefore, in this paper we set out to deriving a typology of SNSs as the basis for future meta-analysis type research and for new cross-case empirical studies. In doing so, our main argument is that user behaviour on SNSs can vary greatly depending on the characteristics of the site such as domain (O'Murchu & Breskin & Decker, 2004) or target group focus (compare Friendster example in Boyd, 2006b), the culture of the member community (compare MySpace example in Rosen, 2007 or Friendster example in Boyd, 2006b), or the role of Social Networking Features (SNFs) on the site.

More specifically, if we want to deduce findings regarding ISN as a phenomenon from researching (a set of) specific SNSs, we need to understand the specific characteristics of the latter and their possible impact on user behaviour. In essence, we have to be able to describe and analyse the concrete manifestation of ISN on a specific social networking platform. We argue that, for doing so, we firstly need a set of criteria to suitably describe SNSs and to further distinguish SNSs into different classes in order to branch out future research in an increasingly complex and diverse field.

Our paper proceeds as follows. In section two, we begin by providing a brief discussion of existing definitions of SNS. Based on this we set out to distinguishing ISN from SNSs. Moreover, we give a short overview of existing research in the field. In section three we derive, based on extant literature, a set of criteria for describing SNSs. This is followed by a classification of a set of 60 social network sites on the basis of which we arrive at a typology of SNSs featuring seven distinct types. In section four we discuss the types and derive distinct sets of research questions for each of them, which illustrates not only the value in investigating ISN phenomena across a set of different types of SNSs, but also provides possible directions for future research. We conclude the paper with a short summary.

2 LITERATURE REVIEW

We propose to distinguish between the phenomenon of Internet Social Networking (ISN) and its concrete manifestations in existing Social Networking Sites (SNSs). In the following, we will first define ISN and give examples of observations on this phenomenon and then derive an SNS definition.

2.1 Internet Social Networking

ISN can be understood as the phenomenon of Social Networking on the Internet. Hence, the concept subsumes all activities by Internet users with regard to extending or maintaining their social network. We draw on social network analysis theory for further characterising the concept (Carton & Wellman, 1999). A social network thus is defined as a set of individuals who establish with each other links of some kind, such as acquaintance or friendship (Newman, 2003). As such, the individuals and their activities in the social network are interdependent and the linkages are channels for transfer of immaterial resources (Wasserman & Faust, 1994). Hence, our unit of analysis is not the individual, but the collection of individuals represented in the social network as well as the linkages among them.

Existing ISN research typically investigates phenomena such as the self-presentation of people by way of SNS profiles (e.g. Kreps, 2008; Lampe et al., 2007) or friends lists (e.g. Donath & Boyd, 2004; Rosen, 2007) or phenomena such as social browsing and searching (e.g. Lampe & Ellison & Steinfield, 2006), which describe the ways in which users utilize their networks of friends. Other phenomena, more concerned with the utility of ISN, are the maintenance of weak tie networks (e.g. Paul & Brier, 2001; Schaefer, 2008) or the initiation of new contacts through web sites (e.g. Ellison & Heino & Gibbs, 2006; Thew, 2008). In doing so, research into ISN is typically targeted at observations made in SNSs, as the concrete manifestation of ISN on the Internet.
2.2 Social Network Sites as manifestation of ISN

Boyd and Ellison define Social Network Sites as “web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system. The nature and nomenclature of these connections may vary from site to site” (Boyd & Ellison, 2007). While others have criticised this definition on the grounds that it is too wide and includes all sites that feature social network of any kind (and not just as core features) (Beer, 2008), we agree with the wider interpretation by Boyd and Ellison. Otherwise, research into many sites offering SNFs as non-core features would be left out.

We argue that research on sites where SNFs are not the core features (e.g. Holme & Edling & Liljeros, 2004; Kumar et al., 2006; Maia & Almeida & Almeida, 2008) can contribute significantly to a better understanding of the phenomenon of ISN in general. It should be taken into account that ISN might manifest in a different way on these sites. Examples are the Chinese SNS QQ (www.qq.com), the most popular Korean SNS (Choi, 2006) Cyworld (www.cyworld.com) and the French SkyRock (www.skyrock.com), which have started as Instant Messaging Service (QICQ), discussion forum or Weblog respectively. Hence, research into these sites might contribute to understanding how a social network starts to form and how this is reflected in the concrete usage of the site. One popular example today is YouTube (www.youtube.com), the world’s leading video sharing website. Also, at Youtube the SNFs are mostly focused on the development, presentation and community rating of video content (Maia et al., 2008). Therefore it offers a very specific view on ISN as a phenomenon.

Henceforth, we follow the above definition and regard all websites that implement any features for enabling Social Networking as SNSs. In this definition all sites are included that support/enable Social Networking regardless of whether it is the core/defining or a none-core feature of the site. It is worth mentioning that no consensus exists in the literature with regard to how narrow or wide the term SNS should be defined (e.g. should it include technologies such as weblogs). We argue that our proposed distinction between the phenomenon of ISN and SNSs can help to overcome this problem as it offers the opportunity to classify both core and none-core SNSs. By classifying SNSs using a set of criteria such as domain (O'Murchu et al., 2004), target group focus (Boyd, 2006b), the culture of the member community (compare MySpace example in Rosen, 2007), or the role played by SNFs on the site, the impact different SNSs and their specific characteristics have on the phenomenon of ISN can be investigated more specifically. By spelling out the specifics of different manifestations, i.e. different types of SNSs, research into phenomena such as self_representation, social grooming or social browsing might gain credibility. Comparison studies using cross-case approaches are then able to compare ISN across different types of SNSs.

In the following section we will draw on the existing body of research on SNSs. We will show that research is fragmented and few efforts have been made to align observations made based on different SNSs. In doing so, we will motivate the necessity of a classification of SNSs.

2.3 Fragmented research in an emerging research field

Existing research is most often characterised by a focus on one specific SNS (e.g. Schaefer, 2008). Most studies also concentrate on specific aspects of this SNS, like the self_presentation in profiles (e.g. Lampe et al., 2007; Liu, 2007), the value of friendship_links (e.g. Fono & Raynes_Goldie, 2006; Rosen, 2007), the network_structure (e.g. Holme et al., 2004; Maia et al., 2008), the relation to offline networks (e.g. Choi, 2006; Ellison et al., 2007) or security/privacy issues (e.g. Govani & Pashley, 2005; Gross & Acquisti, 2005). Only some studies research multiple SNSs (e.g. Ahn et al., 2007; Dwyer et al., 2007; Lenhart & Madden, 2007) or take a more general view on the phenomenon of ISN (e.g. Donath & Boyd, 2004; Kreps, 2008).

Even though similarities can be found in the results gained with different SNSs these results cannot be easily generalized (Hargittai, 2007). The existing body of research might entice scholars to mixing the
results gained from the various, often very different, SNSs in order to form a general understanding of ISN, which however is likely to lead to problematic conclusions. The vast majority of SNS studies deal with Facebook. Other SNSs that have been repeatedly researched are MySpace (e.g. Boyd, 2006a; Dwyer et al., 2007), CyWorld (e.g. Choi, 2006), LinkedIn (e.g. Thew, 2008) and Xing (www.xing.com) (e.g. Schaefer, 2008). Only little research exists on other SNSs. Such a concentration on very few SNSs potentially prohibits identification of specific kinds of behaviour that might only exist on certain other SNSs.

Comparing the results of studies on SNSs it becomes obvious that the ISN phenomenon does not manifest in the same way across SNSs, but that significant differences can be observed in site usage. For example, people seem to use business and leisure-related SNSs not only for different reasons, but also in a different ways. On business-related SNSs for example the presentation of oneself can serve as a potential gateway to new employments or business contacts (King, 2006). Therefore, self representation is done very carefully (Schaefer, 2008). This does manifest in the profile description as well as in the choice of contacts (Thew, 2008). The usage of leisure-time SNSs in contrast can be characterised as being much more playful (Sledgianowski & Kulviwat, 2008). Profiles are filled up with information about favourite music, artists or TV-shows, personal heroes and every kind of pictures (Liu, 2007). The choice of contacts is much more unstrained. The search for a romantic partner by users of dating-related SNSs again can result in a different form of self-presentation; users tend to present their “ideal self”. Due to risks of misrepresentation, users also adopt various strategies to proof the credibility of their profile (Ellison et al., 2006). This implies that a comparison of results on the usage of different SNSs needs a conceptual understanding of their differences.

All in all, we face a highly fragmented marketplace of SNSs. Sites are characterised by different focus and functional settings, by an integration in different real world communities, and by a significant variance in user count. This fragmentation, heterogeneity and diversity are not mirrored sufficiently in research yet. Moreover, current research seems to be unaware of this diversity. In contrast, current research seems to treat all SNSs as one of a kind. While existing research has pioneered the field in achieving a first overview of the marketplace and initial understandings of ISN phenomena, we think that now is the time to take stock of the actual variety of SNSs existing in the marketplace in order to take ISN research to the next level. In the next section we carry out a classification of SNS, before we discuss the role of our classification in future research.

3 CLASSIFICATION OF SOCIAL NETWORK SITES

For classifying SNSs we first analysed the current body of research in order to derive criteria for differentiation. Subsequently, we identified SNSs in the marketplace and applied the criteria to them. We were able to derive six criteria for classification and we identified seven different classes of SNSs.

3.1 Criteria for Classification

Based on an extensive literature review, we identified six criteria for classifying SNSs, all of which are briefly described in the following sections.

**Relationship Notion:** One core element of SNSs is displaying the connections that exist between users (Donath & Boyd, 2004). In doing so, the relationships between two users do not have the same label or the same notion across platforms. Popular labels for relationships are for example “friends” or “contacts” (Boyd & Ellison, 2007). But more importantly these relationships can reflect very different understandings of who is a friend or contact online. The meaning of friends online and offline can be both diametric or exactly the same (Boyd, 2006a). Even though the relationship notion might be specific to every single user (Ofcom, 2008; Schaefer, 2008) it is also highly dependent on the SNS. Two major aspects have to be mentioned: (a) the culture on the SNS and (b) the main purpose of the SNS. The emerging culture (a) found on an SNS can shape the understanding of the value of a relationship. On MySpace for example, encouraged by the system functionality, the collection of as
many friends as possible is much more common than on most other SNSs (Rosen, 2007). Differences in the interpretation of ‘relationships’ have also been observed across SNSs with different purposes (b), like business, leisure-time, dating or online-gaming SNSs (Boyd, 2006a; O'Murchu et al., 2004). Relationships can be characterised as business-partners or colleagues on business-related SNSs, or as friends or acquaintances on leisure-time related SNSs. On online gaming-related SNSs relationships are more with ‘playfellows’ than real-life friends. The characteristic of “relationship notion” thereby offers to differentiate between SNSs according to different interpretations of relationships influenced by site purpose and emerging culture.

Purpose of Usage: Whether the intrinsic motivation for SNSs usage is largely hedonistic, altruistic or utility-based, is expressed in the characteristic “purpose of use”. Whereas SNSs like Facebook or MySpace are mostly used for hedonistic purpose (Sledgianowski & Kulviwat, 2008), SNSs concentrating on business matters like LinkedIn or Monster.com have a clear focus on utility (Thew, 2008). They can act as mediators for job assignments or useful business contacts. The usage of SNSs that focus primarily on information exchange or the dissemination of multimedia content is mostly hedonistic in nature. Exceptions are the usage of SNSs concentrating on health issues, being utility based, or of SNSs seeking for social good like TakingItGlobal.org, which is rather altruistic in nature.

Role of SNFs: SNSs can be differentiated by SNFs being the core features, like in the case of Facebook, MySpace or LinkedIn, or none-core features like on YouTube or Flickr (Beer, 2008; Boyd & Ellison, 2007). Sites not implementing SNFs as the core features can use SNFs as added value or as an enabler. Good examples for using SNFs as added value are dating sites whose focus is on the mediation of contacts to potential dates. The building up of a social network among users can provide additional quality information about users as the social network of a person can give insights into that person’s life and personality (Donath & Boyd, 2004). Thereby information on the social network of a person can help identify whether s/he is a possible partner or not. Websites focusing on health issues can use SNFs as an enabler to foster information exchange between professionals and patients (Kamel Boulos & Wheelert, 2007). An example for a professional health network is theijjs.com, an SNS build around the International Journal of Surgery.

Mode of Usage: The way people adopt the functionality of an SNS can vary greatly depending on the context of the site as well as the community represented on it. This can be illustrated by again comparing leisure-time and business-related SNS. In leisure-related SNSs, users act relatively informal and unconcerned regarding their self-presentation (Govani & Pashley, 2005; Liu, 2007; Sledgianowski & Kulviwat, 2008). The messaging functionalities are used intensively and relationship requests are only very rarely denied (Ito & Horst & Bittanti & Boyd & Herr-Stephenson & Lange & Pascoe & Robinson, 2008; Ofcom, 2008). On business-related SNS users seem to care more about self-presentation. The profile needs to be appealing to potential employers or business partners (King, 2006). Messaging functions are only rarely used (Thew, 2008). Usage is concentrated on a favourable self-presentation whereas usage of leisure-related SNSs focuses on interaction with others. Hence, we differentiate between the modes of usage “interaction” and “self-portrayal”.

Target and Domain Focus: The most popular SNSs today count more than one hundred million users (Schonfeld, 2008; Zuckerberg, 2008). SNSs like MySpace or Facebook, limited to a specific audience in the beginning (music/students), opened up to attract more and more users eventually seeking market domination. A large number of users is not only advantageous for the provider, but also for users, who are able to connect to more other users. But this also implies that users can only present one identity to all possible contacts, be it business contacts, parents or co-students. This can have negative effects on the communication taking place within a specific social group on a SNS (Boyd, 2006b). Hence, even though hidden behind the success of the “big players” an increasing number of domain and target group specific SNSs have emerged (Green, 2008). Open source platforms, such as elgg.org, or full service providers, like ning.com allow social groups to easily create their own SNSs. On ning.com alone thousands of SNSs have already been created, concentrating on specific target groups like fire fighters (firefighternation.ning.com) or college students (playboyu.com), or on domains like sports (streeball.com) or gothic living (fairiesvampires.com).
3.2 Classification

Using the above-described criteria we characterized a total of 60 SNSs. Through techniques of grouping and displaying (see Miles & Huberman, 1994), we were able to derive seven main classes/types of SNSs. Figure 1 gives an overview providing four examples for each category.

Public-SNSs do not limit their potential audience by any means. Some started with a focus on domain-topics or target-groups but abandoned these restrictions in favour of further growth. Consequently, the SNSs with the biggest user group (Facebook, MySpace, QQ or CyWorld) can be found in this class. Public-SNSs are core-SNSs that are used for interaction with a hedonistic purpose. The self-presentation is playful (Sledgianowski & Kulviwat, 2008) and the friends online do often match with friends offline (Ellison et al., 2007; Paul & Brier, 2001) even though this differs slightly between the certain sites of this class (Rosen, 2007).

Getting into contact with potential business-partners and looking for employments or employees are the predominant usage patterns on Business-SNSs (Purpose of Use: utility). These SNSs are less used for communication. Characteristic is a very careful design of the self-presentation concerning the profile as well as the contact list (Schaefer, 2008; Thew, 2008). Contacts can be real-world contacts, distant acquaintances or even users not known from the offline world (Thew, 2008). SNFs are usually the core features with the exception of recruiting sites, which use SNFs as additional features. The most popular SNS in this class is LinkedIn.com with more than 30 Million users.

Content-SNS focus on the production, sharing and discussion of content such as pictures (Flickr.com), video (YouTube.com), music (imeem.com) or stories (tokoni.com). The manifestation of ISN on this type of SNS has not been widely researched as yet. SNFs on the sites are mainly used for enriching the discussion on the content (role of SNFs: adding).

Target-SNSs are targeted at certain real-world groups like students (studiVZ), mothers and mothers-to-be (cafemom.com) or people of a certain age (like platinnetz.de: over 50/ or clubpenguin.com: children). With the notable exception of focusing on a specific target group these SNSs are very similar to Public-SNSs. The major Public-SNSs Facebook started as a Target-SNSs focused on students until it was opened to a wider public. However, it is to be expected, that the bounded character of social networks will lead to different behaviour on the SNSs, as users tent to feel less observed in such environments (Boyd, 2006b).

Domain-SNS aim at bringing together people on a specific domain-topic, like sports (ruku.com: rugby), travel (passportstamp.com) or health (patientslikeme.com). Like Target-SNS, Domain-SNS are comparable to Public-SNS. But again the focus on a certain topic domain can influence ISN manifestation on the SNS. For example, Domain-SNS concerned with health issues, where patients can find assistance, will most likely be used in very specific ways. Little research has been conducted on Domain-SNSs so far.

Users of Activity-SNSs usually follow a certain goal, which can be meeting a romantic partner, a playfellow for an online game, or business contacts for setting up a project. Hence, Activity-SNSs are strongly grounded in real life and aim at mediating contacts in a specific domain. The purpose of use can vary depending on the domain like charity (altruistic), business (utility) or online gaming (hedonistic). Many Activity-SNSs are none-core SNSs.

Micro-SNSs can be very different in their character and very closely related to other SNS-classes. The major aspect for differentiation is neither a domain focus nor a specific aim, but their size. Micro-SNSs usually only have a few hundred to a couple of thousand users. They are used to accompany conferences (fowa-miami.crowdvine.com), for supporters of a sports team (spiritoff12.com) or are dedicated to students of a specific university (community.brighton.ac.uk). The development of Micro-SNSs is only possible due to providers delivering the technologies or services (see above).

Figure 1. Classification of Social Network Sites
4 DISCUSSION

We differentiated between ISN as a phenomenon and SNSs as its concrete manifestations, which can take different forms. In order to explore the latter, we classified SNSs and identified seven classes. With this we seek to build ground for more structured research on 1) the phenomenon of ISN and 2) the specifics of certain SNSs and types of SNSs.

4.1 Research on ISN

Until now, our understanding of the phenomenon of ISN is rather limited. This is despite a considerable body of research on SNSs. We face a highly fragmented marketplace with different classes of SNSs. This fragmentation is not reflected in current research. Rather, SNSs are treated as one of a kind. To better understand the phenomenon we need to understand the specific characteristics of a set of SNSs and their possible impact on user behaviour. With our classification we want to provide a framework for integrating current research results in meta-studies. It is also intended as a means to sensitise future research to the, often quite subtle, differences between certain SNS as object of research. Also, when we want to deduce findings on ISN as a phenomenon from researching (a set of) specific SNS we need to understand their specific characteristics, as they are likely to impact on user behaviour and the concrete manifestation of ISN on the platform.

A recent study by the Office of Communication (UK) classified different types of users and non-users (Ofcom, 2008). One example is the “intellectual rejecter” as a non-user who thinks of ISN as “a waste of time”. However, this might not be true for utility-based SNSs. The different types of users characterised could be a starting point for investigating user types in different SNS classes. Also, an analysis of profile data across the different classes promises to reveal different strategies of SNS usage. Henceforth, whenever we want to compare or draw conclusions from existing research, the classification might be useful as a device for judging, validating and interpreting these results, knowing that the type of SNSs, from which the specific findings have been derived, exhibits certain characteristics. Moreover, each type of SNS (as manifestation of ISN) might offer a unique, different, even novel perspective on ISN as a phenomenon.

4.2 Research on SNS classes

The current body of research is mostly concerned with Public-SNSs (cf. the overview in Boyd & Ellison, 2007). Attention is also paid to Business-SNSs (e.g. Schaefer, 2008; Thew, 2008). On the other types, such as Content- (e.g. Maia et al., 2008), Activity- (e.g. Ellison et al., 2006), Target- (e.g. Byrne, 2007) and Domain-SNSs (e.g. Mellins, 2008; Ploderer et al., 2008) only single studies have been conducted. To our knowledge no research has been conducted so far on the relatively new class of Micro-SNSs. In the following, we present some directions for further research on the SNS classes.

Recent traffic statistics on the main Public-SNSs like Facebook and MySpace show, that the number of page views per user is decreasing on these sites (Alexa.com, 2008). This is in contrast to the constant growth in user numbers and reach, which is in line with the platforms’ search for market domination (Schonfeld, 2008). However, it has been argued that the growth of the social network, especially in new user groups, can be a threat to SNSs (cf. Facebook example in Boyd, 2006b). However, it is yet to be seen how the constant growth in user numbers might ultimately change the main Public-SNSs. Research also needs to be conducted on how growth influences user behaviour. Another issue most prominently discussed in the context of major Public-SNS is one of security (recent examples are: Boyd, 2008; Felt & Hooimeijer & Evans & Weimer, 2008; Ybarra & Mitchell, 2008). Users present large amounts of data on themselves without fully comprehending what they are doing (Govani & Pasley, 2005; Gross & Acquisti, 2005). The benefits SNSs provide to their users are very closely interlinked with their potential abuse. Even though a considerable body of research exists on this topic, more research is needed in order to understand how the benefits can be achieved, while minimising the potential risks at the same time.
Users seem to be more careful in their self-presentation on Business-SNSs. This observation should be substantiated by investigating the more concrete differences in the adoption and use of SNFs, for example with regard to the information published in profiles on Business-SNSs in comparison to other SNS classes. Furthermore, Business-SNS claim to improve inter- and intra-company communication in providing contact to potential business-partners. However, this claim still warrants verification.

In Content-SNSs SNFs are provided as additional features and therefore it can be expected that they are used differently compared to core-SNSs. Also the concrete usage patterns are likely to differ depending on the content that is shared on the Content-SNSs. The variety of possibilities for using SNFs as an added functionality and how usage behaviour is affected thereby should also be investigated. Serving a real-world group, Target-SNSs can provide insights on processes of transferring real world contacts online. Especially interesting is a comparison of the behaviour of users on Target-SNSs and other SNSs. Potentially, self-presentation might be less important on such SNSs, when taking into account that the online contacts are often already known from a real world context. Profiles might be more ironic and playful drawing on the knowledge existing from real world contexts.

Until now, only a few findings concerning the adoption of SNFs in Domain-SNSs can be identified. It is unclear whether Domain-SNSs are similar to Target-SNSs or whether site usage is mainly focused on discussing domain matters. It is likely that within the class of Domain-SNSs considerable differences in the adoption might be observable, considering the variety of possible domains (health issues vs. sports discipline). Especially on health related Domain-SNSs the quality of exchanged information and of services should be analysed and threats of misuse should be identified. Addressing a very important part of life, research should search for evidence whether the usage of health-related Domain-SNSs can be helpful or might even be problematic.

Theoretically, Activity-SNSs have a high potential for creating new real-world relationships as users seek to find partners for certain activities. This characteristic of Activity-SNSs can bear significant risks in light of the current security discussion; a recent homicide case was linked to the usage of such an SNS (Ulrich, 2008). Further research might investigate strategies for minimising such risks for the users. With regard to the ISN phenomenon, Activity-SNSs can give insights into different strategies for attracting potential partners. These strategies might in turn influence the design of user profiles, as well as the communication behaviour. While some research exists, in-depth analyses are still missing.

Micro-SNSs have only a relatively small user group. Nevertheless, users take the effort of maintaining an additional profile even for this limited audience. The underlying motives might be subject of future research. However, it is still unclear whether the proliferation of Micro-SNSs is only a short-lived phenomenon. One possibility might be that some survive and grow and others just disappear. A second scenario could be that usage of interfaces (like provided for example by elgg.org) leads to an interconnection of various Micro-SNSs, forming a community comparable to major Public-SNSs, but more diverse in terms of user base.

5 CONCLUSION

We proposed to distinguish Internet Social Networking (ISN) as a phenomenon from its concrete manifestations in the various Social Network Sites (SNSs) in the marketplace, through the implementation of specific Social Networking Features (SNFs). We provided definitions for ISN and SNSs and more importantly proposed a classification of SNSs grounded in real-life marketplace variety. We derived seven SNS-classes: Public-SNSs, Business-SNSs, Content-SNSs, Target-SNSs, Domain-SNSs, Activity-SNSs and Micro-SNSs. Finally, we identified future research directions for both the phenomenon of ISN in general and with regard to the various SNS classes. Most importantly, meta-research seems appropriate in order to align the already existing findings. Consequently, we hope that our paper might indirectly contribute to a better understanding of the ISN phenomenon and that our classification is useful as a sensitising device in comparing research on various SNSs. Our classification should make existing research accessible for conceptually sound meta-analyses. Our characterization of SNSs is based on the current body of literature and an analysis of the marketplace.
While our classification provides a state of the art overview of the SNS market, it is likely to further change and differentiate with the further proliferation of the marketplace. The market of SNSs is still a “moving target”, therefore our classification needs to be revised and updated from time to time.

Abstract

Law enforcement agencies are currently concerned with the increasing availability of virtual child pornography. Virtual child pornography refers to computer-generated images where no real child is involved, but which nevertheless raise important ethical and legal issues. There is an ongoing debate whether the possession of virtual child pornography should be criminalised. As this paper will show the criminalisation of such images is a controversial issue with arguments for and against making it a criminal offence. This paper aims to contribute to the debate by offering a definition of virtual child pornography and considering the legal and policy arguments that are put forward as justifications for the regulation of such material. This paper contributes to the theoretical field of critical information systems research by highlighting how the main interest of critical research, namely emancipation can be furthered or hindered by legal developments. We will explore how the idea of emancipation can be applied in the area of virtual child pornography. Furthermore the paper aims to contribute to the debate of this topical issue and thereby support policy developments on a national and international level.

Keywords: Virtual child pornography, regulation, critical information systems research, emancipation
1 INTRODUCTION

Recently there has been concern in the media that those with a sexual interest in children are ‘acting out’ their fantasies in virtual worlds such as Second Life. For example, in an area within Second Life, called ‘Wonderland’, young “children” were offering sex in a playground. The young children were in this context not real children, but graphical representations and the playground was a virtual playground created with computer software in this technological world. This incident demonstrates one form of virtual child pornography, namely computer-generated images (CGI), which is created wholly through computers and does not involve the abuse of real children but nevertheless raise important legal and ethical issues (Oswell, 2006). The term virtual child pornography refers to CGI drawings, paintings and cartoons portraying sexual representation of children. It should be noted that ‘virtual child pornography’ and ‘pseudo-photographs’, also called ‘morphed images’, are not the same thing. Pseudo-photographs consist of a photograph or a collage of photographs manipulated with digital techniques (Taylor and Quayle, 2003). As Gillespie (2008) points out, the quality of virtual child pornography varies strongly but some of the CGI appear to be of ‘photo-quality’ and can hence appear to be very realistic. It also highlights the importance of placing virtual child pornography in its wider context where technological developments enable easy sophisticated production of this kind of material. In addition to the Second Life incidents concerns are expressed by the law enforcement agencies and welfare organisations about the increasing availability of virtual child pornography, which has given rise to the question whether the possession of this kind of material should be criminalised (Home Office, 2007). Ireland is one of the few countries to have introduced legislation specifically encompassing the production and possession of virtual child pornography (sections 5 and 6, Child Trafficking and Pornography Act 1998) although it has rarely been used in practice. The Swedish legislation regarding child pornography criminalises the production, distribution and possession of ‘virtual’ child pornography through its formulation ‘anybody that depicts a child in a pornographic image’, ‘distribute such image’ or ‘possess such image’1. The UK government recently launched a consultation process suggesting that the law in England and Wales could be altered to criminalise possession of such material (Home Office, 2007). The government highlights in their report that there is no existing evidence suggesting a direct link between possession of this kind of material and the increased risk of sexual offending against children (Home Office, 2007) whereas some researchers (Quayle et al, 2008) have noted that virtual child pornography such as CGI can be used as part of the solicitation process and that the production, distribution and possession of child pornography, whether virtual or not, could be considered an exploitation of children. While most people agree that child pornography should be illegal there are critical voices raised about the criminalisation of virtual child pornography that does not demonstrate a direct link of harm to children (Williams, 2004). One of the main arguments in the debate regarding this issue is whether it is appropriate for the law to regulate peoples fantasies and imaginations through the creation of a ‘thought crime’ (Home Office, 2007) or whether this is a threat to the individual’s privacy and right of freedom of expression. Privacy and freedom of expression, although important civil liberties, have been in the focus of the civil liberties and technology debate for more than a century (Wong, 2005). One can however argue that they should not be considered as absolute rights and that they should be balanced with other rights, and not take the precedence over other rights, such as the right of the child not to be exploited or abused (Eneman, 2005).

The above references to current legislation and consultation processes in different countries show that virtual child pornography is considered an important issue. It seems to be intrinsically linked to the abuse of children, which is one of the most problematic areas of misuse of information and communication technologies (ICT). Virtual child pornography touches on deeply held moral

---

1 The prohibition of such depiction does not include drawings or paintings produced for artistic merit. For further information see the Swedish Code of Statutes, the Penal Code, Chapter 16, Crime against public order, 10 a §.
convictions, where subjective opinion and moral position tend to dominate the debate rather than rational arguments (Taylor and Quayle, 2003; Sandywell, 2006; Luck, 2008). This affects the way we perceive technology and its use in society with such tensions being evident in the desire for technology-related legislation (Gillespie, 2008) which means it is a playing field for social conflicts and negotiations. Even though we know that ICT is used for harmful content such as the dissemination of child pornography (Eneman, 2009; Gillespie, 2008), little academic research exists in relation to the use of ICT to produce and disseminate harmful content. The specific subject in this paper, virtual child pornography, has not previously been researched using a critical lens in the area of information systems or ICT. Adam (2005) emphasizes the importance of adding a critical perspective when discussing crimes against children such as child pornography, to avoid that subjective moral opinions take precedence over rationale arguments in the debate. Finally, it is an important area for critical investigations because it relies on a number of assumptions that are worth exploring and it is related to power relationships that call for a more detailed analysis. This paper addresses therefore the question of virtual child pornography from a critical angle (Stahl, 2008) and aims to contribute to the debate by offering a definition of virtual child pornography and considering the legal and policy arguments that are put forward as justifications for the regulation of such material.

This paper contributes to the theoretical field of critical information systems research (CISR) by highlighting how the main interest of critical research, namely emancipation (Alvesson and Deetz, 2000; Cecez-Kecmanovic, 2005; Stahl, 2008), can be furthered or hindered by legal developments. We will explore how the idea of emancipation can be applied in the area of virtual child pornography. This will entail a discussion of the stakeholders whose interests are touched upon. We will ask what emancipation can mean (Stahl, 2008) in the context of virtual child pornography and how the current legal framework and planned developments thereof are conducive to it. Furthermore the paper aims to contribute to the debate of this topical issue and thereby support policy developments on a national and international level. This paper is based on an analysis of the consultation paper (Home Office, 2007) examining whether England and Wales should criminalise possession of virtual child pornography. In our analysis of this document we have focused upon the arguments used for and against criminalising possession of virtual child pornography. This paper is organised as follows: in the next section the theoretical framework, critical information systems research (CISR), is presented with a focus on the theoretical concept of emancipation. Section three describes the phenomenon virtual child pornography. This is followed by a discussion in section four and then the paper is closed by a conclusion in section five.

2 THEORETICAL FRAMEWORK

An emerging research field within the IS discipline, relevant for this paper, is critical information systems research (CISR) (Howcroft and Trauth, 2005). CISR can be seen as a reaction to the mainstream IS research which tends to assume that technological innovation is ‘inherently desirable’ and beneficial to all (McGrath, 2005). The use of ICT for the creation of virtual child pornography is an illustrative example of how ICT can be used for harmful purposes and raises challenges for society (Gillespie, 2008). CISR is based on ‘critical theory’ (Klein and Huynh, 2004; Croon-Fors, 2006). ‘Critical theory’ is not a unified theory ‘but rather a set of loosely linked principles’ (Klecun, 2005), with a commonality ‘to change the status quo and promote emancipation’ (Alvesson and Deetz, 2000; Stahl, 2008). Critical IS researchers use a wide spectrum of critical social theories (for example Bourdieu, Foucault, Habermas) to critically question established assumptions about the technology, its use and its implications (Cecez-Kecmanovic, 2005, Willecocks, 2006). Engaging in CISR entails the study of the research object with the aid of concepts relevant to critical theory, for example domination, power, control, emancipation etc (Cecez-Kecmanovic, 2005). In addition to using relevant concepts, the research object should be placed in a wider historical, political, social and economic context (Alvesson and Deetz, 2000). By critically questioning ‘social realities’ and providing alternative insights how these ‘realities’ are historically, politically and socially constructed and strongly shaped by asymmetries of power in society, we are able to move beyond established
definitions and assumptions and can achieve emancipation from traditional existing structures (Cecez-Kecmanovic, 2005; Alvesson and Deetz, 2000). The central aim in critical IS research is its deep interest of emancipation (Stahl, 2008; Alvesson and Deetz, 2000). Stahl (2008) highlights however that there are fundamental problems involved with the critical intention to emancipate, for example when the research subjects don’t prefer to be emancipated. The emancipatory perspective in this study refers to emancipation on a societal as well as an individual level.

It is important to note that there are numerous other critical movements that refer to particular areas of research. With regards to our topic of virtual child pornography which is sometimes subject to legislation, it is worth pointing out that an established tradition of critical studies in the area of law exists (cf. Kelman, 1987; Unger, 1986; Mansell et al., 1999). These critical legal studies have a similar interest in emancipation and build on a similar set of theories, but they often emphasise other aspects, which we cannot reflect in full in this paper. Our aim here is not to give a comprehensive review of the critical literature but to show that a critical angle can provide a better understanding of the social consequences of ICT. Using the central concept of emancipation and related critical topics, such as ideology or rationality, we hope to show that seemingly uncontentious issues such as legislation of a morally repugnant act such as the production or possession of visual child pornography are in fact complex and deserve detailed attention. We use some of the thoughts of critical theory and investigate in how far they enlighten our understanding of virtual child pornography and its regulation. Our aim is not to come to a final judgment on whether or not virtual child pornography should be banned but rather to show how critical issues could be framed. The result of this will be a wider understanding of some of the problems associated with ICT use in society, which may influence public perception as much as policy making and further research.

3 WHAT IS VIRTUAL CHILD PORNOGRAPHY?

It is necessary to define what virtual child pornography is. This is not necessarily easy because, to an extent, “child pornography” itself is not readily defined, even within International law. The UN Optional Protocol to the Convention on the Rights of the Child on the Sale of Children, Child Prostitution and Child Pornography has perhaps the widest definition when it talks about any representation “by whatever means” of a sexual representation of a child. This could conceivably include non-visual depictions, for example text or audio files. This would tally with some definitions of child pornography produced by, for example, Interpol (see Gillespie, 2008). Other International instruments are more restrictive and focus on, for example, visual depictions (see, most notably, the Council of Europe Convention on Cybercrime, Council Framework Decision 2004/68/JHA on Combating the Sexual Exploitation of Children and Child Pornography and the Council of Europe Convention on the Protection of Children Against Sexual Exploitation and Sexual Abuse) and most legal systems similarly base themselves on visual depictions. Further problems with the definition of child pornography include the age of a child which has traditionally differed between jurisdictions (usually based on the age at which a child can consent to sexual intercourse). Whilst some international instruments continue to adopt this approach, others (most notably the UN Optional Protocol and Council Framework 2004/68/JHA) reject this approach and suggest that “child” should mean any child under the age of majority (universally set at 18 under the UN Convention on the Rights of the Child). When the Council Framework is fully implemented this will have the effect of standardising the age of a “child” to 18 across the member countries of the European Union (Gillespie, 2008 but see Gillespie, 2004 for a discussion on the propriety of such a change).

Until comparatively recently, visual depictions meant, in essence, photographs but the development of ICT blur the boundary between photographs and other forms of realistic visual depictions. Child Pornography has traditionally been seen as the record of child sexual abuse or exploitation of a real child (Taylor and Quayle, 2003) but advances in ICT meant that the depictions may not necessarily involve a real child or show it being abused. For example, morphed images became increasingly recognised. A morphed image is where a real photograph is digitally altered. This can take a number
forms and may continue to involve the exploitation of a child. For example, the alteration could involve superimposing the face of a child onto an (adult) pornographic picture, or removing the image of a child (for example eating an ice-cream) and superimposing it onto a pornographic picture so as to make it look like the child is participating in a sex act. Such images can still be considered sexually exploitative since although no abuse has necessarily occurred to the child, it remains exploited since a recognisable picture of the child is displayed purporting to show it engaging in sexual activities.

A second form of morphing is to take an adult pornographic image and, using a graphic manipulation package, transform the image into a child. So, for example, the hips of the female could be slimmed, breast size be reduced and pubic hair airbrushed out or thinned. The resulting image would appear to show a child. Again, where it shows a recognisable person this could be said to be exploitative since a person recognising the person portrayed may think (wrongly) that the person posed sexually whilst a child.

Criminalising such exploitative images is perhaps less problematic since they amount to an interference in the personal integrity of the subject shown. However ICT also allows for the creation of purely-fictitious images. Complex and realistic Computer Generated Images (CGI) of children can be produced. Such images differ from morphed images in that a real person is never involved. Whilst it is, of course, conceivable that a real person could be modelled, it is equally likely that a person will simply create a representation of their desired body-type. Accordingly CGI child pornography cannot realistically be considered abusive since there is no ‘real’ child. It is submitted that the lack of exploitation allows for a differentiation to be drawn between morphed and CGI images. Accordingly for the purposes of this paper we will consider “virtual child pornography” to exclude morphed images, and instead to constitute solely those images that are wholly generated by a computer, i.e. a “virtual child”.

The term “virtual child pornography” will be used because although the term “child pornography” has fallen out of favour with many law enforcement and child protection organisations, it remains a term readily used within International law (see the UN Optional Protocol and related European instruments discussed above). It is not necessary for us in this paper to define “pornography” save to state that we are concerned with images that purport to show a “child” involved in sexual activity or an image that focuses on the genitalia of a child (in other words, in effect adopting the definition used by the UN Optional Protocol (Article 2(c)).

3.1 Arguments for and against the criminalisation or legalisation of virtual child pornography

Now that a definition of virtual child pornography has been established it is possible to consider whether virtual child pornography should be criminalised. Most legal systems criminalise the production and dissemination of child pornography and, whilst some have argued to the contrary (see, for example, Ost, 2002), most systems also criminalise the possession of child pornography. Certainly in International law, all four international instruments identified above require member states to criminalise the production, dissemination and possession of child pornography.

The justification for criminalising child pornography is that it is inextricably harmful to children. The production of child pornography requires a child to be abused and those who possess the images are considered to be fueling the demand for the production of new images to be traded (Taylor and Quayle, 2003). Similar arguments exist for morphed images where it can be said that a child or other person will be exploited and that this can cause secondary harm through psychological distress (Palmer, 2005; Gillespie, 2008). However can the same be said to be true of virtual child pornography where there is no real person to be identified or caused either primary or secondary harm?

It is notable that International law differs in its treatment of virtual child pornography. Whilst the UN Optional Protocol undoubtedly includes virtual child pornography through its definition which encompasses the production of visual representations by any means and also expressly includes simulated sex acts, other international instruments are less clear. For example, the Council of Europe
Convention on Cybercrime expressly states that member States can decline to criminalise fictitious child pornography (Article 9.4), something replicated in the Council Framework Decision (Article 3.2(a), (c)) and Convention on Sexual Exploitation on Children (Article 20.3).

Some have argued that virtual child pornography can be harmful especially since it can be used, for example, in the grooming process (Quayle et al, 2006) but the question is whether this justifies the criminalisation of such images or whether it would be better to criminalise the use of such images. For example, if the concern is that such images can be used in the grooming process then surely the better strategy would be to criminalise grooming rather than the images? Certainly this argument is put forward by some who suggest that in the absence of evidence to the contrary, it is difficult to justify the criminalisation of the possession of images just on the basis that they might be misused (Williams, 2004). The counter-argument is that proving grooming is not necessarily easy (Gillespie, 2008) and that tackling the images rather than their use would, at least, allow them to be removed from circulation, thereby potentially preventing their use in grooming.

The tension that exists over the criminalisation of virtual child pornography can be best summarised as the competing interests of free speech and the protection of the individual (children). A difficulty in discussing this issue is identifying the precise meaning of these concepts. The European model of “free speech” is traditionally considered to be encapsulated within Article 10 of the European Convention on Human Rights, the “freedom of expression”. The other competing form is that contained within the United States Constitution, with the First Amendment being considered to be one of the most important constitutional safeguards.

Within Europe there has been no direct challenge to the criminalisation of virtual child pornography although challenges have been brought against various forms of pornography, including child pornography. The standard way of dealing with such matters was set out by the European Court of Human Rights (ECtHR) in Handyside v United Kingdom (1976) 1 EHRR 737 where it was held that a direct nexus of harm did not need to be shown in order to interfere with the right to freedom of expression, and that interference to uphold the morals of society would suffice where it was proportionate (see, also, Müller v Switzerland (1991) 13 EHRR 212). Others have suggested that criminalising the possession of pornography or providing an objective definition for pornography amounts to an interference with Article 8 of the ECHR but the ECtHR has again been relatively robust in rejecting such challenges (see, for example, Wingrove v United Kingdom (1997) 24 EHRR 1 and O’Carroll v United Kingdom (2005) 41 EHRR SE 1).

However the same is not true within North America. Perhaps the most notable case to rule on this matter was Ashcroft v Free Speech Coalition (2002) 122 S.Ct 1389 but the Supreme Court of Canada has also addressed this matter in R v Sharpe [2001] 1 SCR 45. The US Supreme Court held that legislation that purported to criminalise virtual child pornography was unconstitutional since it infringed the First Amendment. The Court held that virtual child pornography did not lead to any harm being caused to a child and rejected the suggestion that such material could encourage sex offenders to abuse children although, it should be noted, that this was in part because the US Government did not adduce cogent evidence to support such a link.

In terms of the law (for these purposes defined universally) it can be seen that there is no agreement as to whether virtual child pornography should be criminalised. In this paper we seek to set out the competing reasons why virtual child pornography should, or should not, be criminalised.

4 DISCUSSION

In this section we will critically analyse the emancipatory effects of the arguments, presented in the previous section, regarding criminalising or legalising virtual child pornography.
One of the arguments brought forward to support the criminalisation of virtual child pornography is that such images are used in the grooming process with real children (Quayle et al, 2006; Home Office, 2007). It is accepted that part of the “grooming” stage of the cycle of abuse (the cycle of abuse is a model that shows how an offender will seek to befriend a child so as to permit acquiescence to sexual acts: see Gillespie, 2008) may be to show children pornography to help “normalise” sexual activity (Taylor and Quayle, 2003). Virtual child pornography could be used to show images that purport to show children being happy to participate in such activity (in a way similar to the way it is known that morphed photographs do). This means that virtual child pornography could be used to harm and abuse real children. The US Supreme Court was, however, unconvinced by such approaches. It is questionable whether this argument justifies the criminalisation of such images or whether it would be better to criminalise the use of such images. Otherwise the criminalisation tends to be created on the basis that they might be misused (Williams, 2004).

Some authors have suggested that it is becoming increasingly difficult for law enforcement to differentiate between real, morphed and virtual child pornography (Edwards, 1995). If this is correct, then it could be argued that one reason for criminalising such material is to ensure that vital investigative time is not wasted in searching for victims that are not, in fact, real. It could also be difficult for successful convictions if the prosecutors have to prove for each image that it depicts a real and not a virtual child. It is suggested that this can create situations where the prosecuted can operate with impunity (Levy, 2002). A counter-argument is that the same sophisticated technology that can be used to create virtual child pornography, could also be used by law enforcement to distinguish between real and virtual child pornography. Another complex and important issue is how to determine the age of a fictional character. The risk of subjective interpretations of the age of a computer-generated representation is problematic.

Interestingly in Ashcroft v Free Speech Coalition the Supreme Court held that they accepted in principle that this could act as a justification for criminalising such material (2002) 122 S.Ct. 1389 at 1406). The Attorney-General had not, in that case, managed to identify a real case where such confusion had occurred but as technology develops it becomes easier to identify cases where such confusion occurs, potentially raising this as a live issue.

There are many things innocent in themselves...such as cartoons, video games and candy, that might be used for immoral purposes, yet we would not expect those to be prohibited because they can be misused. (Ashcroft v Free Speech Coalition (2002) 122 S.Ct. 1389 at 1402 per Kennedy J.)

Some would argue however that there is a difference between morally neutral 'things' such as cartoons and sweets and those that are morally 'doubtful', and that it is easier to justify an interference with the possession of such matters, this would seem to accord with the European model of the treatment of freedom of expression discussed later. However this does highlight the question as to whether the justification for criminalising such matters is based on a freedom of abuse or an interference to uphold the morality of society.

There have been cases where the police have been unable to prosecute because the suspects were only found in possession of drawings and cartoons: no illegal photographs or pseudo-photographs were discovered. As it is currently legal to possess this material (accept from Ireland), the police then have to return it to the person in possession of it regardless of what it portrays. Making it a criminal offence allows the police to take the images away from the offender and out of public circulation.

Moreover, there is increasing concern among child welfare experts and the law enforcement that the problem will increase as technology becomes more sophisticated. There are already indications that
websites featuring animated images depicting child sexual abuse are on the increase. These are often hosted abroad, beyond our jurisdiction. As technology advances a gap in the law is starting to emerge.

4.2 Problematic empirical assumptions about relationship between VCP and abuse

It is also suggested that the possession and circulating of such images can legitimise and reinforce inappropriate perceptions of children, and while being unregulated, allow the development of a sense of social acceptance towards child sexual abuse. In addition, one could argue that virtual child pornography leads to secondary victimisation where victims of child abuse re-live their abuse when they are exposed to such images. There is however still a lack of empirical evidence showing any direct link between the possession of such images and sexual offending against children (Quayle et al, 2006). This means that we need more research about the connection between looking at computer-generated images and committing sexual abuse to be able to use that as argument for criminalising such images. Levy (2002) uses the following argument to support the legalising of virtual child pornography: "there is every reason to think that if virtual child pornography is legal, pornographers will abandon production of actual images of children in favor of it ... why take the risk of a jail term for producing actual pornography when a simulacrum can be produced legally?" One major problem with this argument is that it is not empirically underpinned. This viewpoint is relevant to our argument because it shows that the uncontroversial aim of protecting children from abuse can easily be turned into an argument for the legalisation of virtual child pornography. The problem with this turn of the argument is that it relies on similar empirical assumptions as the opposing argument and that the empirical studies available do not conclusively support one or the other.

A particular difficulty in this area is deciding what the research and studies shows. The Williams Committee concluded that it was not possible to show any link between pornography and sexual violence beyond that which occurs in the making of the images (Williams, 1979). Whilst law enforcement officers, and those who work closely with them, believe that the link between the possession of pornography and further abuse of children is proven (Long, 2002), others believe that the link is more tenuous (Taylor and Quayle, 2003). Within the United States of America and Canada, this absence of a link was considered an important reason for questioning the legal justification for criminalising the possession of such material (R v Sharp [2001] 1 SCR 45 at [28]).

4.3 Emancipation through freedom of fear and moral convergence

While it is difficult to come to an unambiguous conclusion whether criminalising or legalising of virtual child pornography is more conducive to the freedom of children from abuse, a different argument can be made for the criminalising of virtual child pornography from the viewpoint of a shared moral point of view. It is difficult to deny that the vast majority of members of the public in most countries are morally opposed to virtual child pornography. The root of this opposition may be in a desire to protect children, but its expression is independent of such considerations. To put it differently, most people think that child pornography is repulsive, whether or not its production involved the abuse of real children. Criminalising virtual child pornography on this basis can be seen as an attempt to cast into law the moral perceptions that a populations holds. This is arguably one possible goal of legislation, which supports shared moral norms.

A related argument could then be that outlawing virtual child pornography can lead to freedom of fear of the very existence of such material. Parents may fear that their children view such material or that its existence may increase the probability of their children being abused. Other members of society may just find the thought of the existence repulsive and live a better life just because the possibility of its existence is reduced.

Following this type of argument, it is easier to understand why the UK government, for example, thinks that criminalisation of virtual child pornography may be justified by the "inappropriate feelings
towards children" that it may engender (Home Office 2007). The issue is no longer related to children and their protection but to a majority view of what is considered normal and appropriate.

The problems of this approach are easy to see. Moral preferences change over time and are culturally relative. There are numerous examples of sexual moralities (Foucault, 1998) that have changed drastically over time. Homosexuality can serve as an example of sexual practices that were seen as abjectly repulsive by a majority of the population and therefore outlawed. If moral convergence or consensus is the main reason of criminalising virtual child pornography, then one needs to understand that such preferences are subject to change over time and that regulations may change as a consequence.

4.4 Emancipation as expressed in freedom of speech and expression including in VCP

It has been noted that virtual child pornography could be considered an important aspect of freedom of speech. “[p]aedophilia may be a form of expression involving fantasies and imaginings which may be explicitly important to minority sexual groups, the paedophiles.” (Akdeniz, 1997). Certainly such arguments would chime with judicial expressions of freedom of expression:

"[Article 10(1)] is applicable not only to “information” or “ideas” that are favourably received or regarded as inoffensive or as a matter of indifference, but particularly to those that shock, offend or disturb the State or any sector of the population. There is no point guaranteeing this freedom only as long as it is used in accordance with accepted opinion.”

Otto-Preminger Institute v Austria (1995) 19 EHRR 34

It became clear in the case of Ashcroft v. The Free Speech Coalition that the issue of criminalising virtual child pornography is controversial. The court ruled that it would be a ‘thought crime’ to criminalise such images, since it is digitally created images without a real victim and therefore protected by freedom of expression. Freedom of expression therefore goes beyond the right to publish or hold "nice" images or information and should include material that society may object to. That said, freedom of speech and freedom of expression are both considered to be qualified rights but the key question that arises therefore is whether criminalising virtual child pornography can be said to be necessary and proportionate.

4.5 Ideologies and Hidden Agendas

One of the issues that critical research is keenly aware of is the question of ideology and hidden agendas. Ideologies can be defined as one-sided perceptions of certain social realities that benefit some and disadvantage others (Freeden, 2003; Hawkes, 2003; McLellan, 1995). Ideologies are typically removed from critical discourses via a range of different mechanisms. Central among such mechanisms is the use of language in a way that renders it impossible for participants in discourses to question particular assumptions. In the case of virtual child pornography, one could argue that a central term that betrays ideological assumptions is the use of the term virtual child pornography itself. By using the term "child pornography" in conjunction with "virtual", it becomes very difficult to argue that the artefacts and the way they are produced can under any circumstances be acceptable. The strength of the moral argument against child abuse is such that even the attempt to ignore it is doomed to failure. We are thus witnessing a use of language that impregnates itself against questioning. "Virtual child pornography" carries strong moral connotations and thereby forces discourses in a particular direction. This hardening of discourses is an issue that critical research typically aims to expose. The use of language for ideological purposes is not confined to virtual child pornography. In the area of ICT metaphors such as that of a "virus" for self-replicating programs or of "piracy" for the infringement of intellectual property regulations have been noted before (Stahl, 2007).
Luck (2008) highlights that there are ethical and moral aspects involved when discussing virtual child pornography. He argues that even though most people think 'murder' is wrong, 'virtual murder' in computer games is socially accepted since no 'real' person is actually 'murdered' within a computer game. Luck (2008) then applies this argumentation in the context of 'virtual paedophilia' and question if we should view 'virtual paedophilia' in the same way as with virtual murders since no 'real children are actually being abused in virtual child pornography. His conclusion is that there is a 'possible inconsistency in the social acceptance of virtual immoral acts' when comparing 'virtual murder' in computer games and 'virtual paedophilia'. This logic is questionable since Luck does not differentiate between "killing" and "murder", which are distinct concepts with different meanings. Murder is the unlawful killing of an innocent person. Virtual killing is normally premised on the basis that your player is a 'good' person (police, soldier or some other authority person etc) killing the 'bad' person. While Luck's argument may not hold due to conceptual inaccuracies, the question of consistency of treatment of moral and legal issues in virtual environments remains pertinent.

Notwithstanding the validity of Luck's argument, one can observe the use of language with regards to virtual child pornography that suggests that there are hidden agendas. A prime example of this is the UK consultation document (Home Office, 2007). It is clear that its proponents are in favour of outlawing virtual child pornography. The document is clear in that such an approach would be a departure from existing legislation: "A change to the definitions [of child pornography so as to include virtual material] […] would be a significant shift in the thinking behind the existing legislation which was designed to protect real children from abuse" (p. 6). The report states this in the knowledge that its authors are "… unaware of any specific research into whether there is a link between accessing these fantasy images of child sexual abuse and the commission of offences against children,…" (p.1). The purpose is thus to penalise "inappropriate views about children" (p.1).

Despite this clear indication that the proposed legislation is one that aims to reinforce moral convictions, the authors nevertheless imply that it will contribute directly to the protection of children. In their foreword to the report, the authors say that "Technology has advanced to the point that photographs of real children being abused can be manipulated into cartoons or other depictions. Possession of these images is not caught under existing legislation…” (p. i).

What we are observing here is the use of rhetorical devices to achieve an aim. There is nothing fundamentally wrong with rhetoric but in this case it is used to promote legislative aims that would require an ethical and legal underpinning which is possibly at odds with established views. This is a typical instance of interest to critical research because it exemplifies the use of hidden agendas and ideologies for particular purposes. It would thus be an interesting exercise to investigate the history of the consultation document. Who launched it and what did they have to gain by it? This is a complex question that lies beyond the scope of this conceptual paper, but it is a question worth following up.

5 CONCLUSION

The aim of this paper has been to highlight some of the issues and open questions surrounding virtual child pornography. The topic was chosen because it is related to questions of use, misuse, and regulation of ICT. It is an interesting and highly emotional topic that is not often treated in much depth by information systems scholars, even though computer misuse is often seen as a major problem for the organisational use of ICT.

Using a critical lens we have argued that the topic of virtual child pornography requires detailed understanding of technology as well as its social, ethical, and legal context. The theoretical contribution of the paper is to show that critical ideas can help shed a better light on such issues. The central idea of emancipation may help to better understand some of the arguments surrounding questions such as the legalisation or criminalisation of virtual child pornography.

A critical reflection of research is typically seen as a hallmark of critical research. In this spirit, we need to acknowledge that the paper has not covered all possible angles. One aspect we have omitted
was the economic one. Critical research typically aims to cover the social context of its topic and the economic environment is often seen as central for the explanation of social phenomena. It would certainly be plausible in the area of virtual child pornography given the dominance of adult pornography on the internet and its importance as a piloting technology for most e-commerce interactions.

Another possible improvement would be to provide a more fine-grained ethical analysis of the issues. If virtual child pornography is about moral beliefs, then the question of emancipation should cover the issue of ethical justification of such moral beliefs. The US supreme court arguably followed a utilitarian line of argument when it ruled that free speech was more important than the moral downsides of virtual child pornography. However, such a view would need to be analysed in more depth, which should lead to a more in-depth understanding of the meaning and realisation of virtual child pornography. Furthermore, there are empirical questions about the relationship between consumption of virtual child pornography and abuse of children. A critical piece of research would need to investigate in more depth how such relationships can be established and in what way empirical results can be used as a basis of legislation.

Despite these limitations, we nevertheless believe that this paper makes a substantial contribution to the debate surrounding virtual child pornography while, at the same time, having shown the relevance of critical research when applied to ICT.

Abstract

Using bibliographic data extracted from an Endnote database, social network analysis techniques were used to generate and analyse a network of co-authors with the aim of developing an understanding of the research community that produces the research knowledge published by the Australasian Conference on Information Systems (ACIS). The ACIS community was found to be a healthy small-world community that kept evolving in order to provide an environment that supports collaboration and sharing of ideas between researchers. It was also found that, unlike a similar analysis of the European Conference (ECIS), the Australasian scene was not dominated by a couple of key researchers as quite a significant number of popular researchers were identified.

Keywords: social network analysis, Information Systems discipline, co-authorship, collaboration
1 INTRODUCTION

Interaction between researchers is well known to be the essence of research practice. Researchers interact not only to communicate research activities but also to collaborate with each other to co-produce research and co-author research results (Melin & Persson 1996). Since collaboration has the potential to promote research activity, productivity and impact, it should be encouraged, supported and monitored. Although it has been argued that co-authorship is no more than a partial indicator of collaboration, Laudel (2002) found that a major part of collaboration is not acknowledged as co-authors. Several studies (for instance, Patel 1973) have shown that there is a positive correlation between collaboration and co-authorship. In fact, co-authorship is one of the most tangible and documented forms of research collaboration (Glänzel & Schubert 2004).

A co-authorship network is a social network consisting of a collection of researchers each of whom is connected to one or more other researchers if they have co-authored one or more papers. This is based on the reasonable assumption that researchers who co-author a paper are acquainted with each other, although there are many researchers who know each other quite well but have never written a paper together. Such a network can be represented as a set of nodes (or vertices) denoting co-authors joined by edges (or links) denoting research acquaintance.

Social Network Analysis (SNA) is a sociological approach for analysing patterns of relationships and interactions between social actors in order to discover underlying social structure such as: central nodes that act as hubs, leaders or gatekeepers; highly connected groups; and patterns of interactions between groups (Wasserman & Faust 1994). SNA has been used to study social interaction in a wide range of domains. Examples include: collaboration networks (Newman 2001a), directors of companies (Davis & Greve 1997; Davis, Yoo & Baker 2003), organisational behaviour (Borgatti & Foster 2003), inter-organisational relations (Stuart 1998), computer-mediated communications (Garton, Haythornthwaite & Wellman 1999), and many others.

In this study, we propose to use SNA to study the community of researchers who publish their papers in the Australasian Conference of Information Systems (ACIS) in order to reveal interesting patterns and features within this academic community. With the help of SNA, we hope to develop an understanding of the research community that produces the research knowledge published by ACIS by answering the following: Is the network a random structure or does it display recognisable properties? Is the community highly clustered around a few high profile researchers or is influence spread among a number of researchers? Who are the influential members of this community? What are the weaknesses or strengths of this network?

Clarke (2008) has recently completed a retrospective review of the Information Systems discipline in Australia based on new research and revisiting the work of Culnan (1986; 1987), Land (1992), Barki et al. (1993), Avgerou (1999), Pervan and Cecez-Kecmanovic (2001), Galliers and Whitley (2002) and Banker and Kauffman (2004). He notes that IS emerged as a discipline in the 1960s in Australia, formally from the old Caulfield Institute of Technology (now embedded within Monash University) and has grown now to a community of some 700 with explosive development from the 1970s onwards. Clarke notes further that “the emergence of the IS discipline was in historical terms brisk, but to an observer at the time would have appeared laboured and wayward”. However, by the end of the 1980s all but the two oldest universities (Melbourne and Sydney) had specialist organisational units in IS. What is clear from this research and others reported in a newly edited book by Gable et al. (2008) on the Information Systems discipline in Australia is that the discipline and its associated conference (ACIS) has grown significantly reaching its peak after 2000 and which subsequently has generally shown a decline in research output, student graduates and student demand, albeit at a time of skills shortages in IT in Australia generally. The ACIS conference emerged in 1990 as a response to the growth in research activity in Australian universities.
2 RELATED WORK

The idea of studying research collaboration patterns using bibliographic data is not new as there is a substantial body of literature in Information Science dealing with co-authorship patterns (Crane 1972; Persson & Beckmann 1995; van Raan 1990). Using co-authorship networks to study collaboration patterns between researchers is also not a new idea since with the availability of large bibliographic databases, it is relatively easy to construct large social networks with high reliability. These networks are true social networks, in the sense that it is very likely that two authors who write a paper together are acquainted with each other (Newman & Park 2003).

Scientific collaboration networks were studied for three disciplines, namely: physics, biomedical research and computer science using bibliographic data from four databases for the period 1995-1999 (Newman 2001b). In all three networks, a giant component of researchers was found to exist in which there is only a short path of intermediate acquaintances between any two researchers, hence all networks studied displayed the “small world” property. Some differences found between the disciplines studied were: (1) on average, researchers from experimental disciplines have larger number of collaborators than those from theoretical disciplines (largest average number of collaborators found in high-energy physics), and (2) the degree of network clustering is much lower in biomedicine than in the other disciplines (indicating less social organization in biomedicine). A similar study was performed for the disciplines of mathematics and neuro-science using bibliographic records from an electronic database for the eight-year period from 1991 to 1998 (Barabási et al. 2002).

Research collaboration within the Information Systems discipline has also been studied as social network analysis has been performed for both the International Conference on Information Systems (ICIS) (Xu & Chau 2006) and the European Conference on Information Systems (ECIS) (Vidgen, Henneberg & Naudé 2007). Social network analysis of ICIS was conducted using bibliographic data for the period 1980 to 2005 available from the Association of Information Systems to study the social identity of the discipline (Xu & Chau 2006). Among other things, results showed that: (1) the community of international IS researchers is well connected and they frequently interact with each other, (2) there exists a giant component of well-connected and most productive authors, and (3) the network has evolved healthily over time with the addition of new members and the improved connection among members.

The ECIS analysis was performed using bibliographic data from an Endnote database available from the London School of Economics for the period 1993 to 2005 (Vidgen, Henneberg & Naudé 2007). Research contributions were separated into research papers and panels and two networks were generated and analysed. While the panel network displayed small world properties, unlike other collaboration networks, the co-authorship network displayed only a few “small world” properties and hence a lesser sense of social cohesion than would be expected. Although social network analysis of the Information System discipline has been performed at the international and European levels, to the best of our knowledge, it has not been attempted for the Australasian scene yet, other than a study of frequency of publication locations by Australian authors in IS by Sellitto (2007), hence the motivation for the present work.

3 METHODOLOGY

Social network analysis (SNA) has emerged as a key technique in the social and behavioural sciences as well as in other major disciplines (Wasserman & Faust 1994). The main focus of SNA is on the relationships among social entities (e.g. communications among members of a group) and it makes use of a variety of statistical and visual analyses to achieve this. Although, social networks were initially studied in the social sciences, such studies were restricted to rather small systems viewing these networks as static graphs consisting of nodes representing individuals and links representing various quantifiable social interactions. In contrast, recent approaches rooted in statistical physics focus more
on large networks searching for universalities both in the topology of the network and in the dynamics
governing its evolution (Barabási et al. 2002).

Recently, SNA has been increasingly used as a structured way to analyse the extent of informal
relationships (among people, teams, departments, or even organisations) within various formally
defined groups (Cross et al. 2001). SNA makes visible these otherwise invisible patterns of
interaction, to identify important groups in order to facilitate effective collaboration (Cross, Borgatti &
Parker 2003). Thus, SNA helps to identify and assess the health of strategically important networks in
an organisation. In the context of this study, we are using SNA to gain an understanding of the nodes
(co-authors) and relationships (those who wrote a paper together) in the co-authorship network.
Clearly, there are many different metrics that can be used to assess such networks. At an aggregate
level, we will analyse the network as a whole in order to identify important major groups or
components within the community of researchers, and for the giant or core component we will use
measures that can give an indication of the productivity of the network (i.e. density of the network),
speed of communication within the network (diameter of the network), etc. At a lower level, we will
analyse the nodes of the network using several measures of centrality to find out who the most popular
and influential researchers are within the ACIS community.

4 DATA COLLECTION AND PROCESSING

The bibliometric data used in this study is based on bibliographic data extracted from an Endnote
database available from the ISWorld Net Research and Scholarship page\(^1\) of the Association for
Information Systems. The Endnote database contained all research papers published by ACIS from
1990 to 2006.

The contents of the Endnote database were exported in XML format in order to facilitate further
processing. Since we are only interested in co-authored publications, all papers written by single
authors were ignored. This was achieved by writing a small Java program to extract a list of co-authors
on a paper-by-paper basis. Another custom-written Java program was then used to convert this list of
authors into a network file to the DL format which is readable by UCINet (Borgatti, Everett &
Freeman 2002), the software used for most of the social network analysis in this study. Apart from
generating the DL file, the Java utility was programmed to output a list of authors sorted in
alphabetical order which was visually inspected to discover typographical errors (e.g. Peta Dark
instead of Peta Darke) and inconsistencies in authors’ names, especially those with middle initials who
used them part of the time (e.g. Brian Corbitt instead of Brian J. Corbitt) and those with aliases (e.g.
Kit Dampney instead of C. N. G. (Kit) Dampney). A more subtle typographical error was the use of a
left apostrophe instead of a right apostrophe (e.g. Paul O’Brien instead of Paul O’Brien) in the Endnote
database. Data cleaning was a highly iterative activity and consumed a large part of the data
processing activities. Once the co-authorship data was in UCINet’s DL format, various statistical
analyses were performed using UCINet at network and co-author levels and the results of these
analyses are reported and discussed in the following sections. Visualisation of the co-authorship
network (or parts of the network) was performed using Pajek (Batagelj & Mrvar 1998), another
popular SNA software.

5 NETWORK ANALYSIS

Recent analysis by Gable (2008) shows that at the ACIS conference ten universities (Monash,
Melbourne, Edith Cowan, Curtin, Deakin, QUT, Wollongong, UNSW, Tasmania and Victoria) have
contributed the vast majority of papers. This paper reports on the broader perspective of the people
involved as a number of key people have moved from one university to another as universities try to
shore up quality and buy expertise to strengthen or develop existing or new departments. Table 1

\(^1\) http://home.aisnet.org/displaycommon.cfm?an=1&subarticlenbr=395

Proceedings ECIS 2009
shows the evolution of the ACIS community during the period 1990 to 2006. The cumulative number of papers presented at the conference grew from 15 in 1990 to 1333 in 2006 while the cumulative number of co-authored papers grew from nine to 820 during that time frame. As of 2006, the percentage of co-authored papers represents 69% of the total number of papers.

The size of a social network is denoted by the number of actors or nodes (co-authors in this case) and it gives an indication of the likelihood of interaction between nodes; the bigger the network, the greater the likelihood of interaction between co-authors. However, the bigger the network, the more difficult it becomes for everyone to be connected with each other and when the network is not fully connected, it contains a number of sub-networks (called components) for which there are no paths between nodes from one sub-network to another sub-network. The number of co-authors in the ACIS network grew from 19 in 1990 to 1256 in 2006 while the number of co-authors in the main component (the largest sub-network in which there is a path from a co-author to any other co-author) grew from three in 1990 to 587 in 2006. As of 2006, the percentage of co-authors in the main component represents 46% of the total number of co-authors. It should be noted that the main component is not a fully-connected network (i.e., everyone is not connected to everyone). The degree of connectedness of a network (or sub-network) is given by the density measure, which is the percentage of the number of actual connections over the total number of possible connections. The density of the main component dropped from 33.33% in 1990 to 0.24% in 2006.

Another interesting feature of a network is an indication of the amount of time for a communication to pass through the network. A commonly-used measure is the diameter of the network; the shorter the diameter, the faster the diffusion of communications. The diameter of a network is measured by the longest geodesic distance in the network with the geodesic distance being the shortest path (in terms of number of links or connections) between any two nodes. So far, the diameter of the network has grown to 9, slightly more than what would be expected from a “small-world” network. One of the main characteristics of a small-world is the so-called “Six Degrees of Separation” phenomenon in which it is claimed that everybody on the planet is separated by only six other people (Milgram 1967; Watts 1999).

The structure of the ACIS network of co-authors displays small world properties because co-authors are well-connected, and are close to each other. Hence, information and knowledge can be transferred effectively in the network, although in practice the flow of information might be different from the established formal network structure, and is thus acknowledged as a limitation of the study (Cross, Borgatti & Parker 2002).

</table>
In order to give an idea of the evolution of the ACIS co-authorship in time, cumulative networks were drawn from 1990 to 2005 and assembled in Figure 1. Since the main component was rather small in the early years (1990-1994), the first four pictures show the complete network (with the main component in the middle of the network) while the rest of the pictures (1995-2005) show only the main component. It can be seen that the main component started to become significant around the year 2000.

![Figure 1: ACIS Network evolution (1990-2005)](image)

The state of the ACIS network in 2006 (most current at the time of writing) represented using its main component is shown in Figure 2. We chose to represent the co-authorship network as a directed network i.e. directed links from the main author to his/her co-authors. The thickness of the links gives an indication of the number of co-authored papers between a main author and the particular co-author. Although the network shows the high popularity of certain individuals (e.g. Graeme Shanks), it also shows that the scene is not dominated by a few individuals as there is quite a range of well-connected individuals. A more detailed analysis of popular individuals follows in the next section.

6 EGO ANALYSIS

After having analysed the characteristics of the ACIS network as an entity, we now analyse it in terms of the individual actors or “egos” that make up the nodes of the network. More specifically, co-authors are analysed in terms of their centrality in the ACIS network. The idea of centrality of individuals was one of the earliest used by social network analysts and the origins of this idea can be found in the sociometric concept of the star i.e. the most popular person or the person at the centre of attention (Scott 2007). Thus, a central actor is one at the centre of a number of connections i.e. an actor with a large number of direct links with other actors.
Centrality is measured by the degree of the various nodes in the network, with degree representing the number of other nodes to which a node is adjacent. This measure of centrality is known as local centrality since indirect connections to the particular node are ignored. Thus, the notion of centrality has been extended to global centrality (Freeman 1979) to include the distant connections of the nodes. This is measured by the closeness of the nodes to other nodes expressed in terms of the distances among the various nodes. Betweenness (Freeman 1979) is another centrality measure which measures the extent to which a particular node lies between the various other nodes of the network. A node of relatively low degree may play an important intermediary role (e.g. broker, gatekeeper, etc) and hence be a central node in the network. Eigenvector (Bonacich 1972) is another measure of centrality proposed based on the belief that the centrality of a particular node cannot be assessed in isolation from the centrality of all the other nodes to which it is connected. Centrality scores are assigned to nodes based on the principle that connections to high-score nodes contribute more to the score of the particular node than connections to low-score nodes.

The term structural hole was coined by Burt (1992) to refer to some important aspects of positional advantage (or disadvantage) of actors in a network. He developed a number of measures to explain how and why the ways actors are connected affect their constraints and opportunities and hence their behaviour. Table 2 shows the top 30 actors ranked on the centrality measures previously discussed, namely: (1) degree, (2) betweenness, (3) closeness, (4) eigenvector, (5) and structural holes.

Since we chose to represent our co-authorship network as a directed network (because the author selected the co-author for writing the paper), a centrality degree analysis yielded two scores: out degree (number of connections sent out i.e. as main author) and in degree (number of connections received i.e. as co-author). The first part of Table 2 shows the ranking of the top 30 individuals on the out degree score while the second part of the table ranks individuals by the in degree score. The top
scorers in terms of out degree (main author) are: Michael Rosemann closely followed by Graeme Shanks, Jennie Carroll, Dubravka Cecez-Kecmanovic and Julie Fisher. The individuals with high out degree scores can be thought of as having high influence in the network while those with high in degree scores as prestigious or popular individuals. The most prestigious individual is Graeme Shanks followed by Michael Rosemann.

In regards to betweenness centrality, the top individuals are: Graeme Shanks followed by Jennie Carroll. Thus, Shanks and Carroll can be viewed as leaders in the ACIS network since being on the shortest paths between other individuals they are able to control the flow of information in the network. The leading individuals in terms of closeness centrality are: Graeme Shanks closely followed by David Arnott, Jennie Carroll, Julie Fisher, Linda Dawson and Peter O'Donnell. Since closeness centrality measures the distance of an individual to all others in the network, the closer an individual is to others, the more favoured that individual is. Individuals with high closeness scores are likely to receive information more quickly than others as there are fewer intermediaries between them. Graeme Shanks is by far the leading individual when the eigenvector centrality criterion is used. This means that he is connected to many other individuals who are well connected and thus is most likely to receive new ideas.

Structural holes was measured in terms of Effective size of the network i.e. the number of connections an individual has, minus the average number of connections that each individual has to other individuals. Graeme Shanks followed by Michael Rosemann again led on this criterion suggesting that they have more opportunities to act as brokers or coordinators. From the ego analysis, it can be seen that, unlike the ECIS community, influence in ACIS is not limited to a few individuals (Vidgen, Henneberg & Naudé 2007).

7 VISUAL ANALYSIS

The top-ranking 30 actors for each centrality criteria mentioned in Table 2 were merged and an ego network (sub-network) made up of only these actors and their collaborators extracted from the main component sub-network in an attempt to visually identify any leading individuals. The resulting network is shown in Figure 3. From Figure 3, it can be seen that Graeme Shanks and Michael Rosemann are significant individuals. It can also be seen that there are other popular individuals, such as (limited to a few names in alphabetical order as the list can be quite long): Jennie Carroll, Dubravka Cecez-Kecmanovic, Brian Corbitt, Julie Fisher, Guy Gable, Michael Lane, Graham Pervan, Peter Seddon, Craig Standing, Paul Swatman, and Paula Swatman. Figure 3 further reinforces the previous finding (from the ego analysis) that there are quite a number of key researchers in the ACIS community. Another possible limitation of the study is that the cumulative approach used to include authors in the network does not remove authors who for some reason or another are no longer present. However, in the current study this was not the case as the main actors identified are known to be still active.

8 DISCUSSION

The key findings of this study of the community of ACIS researchers are: (1) the total number of papers presented at the conference has been constantly growing since the establishment of the conference, (2) currently the percentage of co-authored papers represents 69% of the total number of papers, (3) the network contains a significantly large main component which includes 47% (587 individuals) of the total number of co-authors, (4) the main component exhibits small-world characteristics (nodes that are well-connected and close to each other), (5) although Graeme Shanks and Michael Rosemann seem to be very popular individuals, they are closely followed by a number of other popular individuals.

The positive evolution of the main component of the ACIS network coupled with the presence of a number of key individuals (rather than a few) are evidence of the healthy status of the ACIS
community. They are proof of the ability of the community to attract new members over the years and to produce new generations of popular researchers. It is worth noting that although popular researchers play an important role in the ACIS network, other researchers are also important as without them is no ACIS community.

Figure 3: Main actors sub-network

The existence of a number of key researchers in the ACIS community provides several advantages. Firstly, it ensures the diversity of research within the community as a large number of popular researchers would decrease the likelihood of performing similar research. Secondly, the ACIS community is resilient since removing a few key persons from the community (e.g. retirement, etc) will not cause it to fall apart as other key persons will ensure its continued existence. Thirdly, succession planning is a smooth and effective process as the large number of current generation popular researchers train their doctoral students and junior collaborators to form a large pool of researchers from which new popular researchers will emerge to lead the community in the future.

The structural properties of the ACIS network also indicates the existence of some potential problems with the community. Since the diameter of the network is slightly wider than desirable (nine instead of six), it is possible that information might not travel quickly enough for effective collaboration. However, the diameter of the ACIS network is still better than the diameter of 31 for the ECIS network (Vidgen, Henneberg & Naudé 2007). Although the presence of many key researchers guarantees free and open debate which is the lifeblood of academia, the uptake of new ideas might meet with more opposition (e.g. political resistance, resistance to change, etc) because there are more people to convince and hence greater likelihood of disagreements.
9 CONCLUSION

In this paper, we used SNA to study the interactions between co-authors of research papers presented at ACIS. SNA provides techniques to analyse the structure of a network as an entity as well as with techniques to analyse individual nodes (egos) and their place in the network. Using SNA metrics and visualisation techniques we were able to reveal structural characteristics of the ACIS co-authors community and identify influential members of this community. The ACIS community was found to be a healthy small-world community that kept evolving in order to provide an environment that supports collaboration and sharing of ideas between researchers. It was also found that unlike Europe, the Australasian scene was not dominated by a couple of key researchers as quite a number of such people were identified.

Future work that could be undertaken to provide a better understanding of the ACIS community includes: (1) identification of the various groups that exist in the network and their research topics (using keyword analysis), and (2) incorporating institutional information in the analysis. Since most researchers publish in more than one conference or journal, the analysis of bibliographical data from ACIS cannot give a complete picture of the Australasian IS authorship patterns. Thus, for a more complete coverage of the IS discipline in Australasian, the boundary of the network should be extended to include other IS-related conferences and journals.

USING INTERPRETIVE STRUCTURAL MODELING TO UNCOVER SHARED MENTAL MODELS IN IS RESEARCH

Abstract

The role of grounded approaches has been advocated for long in IS research. However, the inherent subjectivity of such approaches and the apparent lack of a basis to validate or even replicate such research has often been the subject of debate among IS researchers. As a result, many IS researchers tend to fall back on variance-theoretic approaches to conceptualize, design and operationalize their research. In this paper, we show how a grounded approach, interpretive structural modeling (ISM), can be used to qualitatively elicit individual cognitive structures. Further, we show how it can be applied to derive the shared aspects of such a structure across many individuals. We use the well-known technology acceptance model (TAM) to demonstrate the utility of our approach. We conclude the paper by discussing the strengths and weaknesses of this approach.

Keywords: Interpretive structural modeling, information system, user acceptance, inductive research, research methods

1. INTRODUCTION

ISM is a graph-theoretic method that belongs to the causal mapping family of approaches. It can be used to address problems that are complex and subjective. The ISM approach is useful when a multilevel research design is required where the outcome of the research cannot be predicted based on available research (Klein and Kozlowski, 2000) – implying the use of both theory- and data-driven approaches for research.

Our objective in this paper is to demonstrate the effectiveness of interpretive structural modeling (ISM) in carrying out inductive research in information systems (IS). We have focused on inductive research (data-driven) because of the relative paucity of such research in the IS literature. While we believe that inductive approaches have the potential to contribute significantly to both theory and practice, we are also aware that theories that are grounded in data tend to be relatively harder to defend. The essential premise for the use of such approaches by a researcher tends to be that existing theories do not account for the complex phenomena that a researcher faces. It is implicit in inductive approaches that a careful study of the phenomenon will reveal the hidden patterns that a researcher believes exist.

Using the ISM approach, we suggest a way to efficiently elicit and synthesize user responses with respect to complex phenomena. We demonstrate that ISM can help to operationalize research approaches that can be considered a grounded theory by using graphical techniques to extract underlying structures from data. These structures would form what is often the outcome of grounded theory – revealed thought patterns. We believe that individuals share aspects of cognitive structures that they form about technology and its use. Such shared aspects across individuals can be used to develop theoretical models which can be tested and validated subsequently. We refer to the shared aspects of cognitive structure across individuals as shared mental models in this paper.

Proceedings ECIS 2009
We apply non-directed and non-model-driven approach of ISM to generate a well-accepted and well-known theoretical model, technology acceptance model (TAM). We would like to clarify that the focus of this paper is not to replicate or revalidate TAM model but to just use it as an example to demonstrate the application of ISM approach to generate theoretical models in IS field. By showing that such theory-generation is possible, we hope to persuade IS researchers to employ this technique appropriately in settings or phenomena for which theories do not yet exist. While other causal mapping techniques have been used in IS research (Nelson et al., 2000; Tan and Hunter, 2002), the ISM approach is different in that it is relatively more efficient (in some cases) and lends itself to being replicated more effectively.

Since we are not sure about the level of familiarity with ISM methodology among IS researchers, we introduce ISM methodology first. We then describe how the characteristics of problems (especially complexity and subjectivity) that IS researchers face make the problems well suited for being scrutinized with ISM. We then take up a well-tested theory in IS research (the technology acceptance model - TAM) and show how ISM can be used effectively to develop a TAM. After analyzing the results, we discuss the implications of ISM for IS research in general and elaborate on its strengths and weaknesses. Finally, we suggest areas of IS research that could benefit from the use of ISM.

The contribution of this paper lies not so much in the novelty of the particular finding – but in the novelty and potential of data collection and analysis and how ISM approach can be used in IS research. Since we were able to recreate the TAM structure, we are encouraged to suggest ISM as a viable research approach for many IS research problems that are inherently inductive and qualitative in nature.

2. EXPLANATORY FRAMEWORKS IN IS RESEARCH

We start with the premise that no IS research is either completely inductive or completely deductive. To that extent, development and/or extension of the theoretical framework is often the precursor to empirical support for that theory. However, a major problem with existing approaches to theory development (and research, in general) in IS is the fragmented adhocracy, a result of the federated research framework at work (Landry and Banville, 1992; Hirschheim et al., 1996). Given the richness of the field and the absence of normative or prescriptive frameworks, researchers and consumers of research (who are primarily other researchers) tend to align themselves with a well-established set of ideas or work on a well-known problem. Researchers usually adopt approaches that tend to reconfirm existing theories in a different context or marginally extend them. In doing so, researchers protect themselves from criticisms from other groups that do not agree with their assumptions or beliefs. This framework certainly allows for a thousand flowers to bloom – and enriches the IS field. However, in being overly theory driven, IS researchers may end up playing to the wrong gallery – that of other researchers. However, if IS is an applied discipline, then practitioner-driven research can also be effectively and rigorously incorporated into the IS research process. Stated differently, research that is grounded in data, and which need not be subjected to the researcher’s interpretation, can also be useful to investigate multiple phenomena.

The notion of causality in IS research has long been held to the same standards as those of its stronger and better-established disciplines like psychology and economics. The plurality of perspectives in IS research has certainly led to stronger criticism and a shared awareness/need for rigor. This plurality has also resulted in a variety of “explanation types” in IS research. Since the field of IS is built from both natural and artificial scientific disciplines, Hovorka et al. (2003) argue that explanation types depend on the reference disciples through which research phenomena are understood and research agendas are shaped. Hovorka et al. (2003) provide the following types of explanation types: descriptive/structural explanation, covering-law explanation, statistical relevance explanation, pragmatic explanation and functional explanation. While majority of IS research was categorized as statistical relevance (35%), a significant proportion of explanation in IS research was categorized as descriptive/structural explanation (25%) and framework or model-based (23%). The emergence of process-theory (Soh and Markus, 1995; Crowston,
2000; Kanungo, 2003) perspective in IS research points to the need for alternate methodologies to support descriptive/structural explanation option.

Our approach, in this paper, can be considered to belong to the descriptive and pragmatic explanation categories. We take advantage of the fact that human knowledge, "consists of models constructed by human beings" (Warfield, 1998). Our approach focuses on modeling complex entities created by the multiple interactions of components by abstracting from certain details of structure and components, and concentrating on the dynamics (or linkages) that define the behaviors, properties, and relationships that are internal or external to the system.

3. INTERPRETIVE STRUCTURAL MODELING (ISM)

ISM falls into the soft operations research (OR) family of approaches. Soft OR methods can be used to augment traditional quantitative methods, but do not replace traditional tools and techniques (Glasgow, 2000). ISM is a process that helps groups of people in structuring their collective knowledge. The term ISM refers to the systematic application of graph theory in such a way that theoretical, conceptual, and computational leverage is exploited to efficiently construct a directed graph, or network representation, of the complex pattern of a contextual relationship among a set of elements. In other words, it helps to identify structure within a system of related elements. It may represent this information either by a digraph (directed graph) or by a matrix. Interpretive Structural Modeling results in a “directed graphic representation of a particular relationship among all pairs of elements in a set to aid in structuring a complex issue area” (Porter, et al., 1980).

There are three broad steps for developing an interpretive structural model. Step 1: ISM begins with an issue or problem (Hansen et al., 1979). Step 2: The next step is to identify the elements that comprise the issue context are listed. Step 3: In the third step, pairs of elements are compared graphically or in a relation matrix, using a contextual relationship, which is mostly a verb or a verb phrase. Typical generic verbs are “influences” or “causes” and verb phrase are “leads to” “is more important than”. Following the selection of the contextual relationship, a graphic representation of the mental model is constructed using the approach described later in the subsequent paragraphs. Mizuno (1988) describes the relationship diagram as a tool that “clarifies intertwined causal relationships in complex problems or situations in order to find appropriate solutions (p. 87).” The relationship diagram, therefore, provides a visual means of mapping out the causal and/or associated relationships in the development of a coherent theory (Anderson et al., 1994). Warfield and Perino (1999) elaborate on the utility of ISM further as the representation of a problematique because it captures the richness and the variety of complex phenomena. A problematique is a graphical portrayal – a structural model – of relationships among members of a set of problems (Warfield and Perino, 1999).

Application of ISM Approach

Having discussed the ISM methodology, we now demonstrate the application of ISM approach to uncover shared mental models. The shared mental model can be treated as a tentative theoretical framework because it captures how respondents commonly understand and explain a phenomenon under consideration. We applied ISM to a well-studied phenomenon in IS – information system use. We took this approach because we wanted to demonstrate the effectiveness of this technique by validating our

1 A process framework is denoted by \( Y = F(C) \) where \( Y \) is the set of outcomes or consequences of a process, \( C \) is the set of considerations or elements in the process, and \( F \) is the network linking the considerations to each other and to the outcomes. Process models are often considered to be complementary to models that lend themselves to variance-theoretic approaches – in other words statistical models.

2 This tentative theory can then be subjected to variance theoretic approaches. For instance, a model generated using ISM could be statistically validated (or, for that matter, invalided).
results with a well-tested theory. We used ISM (Sage, 1977; Warfield, 1973, 1974) to collect, analyze and synthesize the data. Following the three broad steps described above, we first identified the problem at hand. Our problem was to understand IS use behavior at the individual level. The IS usage context that we focused on was spreadsheet usage. We selected spreadsheet usage because it is a well-known and ubiquitously available application and yet there is enough variety in terms of its use and acceptance in different usage contexts.

The next step was to identify and list the elements that are relevant in the problem context. For this we chose to provide the respondents with a superset of elements from Venkatesh et al’s (2003) unified technology acceptance model shown in Table 3. The expectation was that not every user will find every element useful or relevant in the context of IS use. We added an additional element, IT-enabled productivity, to the list of elements from Unified Theory of Acceptance and Use of Technology (UTAUT). This theory is an extension of TAM. Users were given the option of providing any other elements that they believed would influence IS use. As stated before, all research can be construed as part inductive and part deductive. For this research, this step was useful to provide an initial list of elements that each individual user considered to be important to the aspect of IS use. In doing so, we were also able to obtain a set of elements that were common to all respondents.

Table 3. Set of Elements Used in the Study

The third step was to compare pairs of elements graphically or in a matrix. The contextual relationship that we used in this study was “influences.” This forms the essence of the inductive process – where each user performs pair-wise comparisons among elements of the set of variables and a final structure emerges. It is important to reemphasize at this point that although we limited ourselves to the nine elements of UTAUT, we did not specify a research model nor did we specify any variables to be dependent or independent. This is what makes this approach inductive and the theory emergent.

The data elicitation protocol was based on a structured interview. Every respondent was provided with a 9 x 9 matrix shown in Appendix A. The user was instructed that she would have to fill out the upper triangular only. To do that, the user would engage in a pair-wise comparison of elements. For instance, to
compare the PE and EE pair the user would answer “yes” to only one of the following three questions: Does PE influence EE? Does EE influence PE? Are EE and PE unrelated? If the element in the row led to the column element, it was coded as \( \rightarrow \). If the element in the column led to the row element, it was coded as \( \leftarrow \). Lack of a relationship was coded as O. While filling out this the researcher (or the research assistant) would also document the reason(s) for why the respondent chose a particular relationship between two elements. These would typically be direct quotes from the respondent explaining her response. As shown in Appendix B, every respondent was requested to make 36 pair-wise comparisons.

We collected pair-wise comparison data from 88 individuals. These individuals were selected randomly from four organizations to which graduate research assistants were provided access. The average time for an interview was one and a half hours. The interviews typically started with the researcher explaining to the respondent the study protocol. Most of the time was used up by the pair-wise comparisons and an explanation of the constructs along the way. The interview typically ended with the interviewer collecting data on the respondent’s gender, age (age range), experience with computer use (in years) and voluntariness of use of spreadsheets (descriptive). These data items have not been used in this research paper. The interviewer also collected respondents’ justification for their inputs to pair-wise comparisons. This was, typically, a single sentence and, sometimes, a small paragraph.

4. ANALYSIS AND RESULTS

While we collected data based on all the elements shown in Table 3, in this paper we report on a subset of the data – one that pertains to TAM. Table 4 shows how responses were distributed. For instance, we can see that 33 out of 88 respondents believed that effort expectancy influences performance expectancy. In the same cell, 29 out of 88 respondents believed that performance expectancy influences effort expectancy and 26 out of 88 respondents believed that there is no relationship between performance expectancy and effort expectancy.

</tbody>
</table>

Table 4. Frequency of Responses (numbers show the frequency distribution of responses)

Each individual’s response results in a directed graph. That graph captures how an individual understands the linkages between the elements and can be considered to be the individual’s mental model. The shared mental model across individuals is captured by the degree of overlap across all the individual directed graphs. In order to seek out those common patterns from these data, we employed the straightforward counting technique for aggregating data across individuals based on Kanungo et al., (1999). In order to retain the “shared” component of the mental models we had to define a minimal level of sharing. This
Based on the 50% cut-off, the following relationships (PE \( \rightarrow \) BI, 54.65%; EE \( \rightarrow \) BI, 74.71%; EE \( \rightarrow \) Use, 55.56%; and BI \( \rightarrow \) Use, 64.93%) emerged as being common across a majority of respondents. For the other relationships, no clear relationship emerged as dominant and hence that lack of clarity was coded as the absence of an agreed upon relationship. The final relationship matrix we obtained is shown in Table 5.

</tr>
</tbody>
</table>

*Table 5. Final Relationship Matrix*

This translates into the binary relationship matrix shown in Table 6. The elements in the diagonal are 1 because every element (from a reachability\(^3\) standpoint) can “reach” itself. As mentioned before, the “V” coding implies that the row variable influences the column variable and not vice versa. So, for instance, in the case of PE and BI, PE influences BI. That means that the element in row 1 and column 3 (excluding row and column headings) will be 1, while the element in row 3 and column 1 will be 0. The lack of a well-agreed relationship is coded as zeros.

<table>

</tr>
</tbody>
</table>

*Table 6. Binary Relationship Matrix (1 implies a relationship exists)*

Next, we identified the levels associated with each element by identifying the reachability and antecedent sets. This iterative process is shown in Tables 7 and 8. Essentially, for all the reachability sets that are proper subsets of antecedent sets, we associate the same level and eliminate those variables or elements for the next iteration. We do this till we have no more reachability and antecedent sets to compare.

*Table 7. The Reachability Set and the Antecedent Set*

\(^3\)“Reachability”, in this case, has to do with relations between elements. Relations between elements are assumed transitive in ISM. In other words, if A “leads to” B and B “leads to C”, then A “leads to C”. From a causality standpoint, every element if perfectly correlated with itself.
Table 7 shows that PE and BE are at the same “level” (level 1) in the hierarchy of the elements that need to be structured. Table 8 shows that BI is at level 2. This partitioning of elements into levels creates the “structural” model that adds value to the graph by preventing it from being a non-directed graph.

</tr>
</tbody>
</table>

*Table 9. Final Levels for Elements*

The final structure is constructed using information from Table 7 and Table 4 (steps shown in Appendix B). In this case, there are no transitivities to be removed; hence we retain the graph shown in Figure 3. It is to be noted that this “model” emerged from the data as it were as opposed to us framing the relationships in any predefined manner.

![Figure 3. Final Influence Structure](image)

Given the contextual relationship (*influences*), we can read this diagram to convey the following: performance expectancy (PE) and effort expectancy (EE) influence behavioral intention (BI), which influences IS use (Use). While Figure 3 shows the consensus structure, it is important to keep in mind that there are 88 (number of respondents) possible graphs.

5. **DISCUSSION**

The key objective of this paper was to show how a non-directed and qualitative approach could be used to replicate results from a validated line of research. The final result in Figure 3 shows that the model that emerges from the ISM process is structurally identical to the one suggested by Davis (1989). The primary contribution of this research paper lies in demonstrating that ISM is an efficient and effective method to undertake research that is aimed at theory development based on an inductive approach. In the remainder of this section, we discuss the scientific contributions and implications, practical implications, and limitations of our work.

The structure of equations, variables, and parameters of module is visualized by the ISM hierarchy (Warfield 1976). Since the directed graph consisting of extracted linkages does not explain the whole systematic order of cause-effect relationships, a researcher may not be able to grasp how to calculate an output variable from other input variables and parameters. The structural analysis by ISM classifies...
variables and parameters according to the hierarchical levels, which are obtained by finding a set of nodes that cannot reach any other nodes except the set itself. The hierarchically organized directed graph ensures that only linkages from a lower level to an upper level are included in the entire graph; however there is no reverse directional arc. Nodes at the same level tend to imply that they codetermine or co-influence elements in the subsequent level.

An important part of the entire exercise needs to be underscored at this stage. There was no a priori definition of a dependent variable. Nor was there any a priori definition of an independent variable. However, as argued by Bougon and Weick (1977), who used a variant of this technique as causal maps, the variables on the left, middle and right can be treated as the set of givens, means and ends respectively. As a result, such a model, once it emerges from research, can subsequently be subjected to further empirical scrutiny by subjecting each element pair to tests of correlations individually or using structural equation modeling or path analysis.

It is also important to note from our data collection and analysis process that we have provided a robust framework for stepwise refinement and synthesis. Both the ability to do stepwise refinement and synthesize multiple inputs are important for inductive research. Stepwise refinement is important from the standpoint of localized attention to a specific phenomenon at any given point in time. When a respondent deals with pairs of constructs, it is hoped that she is concentrating on those two constructs only (and operationalizing the ceteris paribus assumption). The essential idea is to build a larger conceptual model piece by piece. Two types of synthesis have also been demonstrated in this paper. The first is the synthesis of pair-wise information into a larger graph and the second type of synthesis is the aggregation of multiple respondents’ viewpoints into a single graph.

Depending on the nature of the contextual relationship, the derived ISM can be considered to be a causal graph or a causal structure. In this study, given the contextual relationship that we have chosen (“influences”), it would be appropriate to consider the emergent graph as a causal model. However, in case we had used “is more important than” as the contextual relation, then the emergent graph would be more meaningful as a priority structure and it would not be even appropriate to consider it to be a causal structure. This is a framework that allows qualitative research to be efficiently replicated. One of the major challenges of qualitative research is that it often has a significant interpretive component. Here the interpretation is left almost entirely to the respondent and the researcher can focus on addressing the rigor of the research protocol.

Like other methodologies, ISM too has its weaknesses. One weakness of this approach includes respondent fatigue. We have found that comparing 36 pairs of elements got the respondents bored – especially toward the later stages of the pair-wise comparison process. In addition, some respondents could not really shut out other elements while dealing with a specific element pair. For instance, a respondent, while comparing PE and EE stated that PE influences EE and her explanation was that “I find the spreadsheet easy to use because I use it a lot; and I use it a lot because it improves my job performance.” While collecting data, we tended to avoid “educating” the respondent in real-time and “contaminating” the data.

It is also natural for other researchers to question the validity of this approach and, in particular, question the relevance of the cut-off value of 50%. Our argument is that if at least fifty percent of respondents agree on something, then there is something of significance there. Just as in the case of p-values (probability of making a type I error) in inferential statistics, if researchers want additional stringency they can reduce the alpha value (maximum allowable type-I error) from 0.05 to 0.01, we could, in our case, increase the threshold to 60 or even 70 percent. However, we have found that it is revealing for the researcher to start with a lower threshold and incrementally increase the threshold to unravel more resilient graph or causal structures.

A third weakness of this approach, as it has been presented here, is that there is no mention of the strength of the relationships between variables. However, there are multiple resolution frameworks for this
problem. In the context of causal or influence maps, there are many approaches that can be used to impute the strength of the causal or relational connection. Techniques like social networks and matrix algebra (Axelrod, 1976; Carley and Palmquist, 1992), system dynamics (Eden et al., 1992), relation algebra (Chaib-Draa, 2002), neural networks (Rossi et al., 1983), and Bayesian probabilities (Nadkarni and Shenoy, 2004) have been used.

We feel that IS researchers adopting an emic stance to IS research can use this approach to complement traditional research approaches. An *emic* analysis of phenomenon is based on internal structural or functional elements of a particular cultural or organizational system. An *etic* analysis is based on predetermined general concepts external to that cultural system (Lovelace, 1984). Since, we have adopted an *emic* perspective that provides the "insider's" or "native's" interpretation of or "reasons" for his or her customs/beliefs, this specific perspective can and should be used to compare and contrast with the *etic* perspective which is the external researcher's interpretation of the same beliefs or relationships. In other words, this approach can be very useful to compare an IS practitioner’s (user’s or manager’s) mental models from what things mean from an analytical, anthropological perspective.

It would be pertinent to point out at this stage that ISM, as a research approach, may have appeared to be overkill when dealing with four variables. We need to keep in mind that our purpose was to demonstrate the efficacy of ISM. Needless to say, ISM is far more effective when a researcher is confronted with a large number of variables (maybe 10 or more) and where causal ambiguities are a result of the novelty of the phenomenon or the inherent complexities.

Finally, the method, as explained in this study, may not appear as inductive as suggested in the introduction. This is because, it may seem that ISM can only be used to generate models of which the elements are already known. ISM, as shown here, is capable of generating the relationships between the elements. In order to elicit a shared mental model, a variant of the approach presented here, would work better. This would involve a two-step approach in which first the elements are collected followed by the relationships. This is the suggested approach for researchers planning to adopt this approach.

### 6. CONCLUSIONS

In this study, we were able to show that a qualitative, open-ended and respondent-driven approach successfully generated a well-accepted model (theory). The main implication for researchers is that the use of such approaches can form an extremely effective and efficient method for capturing the shared mental models of IS practitioners. It allows IS researchers to perform research that is interpretive and grounded in data efficiently. This is important because, in many instances, IS phenomena are so dynamic and changes occur so fast in the IS domain that it is unreasonable to expect researchers to study stable phenomena and replicate or disconfirm results obtained by other researchers. Moreover, what happens in the field, more often than not, drives academic IS research – and not the other way round. Hence, it is important to employ methodologies like ISM that efficiently allow the capture and synthesis of practitioners’ viewpoints. From a practical perspective this approach is even more valuable because this approach is context sensitive and can be replicated effectively by researchers across contexts. By using ISM we have been able to “focus on the concerns of practice, provide real value to [IS] professionals Benbasat and Zmud (1999, p. 5)” and apply a balance of pragmatic and academic tone.

This table shows the overall data collection framework. Users were requested to fill in this table with \( \Phi \), \( \vec{\Phi} \) or O based on the protocol explained in the body of the paper. Cells that are shaded darker (cell numbers 1, 2, 4, 5, 9, 11, 12 and 27) have been used for analysis in this paper. The cell numbers were used by the respondents and interviewers to link their responses with justifications for those responses.

Appendix B

The following steps outline how the interpretive structural modeling methodology is implemented:

i) **Identify elements**: The elements of the system are identified and listed. This may be achieved through past research, brainstorming, or using the nominal group technique.

ii) **Establish a contextual relationship**: A contextual relationship between elements is established, depending upon the objective of the modeling exercise. This is a verb or verb phrase like “increases” or “is more important than” or “leads to.”
**iii) Prepare a reachability Matrix:** For the contextual relation from element $E_i$ to $E_j$, but not in the reverse direction, then element $E_{ij} = 1$ and $E_{ji} = 0$ in RM. For the contextual relation from $E_j$ to $E_i$, but not in the reverse direction, then element $E_{ij} = 0$ and $E_{ji} = 1$ in RM. For an interrelation between $E_i$ and $E_j$ (both directions), then element $E_{ij} = 1$ and $E_{ji} = 1$ in RM.

To represent that $E_i$ and $E_j$ are unrelated, then element $E_{ij} = 0$ and $E_{ji} = 0$ in RM.

**iv) Perform level partitioning:** Level partitioning is done in order to classify the elements into different levels of the ISM structure. For this purpose, two sets are associated with each element $E_i$ of the system - A *Reachability Set* ($R_i$) that is a set of all elements that can be reached from the element $E_i$, and an *Antecedent Set* ($A_i$), that is a set of all elements that element $E_i$ can be reached by. In the first iteration, all elements, for which $R_i = R_i \cap A_i$, are Level I Elements. In successive iterations, the elements identified as level elements in the previous iterations are deleted, and new elements are selected for successive levels using the same rule. Accordingly, all the elements of the system are grouped into different levels.

**v) Develop canonical matrix:** grouping together elements in the same level develops this matrix. The resultant matrix has most of its upper triangular elements as 0, and lower triangular elements as 1. This matrix is then used to prepare a Digraph.

**vi) Draw the digraph:** Digraph is a term derived from **Directional Graph**, and as the name suggests, is a graphical representation of the elements, their directed relationships, and hierarchical levels. The initial digraph is prepared on the basis of the canonical matrix. This is then pruned by removing all transitivities, to form a final digraph.

**vii) Create the interpretive structural model:** The ISM is generated by replacing all element numbers with the actual element description. The ISM therefore, gives a very clear picture of the system of elements, and their flow of relationships.

THE SIGNIFICANT OTHERS OF SUBJECTIVE NORM -

A SCIENTOMETRIC STUDY OF SUBJECTIVE NORM IN IS TOP-JOURNALS OVER TWO DECADES

Eckhardt, Andreas, Goethe-University Frankfurt, Centre of Human Resources Information Systems, Grueneburgplatz 1, 60323 Frankfurt a. Main, Germany, eckhardt@is-frankfurt.de

Abstract

Undoubtedly social influence in IS research is an issue that needs to be much more clearly examined. In order to assuage the wants for more research in this field we conducted a scientometric analysis of subjective norm in the IS top-journals of the JAIS ranking for the last two decades. In total 113 empirical and conceptual research models predominately in adoption research contained the factor subjective norm. The results revealed that subjective norm is just in seven of ten models a significant antecedent. To gain more knowledge about this problem we followed the ideas of social psychology and marketing researchers and correlated the strength of the impact of subjective norm with its measurement as well as the impact of intention with the impact on other endogenous variables. The results show a significant negative correlation between the significant antecedent subjective norm and its original measurement, the perceived opinion of important others. Furthermore it revealed a significant negative correlation between the significant impact of subjective norm on intention and the significant impact on other endogenous variables.

Keywords: Subjective Norm, Social Influence, Scientometric Study, Meta-Analysis
1 INTRODUCTION

“There’s one advantage to being 102. There’s no peer pressure.” (Wolfberg 2008)

In older ages the social influence of referent groups in private, public or workplace contexts might be not that important anymore as Dennis Wolfberg - a US comedian - assumed but it is exceptionally important in the whole life before. As we are confronted almost throughout our daily complete behavior by the opinions, actions and advices of important others (Fishbein and Ajzen 1975; Triandis 1971) it is not surprising that subjective norm or social factors are an important determinant for an individual’s intention and behavior respectively to use or adopt a specific technology or information system (e.g. Thompson et al. 1991; Lewis et al. 2003; Lee et al. 2006). However two decades after the introduction of the Technology Acceptance Model (TAM) (Davis et al. 1989) IS research still struggles to define and measure social influence appropriately. Various researchers have claimed for "more sophisticated methods for assessing the specific types of social influence" (Davis et al. 1989), “additional research that clarifies the precise role of social pressure in technology acceptance” (Agarwal 2000) or “further research that should study if this factor generate any direct impact on intention to adopt” (Lu et al. 2005). Compared to other classic technology adoption parameters subjective norm or social influence never reached their path significance for the impact on an individual’s behavioral intention or other endogenous variables (Schepers and Wetzels 2007). Therefore other researchers suggest “that social norms need to be conceptualized in a more distinguishing manner to capture the nuances of the social environment” (Srite and Karahanna 2006).

In the JAIS special issue on TAM in 2007 Benbasat and Barki recommended for further research in this field to get back to the underlying Theories of Reasoned Action (Fishbein and Ajzen 1975) and Planned Behavior (Ajzen 1985) (Benbasat and Barki 2007). So we focus our research on two specific aspects of social influence in the underlying theories: its concrete measurement and its general role in dependence with other parameters.

Surprisingly besides being insignificant (e.g. Mathieson 1991; Hsieh et al. 2008) or excluded due to insignificance (e.g. Davis et al. 1989; Ha et al. 2007) from numerous empirical models, the parameter subjective norm or social factors was never critically questioned in IS research like in other fields as social psychology or marketing. Researchers with these backgrounds particularly criticized the basic measurement of subjective norm in the underlying theories (Fishbein and Ajzen 1975; Triandis 1971) as not distinguishing enough to analyze social influence appropriately (e.g. Ahtola 1976; Miniard and Cohen 1983; Liska 1984). In their opinion is “the person’s perception that most people who are important to him think he should or should not perform the behavior in question” (Fishbein and Ajzen, 1975) not adequately as an individual does not feel the pressure of collective important others, but of individual groups as peers or superiors in a working environment respectively friends or parents in a private environment (Eckhardt et al. 2008). Within this approach we aim to reassess these points of critique for IS research by conducting a scientometric study of all IS top-journals of the JAIS ranking (Lowry et al. 2004) for the last twenty years. With the results of this study and the help of a correlation analysis we would like to answer the following research question:

RQ1: Is there a correlation between how Subjective Norm is measured and the significance of the impact?

Furthermore another point of critique regarded the relationship between attitudinal and normative beliefs (Liska 1984; Miniard and Cohen 1983). Social psychology and marketing researchers discussed that a further weakness of the TRA (Fishbein and Ajzen 1975) is its complete ignorance of a causal relationship between attitudes and social norms (Liska 1984). Fishbein and Ajzen regarded these effects as totally independent. It was mentioned that these effects might be independent by definition but not independent by reason as well as statistically interactive (Liska, 1984). Despite the inclusion of potential interaction and dependency effects in the Theory of Planned Behavior (Ajzen 1985) and the confirmed importance of a further examination (Yang and Yoo 2004) this fact was barely observed in further research approaches. By analyzing the data of 113 empirical and conceptual
models containing the factor subjective norm or social influence found through our scientometric study we address the following second research question:

RQ2: Are there any correlations between the influence of subjective norm on behavioral intention and the influence on other endogenous variables?

We answer both research questions with a correlation analysis in SPSS v.16. Beforehand we describe the theoretical derivation of the observed factor subjective norm or social influence and its function in the underlying Theories of Reasoned Action (TRA) and Planned Behavior (TPB) (Fishbein and Ajzen 1975; Ajzen 1985) as well as Interpersonal Behavior (TIPB) (Triandis 1971; 1980) in section 2. The following section includes the introduction of our research method (scientometric study) and the description of our data pool plus details regarding the search process and the database access. After the descriptive statistics and the correlation analyses in section 4 we discuss the results of our approach. By concluding our scientometric study about subjective norm we provide implications for further research in section 6.

2 THEORETICAL BACKGROUND

After the detailed description of our research objectives and its related research question in the introduction we will use this section to briefly describe the theoretical background of subjective norm respectively social influence in IS research especially in the field of technology adoption, acceptance and usage. Furthermore we introduce the underlying theories and models which include the parameter subjective norm.

2.1 The Term Subjective Norm

The origin of the term subjective norm or social influence lies in the cradle of social psychology research back in the early fifties of the 20th century. Luminaries in social psychology research as Solomon Asch, Kurt Lewin or Leon Festinger introduced and experimentally proofed the concept of social influence as a pressure of conformity on an individual human being to act conform to the behavior of a distinct group or person (Asch 1951; Lewin 1952). This also includes a continuous comparison from an individual’s point of view with the behaviors, opinions, actions of peers (Festinger 1954). Social influence expresses itself in an individual person as a change of thinking or feeling concerning a specific behavior due to communication with another individual or a person. In 1962 the knowledge about this topic was further deepened by the work of Everett M. Rogers on the diffusion of innovations. Within his approach Rogers describes social influence as norms or the roles of opinion leaders and change agents in innovation diffusion in a distinct social system which is defined as “a set of interrelated units that are engaged in joint problem solving to accomplish a common goal” (Rogers 2003)

Altogether the term social influence in IS research could be predominately related to the concepts of peer pressure and social comparison in a distinct social system (Eckhardt et al. 2009). The construct subjective norm as well as social factors was than founded about 10 years later, introduced within the competing Theories of Reasoned Action (Fishbein and Ajzen 1975) and Interpersonal Behavior (Triandis 1971). A first approach adapting the factor social influence for management literature and forming a factor of subjective norm was made by Gerald Salancik and Jeffrey Pfeffer who built a conceptual framework to describe social information processes on an individual’s job attitude (Salancik and Pfeffer 1978). The introduction for subjective norm in IS research started with an exclusion from the Technology Acceptance Model (Davis et al. 1989) due to insignificance. Subsequent approaches in technology adoption including subjective norm kept the balance between significant (Thompson et al. 1991; Taylor and Todd 1995) and insignificant results for the factor of subjective norm (Mathieson 1991; Dishaw and Strong 1999). Beside these mixed results one thing remained over the years, a large number of IS researchers requested a further investigation of this “unloved child” of technology adoption research (Davis et al. 1989; Agarwal 2000; Lu et al. 2005).
Beyond technology adoption research subjective norm or social influence was comparatively seldom used in IS research. But there are some examples as Austin et al. (1993) who evaluated the factor social influence in the context of who controls the technology in group support systems (Austin et al. 1993). Other researchers included social influence in the context of media richness concerning electronic communication (Schmitz and Fulk 1991). For this purpose Janet Fulk and her co-authors Schmitz and Steinfield developed a social influence model of technology use to incorporate the influence of workplace referents such as superiors or co-workers on the use of electronic communication (Fulk et al. 1990). Also in the field of IT turnover first approaches were made to observe the impact of social influence in the form of social support on an IT professional’s turnover intention (Lee 2002).

Overall it can be concluded that a majority of empirical and conceptual models including any term of subjective norm, social influence, normative beliefs, social norms, etc. in IS research is related to the field of technology adoption, nevertheless social influence appears in a great variety of synonyms as social support in IT turnover (Lee 2002), as social presence in telecommunication (Short et al. 1976) and in online auctions bidding behavior (Rafaeli and Noy 2005) or as social status in virtual team management (Austin et al. 1993) in other IS domains as well.

2.2 Basic Theories Including the Term Subjective Norm

As concluded in the previous subsection a majority of empirical and conceptual models including a factor for social influence in IS research could be related to technology adoption research. The list of popular and frequently cited adoption models is countless, starting with the most famous Technology Acceptance Model (TAM) (Davis et al. 1989), the Model for PC Utilization (Thompson et al. 1991), the Model of Adoption of Technology in Households (Venkatesh and Brown 2001) up to the UTAUT Model (Venkatesh et al. 2003), just to name a few. All of these adoption models and almost all remaining of the not mentioned ones base upon two competing behavioral theories from social psychology research: The Theory of Reasoned Action (Fishbein and Ajzen 1975 and its extension the Theory of Planned Behavior (Ajzen 1985) as well as the Theory of Interpersonal Behavior (Triandis 1971; Triandis 1980).

A lot more recently published research models have their seeds in the Theory of Reasoned Action (TRA) and the Theory of Planned Behavior (TPB) by Icek Ajzen and Martin Fishbein (Fishbein and Ajzen 1975; Ajzen 1985). The objective of their theories is to explain the determinants that predict an individual’s specific behavior and the behavioral intention to adopt the respective behavior. The antecedents for an individual’s behavioral intention are an individual’s attitude toward the behavior, perceived behavioral control and subjective norm. Subjective norm is referred to as “the perceived social pressure to perform or not to perform the behavior as a sum of the perceived expectations of specific referent individuals and/or groups weighted by the individual's "motivation to comply" with those expectations” (Fishbein and Ajzen 1975).

Interestingly although accepted within the psychological literature and founded before the TRA the Theory of Interpersonal Behavior by Harry Triandis (1971) has not been used frequently within the IS context. Just a few but highly significant approaches include this theory as underlying (Thompson 1991; Lee et al. 2001). Already in 1971 Triandis argued “that an individual’s behavior is influenced by social norms, which depend on messages received from others and reflect what individuals think they should do” (Triandis 1971). Nine years later, Triandis expanded this term and called it social factors, that is, "the individual's internalization of the reference groups' subjective culture, and specific interpersonal agreements that the individual has made with others, in specific social situations" (p. 210). The reference groups’ subjective culture includes norms (self-instructions to do what is perceived to be appropriate and by members of a distinct culture in a certain environment and situation); roles (which are related with behaviors that are considered appropriate but concerned to persons holding a particular position in a social system, society or group); and self concept (abstract
categories with highly emotional components) (Triandis 1980). Both extended theories (Ajzen 1985; Triandis 1980) are shown in the following Figure 1.

![Figure 1. The Theory of Planned Behavior (Fishbein and Ajzen 1975; Ajzen 1985) and the Theory of Interpersonal Behavior (Triandis 1971; Triandis 1980)](image)

To what extent these theories are related to the criticism for measurement and role definition of subjective norm as described in the introduction will be analyzed with the help of our scientometric study in section 4.

3 RESEARCH METHODOLOGY

The objectives of this section are to introduce our research method, the scientometric study, to argue why we chose the JAIS ranking of 2004 (Lowry et al. 2004) as our data pool and to describe how we searched through this large amount of data to find valuable content for our scientometric study about subjective norm in IS research.

3.1 Research Method

We chose scientometrics as research method for our literature review about subjective norm. Reason for that choice was the adequacy of the scientometric analysis for our research approach as it answers particular questions about way and form IS researchers publish their contents. For example researchers defined scientometrics as the quantitative study of research (Davis 2001) or the scientific study of the process of science (Lowry et al. 2004). In this context it needs to be outlined how this research method differs from regular surveys. Hunter et al. (1982) highlighted the major difference between both forms. A survey is used to collect data about people’s behavior, opinion or background. On the contrary a scientometric analysis focuses on the article itself and not the observed people (Hunter et al. 1982). With employed tools as citation analysis or meta-analysis a scientometric analysis observes the affiliations of authors, paper abstracts and texts or references and appendices. Overall scientometric studies are considered to become very important and highly valued for scientific research in future (Straub 2006). Detailed information about the ranking we observed and the way we accessed the included journals is described in the following subsection.

3.2 Data Pool and Included Publications

If you conduct a scientometric analysis major questions a priori are: How far do you want to go and where you got to draw the line? Unlike other already conducted quantitative meta-analyses on subjective norm that included dissertation theses and conference proceedings (Schepers and Wetzels 2007) or journal articles from other research domains as marketing or social psychology (Eckhardt et al. 2008) we focus in our approach solely on IS top journals. In order to exactly define and concentrate our approach we decided to choose a journal ranking as boundaries for the scientometric study. There
is a broad range of IS journal rankings at present with different foci national and international so we had to analyze several rankings to find the perfect fit to our research objectives. Finally we decided to use the JAIS ranking by Lowry et al., published in 2004. It is one of the most cited IS journal rankings and part of the MIS journal rankings of the Association for Information Systems and widely known as an extremely comprehensive ranking of IS journals (Mbarika et al. 2005) with an outstanding reputation. In total we included all 48 journals of the five world rankings in our scientometric study. We started our approach two decades ago and searched through every single issue since 1988 of all 48 journals included in the JAIS ranking (Lowry et al. 2004), more than 20,000 articles overall. We accessed these journals for our scientometric study via literature online databases and electronic libraries. The actual search process with its related search criteria will be described in the following subsection.

3.3 Database Search Process and Criteria

With the objective to conduct our scientometric study we accessed the included IS journals via ten databases and electronic libraries. These sources were in alphabetical order: ACM Digital Library, AIS Library, EBSCOhost, Elsevier, Emerald, IEEE Xplore, JSTOR, Palgrave Macmillan, ScienceDirect and Wiley InterScience. IS journals which were not accessible via one of these sources were retrieved with the help of colleagues in other universities and IS research institutions.

Two main search techniques were mostly provided by the respective databases or e-libraries, the “General Search and the “Advanced Search”. Both search techniques include the Boolean operators (“AND”+”OR”) to facilitate the search with more search items. Like other literature research approaches (e.g. Dwivedi et al. 2008) we predominately used the “General Search” as it allowed us to repeat our searches frequently with consistent results and without any confusion. For the purpose of finding all relevant IS journal articles we started our search with the term “Subjective Norm” and several synonyms or related terms already found in literature (Karahanna et al. 1999; Lewis et al. 2003: Lee et al. 2006; Kim et al. 2007) and used in other meta-analyses (Schepers and Wetzels 2007) as “Social Influence”, “Normative Beliefs”, “Social Norm”, “Social Pressure”, “Social Exchange”, “Peer Group Influence”, “Peer Group Norm”, “Peer Group Pressure”, “Peer Pressure”, “Superiors Influence”, “Superiors Pressure”, “Friends Influence”, etc. Our scientometric search was restricted to incidences of any of these search terms appearing in the body of the text or the article title. In order to sharpen and improve our results we added further information as frequently underlying models or theories which imply subjective norm as well as the names of the related and frequently cited authors. Therefore in databases as EBSCOhost we used extended search terms as the following example for the search through the journal Information Systems Research:

JN "Information Systems Research" AND (TX "technology acceptance model" OR TX "Venkatesh" OR TX "Ajzen" OR TX "subjective norm" OR TX "TAM" OR "TAM"2 OR TX "theory of planned behavior" OR TX "theory of reasoned action" OR TX "social influence" OR TX (important N2 me) OR TX "normative beliefs")

This search style resulted in the extraction of 1,856 articles providing topics and content related to social influence in IS research. All 1,856 records were then analyzed manually to examine and crosscheck their relevance for the overall study. A number of further analyses were then performed afterwards to categorize the findings due to their title, author, year of publication, research subject as well as most important to the individual role of subjective norm its significance, measurement and impact as exogenous and endogenous variable on further endogenous variables. After the categorization process all results were stored and coded within a database. In total 113 articles (107 empirical models and 6 conceptual frameworks) were included for our scientometric study. The results were first coded in SPSS v.16 and then counted and percentage values generated. The complete descriptive statistics is shown in the following Table 1. The empirical evaluation of these data and the implying correlation analyses are presented in the following section 4.

Table 1: Findings of the Search Study

Proceedings ECIS 2009
4 RESULTS

After the theoretical derivation of subjective norm and the description of its explicit role and measurement in the underlying theories in section 2 and the introduction of our research method in section 3 we present in this section the descriptive statistics of our scientometric study as well as the evaluation of the collected data with the help of a correlation analysis. For information about these journals including the parameter subjective norm as title, authors, name of journal and year of the publication, see Table 1. To answer the research questions asked in the introduction we collected explicit data regarding the measurement and of subjective norm.

Generally spoken the degree of significance of subjective norm or social influence in the empirical models analyzed is low. We found the parameter in 31.7 percent of all empirical models observed as an insignificant antecedent for an individual’s behavioral intention or further respective parameters as the specific behavior, attitude, perceived usefulness, perceived ease of use, perceived enjoyment, trust, etc. In 68.3 percent of all empirical models subjective norm was found as a significant antecedent for the parameters mentioned before. Compared to other meta-analyses as one by Wetzels and Schepers (2007) this represents a slightly lower percentage for the significant impact of subjective norm. They found the parameter as a significant antecedent for intention in 86.4 percent of all articles observed, for perceived usefulness in 91.7 percent and for perceived ease of use in 66.7 percent of all articles. However compared to our approach they used a much smaller sample size with 51. Additionally they included conference proceedings as well as not ranked IS journals in their approach and did not limit their findings to IS top-journals as we did. Compared to other regular adoption parameters as perceived usefulness, perceived ease of use or attitude, who were found significant on average in more than 90 percent of all cases in other meta-analyses (Ma and Liu 2004; King and He 2006) subjective norm is substandard regarding its significance.

Following the descriptive statistics of our scientometric study we analyze the correlations within the dataset with regard to our research questions. Therefore we collected the individual measurement items of each model observed according the following classification (Eckhardt et al. 2008): (1) private environment (Private), (2) workplace environment (Job), (3) important others (Important) and (4) public environment (Government). Furthermore we analyzed if subjective norm significantly influences an individual’s behavioral intention (SigInt), not significantly influences intention (NoSigInt), significantly intention with determinants (SigIntDet), not significantly influences intention with determinants (NoSignIntDet), significantly influences other endogenous variables (SigOther) or not significantly influences other endogenous variables (NoSigOther).

The following Table 2 shows the correlation between the values and factors mentioned above. As one can see there are a few interesting outcomes. With respect to our first research question we can note a significant negative correlation for p < 0.01 between subjective norm as a significant antecedent for intention and its measurement with the items of important others. Additionally interesting in this context is the significant positive correlation between subjective norm as a significant antecedent for intention and its measurement with influence groups of working environment. Therewith we can conclude that if subjective norm has a significant impact on behavioral intention in most cases the measured items are influence groups from the working environment and not the originally measured important others of the underlying definition by Fishbein and Ajzen’s Theory of Reasoned Action (Fishbein and Ajzen 1975). Concerning our second research question we evaluated a significant negative correlation between the significant influence of subjective norm on intention and the significant influence of subjective norm on other endogenous variables. So we can summarize for this correlation that if subjective norm has a significant impact on intention a significant impact of subjective norm on further endogenous variables as attitude is uncommon.

**. The correlation is significant for p < 0.01 (2-sided).

Table 2. Correlation Analyses

4.1 Limitations

Due to the research design our approach is limited through some facts. We might have found not all articles including subjective norm in our scientometric study because of the search mode we conducted within the literature databases. Furthermore the results of the correlation analysis for our second research question must be a little toned down as the significant antecedent subjective norm as for intention is not only negatively correlated with the significant antecedent subjective norm on other endogenous variables but also with the non significant antecedent subjective norm.

5 DISCUSSION

In a current research article analyzing the social influence of workplace referents on an individual’s IT adoption and non-adoption the authors sum up that a single cumulative subjective norm measure might be too naïve (Eckhardt et al. 2009). With regard to our results (see Table 3) this statement can be supported as we found a significant negative relationship between a significant impact of subjective norm and the original measurement of important others in the Theory of Reasoned Action (Fishbein and Ajzen 1975). Hence researchers using this theory or one of its numerous advanced versions need
to take into account that individuals perceive the influences, behavioral patterns and actions of their social environment quite differently as opinions and suggestions of their life partner, parents, children, etc. could not be equally treated to these of superiors, peers or subordinates. Comparable to the differences between regular IT adoption and household adoption social influence of referent groups differs according to the respective environment. A first step could be a classification of this social environment in private, job and public environment like we did in our approach. Nevertheless a precise social environment analysis before empirical surveys will be a necessary precondition for future approaches in technology adoption containing a construct for social influence.

Table 3. Research Results and Implications

6 IMPLICATIONS FOR FUTURE RESEARCH

We motivated our approach in the beginning with the results and implications for further research by other researchers and can conclude in the end that there is still a distinct need to measure, define and use the parameter in IS research in the appropriate way. Our scientometric study of subjective norm in IS top-journals over the last two decades revealed that this factor is just in seven of ten cases a significant antecedent for behavioral intention or other endogenous variables. Compared to other regular parameters of predominately empirical adoption models as attitude, perceived usefulness or perceived ease this represents a comparatively low percentage (Wetzels and Schepers 2007; Ma and Liu 2004; King and He 2006). In order to clarify the understanding of social influence in IS research and to solve the problem of a frequent insignificance of subjective norm we adapted ideas and suggestions of social psychology and marketing researchers and analyzed the measurement and dependence of this parameter. Based on the data of 113 empirical and conceptual research models including subjective norm we conducted a correlation analysis to answer our research questions regarding measurement and dependence of subjective norm. The results showed a significant negative correlation between a significant impact of subjective norm on behavioral intention and the original measurement of important others by Fishbein and Ajzen (1975). Although we have not found a significant correlation between insignificant results for subjective norm and the measurement of important others, the results reveal that the general idea of the basic measurement detractors (e.g. Ahtola 1976; Miniard and Cohen 1983; Liska 1984) seem to constitute a reasonable start for further research. A further result based on the thoughts of social psychology and marketing researchers concerning our second research question reveals that a significant impact of subjective norm on behavioral intention is significantly negative correlated with the significant impact of subjective norm on other endogenous variables. This implies that there might be interdependencies between subjective norm and other parameters as attitude (Liska 1984; Miniard and Cohen 1983). Further research needs to clearly examine in this point how subjective norm or social influence could be formed without interdependencies to explain and affect an individual’s intention and within his actual behavior.

Abstract

Customs is one domain which has faced the need for information systems in a globalizing world. In customs there is a need for close collaboration between business and government in order to build robust technological infrastructures supporting processes related to export and import of goods. This has led to a move towards eCustoms. This case study reports from a longitudinal study of a Danish exporter which has faced the challenges of implementing eCustoms in its daily operations. The introduction of eCustoms to replace the existing customs infrastructure based on the Single Administrative Document (SAD) has led to new challenges for the Danish exporter such as de-standardized procedures and increased reporting. The particular contribution of the study is the observed longing to the “good old paper-based days” where things were more standardized than after the digitalization of the processes. The study is interpreted through the lens of “double infrastructures”. The underlying assumption guiding the study is that eCustoms represents one infrastructure on top of another well established infrastructure of global trade.

Keywords: eGovernment, interorganizational systems, global information systems, cross national studies.
1 INTRODUCTION

One effect of a globalized world is the increased traffic of goods from one country to another. That calls for new customs procedures. The phenomenon customs has been known for centuries and the privilege of duty leverage has been executed by local rulers for ages. The rulers’ power scope was often based on features of the landscape such as mountain passes or straits such as the Strait of Gibraltar or the entrance to the Baltic Sea, which could be monitored and governed with relatively few resources such as groups of scouts overlooking the landscape. The scouts could then target caravans or ships with goods via horseback or small boats. With the emergence of national states the customs procedures have developed to more comprehensive and predictable procedures. Furthermore, has the development of technologies led to much more robust monitoring techniques and control mechanisms which have led to an extensive administrative burden for businesses. The domain of eGovernment, of which eCustoms can be seen as a subset, has recognized that IS holds the capacity of reduction of the administrative burden (Lenk 2002) and any reduction in administrative tasks is welcomed by businesses which often consider their interaction with the public sector to be a burdensome task (Fountain & Osorio-Urzua 2001).

What has brought the issue of customs on the information systems (IS) agenda is an increased call for efficiency, security and streamlining of procedures (Tan, Klein, Rukanova, Higgins & Baida 2006). Somehow the current standardized customs infrastructure based on the Single Administrative Document (SAD) has to be improved. It is a general belief that IS hold the capacity of strengthening efficiency, providing tools for security and furthermore being an instrument for streamlining of procedures. This has led to a keen interest for eCustoms from national and supra-national bodies such as the EU and WTO. eCustoms represent a complex mix of stakeholders from national governments, international trade, regulatory bodies and businesses. To increase complexity on top there is the technology dimension which has to accommodate the needs for interoperability, transparency, security and so on. The interorganizational information systems involving public and private parties require robust standards and infrastructures which can support the mutual interest in seamless administration of export and import.

The impact of implementing administrative IS in organizations is well studied and studies that report challenges and problems are numerous (McKeen & Smith 2002). Explanations to the problems organizations face include resistance to change and redistribution of power, limited understanding of systems and poor integration of systems (Markus 1987). At the inter-organizational level one well reported obstacle is standards (Damsgaard & Truex 2000). Standards are crucial for supporting interoperability and ultimately necessary for building robust infrastructures.

In this paper we report on a case study of eCustoms implementation in Denmark. The general purpose of the study was to further the understanding of IT’s role in IT-enabled infrastructures. The research was triggered by the discovery that the European move from paper-based administration of customs to digital means of data transfer has created a vacuum of standards. This has led to derogation of an infrastructure built on top a well functioning infrastructure. Contributing to the purpose above, we will in this paper seek to explain how digitalization has generated constraining conditions for an information infrastructure.

Section 2 presents literature dealing with eCustoms and standardization and introduces our analytical tool for the case, the concept of infrastructure. Section 3 presents the applied research approach. Section 4 presents the case of European eCustoms, a move from highly standardized paper-based customs practices to de-standardized eCustoms practices. In Section 5 the case of eCustoms is analyzed in the light of infrastructures. Finally, Section 6 provides some reflection on the case and it delivers our conclusions of the SAD story of eCustoms.
2 THE SIGNIFICANCE OF INFRASTRUCTURES IN THE DOMAIN OF E-CUSTOMS

“International trade is characterized not only by the physical movement of goods across national boundaries but by voluminous paperwork that captures information pertinent to identification, delivery, and government control of transported goods” (Teo, Tan & Wei 1997).

This section will present international trade as consisting of two parallel flows. One is the physical flow of goods and the other is the information flow. We approach the systemic view of these flows as infrastructures. Infrastructures that since long doubtlessly have been bulky and awkward, but still functioned in a harmonized manor.

2.1 The double infrastructures of international trade

Since historic time routes of trade has been utilized to transport salt, glass, gold, spices etc. from one continent to another. Examples include the Silk route to and from the Far East and the Amber road covering Europe from North to South. With technological developments camels and sail-boats have been replaced by planes and cargo-ships which today move goods round the globe basically following the same routes. It is our claim that international trade is an infrastructure, a physical infrastructure. It is “something upon which something else operates” (Star & Ruhleder, 1996) namely the movement of goods. The robustness of the shipping industry infrastructure is well documented (see for example Stopford 1997). It is beyond the scope of this paper to elaborate further on that issue and it is furthermore less relevant in this context where focus is on the administrative procedures related to export rather than on the physical movement of the goods.

It is recognized that the two layers of infrastructure can be difficult to separate. An example is the introduction of a smart seal, the TREC device, which is attached to a container (Baida, Rukanova, Liu, & Tan 2007). The TREC is a container-mounted device which has a mobile receiver tracking the container’s precise location with sensors monitoring environmental parameters in the container, the physical state of the container, and communication modules for exchanging data (e.g., via handheld devices, via satellite, GSM/GPRS or short range wireless). Data which for example can be transferred to customs offices. However, for the purpose of simplicity the two layers are separated and in the remainder of the paper the term infrastructure refers to an administrative customs infrastructure.

On top of the physical infrastructure which secures the movement of goods there is another infrastructure, the administrative infrastructure of customs. Customs deals with the administrative procedures related to import and export. It registers what goes where to who, making sure that tax and excise is paid in the right amount to the right authorities. Customs is regulated thoroughly by national governments and international agencies such as the EU and the World Trade Organization (WTO). The regulation serves as a strengthening of the infrastructure making it more and more fine-grained with respect to security and control. The administrative burden of customs is at large delegated to the businesses and exporting businesses have the responsibility to report the flow of goods but national customs authorities have the right (and obligation) to perform physical control at the site of the exporter.

2.2 Information infrastructures

In IS research infrastructure has often been discussed within the domain of interorganizational information systems (IOS) (see for example Kurnia & Johnston 2000). Most of the literature on IOS appeared in the mid 1990s where there was attention on the benefits of IOS as a tool for improving business performance. By using IOS as point of reference for infrastructure it is taken for given that organizations are able to exchange data electronically via computer based networks using standardized messages (Cash & Konsynski 1985). The Cash and Konsynski article was one of the first academic
works where IOS was defined: “IOS consists of a computer and communication infrastructure that permits sharing of information systems (IS) applications across organizational boundaries” (p.135).

IOS is thus a combination of IS and an interorganizational environment and has as a consequence essentially both technological and organizational characteristics (Johnston & Vitale 1988). The interorganizational environment consists of supply chains, trading partners, standards organizations, industry bodies, transport companies, trade associations, software providers etc. (Kurnia & Johnston 2000). The scope of the systems, the involvement of different organizations with differing goals and the range and nature of possible relationships between the parties involved makes the situation one of extreme complexity (Gregor & Johnston 2001). That is in particular the case in relation to eCustoms which involves public and private organizations and different nations, supranational entities (e.g. EU and WTO), and finally different economic zones (e.g. EU and the US) which have to agree on a standard.

The topic on IT standardization represents a long term issue which has remained unresolved for decades. It has been argued that “Standardization forms a key feature of modernization” (Hanseth, Jacucci, Grisot, & Aanestad 2006). eCustoms is by the EU seen as an modernization project and standardization should accordingly be addressed. One of the well described chapters in that ode relates to EDI, where no standard has been agreed upon so far, and it is highly unlikely that there would be one in the future (Damsgaard & Truex 2000). Although it is recognized that standards and standard-setting agencies are prerequisites for successful implementation of eCustoms, agreeing on international standards and achieving interoperability between different standard-based systems across the EU member states and at an international level remains still a great challenge (Henriksen, Rukanova and Tan 2008). The challenge is among other factors driven by socio-political traits, which influence the collaboration across organizations (Damsgaard & Lytyinen 1998, 2001).

These traits are among others related to the interorganizational and networked aspects which are not centrally controlled by any authority. It involves the linking of organizations which imply that organizational boundaries are lowered leading to increased transparency, the dependency on critical mass and, the dependency of infrastructures to secure efficient and reliable transactions between trading partners (Damsgaard & Lytyinen 1998, 2001). Those aspects have to be considered when studying the drivers and barriers for adoption and diffusion of IOS including eCustoms. It may be technically possible to fulfil the requirements for an IOS outlined by Johnston and Vitale (1988) twenty years ago but the socio-political challenges constraint the building of an administrative infrastructure. This aspect is eminently demonstrated in the case of customs where different stakeholders have different vested interests which are necessarily not compatible with a global standard.

In their study of the tension of flexibility versus standardization of information infrastructure Hanseth, Monteiro and Hatling (1996) discuss the need for shared international standards from a socio-political perspective. They argue that it is possible to have bilateral agreements among a limited number of communication partners. It is however not cost-effective or even possible in the long run if communities are to share an infrastructure based on bilateral agreements. An information infrastructure holds according to Hanseth et al. (1996) seven characteristics: shareable, common, enabling, physical embodiment of an architecture, enduring, scale, and economically sustainable.

Star and Ruhleder (1996) argue that there is a common misconception of infrastructures where they are seen as something which are built and maintained and which sinks into an invisible background but which is still there at hand and completely transparent. In their article they emphasize that an infrastructure is something upon which something else “runs” or “operates” but it is not completely transparent and also often not invisible. Star and Ruhleder (1996) define eight dimensions of infrastructure (see Table 1). Star and Ruhleder (1996) stress that the eight dimensions of infrastructure are without an absolute boundary and furthermore that infrastructure is something which is not stripped of use. The eight dimensions will be applied in the analysis of the eCustoms case.

Our presumption is thus that customs can be analyzed as double infrastructures of which the physical flow of goods is one part and the information flow is the other. The information flow we approach by the eight dimensions of infrastructure by Star and Ruhleder (1996). The methodological section below describes our work of collecting and analyzing data to fulfil this setup.

3 METHOD

The study of eCustoms is based on a longitudinal project on eCustoms implementation throughout Europe involving multiple stakeholders from government, businesses, a standardization body (UN), and academia. The project started January 2006. The project is built around the concept of Living-Labs (LLs). Based on collaboration in LL issues are identified and further explored among the involved partners. The present study reports from the specific experiences gained in the third LL of the project which is situated in Denmark. The Danish LL focuses on export of food and involves a major dairy producer (DairyComp), Danish customs (Customs), a Danish software producer (SoftComp), and finally researchers from national and international institutions.

The significance of the two previous LL in the project should not be underestimated. The previous LLs have provided a thorough understanding of eCustoms especially among the practitioners who have achieved an opportunity to share experiences across countries on a more informal basis than normal. The LLs should therefore be seen a cumulative process where all participants learn from each other and bring in the knowledge from earlier LLs and work practices in general.

The data which is used for this paper has been collected via different means including company visits, 9 workshops involving all partners of the project, 5 general project meetings, 4 specific Food LL meetings with stakeholders involved in the Food LL, email exchange after meetings, study of minutes and other written documentation provided by the food producer and the national customs authorities. Minutes of meetings taken by researches have been distributed to all participants for approval and commenting. During the project extensive written reporting in the form of deliverables has been produced due to the character of the project, which is EU-funded. These sources of data provide a robust material for documenting data which in nature is unstructured and qualitative.

The data collected in the project covered many different theoretical perspectives and areas of interest as the project objective is to find a solution to a real world problem. The idea of double infrastructure as theoretical lens was triggered in workshops with DairyComp and Customs. Following the idea 10 interviews were made with DairyCorp (4), Customs (3), the developer of DairyComp’s eCustoms...
interface, DairyComp’s logistics service provider, and one other national customs organization (Swedish customs) to explore the explanatory potential of the infrastructure concept. Interviews were recorded and documented by notes. The interviews were guided by the dimensions of infrastructure and were conducted as iterative process towards saturation – meaning a search for being able to describe European eCustoms as an information infrastructure.

4 FROM PAPER BASED TO ELECTRONIC CUSTOMS PROCESSES IN EUROPE

The inspiration to this paper is based on a dialogue between an exporter and a customs officer which took place during a project meeting in summer 2008:

Exporter: The dream scenario [of eCustoms] would be a return to the SAD [single administrative document].

Customs officer: Yes, that is the ultimate example of standardization.

The small dialogue illustrates the problems of implementing eCustoms with respect to finding a suitable and universal standard for exchange of data.

4.1 The paper-based customs infrastructure

In the 1980’s, a company that was an active exporter or importer on the European market had to deal with a set of more than 200 different forms to cover different customs procedures, in different countries and for different modes of transport. As a response to the call for a reduction of the administrative burden for economic operators in an all the time more and more globalized arena for businesses the single administrative document (SAD) and related legislation was introduced in the EU. SAD, specified by the EC in Regulation No 1875/2006 and No 648/2005, presented a general form for all types of customs declarations that was applicable to 18 European countries.

The original SAD was introduced January 1st, 1988. Originally 18 countries did employ the document as standard for their customs declaration. In 1993 the SAD disappeared from trade within the EU as a result of the creation of a common internal market. Ten years later, in 2003, the SAD was reintroduced. The plan was to adapt to the evolution that had occurred since its first creation. The required data to submit was reduced by about a quarter, but perhaps more important was the further diffusion of the SAD as a standard for customs declarations. When the reformed SAD and attached legislation was taken into practice by 2007, the format was adopted by more than 30 countries, including for example Russia.

The SAD was originally a set of 8 copies of the same document printed on carbon paper which was handed out to the different authorities during the journey of the goods. All copies had a specific purpose. The first copy was for the country were export formalities where carried out, the second was used for statistics in the export country, the third copy was returned to the exporter, and so on. Some fields where mandatory to collect for all countries, while some fields were optional to collect. The SAD standardized data was submitted to national customs and with one and the same operation a company could do export clearance, issue the transport document (customs), and prepare the clearance in the country of destination.

4.2 Introducing eCustoms

DairyComp is one of Europe’s largest dairy companies with export from several European countries. Major export destinations include the usual suspects Russia, USA, and China but also large customers of milk powder such as Oman and the Dominican Republic. Since a few years, DairyComp submits data needed for customs procedures when exporting from Denmark electronically through the Danish
“e-Export system” which has been massively diffused among Danish exporters (Bjørn-Andersen, Razmerita and Henriksen 2007).

Customs messages can still be sent through a paper based equivalent which it is possible to use for companies who by some reason do not want to or is not able to submit export data electronically. The paper-equivalent is still based on the SAD. The data model is a field by field translation of the SAD-fields that the Danish customs were using prior to the computerization. The e-Export system can be reached through either UN/EDIFACT messages or XML messages. At present there are no international standards for electronic customs declaration messages through XML. Regarding UN/EDIFACT directory D96.B is used. The sent messages are based on a range of UN/EDIFACT documents.

Regarding data meaning, the e-Export system benefits from being a direct derivation from the SAD, since the need for specifying data meaning was highlighted already when the SAD was introduced. A substantial amount of work was already done by UN/CEFACT, ISO, and the EC/TAXAUD to specify the meaning of data. Also for such fairly interpretable fields such as “product description” there are appropriate guidelines on how to provide and interpret data.

According to Regulation (EC) No 648/2005, member countries of the European Union are expected to implement systems that can handle automated risk analysis of exported and imported goods by June 2009. Simultaneously the European customs organizations are implementing or revising eCustoms.

Besides the mandatory fields the SAD presents a number of optional fields that national customs can demand if they want to. In reality, this have in led to that different XML schemas are used for the data transfer related to export declarations. Although not investigated, it is very unlikely that any two European countries would have implemented exactly the same XML schema without purposely collaborating on the matter. Consequently, although not deviating from the stipulated data model the transferred data differs from country to country. Besides the differences in data model, eCustoms also differs in the mode of transfer between company and customs, as well as in timing of implementation. New regulation is implemented at different dates in each country.

The DairyCorp delivers a very illustrative example of the de-standardized processes within a small geographical scope. DairyCorp also has business activities in Sweden an it exports from Sweden too. The two branches of DairyCorp have implemented different versions of eCustoms solutions in order to live up to national standards and regulation. Both the Danish and the Swedish eCustoms solution build on the SAD, but the implementation still differs from each other.

The SAD reform was introduced as a step towards digitalizing customs operations into a process that by the EU is named eCustoms. The European eCustoms project has a span that covers development of customs processes until 2013. In a first phase of the eCustoms project, submissions to national customs were to be possible via electronic data transfer. The outcome of that development is that almost every country that before applied the very same, standardized SAD for customs clearance now have developed individual eCustoms solutions that enforce companies to set up individual export processes for each country where the company is exporting from. In short, the introduction of eCustoms has led to a de-standardization of European export processes. Ultimately leading to a breaking of an infrastructure which had demonstrated its robustness during the paper-based days but which had been lost in the process of digitalization because each and every country has developed its own system based on standards which are not interoperable beyond its borders.

5 FROM PAPER BASED CUSTOMS TO ECUSTOMS: LOSING THE INFRASTRUCTURE IN THE DIGITALIZATION

As our field data suggests while one infrastructure, the administrative customs infrastructure, goes through radical and extensive changes the corresponding, physical trade infrastructure tries to keep on as usual. International trade is steadily increasing due to the general demands in the markets. But as
Table 2  
Eight dimensions of infrastructure applied on the eCustoms infrastructure

<table>
<thead>
<tr>
<th>Infrastructure dimension</th>
<th>Characteristics of dimension</th>
</tr>
</thead>
<tbody>
<tr>
<td>Embeddedness</td>
<td>Infrastructure is sunk into other structures, social arrangements and technologies. The dimension of embeddedness is lost because the SAD is not supported by the technologies adopted by the different exporting countries. Business is going global with international trade networks, delocalized operations but customs organizations are still to some extent working in national silos.</td>
</tr>
<tr>
<td>Transparency</td>
<td>Infrastructure is transparent to use and invisibility supports the use of it. It does not need to be invented each time it is used. Infrastructure differs from country to country. For a company used to export to one European country has to relearn when exporting to another European country. The eCustoms infrastructure of today is not invisible but has to be manipulated and maintained by humans in order to fulfil its task.</td>
</tr>
<tr>
<td>Reach or scope</td>
<td>Infrastructure has reach beyond a single event. Its reach or scope is either spatial or temporal. The eCustoms infrastructure is intended to be a backbone for all trade processes in and out of Europe. By interfacing with exporting companies’ systems, data from internal systems and export data should flow seamlessly and without human intervention.</td>
</tr>
<tr>
<td>Learned as part of membership</td>
<td>Outsiders of the infrastructure encounter the infrastructure as a target object to be learned about. Russian customs adopted SAD but will not adopt eCustoms that match each European country. For transit goods, goods that only passes through the EU on its way to a non-EU destination, the EU has managed to develop one single system. This system and its output is recognized by Russia as valid proof for the control of goods. Thus, a well-functioning eCustoms infrastructure for Europe has potential of being recognized.</td>
</tr>
<tr>
<td>Links with conventions of practice</td>
<td>Infrastructure both shapes and is shaped by the conventions of a community of practice. Customs builds on an extensive tradition of trade processes. In regions (i.e. Scandinavian countries) they resemble to each other. eCustoms will further the tradition. As eCustoms systems are implemented and have to be used by exporting companies they stipulate the conventions of practice.</td>
</tr>
<tr>
<td>Embodiment of standards</td>
<td>Infrastructure takes on transparency by plugging into other infrastructures and tools in a standardized fashion. The different national eCustoms systems have different interfaces to exporting companies. Exporting from all European countries would require 27 different interfaces. The eCustoms systems follows the same process flow but have differences in the data model, the way of transferring data, and the timing of implementation. The consequence is that all systems that basically performs the same task and fulfils the same purpose needs to be treated as completely different systems.</td>
</tr>
<tr>
<td>Built on an installed base</td>
<td>Infrastructures develops based other bases for example do optical fibres run along railways or roads which represent existing bases or infrastructures. eCustoms builds on Internet, XML and web-technologies. Both companies and customs organizations already use Internet for various purposes. In Denmark it is possible to use Internet and the FTP protocol to upload messages for keeping control of what is exported and when.</td>
</tr>
<tr>
<td>Becomes visible upon breakdown</td>
<td>The normally invisible quality of working infrastructure becomes visible with it breaks. The differences have become visible after the migration to eCustoms. DairyComp has to implement different solutions for eCustoms in each country where they export to. When the implementations are working at both DairyComp’s site and at the national customs organization data is available when needed without any human intervention. When any of national eCustoms systems breaks down DairyComp has to put their export processes in that country on hold and fall back on paper-based procedures.</td>
</tr>
</tbody>
</table>
captured by Star and Ruhleder (1996) the double infrastructures are interrelated and a rupture in one of the structures causes problems in the dependent infrastructure. Table 2 presents an overview of eCustoms according to the eight dimensions of infrastructures by Star and Ruhleder.

5.1 Consequence of the constraining infrastructure

eCustoms in the EU is being introduced due to several different reasons. One of them is to reduce the administrative burden for companies who have business throughout Europe (TAXUD, 2007). By harmonizing and digitizing customs processes increased security and control should lead to a decrease in the administrative burden for pan-European companies – not the opposite. In the light of this objective we analyzed the consequences of national differences in regulation implementation.

The consequence of eCustoms implementation for DairyComp can be summarized as follows:
- A need for several export departments – one for each country.
- Different system modules reporting to each customs respectively.
- Additional system development costs of >100,000 Euro per new export country.
- Additional maintenance costs, which normally are substantially larger than the development cost for IT systems.

Today not all national customs require DairyComp to do electronic reporting in their export declarations, therefore DairyComp has chosen not to if not required. The reason is that the development and future maintenance cost of extending the existing system with a module for handling electronic export declarations would far overshadow the efficiency gains. DairyComp investigated the cost of developing such a module and had an offer of about 100,000 Euro. Costs which are not directly serving as a means for improving production process but rather just contributing to the improvements of the infrastructural technologies (Carr 2004).

This represents a paradox in relation to the overall eGovernment discourse where the belief is that implementing of initiatives such as eCustoms is a means if streamlining processes (Andersen 2004). The implementation of eCustoms only on a partly basis leads to reduction in work because the procedures of traditional paper handling has to be maintained along with the new electronic reporting procedures which are not standardized.

5.2 Revisiting the standardizing effect of IT

As mentioned above do Hanseth et al. (2006) state that “Standardization forms a key feature of modernization”. They do however similar to the eCustoms study observe that efforts towards standardization led to de-standardization. They state: “The end effect was the undermining of the order-making and increased disorder …. where efforts and actions taken toward standardization and stability lead to an opposite result.” (Hanseth et al. 2006, p. 567).

The idea of the European eCustoms initiative is to have a harmonized set of export processes in all European countries. Assuming that the outset is successful by 2013 which is the currently targeted date, the level of standardization should have reached the levels of the highly structured procedures driven by the paper-based SAD-form. Figure 1 highlights that the constraining of an existing, well-functioning infrastructure is followed by a transition phase in which the degree of standardization drops significantly. With the perspective of double infrastructures it becomes apparent that any dependent infrastructure suffers from the obstacles created by the move towards the implementation of de-standardizing practices such as eCustoms.
Discussion and Conclusions

Based on longitudinal interaction with different stakeholders in eCustoms we make the following contributions. We introduce the concept of double infrastructure and show its relevance for understanding how the transition to eCustoms affects international trade. Using the infrastructure concept, we have also been able to explain how one specific eCustoms project, the European eCustoms project, disrupts an existing infrastructure and constrains the corresponding physical infrastructure. Based on our findings, we question the well-established assumption that introduction of IT per se leads to higher levels of standardization. Our research suggests the presence of a transition state in which current infrastructures may constrain the corresponding physical infrastructure due to the introduction of IT. The finding extends the current understanding of the interplay between information systems and physical infrastructures in the concept double infrastructures.

Interactions between government and business differ in nature and often have conflicting goals (Thompson, Rust & Rhoda 2005). Businesses want to reduce the administrative burden and government wants to increase control and security. IT has been seen as the panacea to solve this conflict. In the eCustoms case IT can be the means which breaks the vital infrastructure which is prerequisite for lifting the administrative burden thereby solving the burdensome interaction between businesses and government. The administrative infrastructure is broken but exporting businesses are still carrying out the activity. The reason is simple: export of goods is the foundation for many businesses and the interaction with public sector is just seen as a burdensome relationship (Fountain & Osorio-Urzua 2001). Furthermore, the introduction of the concept of eCustoms is just another burden which businesses have to deal with in their interaction with public sector.

Throughout the world governments, national customs organizations, international collaboration organizations and interest organizations are approaching digitization of customs processes. Some parts of the world have come further than others (e.g. Singapore, ASEAN) while others are only just started to approach the idea. Devolving an efficient infrastructure for customs processes is becoming a key challenge for competitiveness of nations and regions. For example, the EU has noted that its food industry is poorly equipped to tackle the increased globalization (Wijnands, Van Der Meulen, & Poppe 2007). The move towards eCustoms is one constituent action in addressing this issue. Thus, the presence of efficient eCustoms infrastructure becomes a democratic principle and a prerequisite for developing countries to compete in a globalized world. As the eCustoms being developed worldwide are based on IS to increase security, traceability and control the absence of such systems will effectively exclude regions without eCustoms from the international trade scene.
With regard to the magnitude of consequences that the move towards eCustoms has for governments and businesses, we encourage more research into the subject matter. One specific contribution that could substantially improve the work with eCustoms (and other similar eGovernment initiatives) is an increased understanding on how effective Regulations are when it comes to IS and where their limitations lay. The current understanding on what can be achieved by regulations is still very limited. Additional perspectives on the transition and its effects are needed. Finally, we also see a need to further the understanding of how the transition can be achieved. Logically applied IS research should be able to play a key role in the transition, but if so there is a need to develop strong relationships with exporters, logistics service providers, customs organizations and other national and international stakeholders. Here the growing interest in IS research as a design science is a prospectus development that we see could be beneficial for improving international trade.

CONTRIBUTION OF INTERNET TO A DEMOCRATIC SOCIETY

Abrar Haider, School of Computer and Information Science, University of South Australia, Mawson Lakes Campus, SA 5095, Australia, abrar.haider@unisa.edu.au

Abstract

Equitable information access and freedom of expression are viewed as essential aspects of a truly democratic society, whereby all citizens are kept informed and enlightened. A natural extension of this ideal is the human need and desire to communicate and exchange information with others. With the advent of the internet, and extraordinary growth in information and communication technologies in recent years, more information than ever before is made freely available and easily shared. Information is now available in a plethora of digital formats and can be exchanged across time zones, countries and groups in seconds, and this makes communicating and connecting easier and more efficient. This paper discusses the role of free flow of information through internet in shaping democratic values. This paper discusses the role of internet as a democratic tool that allows significant benefits for society at large in a dynamic global environment. It concludes that internet’s contribution to democracy has not fully matured and its potential to revitalize democracy and outweigh potential for oppression and control is a dynamic and multifaceted issue in the global environment. Internet, however, has a passive rather than active role in a democratic society. It, thus, influences only those who interact with it.

Keywords: Internet, democracy, information, democratic society.
1 INTRODUCTION

The contribution of the internet to a democratic society is a complex question, as the terms are quite subjective. The term ‘democratic society’ is difficult to define. The definition of democracy is not the purpose of this paper, however the concept needs to be explored to determine the level of influence that the internet has had. Additionally, in a world of increasing ‘globalisation’, the term ‘democratic society’ can mean a global society as well as being defined by geo-political borders. The internet has the potential to be a very powerful tool in the evolution of the democratic society, especially in regard to the accessibility of information; however it also has the potential to undermine the very fundamental concepts of what a democratic society is all about. This paper discusses the role of internet in a democracy, and highlights the power of internet as an information enabler. It starts with a discussion of democracy and the role of information in a democratic society. This is followed by a discussion on the influence of internet on democracy and vice versa. The paper concludes with drawing some conclusions from real world.

2 DEMOCRATIC SOCIETY

The term ‘democracy’ has its origins in Greece, meaning “people rule”, but the concept of democracy and what constitutes a democratic society is a rather personal view. A purest would determine that true democracy would mean equality, that all people would have a voice and participate in the governing of a society. Held (2006, p1) describes democracy as “having some form of political equality”. The author continues to argue that “most recent definitions refer to democracy in terms of a liberal democracy, where the term can only be applied to ‘governmental affairs’ as opposed to economic and social spheres, and that the concept of democracy belongs to the nation state” (Held 2006, p311). Tuzzi et al. (2007, p.31) view democracy as a political concept, concerning the collectively binding decisions about the rules and policies of a group, association or society. Such decision-making can be said to be democratic to the extent that it is subject to the controlling influence of all members of the collectivity (eg. Citizens) considered as equals. The starting point of democracy thus, is effectively ‘popular control’ and ‘political equality.’ Tuzzi et al. (2007, p. 36-37) take it further by suggesting several ‘evaluation’ aspects that define democracy,

a. Rule of law, that the decisional output and implementation of the law are supreme, with independent judiciary and fair resolution of lawsuits required;

b. Accountability, that the elected political leaders are obligated to answer for their political decisions when queried by citizens, opponents or constitutional bodies; this implies an informed public that actively participates in the political process;

c. Respect for rights and achievement for freedoms, that implementation of social, political and economic equality is progressive; and

d. Responsiveness; that those that are governed are able to be satisfied that their demands are met through policies, services and distribution; also requires an informed and engaged public/society.

The concept of representative democracy, such as that in Australia, relies on the view that informed citizens make informed decisions to determine those people who are elected to make decisions on their behalf. The role of the internet in assisting with this concept is to provide access to information to inform citizens to make those informed decisions. With the advances in technology, where information can be transmitted quickly, the notion of global democracy has been envisioned. This is supported by eCommerce, where multinational corporations and mass media have helped to provide a
view of a global society. Klein (2001) suggests there are four preconditions of a democracy, whether the democratic society is a global one or determined by the nations. These preconditions are:

a. Membership – who is allowed to vote?

b. Communication capability - a common language, the ability to transmit and receive information

c. A system of interest aggregation - such as political parties and lobby groups

d. A democratic culture - where people have faith in the ‘system’, that although their view may not have won out, they accept the decision as part of the democratic process

Scholars argue about the role of these preconditions in a global democracy, and suggest that democracy can only remain in the nation state (Held, 2006). Klein (2001) argues that scholars may underestimate the impact of the internet. He implies that the internet reduces many barriers to global democracy. The internet can certainly increase the communication capability, can facilitate the voting of the Membership and possibly aid in promoting interest, but the internet in not able to change or impart a ‘democratic culture’. This feature of Klein’s (2001) democratic society is essential for a democracy, as people need to have faith that the ‘system’ works. If one loses faith in the system, and there is a collective loss of faith, it results in an unstable government. This view is supported by Zinnbauer (2001) who suggests that whilst the ‘internet can act as an independent stimulant for political engagement’ it is unlikely to “install a deliberative democratic culture amongst users”. Samoriski (2002, pp.42-45) believes that the internet has several implications for the public, communities and government bodies. Firstly, because democracy can be harmed by the concentration of power toward economic interests, communications channels (such as the internet) can be tools through which citizens can discover shared interests and ‘demand a more representative government’. Secondly, due to the information that is available on it and accessibility improvements, more citizens should be able to stay informed and thus make higher-quality decisions for democratic self-government (or when choosing representatives). Thirdly, anyone is allowed to have a voice and even antagonistic ideas can be disseminated; and fourthly, due to the internet’s anonymity factor, people are more likely to speak their mind and protest about injustices without fear of retaliation or prejudice.

3 ACCESS TO INFORMATION – A FUNDAMENTAL PRINCIPLE

The fundamental principles of democracy are freedom and equality. For citizens to be active participants in a democracy, they need to be able to make informed decisions that impact on society. This requires people to have the freedom to access information and to have freedom of expression (Hamilton & Ole Pors, 2003). Habermas (1989, cited in Hamilton & Ole Pors, 2003 p 411) suggests that with greater access to information comes greater participation in democratic process. Therefore, the internet as a tool for the access and transfer of information, must certainly contribute to a democratic society, if the information itself is released on the internet.

In Australia we have the Freedom of Information (FOI) legislation, a legally enforceable right to access public information. Whilst it varies from state to state, and federally, in South Australia it aims to promote the transparency of the government. In Queensland there has recently been a review into the FOI legislation where recommendations have been for a more proactive approach to releasing of information, and to change the culture from one of secrecy, to one of openness (Field, 2008). The release of the Queensland review has obviously revealed that there are significant improvements that can be made to their FOI legislation, and the role of the internet in accessing that information will be taken into account.
The proliferation of the internet could be compared to the rise in publications in eighteenth century Europe. Travelling libraries originated in England around 1740 (Chambers et. al., 1995), which opened up a range of reading material to the masses. Whilst these travelling libraries contributed to the spread of information and ideas, there were limitations. Many people in rural Europe were illiterate, which parallels the lack of eLiteracy in developing nations and even in Australia. However, where the revolutionaries and intellectuals in Europe used pictures and the spoken word to ‘drum up support’ and spread ideas, people still need a reasonable level of eLiteracy to access the pictures or the spoken word on the internet.

To overcome the levels of eLiteracy and other socio-economic reasons for lack of access to the internet, the Public Library has extended it’s historical role, to provide access to the information using the internet. As Byrne (2003) suggests “the aim of the Public Library was to offer information to all, no matter what your social or economic status, it is “an institution to educate for democratic living”. Libraries are however public institutions and subject to public funding, which means there is the potential for information to be ‘controlled’ by governments by being tied to funding. In addition, Libraries are have the restrictions of budgets which in turn can restrict the amount of information a library can purchase. The internet is a relatively inexpensive ‘virtual library’, still with restrictions (that will be discussed later), but a wealth of information nonetheless. It is up to Librarians to help people to find the information they require – to turn information into knowledge. When it comes to accessing information, Libraries are paramount and as Byrne (2003) says, “a healthy library supports a healthy democracy, and a healthy democracy supports a healthy library”.

4 BARRIERS TO INFORMATION

Byrne (2003) believes that the internet has “reinforced the democracy paradigm” as there is universal access to information. The statement should be changed to there is the potential for universal access to information. There are a number or barriers to information on the internet. Some of these barriers are being overcome by adding more information to the internet (such as scanning older documents); other barriers will not be so easy to overcome. In fact some barriers are being constructed.

As mentioned previously, two important facets of a democracy are freedom of expression and freedom of access to information however as Hamilton and Ole Pors (2003) discuss, these come with limitations, which vary from country to country, and these limitations have increased since September 11, 2001. Unfortunately, as in society, there are ‘undesirable’ groups in cyber space. Where the internet has the potential for rallying or uniting people with common interests, to participate in the democratic process, so too can the internet be used to unite people of questionable morals. The internet provides a perceived ‘safe space’ for some people to gather together to perpetuate their warped viewpoints, such as Holocaust deniers, paedophiles and terrorists (Joint, 2005). The limitation to freedom of access to information is a contentious issue. Where does protection become censorship? Some scholars (Nijboer, 2004) argue that greater regulation of the internet is not necessary, this is despite the substantial increase in reports of internet violations (hackers, virus’ etc) since 2000 (CERT, 2004 cited in Nijboer, 2004). Concepts such as anonymity on the internet, another core feature of freedom of expression, are no longer preserved in many countries. In Italy, journalists have to register to publish work on the internet, and the Patriot Act in the United States of America, allows for the monitoring of individuals’ internet usage (Nijboer, 2004). These barriers are continuing to be built, obviously having an impact on democracy.
With the improvements in technology, there are also more sophisticated forms of crime and terrorism. With the culture of fear that seems apparent since September 11, does it create a more insular society? Erikkson (1999) outlines the “Network Revolution” and describes a shift in the method of warfare from Radio, mechanised forces and weapons of mass destruction to cyber weapons, precision munitions and high performance special operations. He goes on to write that infrastructure is no longer the vulnerable target, but knowledge and information assets are. As information is more of a commodity, therefore it is harder to acquire, which conflicts with the fundamentals of democracy. Therefore the internet, in this case, has become a barrier to a democratic society.

Censorship and monitoring of Information on the internet is not only conducted by the Government, many major websites are still controlled by rich multinationals or media moguls. In particular, the major ‘traditional’ media has a presence in cyber space, whether it is the electronic versions of a newspaper, a website of their television station or a presence that is not so obvious. In addition to these major websites there is the associated advertising of products or sites. With advertising, people are drawn to specific websites, and when people are drawn to specific websites, there is an element of control. McChesney (cited in Skinner et al. 2005) believes that the way the media is controlled, funded and structured should be part of democratic debate. He argues that the mass media undermines democracy. He also argues that the policies in the USA do not support democratic principles, but instead make it easier for mass media corporations to strike deals and alliances, thus controlling, to a certain extent, the information we, as consumers, receive. Major search engines also support this structure of corporate control where major companies can pay for priority retrieval, so their website is listed first (Novek, 2000). This view is contradicted by Castells (1998, cited in Kellerman, 2000) who suggests that whilst many cultural battles (the battle of the power to impose behaviour) are fought in the media, the media are not the power holders. He argues that the power lies in the networks of information exchange and the use of symbols to relate cultural movements through icons. This view seems to be a little old and does not take into account the level of sophistication of the mass popular media and their ability to combine radio, television and the internet to reinforce their views of the world.

Other barriers to the internet include the socio-economic inequities (Zinnbauer, 2001). Geldof (2005) discusses the difficulties of using ICT’s in developing countries, such as African nations. Politically, the nation needs to be stable, with a clear ICT policy, where the use of ICT’s is linked to the reduction in poverty. There are many politically unstable countries in Africa so if Geldof’s view is correct then many African nations will not have access to the internet for many years. Scholars (Eriksson, 1999) recognise that some Governments/Leaders identify the internet as a threat to their regime, and therefore resist the influence of the internet. Additionally, in many of these developing countries, there needs to be a focus on developing the infrastructure to utilise the internet and provide access for the people. Access is not enough, there needs to be education to develop the skills so people can use the internet. Things we in the West take for granted such as basic literacy. After all it is informed citizens, making informed decisions that are at the cornerstone of a democratic society.

5 OTHER USES OF THE INTERNET IN A DEMOCRATIC SOCIETY

It can be argued that the internet’s biggest contribution to a democratic society is the acquisition of information. There are also other applications that the internet has been used for. Some countries have tried to adapt the internet to the political sphere. In Germany, the parliament has a website where different issues are discussed, facilitated by politicians and in Denmark there were online public
debates in 1999 (Ferdinand, 2000). The internet has made it quicker and easier to contact elected representatives. Once politicians were contactable by ‘snail mail’, now they have email, blogs and participate in online forums. Some politicians have their own website, and at the last Federal election in Australia, Kevin Rudd (current prime minister of Australia) had his own Facebook page. Hansard (traditional name for the printed transcripts of parliamentary debates in the Westminster system of government) is also available online and through ‘youtube’, you can watch policy speeches on demand. As a communication tool, rather than a research tool, the internet has the potential to revolutionise the way we communicate with politicians.

Another aspect of the internet’s contribution to democratic society is the ease in which people can start their own businesses. As one of the features of a democracy is equality, the internet makes it more affordable to start a business. This ‘economic democracy’ has provided many people with the option of beginning their own business, without having to incur the costs associated with leasing a shopfront. Artists, in particular musicians, have found the internet to be a ‘double edged sword’. Some musicians have used their democratic right to free speech and enjoyed the benefit of an economic democracy to launch their careers on the internet. The internet has made information easy to access, easy to download, copy and manipulate (Oddie, 1999). This concept is open to abuse, with many illegal downloading sites or file sharing sites (Napster used to be one, Lime wire is another). Like any right, there is a responsibility, and the responsibility in this case is to use the information we access from the internet in the correct way.

The biggest influence of the internet has been on economic freedoms rather than political; with marketing, procurement and recruiting completed over the internet. Internal efficiency and communications have been boosted since its advent. Although not a democratic ideal that we are looking at specifically, economic freedom to sell, buy and market to a worldwide audience (thus earn an income) has been quite revolutionary (globalisation etc). There has been some impact on politics and subsequent democratic improvement, according to Ferdinand (2000, pp.5-8):

a. Some see the internet (communications and information available through it) as a way for increased transparency of government administration (to outside observers) and thus governments will be more ‘amenable to democratic pressures’;

b. Professional (political) party organizers (particularly in the US) have quickly utilised the internet in campaigns. Not only is the internet less expensive to campaign on (versus large TV campaigns), but it can be used to reach particular demographics and even those that would usually be disenchanted with politics (thus increasing the number of citizens who are interested and participating in the democratic process of elections); and

c. Many national parliaments are using internet to educate citizens about their activities and legislative procedures; who have at least broken down barriers between the political and public spheres.

Tuzzi et al. (2007, p.32) put forward their opinion that evolving information and communication technologies are becoming increasingly relevant in political systems. They also believe that there is a trend of public disengagement with traditional political life; with expressions of demand placed on direct civil engagement (from politicians) in such processes. Howard Dean (2007, p.94), chairman of the Democratic National Committee (ruling body of major US political party the Democrats), believes that the ‘internet is the most significant tool for building democracy since the invention of the printing press. People are now easily able to create, discover and connect with networks [of people] within hours, anywhere around the globe.’ He goes on to reflect over the resultant demands on leaders in terms of two-way communication and authenticity placed by diverse communities of university students, ethnic groups etc with shared interests. Dean (2007, pp.95-98) also believes that the internet:
a. Allows online communities to question political candidates (that may one day represent them) and through sheer people power, change the course of campaign outcomes;
b. Can be used by both party insiders and outsiders to distribute critical video or audio excerpts of slip-ups from opponents, thus gaining momentum;
c. Allows campaign professionals to manage events and support, address concerns of the public and conduct fundraising from large numbers of people;
d. Allows parties to develop social-networking software and tailor it to political activism, getting communities directly involved in campaigns and debate; and
e. Provides pro-democracy citizens of authoritarian nations like Iran or China with the means of evading government interference in exchanging ideas.

6 DOES DEMOCRACY CONTRIBUTE TO INTERNET OR THE INTERNET CONTRIBUTES TO DEMOCRACY

Gutstein (cited in Hrynysyn, 2001) states that a “democratic society rests on a bedrock of freely exchanged public information”. The internet has the potential to contribute to this freely exchanged public information, by providing access to information. Whist the internet contributes to democracy, it is our democratic society that provides the information in the first place. Zinnbauer (2001) takes the viewpoint that the internet can be a tool in the democratisation of a civil society, but it is up to governments to promote democracy through their own policies in relation to Freedom of Information, freedom of speech. In more controlled countries, such as China, there is still access to the internet; however the censorship is a lot greater. This censorship does not prevent the transmission of ideas or information, but it certainly makes it more difficult. So it is the lack of democracy that impacts on the contribution of the internet.

Internet access and its contribution to democratic society has the greatest potential in countries that have the policies to promote access to information. However democracy is facing a different challenge. Ferdinand (2000) discusses the increase in political apathy in the West. This is illustrated by the decrease in the membership of political parties, a decrease in voter turnout in countries that do not have compulsory voting and there is an increase in the public’s dissatisfaction in Parliament. The only exception to this seems to be single issue causes. Single issue causes seem to be enhanced by the internet through Social Networking sites.

The impact of social networking sites, such as Facebook, may open people’s eyes and minds to the political issues of a country at a particular time, and do it in a swift manner. One only has to look at the range of “groups” that occur on Facebook to see the power of conscious raising that can go on. Whether people act on their views though, is another matter. There are 209735 people that are members of the group “F$@! Off Japan, leave the whales alone” (Facebook, 2008 Appendix 1), but what else are these people doing to show their objection, and their active participation? Are they boycotting Japanese goods? Are they writing letters to the newspaper? Are they donating to GreenPeace? Even without these actions, these group members are, engaging in debate, increasing their knowledge, and therefore becoming more informed citizens.

The internet seems to be facilitated by a democratic society, and a democratic society seems to facilitate the internet. When societies provide policies that promote democracy, individuals can freely use the internet for their own purposes, such as promoting their own cultures and views, where these
views can be explored in a safe, not threatening manner (Eriksson, 1999). In countries that do not promote democracy, then this feature of the internet can be perceived as a threat, which leads to censorship, where individuals cannot discuss differing viewpoints (that contradict the view of the government) and an underground culture can develop.

7 CONCLUSION

The improvements in technology have made it easier to access the internet, made the internet faster, and has allowed for more complex information to be placed on the internet. Once a research tool, the internet can now launch careers by providing an outlet to perform music, it can conduct business in virtual shops, it connects people through social networking sites amongst many other features. It facilitates the flow of information - but only to people that seek it. These factors illustrate the contribution of the internet to our (western) democratic society. In terms of how the internet has impacted on democracy, the internet is simply a technology, which is neither good nor bad, but it depends on how it is used (Joint, 2005). In countries that already are a democracy, the internet is another tool to seek information. In countries that have a more controlling form of government, the internet is also controlled, undermining the very principles of democracy. The key word should be potential – the internet has the potential to contribute very positively to the notion of a democratic society, but it is not yet used to its full potential.

Abstract

In the past decades many e-government initiatives have been introduced. Currently, attention is shifting towards enhancing the effectiveness of these initiatives by improving service delivery through organizational transformation. This is called Transformational Government and is often regarded as the next step in the development of electronic government, in which unique cross-organizational processes for customer service request are created. However, the creation of such service processes is cumbersome and even those organizations that have realized successful online service delivery are often hindered in their efforts to achieve transformational aspects such as service orientation and a networked organizational structure. As there is little insight in the barriers that organizations encounter on their path to Transformational Government, this research investigates those barriers by looking at two case studies that have made efforts to transform. The barriers we found include a lack of knowledge about necessary changes, a lack of change in the organization structure and the absence of a transformational mindset.

Keywords: Transformational Government, e-government, barriers, transformation, service delivery.
1 INTRODUCTION

Over the last decade, a first generation of e-government initiatives has been implemented. Many of these projects focused on realizing electronic service delivery to citizens and businesses. Recently, more sophisticated e-government initiatives have been set up that are expected to create results of a more invasive nature: “E-government is being increasingly seen as an enabler for a longer-term transformation of government that goes far beyond online service delivery,” the OECD (2005, p 164) notes. ICT has the potential to improve the performance of government organizations as they become part of networks, but organizations need to understand this potential (OECD e-Government Studies 2005, p 164). In order to achieve these objectives of transformation, a new effectiveness enhancing mindset is deemed necessary: Transformational Government (Irani & Elliman & Jackson 2007).

Governments acknowledge that major changes are needed to achieve the impact on organizations and service delivery that Information and Communication Technology (ICT) within government promised to deliver. Considering the complex, evasive and long-term nature of transformation, much research focuses on stages of growth models that both describe and provide guidance for the development of e-government initiatives (e.g. Andersen & Henriksen 2006; Layne & Lee 2001; Chen 2003; Gupta & Jana 2003; West 2004; U.N. 2002). The idea behind these maturity models is that transformation is expected to happen stage-wise, starting off from developing an information system and, eventually leading to transformed government. However, although a lot of e-government systems have been set-up in a relatively short time-scale (Irani et al. 2007), the “e-government revolution” (West 2004, p 15) is – in reality – falling short of its potential to transform government service delivery (West 2004).

Research in the field of e-government has identified challenges and barriers to its implementation at government organizations (Liu & Hwang 2003; Gil-Garcia & Pardo 2005; Janssen & Cresswell 2005; Coursey & Norris 2008). We argue that literature on Transformational Government can also benefit from identifying barriers impeding the development of e-government towards transformation. Barriers are those factors that can be identified as blocking the adoption of a transformational mindset and, consequently, the goal of achieving a transformed public administration. This paper aims to contribute to research carried out on Transformational Government by investigating why government organizations fail to achieve transformation. This is done by identifying and classifying the major barriers that occur when organizations aim for transformation. The main research question of this paper is, therefore: What are the barriers impeding transformation of government organizations?

This paper is based on two case studies on organizations in the Dutch public sector that have made initial efforts to transform through the adoption of e-government, but encounter barriers to progressing further. This paper is structured as follows. First, a background of Transformational Government is presented in order to provide insight in steps undertaken by organizations aiming for transformation. Second, a framework for barrier classification is derived from literature. Then, the case studies are investigated and the barriers we identify are categorized. After this analysis, the research findings are presented, followed by conclusions.

2 TRANSFORMATIONAL GOVERNMENT

In recent decades, government organizations on all levels have implemented e-government initiatives, such as realizing electronic front offices, creating authentication concepts, and setting up digital vital registries. As a result of legal obligations and widely available information technology, many government organizations have increased their online service delivery to citizens and decreased administrative costs for businesses. Both enhanced efficiency and effectiveness of government services are key objectives in these developments (Irani et al. 2007). Furthermore, some organizations have strived for organizational change to support these initiatives better. However, large-scale effects have not been achieved yet and little transformation of the public sector can be observed. In order for society as a whole to benefit from e-government initiatives, government organizations need to make
sure that they transform in order to realize demand-driven service delivery that truly meets citizens’ and business’ needs.

2.1 Characteristics of transformed government organizations

Transformation can be defined as a “complete change in character, condition” (West 2004, p 15), which refers to the invasiveness of the process. Transformational Government is the mindset that aims for political and organizational transformation of the entire public sector (West 2004; OECD e-Government Studies 2005). This transformation is spurred by the implementation of a large number of e-government initiatives that promise to change the way the public sector functions (Kim & Pan & Pan 2007), for example by encouraging cooperation between public officials and government organizations and the development of cross-agency ‘portals’ (West 2004, p 16). Irani & Elliman & Jackson (2007) extend this idea and define the rationale for Transformational Government as “the exploitation of e-government such that benefits can be realized” (Irani et al. 2007, p 327). From a business perspective, Transformational Government can thus be seen as the value added of e-government initiatives for citizens and businesses.

The realization of such value added requires transformation in multiple directions. Public administration is foremost expected to become more customer-oriented and act more pro-actively towards citizens and businesses in order to deliver these benefits (Peristeras & Tarabanis 2000). Government will then enable “fully integrated and fully executable online services”, as well as “options for website personalization […] and push technology” (West 2004, p 17). Examples include citizens and businesses only providing their information once to any government agency involved in a service, and single contact points in the form of designated websites that function as the unique information- and service access points for all government agencies. Realizing these initiatives requires change to occur not only in the service delivering front office, but also in the back office of organizations (Beynon-Davies 2007). This could lead to cooperation between multiple autonomous organizations and the transformation from a siloed structure to performing tasks as part of chains or networks (Castells 2000). This, in turn, requires that tasks should be assigned to the organization that is best-equipped to carry it out in order to achieve optimization of these processes. Shared service centers can then be formed, in which services from multiple organizations are concentrated in one joint centre (Janssen & Joha 2006). Following these elements, the transformation of public agencies includes some or all of the following dimensions: adoption of service orientation, formation of service chains, business process re-engineering of the back office, integration with other government agencies, formation of shared services, networked or modular organizational structure, and organizational and governance support for transformation.

A major challenge to achieve any of these dimensions of transformational is the structure of the public sector. The landscape of public administration is largely fragmented, as many different agencies exist that are responsible for their own specific tasks and that have a relatively large degree of autonomy. Therefore, transforming the processes of these organizations to form a service delivering chain is a difficult process. Although the introduction of e-government holds great promises for changing the public sector, many authors, therefore, claim that in reality very little of this transformation can be observed (Fountain 2001; West 2004; Coursey & Norris 2008). Furthermore, the practice of transformation is not considered to be one of radical re-design, but rather a process of ‘muddling through’ (Lindblom 1959), in which small, incremental steps are being made that might, in time, lead to change (Wildavsky 1984). These notions run squarely into the ideas promoted by Transformational Government as they claim that there are severe limitations to the capacity of the public sector to transform.

2.2 Classification of barriers to transformation

Research on the implementation of information systems in (government) organizations more often focuses on success factors (e.g. Akkermans & van Helden 2002; Somers & Nelson 2001; Poon &
Wagner 2001; Rosacker & Olson 2008) than on impeding factors or barriers (Liu & Hwang 2003; Gil-Garcia & Pardo 2005; Janssen & Cresswell 2005; Coursey & Norris 2008). Gil-Garcia & Pardo (2005) propose a comprehensive framework for identifying success strategies and challenges for e-government, comprising five categories: (1) Information and data, comprising success strategies such as having an overall plan, continual feedback, and training, (2) Information technology: ease of use, usefulness, and demonstrations and prototypes, (3) Organizational and managerial: project team skills and expertise, leadership, clear and realistic goals, identification of relevant stakeholders, planning, and communication, (4) Legal and regulatory: information technology policies and standards, and (5) Institutional and environmental: leadership, legislative support, and outsourcing and public-private partnerships.

In the field of business process re-engineering (BPR), Al-Mashari & Zairi (1999) identify barriers instead of success factors. Their approach enables us to identify barriers in the field of e-government as well. This fits the field of Transformational Government as there are little cases available in which transformation is an outright success. In the field of public sector change, Janssen & Cresswell (2005) identify barriers to re-engineer the public sector. In order to identify the barriers that government organizations encounter on their path to transformation, this research uses four of the abovementioned categories by Gil-Garcia & Pardo (2005), namely: information technology, organizational and managerial, legal and regulatory, and institutional and environmental. Following Liu & Hwang (2003), however, the two latter categories are grouped under the label of governance. Furthermore, following Hammer & Champy (1993), Al-Mashari & Zairi (1999) and Kim & Ramkaran (2004) we add the category of business processes to our framework. Accordingly, in the case studies that are analyzed in this paper, the factors are found in the following areas: technical, representing (partial) failure at the level of information systems; business process, which includes failure in re-engineering processes or the formation of service delivery chains; organizational and managerial, representing factors at the organizational level, and including cultural failure factors; and the governance category representing institutional factors impeding transformation of public administration.

![Figure 1: framework of categories of barriers impeding the transformation in public administration](image)

## 3 CASE STUDIES

### 3.1 Research problem, methodology and case selection

The focus on barriers impeding the transformation in public administration, instead of the more common success factors, is deliberate. A focus on success factors neglects factors blocking progress. Since there is a lack of cases that portray full transformation, it is not only necessary to know what factors contributed to the success of their partial transformation, but also the barriers that organizations encounter when trying to achieve a stage of transformed government.
Since the field of Transformational Government is still underdeveloped, there is a general lack of theory and research approaches. To research the main question of this paper, we use an interpretivist methodology for in-depth research of organizational case studies since this best fits the complexity of the matter (e.g. Klein & Myers, 1999). In the previous section, the concept of Transformational Government was defined and a number of efforts necessary for transformation are identified. Implementation of some or all of these efforts represents the theoretical ideal of a transformed government in which the effectiveness of electronic service delivery increases. The mismatch between this theoretical ideal and the current empirical state of transformation is used to identify barriers. For analyzing the cases, we use a triangulation of methods (Mingers, 2001). We base our case study research on a combination of research methods, including document analysis and interviews. Insight is needed in the complex organizational context in order to identify the relevant barriers. Single case studies are often seen as inferior to multiple case studies with respect to generalizability (Yin, 1989). Therefore we opted for two cases that are distinct in their size and transformation approach, but share that they are both seen as successful in improving service delivery. A limited number of case studies can be very successful in terms of theory formulation and theory testing (Yin, 1989). Both case studies provide complementary insights in the barriers that impede further improvement in providing the value added that goes with Transformational Government. This case selection method illustrates the goal of this paper, which is not to provide a full growth path to transformation, but to identify the barriers that organizations encounter on their path to transformation.

The cases were analyzed by comparing the vision to the accomplished transformation and determining the factors impeding the development towards the desired situation. The first case study was investigated using seven interviews with management, administrative staff, IT staff and IT architects. The interview results were compared with documentation including press releases and internal documents such as memos, reports, and presentations. This resulted in a list of factors distributed over the four categories described in figure 1. The second case study was investigated in a similar manner, with multiple (semi structured) interviews with people from various disciplines and document analysis being the second method of research.

3.2 Case studies

In order to support government organizations in their efforts to transform, several support programs have been set up in the Netherlands. Benchmarking studies are carried out and best practices are disseminated. Furthermore, local government agencies can receive support from a professional funded by the central government who gives advice tailored to the specific needs of the organization and culture.

During the last decade, the Dutch government actively stimulated the adoption of e-government initiatives, for example by setting a target that 65% of all government service delivery should be available to citizens and businesses online. In 2007, it was concluded that this goal was achieved by all agencies and the directive was changed into the aim that all government websites be awarded a grade seven out of ten. In order to define how this aim should be achieved, a national action program for better service delivery was set up. The main goals of this government-wide action plan are to identify generic e-government components with a focus on architecture and to increase the visibility of the effects on public administration functioning.

The program aims for a comprehensive outlook on electronic government as it not only defines what public electronic service delivery should look like, through defining service delivery criteria and vital infrastructure components, but it also identifies how public administration could enhance its effectiveness. Examples are given of networks of organizations performing services. Although transformation is, thus, an issue of concern for the public sector as a whole, in this study we look primarily at individual government agencies and at transformation on the organizational level.

Within this context, two Dutch cases are investigated. The first case represents a case of a transformed organization, while the other represents transformed service delivery. First, we will discuss a local
government that transformed into a service-oriented organization. This is a front-runner municipality that deployed service architecture. Second, we look at a semi-autonomous public agency that can be considered a good practice of multichannel service delivery because of their radical approach to both organizational structure and electronic service delivery.

3.2.1 Case study 1: organizational transformation in a front-runner municipality

The municipality under study is often viewed as a good practice in the Netherlands for its effort to transform into a demand-driven organization. Early 2000, this municipality’s city council decided that it wanted to become a front-runner in the field of e-government. A four-year action plan was developed which resulted in a high ranking on a government website comparison list. This municipality only succeeded in partial transformation as it transformed its organization, put in place the right technology, but failed to align it with its business processes. The main drivers of the transformation are a focus on service orientation which was implemented by introducing an integration broker, intra-organizational transformation and an ICT-driven organizational re-engineering.

During the implementation of this (first) action plan, the municipality experienced problems in connecting their applications and more and more money was spent on the control and maintenance activities. In addition, they found that the organization was not suitable for demand-driven service provisioning yet. In this project, the organizational structures were not altered and technology actually reinforced the existing structure. To tackle these problems, a new action plan was developed which primarily focused on shaping the organizational conditions and the technology needed for demand-driven service delivery.

The second action plan started with transforming the organization from a siloed structure to a service-oriented organization. Banking and insurance companies were used to serve as an example for this transformation. This was an invasive process which was managed separately from the implementation of ICT and resulted in separate departments for interaction with citizens and businesses. Furthermore, a number of legacy systems was opened up by adding web services. Thereafter, these systems were connected to the website to enable real-time service delivery. After almost two years, it was found that the idea of leveraging legacy systems by opening them up using web services was fruitful, even though it requires standardization and a sound architecture for integrating the various parts. The municipality bought an integration broker architecture that should contain the logic of connecting the website to the applications in the back office.

Later on, the municipality became aware that just having a broker was not enough. It was unclear which process steps should be performed in the front office or back office and what the broker should do. This requires extensive analysis of business processes, a comparison of similarities between these processes and the allocation of processes to the front and back office. In addition, this helped to map process steps to the new organizational structure, clarifying responsibilities and improving processes.

The municipality in this case study transformed its organization, acquired the right technology, but failed to align these systems with its business processes, which proved to be the bottleneck for transformation. The lack of knowledge on how these changes impacted the organization, its processes and the technology, can thus be seen as the main barrier for transformation. Currently, a number of business processes is analyzed and mapped to the broker architecture and website. This has resulted in the creation of several services that can be requested in an integral way and reuse of information stored in the back office. The automation of all business processes is a long-lasting process, as it requires extensive analysis of current processes, its corresponding structures and future possibilities. Furthermore, connections with other organizations are limited; only connections based on well-standardized formats are realized.

3.2.2 Case study 2: front office transformation in an executive agency

The second case studied was a large semi-autonomous executive agency, which is seen as a good practice of multiple-channel service delivery in the Netherlands. The organization is responsible for
millions of interactions with citizens each year. The agency addressed its fragmentation problem by concentrating the coordination of its multiple service channels (and the corresponding departments), into a single department. Although this structure proved very successful for managing the various streams of customer contacts, it did not succeed to transform the organization as a whole. Creating a department specialized in multi-channel management ensured that a state-of-the-art front end was set up, but at the back end, processes and information systems could not keep up with the service provisioning. In other words, service delivery chains were not formed.

The service strategy deployed by the multi-channel department focuses on a number of drivers: efficiency, image, customer satisfaction, and effectiveness. The strategy differs per channel and per customer segment, and for this purpose different service concepts were implemented. For example, customers with complex problems or language difficulties are served at the counter whereas the young and educated are stimulated to use a web-based self-service channel. The organization transformed to a multi-channel service organization with successes both on efficiency and effectiveness. Higher customer satisfaction and lower costs mark the success of this transformation of the front office, but the formation of service chains or networks with other organizations remains a challenge.

The formation of chains was hindered by the legacy in the back office. A main barrier to transformation is, thus, that the back office lags behind the front end redesign. Furthermore, in some service delivery chains, improved cooperation with other organizations would have been desirable, including more interoperability of information systems and a clearer allocation of responsibilities. Moreover, most developments in this case were introduced on an ad-hoc basis, with trial-and-error as the main strategy. The result is an uneven development of a single coordinating department, with back office departments lagging behind.

A second barrier impeding transformation is the absence of a vision on how this agency could enhance its service delivery by becoming part of a network of organizations. Following the trial-and-error approach, its transformation efforts were based on current structures and the desire to improve efficiency and customer satisfaction. Therefore, the transformation efforts reinforced the existing role of the organization. Alternative strategies, for example one that would redefine the organization’s function from a service providing agency to a broker in a service network, were not considered since there was no vision on what a transformed organization should look like or what’s its role in the network could be.

### 3.3 Findings: barriers identified

The two case studies in this paper represent organizations that have transformed partially. Therefore, the transformational efforts observed in the cases are summarized in table 1 in order to demonstrate the barriers that can be encountered when transformational efforts are undertaken. The barriers derived from the two cases are categorized, reflecting the factors that impede the studied organizations’ efforts to transform.

</table>
Table 1:  barriers identified in the case studies

Table 1 shows that barriers were observed at all levels. Furthermore, the common characteristic of the barriers observed seem to be (1) a lack of knowledge of – or mindset for – transformation, despite the presence of a national action plan for improving (online) service delivery, (2) lack of knowledge of the changes necessary for transformation and its implications, and (3) a lack of organizational change that needs to accompany transformational efforts. Possibly, if additional efforts of transformation are attempted, other barriers might be observed.

4       DISCUSSION: BARRIERS IMPEDING TRANSFORMATION

Since we have looked at only two cases studies, the barriers we identified are not generalizable to all government organizations in the process of transformation. However, by selecting two good practices with a different approach to transformation, the barriers found here are expected to apply to most (Dutch) government organizations. If the elements of Transformational Government found in literature are not even realized in these cases, other organizations are expected to have trouble realizing them as well. Therefore, the theoretical underpinnings and the main barriers identified in the cases by use of the framework can help organizations anticipate on these barriers early on in their transformation process. Although not generalizable, this research on barriers for Transformational Government provides valuable insights for both the theoretical advance of the research field and for the challenges faced by practitioners.

The greatest transformational effort undertaken by the organizations under study is the adoption of service orientation, which was identified as one of the dimensions of Transformational Government. In both cases, this was partly realized. However, service orientation was introduced mainly by technical means (such as broker technology) and front end innovations (such as a multi-channel strategy), instead of undertaking a thorough redesign of the organization and its business processes. Re-engineering the processes in the back office could have led to the formation of service provisioning chains throughout the organization. Therefore, while these organizations acknowledge that their service levels could be improved, they fail to implement all organizational changes necessary, such as assigning responsibilities, aligning processes and bridging gaps between front and back office, IT- and administrative departments. Hence, they appear to lack the understanding of how organizational transformation impacts the re-design of their business processes.

Accordingly, not any effort was observed to reposition the organization within the wider context of the public sector by enhancing service delivery through the formation of chains with other organizations.
Often, processes run through multiple departments or organizations. To accommodate this, service chains must be formed, business processes must be re-engineered where necessary, and systems must be able to interact with those at other government agencies. For the municipality under study, this is further complicated by their dependency on third party software vendors. Despite the presence of a national action plan, the organizations under study seem to lack an overarching transformational mindset to connect all those dimensions. Therefore, they have taken small steps on various paths without a clear vision on where they are heading.

In accordance with the theories that look at transformation as being not just a technical issue, we found barriers also at the governance, organizational and process levels. This leads us to believe that Transformational Government is not just about adopting the right technologies, acknowledging client’s wishes or agreeing on standards, but that it is about the fundamental re-orientation of the role and function of an organization as part of a network that offers services to citizens and businesses. Furthermore, it requires suitable governance mechanisms supporting transformed organizations and business processes need to be installed. Focusing on one part only – whether improving systems or setting up a service oriented front office – inhibits the comprehensive organizational and process reform that is needed for transformation. Often, like in the case studies, organizations take too narrow a focus on transformation and neglect the invasive nature of the process on all of the categories we identified.

For government organizations to advance on their path to transformation, we found barriers that need to be overcome, most notably a lack of mindset, lack of process alignment, and a lack of knowledge on implications of the introduction of e-government facilities. Taking these into account requires the public sector as a whole to determine and define where it is heading and how it will attempt to get there; an integral vision on Transformational Government is necessary. As long as this transformational mindset is lacking and knowledge on these changes is still limited, Transformational Government, as foreseen by scholars in many stages-of-growth models, is not likely to be within reach.

5 CONCLUSIONS

This research aimed to contribute to the research field of Transformational Government. This research field studies the transformation effects of e-government supporting enhanced use of ICT for more effective service delivery. In this paper barriers impeding transformation in the Netherlands were identified and categorized. We believe that identifying these barriers complements the present focus on success factors. Using literature review, a classification of barriers was developed consisting of governance, organization, business process and technology. This classification was used to analyze two cases in-depth. Barriers observed in both cases are related to a lack of knowledge on transformation leading to very limited process re-engineering with a front office focus and a failure of using ICT to enhance the effectiveness of e-government initiatives. Furthermore, an urgent lack of a transformational mindset was observed. The core of transformation is in developing a transformational mindset and a vision to guide organizational and service process development, as well as a collaborative culture. Further research should, thus, focus on improving theoretical and practical support for Transformational Government, such as refining current stages-of-growth models to reflect the complex nature of transformation and the difficulties in achieving a stage of transformed government.

Abstract

Multiculturalism is one of the many factors contributing to the growing diversity found within the workforce comprising today’s organizations. This is particularly true in the ICT workplace. Diversity is often investigated in the context of teams and global organizations seeking to improve knowledge management and/or innovation strategies and practices. Understanding the role that culture plays in a multicultural society is complex, understudied and not well understood. Past studies into identifying and comparing different national cultures are difficult to apply to the multicultural context. Even the operationalisation of the culture construct can be problematic or impractical when many ethnic minorities exist. One approach commonly used in Australia is the categorization of individuals and groups into English (or Anglo) background and Non-English Speaking Background (NESB). In this paper we use these categories to investigate if differences can be found in the way in which individuals in these two cohorts respond to workplace situations.

Keywords: Multiculturalism, knowledge usage, non-English speaking background (NESB), workplace based scenarios.

1 INTRODUCTION

Much culture-based research focuses on organizational culture, seeking to answer questions such as what is the culture in a particular or type of organization (Cooke and Rousseau 1988); whether and how the current culture has a positive or negative impact on the organization (Alavi, Kayworth and Leidner 2005); or how a culture can be changed to improve such things as knowledge sharing and reuse (DeLong and Fahey 2000) or to encourage innovation (Amar 2004). However, when it comes to national or ethnicity-based culture, cultural diversity is treated as one, albeit major, independent variable in understanding the attitudes and approaches to knowledge use and sharing (Holden 2002). We seek to break down the ethnicity-based culture variable based on an analysis of empirical data collected in two multicultural Australian organizations and synthesize our findings with the existing culture literature.

Much of the information systems (IS) research to date has relied on Hofstede’s work which oversimplifies culture viewing it primarily at the national level (Myers and Tan 2002). New research is needed to consider the modern multicultural organization due to the effect culture can have on information systems in general and knowledge sharing strategies, knowledge management system design and development decisions, in particular (Ardichvili et al. 2006). The focus of the scant IS literature touching on multiculturalism is more from the viewpoint of diversity, with culture being one of the possible points of differentiation, and how diversity can impact on knowledge management strategies such as how to manage global organizations and teams to more productively create and share knowledge (e.g. Ely and Thomas, 2001; Haas 2006) or how innovation can be driven by putting people from the right cultures together (e.g. Dombrowski et al. 2007). Our focus is instead on knowledge usage and whether people of different cultural backgrounds employ different knowledge
and decision making strategies in the way they respond to problem situations. We see an individual’s response as demonstrating knowledge-in-action or practical intelligence (Sternberg, Wagner and Okagaki 1993) requiring the application of a combination of tacit, explicit and practical knowledge gained overtime through various experiences. In this way we seek to identify the role of culture in knowledge usage, particularly seeking to ensure the approach includes tacit knowledge usage where tacit knowledge is defined as knowledge that one uses to manage ‘oneself, others, and one’s career’ (Sternberg, Wagner and Okagaki 1993). We achieve this by capturing and comparing the responses of employees to a number of workplace-based scenarios along the lines of psychology Professor Sternberg (Sternberg et al. 1995). To narrow the knowledge context, the employees and workplace scenarios are within the domain of Information and Communication Technology (ICT).

2 OPERATIONALISING THE CULTURE CONSTRUCT

Culture has been defined as “the learned ideas, values, knowledge, rules and customs shared by members of a collectivity (such as those based on ethnicity, gender, sexuality, indigeneity, age, disability (Holmes, Hughes and Julian 2003, p.157)). When we speak of multiculturalism the notions of ethnicity and indigeneity are most relevant. Ethnicity has been defined as “the cultural background of a group of people who share a belief in common ancestry. A resource that can be mobilised for identification purposes” (Holmes, Hughes and Julian 2003, p. 154). Within Australia, some 244 ethnic minorities are represented (ABS 2006). The dominant group representing roughly 70% of the population when questioning ancestry (ABS 2006) are the Anglo-Celtic Australians or those of British or Irish background (Holmes, Hughes and Julian, 2003). Indigenous Australians form another separate grouping. Given the stigma of belonging to a minority, the term Non-English Speaking Background (NESB) is a more popular and less offensive term in the Australian context. Another alternative sometimes used, is Language Other Than English (LOTE), but because the term is also used as the name of a program to teach foreign languages at school, we will use the term NESB which is commonly used by the Australian Government as it allows needs to be addressed, such as the need for an interpreter, for a very diverse population. Membership of the NESB cohort is typically identified through questions concerning language/s spoken at home. Thus in our study we ask “if a language other than English is spoken in your home environment, please select these from the lists below”. Up to 4 languages in order of frequency of usage could be selected. We acknowledge this will not necessarily identify each person’s ethnicity but that in a multicultural country with cross-cultural marriages, many second generation Australians (including both authors) and a melting-pot of cultures around you, asking people to identify their ethnicity(ies) may also have been difficult for respondents to articulate. Also, while people tend to identify with the heritage of their parents and the “mother” country, it is questionable whether an individual who does not speak the mother tongue at all has truly been moulded by that culture and to what extent, since language is often quite tightly bound up with culture. This can be seen when a literal translation from one language to another results in nonsense because the ideas, values, customs, etc., embodied in words/phrases from the two languages differ greatly. Our phrasing of the question is different to asking “what languages do you know?” which would include languages learnt at school which does not reveal ancestry or significant cultural influences.

Adopting the above concepts of culture, ethnicity, Anglo, English speaking majority, ethnic minorities and NESB as our starting point, we found that our dataset could be divided into two roughly equal groups where English was the predominant language spoken at home (Anglo group) or a language other than English was the predominant language spoken at home (NESB group).

To guide our discussion and comparison of the cohorts that emerged from our data we used various cultural classifications, dimensions and characteristics from the existing culture literature from sociology, management and organization theory and practice. These include: Hofstede’s (1980) dimensions of power-distance, uncertainty avoidance, individualism-collectivism and masculinity-femininity; Hofstede and Bond’s (1988) concept of Confucian dynamism; Kluckholn and
Strodtbeck’s (1961) time-based types of cultures; Trompenaars and Hampden-Turner (1997) five value orientations: Universalism versus particularism, Communitarianism [collectivism] versus individualism (same as Hofstede’s dimension), Neutral versus emotional [affective], Diffuse versus specific, Achievement versus ascription; Concern for face (Ho 1976); Hall’s (1990) notion of High-context and Low-context and a number of other factors relevant to a study of culture. The complexity and dynamism of culture necessitates that while these characterizations and past studies may provide some explanation new research is needed (Myers and Tan 2002). We have conducted empirical research to identify what behaviours continue to exist in today’s multicultural society. Just as culture is a social construct, multiculturalism is a social construct which has ramifications for organizations in areas such as human resource management, knowledge management, organisational structure, deployment and adoption of technology and so on. In seeking to unpack multiculturalism we pose the following research question.

Research Question: Can patterns be found in the responses of ICT workers on the basis of their cultural background identified via languages spoken at home?

3 METHODOLOGY AND DATA COLLECTION

In seeking to find differences and patterns in the way that ICT workers apply their knowledge, we have employed a technique developed by psychologists at Yale (Sternberg et al. 1995) involving the use of workplace scenarios to discover how someone believes they would act in a given situation. An example of a scenario is shown in Figure 1. The technique is specifically designed as an instrument to measure tacit knowledge (Wagner and Sternberg 1991). Responding to a scenario involves problem solving and decision making. In this way by capturing the response we capture knowledge-in-action which involves the application of practical know-how, tacit and explicit knowledge acquired through education, training and experience. Cultural background may affect our education and training opportunities and achievements; culture will also affect how we (choose to) perceive, remember, (re)apply, receive and transfer the lessons we learnt both formally and informally (Young 2006). Thus we find scenarios to be an appropriate means to tap into the underlying influences of culture on the usage of knowledge.

To provide more structure than free text, assist participant decision making and allow quantitative analysis, the scenarios have a number of possible predefined responses which are measured on two seven-point Likert scales, to capture how the individual believes they would (realistically) and should (ethically) respond, as shown in Figure 1. This design follows from our pilot study in which we found that participants often wished to respond differently depending on whether they thought the response was something they “should do” (ethical response) or “would do” (realistic response). This corresponds to the findings of Wagner and Sternberg (1991a, 1991b). Figure 1 shows the list of six answer options for scenario 5.

Similarly, Chow, Deng and Ho (2000) designed two (2) scenarios concerning the day-to-day operations of a fictitious firm to test a number of hypotheses regarding knowledge usage. For our study we wanted greater ecological validity and domain coverage and used a process starting with interviews with 12 practitioners leading to a pilot survey in order to develop 16 ICT scenarios each with 6 to 13 answer options. The technique required practitioners to elaborate their ‘war stories’ or critical incidents they needed to resolve. Participants were made available to us by the organizations. There was no attempt to capture scenarios related to culture or any of the biographical variables collected in our dataset which included age, gender, languages other than English spoken at home, employment history, professional membership and educational background, with the intention of seeing if any of these variables independently or in combination, resulted in patterns of knowledge usage behaviour. We thus claim not to have intentionally built cultural biases into our scenarios. Each participant was randomly assigned 4 of the 16 scenarios.
A systems analyst in your section has done a superb job in designing a new system for a client organization. The system has yet to pass the coding and post implementation review stage, nevertheless you feel the job that was conducted is worthy of praise.

Because of the demand that exists in the IT industry, and the fact that you know this systems analyst is thinking of ‘moving on’, you are hesitant to immediately congratulate the person for fear of precipitating the person’s departure, believing they may take this as a possibility of gaining promotion in a different firm, or perhaps even branching out into their own company, more than likely with an IS management consultancy bias (something the person had once alluded to).

You are not actually this person’s boss, however you have worked successfully together on a number of projects and realise that it is unlikely you will be working with someone as easy to get along with again.

Rate each of the following responses in relation to the given scenario. It is advisable to read all of the responses before replying.

1. Talk as soon as possible with the analyst and ‘come straight out with it’, telling the person they did a good job, making no mention of employment possibilities in the industry, simply ‘assuming’ they will stay on.

2. Admit to yourself that the workplace is a professional environment and that the IT industry is competitive, the analyst deserves every chance they can get. With that in mind you don’t hesitate approaching the person to congratulate them even if it looks as if you are trying to ‘sidle up’ to them.

3. Consider talking to the team leader and mentioning the hard work put into the exercise by the systems analyst. What the leader decides to do from there is out of your control.

4. Do nothing positive or negative, simply ‘act normal’, if and when the analyst comes seeking advice of any kind you can simply let it slip that you thought they did an okay job.

5. Leave an anonymous congratulatory card on the person’s desk, something which has been word-processed after hours so that the handwriting is not a giveaway.

6. Next time a social occasion arises, just happen to mention ‘off the cuff’ to the analyst’s colleagues that you thought the person did a great job.

### 4 SAMPLE POPULATION AND DATA ANALYSIS TECHNIQUES

The complete data set included data from within the ICT departments of three Australian organizations of size small, medium and large. For the purposes of this paper focusing on culture within a multicultural environment, we have not included the data from our small organization because it was predominately of one ethnic background (Anglo-Celtic). The other two organizations were highly multicultural. The medium-size organization had approximately 1700 employees, 16 of which were ICT workers which can be briefly described as either a machine organisation or professional bureaucracy (Mintzberg 1991) whose main business was furniture retailing, but for whom the section of the organisation under study was the IT branch of the company. The large company had over 10,000 employees with around 1,400 ICT workers. This company was essentially a larger version of the previously mentioned organisation. From the medium size company, 13 of the 16 ICT workers chose to participate. In the large organization, despite having prepared over 1200 personally named
letters, only 165 were given the letters by the organization for political reasons unclear to us; resulting in 108 choosing to participate. Despite our disappointment, these are the limitations of using ‘real’ subjects from industry who can not be ‘voluntold’. To increase the sample size we have combined the data from both organizations. While no two organizations are identical and thus there could be differences due to variations in organizational type or culture, an internal analysis of the organization’s culture would have been a separate study. Further, to consider the effect of the organizational culture on individual behaviour would need to take into account how long each employee had been with the company and what other (types) of companies the individual had already been exposed to. Finally, the data was collected as individual responses and thus concerned individual knowledge usage, not organizational knowledge usage. Our main concern was that each individual included in the study was working in a multicultural ICT workplace.

Using language/s other than English spoken at home as an indicator of cultural background, we found that 69 individuals (49 males and 20 females) from 20-62 years of age reported no language other than English and thus formed our Anglo cohort. The remaining 52 individuals (30 males, 21 females and 1 unknown) whose ages ranged from 20-59 formed our NESB cohort. The distinction into Anglo and NESB groups fits the Australian political view of multiculturalism where Anglo is the ethnic majority and NESB comprise the ethnic minorities. Indigenous Australian languages were not reported, however a considerable number of European and Asian languages were. We note the predominance of males in our sample population, but point out that this roughly 65/35 gender split is higher than the distribution found within the Australian ICT industry and thus the possible bias towards male behaviours is consistent with the ICT workplace domain. Our lack of control over whom and how many participants in each organization, due to political and managerial reasons, resulted in fewer participants and uneven distributions across cohorts and scenarios. This also meant that only statistical analysis of the data was unlikely to provide statistically significant results and that qualitative techniques would be needed to combine the small numbers in order to discover differences and find cultural patterns.

Figure 2: Graphs for Scenario 5 Answer Options 1&3 for English speaking (Anglo) & NESB cohorts
As a first step we conducted quantitative analysis of the Likert-scale responses to each answer-option to determine if differences and patterns between the responses for each cohort could be found. For example, for scenario 5 answer option 1 the mean was 5.625 and 4.25 for the Anglo and NESB cohorts respectively. Based on the numbers we can not claim statistical significance, but we can see looking at Figure 2 that 87.5% (14/16) of the Anglo cohort were positive about this option, 2 were undecided realistically and only one thought ethically that it was a bad choice. In contrast, 41.6% (5/12) of the NESB cohort were realistically negative and only 58.3% were positive. Answer option 3 also shown in Fig. 1, had a means of 4.5 and 5.3 for Anglo and NESB cohorts, respectively, showing a stronger tendency towards favouring the option for the NESB group.

Once a quantitative difference was indicated, we began the qualitative phase of interpretation to determine if the responses were meaningful from a gender or cultural point of view. To achieve this we used a modified version of the technique known as member checking (Lincoln & Guba, 1985). This technique involved testing the data, analytic categories, interpretations and conclusions with members of those groups from whom the data were originally obtained. Acquiring a Likert scale responses to precoded choices does not reveal why someone chose that response. Member checking allows the opportunity to ask why and to gather further clarification and data. However, since the survey participants were anonymous to us and we had no direct access to them, we needed to find others of similar backgrounds to validate our interpretations. However, limitations of member checking have been found (e.g. Morse (1994), Angen (2000) and Sandelowski (1993)) due to conflicts between the researchers and members interpretations, goals and views. Furthermore, it has been found that members may regret having made a certain statement or choice and wish to have their data changed or removed. For these many reasons, we chose then to identify other NESB individuals from the main language groups represented and to ask them if they could interpret why that choice might have been made. We selected four scenarios which showed quantitative differences. Figure 4 includes some extracts from what was provided to our “member group”.

We approached a large multinational software development company to provide us with participants working in ICT who would all share the same organisational culture to act as member checkers. We sought to obtain 5 males and 5 females from each of the main NESB language groups we identified: Eastern European (Russian (2), Serbian (3), Croatian (1), Bulgarian (1), Hungarian (1)), Mediterranean (French (3), Greek (3), Spanish (1); Subcontinental (Hindi (3), Tamil (2); Kannada (2); South-East Asia (Indonesian (4), Tagalog (1); Vietnamese (4); East Asia (Cantonese/Chinese (15), Hakka (1), Hokkien (1), Korean (3), Japanese (1). The company were unable to identify any Mediterraneans or male Eastern Europeans in technical roles. However, the 7 member checkers were from language and gender groups covering 79% of the NESB cohort. Each of our 7 member checkers, summarised in Table 1, received the same four scenarios (ones that we identified to have numerical differences and potentially cultural or gender related interpretations) however, each received the scenarios in a different order to avoid order effects. The IDs in Table 1 are used later in Table 2 to identify the source of a quote.

Using thematic analysis (Boyatzis 1998) which uses recurrence (same thread of meaning), repetition (of keywords, phrases or sentences) and forcefulness (volume, inflection, emphatic language) to identify, analyse, describe and report patterns (themes) across qualitative data, we identified some consistent patterns within the interpretations. Initial themes were reviewed against the cultural traits (e.g. individualistic, achievement oriented) identified from the body of literature that we had studied. Our goal was to see if the behaviour patterns corresponded to a cultural dimension so that we could apply the appropriate label. This would position our findings within the culture literature and answer whether the cultural traits identified primarily through study of one or a small number of national cultures, were still evident within a multicultural society. For example, in the box asking for interpretations of why males had responded a certain way males used the following words: active, proactive, power (2), take on chin, not nag, logical, well thought out, take control (2), problem-solving, don’t leave problems to others, take problem head on, assertive (3), authority, decisive, take charge, take responsibility (2), responsible (3), leader has responsibility, take ownership, avoiding problems is bad (5), runaway is bad, cover up is bad (3), frank (4), truthful, straightforward (2), forthright, factual (2), simple, courage, confident, bad to ask for help (2), clarification-seeking advice okay if junior, well-organised, ambitious (2), like challenge, need achievements acknowledged (3), should give praise and feedback (4), team oriented (3), professional, egoistic (2), work hard to get job done (2).

When females were asked why the females had responded a certain way they used the following words: don’t want to waste time/efficiency (4), avoid overtime/overwork/too much work (3), negotiating (2), involving team, teamwork, professional (13), make own choice, methodical, analytical, consider friends, work and responsibilities, avoid hurting feelings/upsetting others (2), communication and discussion good (6), open communication (3), manipulation/lying/sneak is bad (4), bad to runaway from problem, bad to “pass buck”, good to solve issues, good to take action, avoid confrontation, good to express respect and acknowledge achievement, career, success (3), actively involved, proactive, want to work, do good job, [need to] take responsibility/ownership, gentle, attached, avoid upset, should observe hierarchy (3), hierarchical boundaries, seniority.
The words in bold indicate concepts not expressed by the opposite gender. Interestingly the same individual may have used that term when referring to culture but not to their gender. For example, M2 used the term ambitious 5 times in her interpretations from a cultural viewpoint but not once in her gender interpretation. Terms which arose consistently in the NESB cultural interpretations for members of both genders included: relationships, open communication, avoid conflict/trouble/hurt, deserve recognition/give praise where due, should know place/not interfere, backseat role, teamwork and building is important, individual achievement deserves recognition, praise may be given and received differently, praise should come from superior, shouldn’t say no to a request from a superior or coworkers, consensual decision making, need to go with flow, follow order and social standing, observe seniority, customer is god, group decision, democratic processes rather than authoritative, respect other person, consider well-being of others, okay to have personal/individual career goals, take responsibility for own work and problems, avoid conflict.

Our own interpretations of the responses were based on cultural characteristics identified in the literature including: Collectivism/Individualism (Hofstede 1980; Triandis et al 1988; Trompenaars and Hampden-Turner 1997), Ascription/Achievement-Oriented (Trompenaars and Hampden-Turner 1997) (overlapping with Newman, Summer and Warren’s (1977) improvement/maintaining status quo and merit-based/relationship-based)); and High/Low Context (Hall 1990); concern for face (Ho 1976), diffuse/specific (Trompenaars and Hampden-Turner 1997), affective/neutral (Trompenaars and Hampden-Turner 1997) (similar to Newman, Summer and Warren’s (1977) objective/emotional). In table 2 we provide a summary and snapshot of comments and responses. The interpretations of responses by the same language group revealed a great deal of similarity with the gender responses. This is not surprising since gender and culture are social constructs. Sometimes the response was identical and expressed as “as/see above”. Sometimes a cultural explanation was expressed as “fe/males in this culture …”.

In some cases the strong connection between gender and culture was apparent because a gender specific interpretation was given in the cultural interpretation. For example “females rarely speak up their opinions and more likely to take a ‘backseat’ role even if they don’t agree” (F1). Via this process of qualitative analysis of the member interpretations we identified the following themes: concern for group, group decision making, importance of observing hierarchy and seniority, open communication, importance of relationships, taking responsibility and making decisions, with some individuals expressing individual achievement, ambition, professional and career orientations. Given that the majority of our NESB cohort and member checkers were from cultures identified as collectivist, the more individualistic views offered may indicate that these individuals were attracted to Australia because it is individualistic (in Hofstede’s (1980) studies of 50 cultures Australia was identified as the second most individualistic country after the US). Alternatively, Australia’s culture is likely to have influenced their own views.

When we compare these interpretations with characterisations of genders and the national cultural literature we see that some changes have occurred. These changes may be the result of changes over time, original incorrect characterisations or the change in these individuals due to a process of multiculturalisation. We note that the males when asked to interpret from the point of view of the males, males used terms stereotypically (see Broverman 1972) associated with males (power, challenge, ambitious, assertive, decisive, control). Similarly, our females did the same (gentle, avoiding hurting (ie. Nurturing and caring), following hierarchy (knowing their place)). When it came to a cultural interpretation some of these gender boundaries were relaxed and any of these characteristics could have been used to describe why a response was taken from a cultural viewpoint.

Table 2: Summary of selected answer options and results.
5 DISCUSSION

The small and variable sample size for individual scenarios and the subtleties which can exist in culturally-influenced responses meant that quantitative statistical analysis did not reveal statistically significant results. In the study by Chow, Shields and Wu (1999) involving a comparison of the openness of knowledge sharing within US and Chinese organizations, qualitative analysis of the interviews and responses to closed and open-ended questions using two IT workplace scenarios were able to reveal patterns of differences, which quantitative analysis had been unable to detect and, “in one instance, potentially misrepresented the underlying motivations and behaviors” (Chow, Shields and Wu, 1999, p.580). The value of employing and comparing the results of quantitative and qualitative analysis are captured in the sentiment “Statistics tell one story; [qualitative] research tell the story behind that story” Trauth (2002, p.5).

In our methodology we first identified interesting differences by looking at the numbers and graphs for each answer-option and then qualitatively interpreting the type of behaviour embodied in the scenario and answer-option. However, we were interested to determine if answer-options without (interesting) differences also contained culture-related concepts. After qualitatively evaluating and classifying all 125 answer options, according to the characteristics and dimensions identified from the culture literature, we found that 75 combinations out of the 125 potentially contained cultural issues. That fact that we only found differences worth investigating in 31 of these 75 culturally-relevant scenarios reveals the subtleties which exist in examining culture in a multicultural context.

One approach to multiculturalism is to manage culturally-based expectations (Evaristo 2007). This is firstly only possible if the differences in expectations are understood. Expectations could be managed by enhancing cultural sensitivity training to go beyond fact and generalization to include (virtual) workshops at which individuals of different cultures describe their expectations to specific situations (Evaristo 2007). Indeed this is similar to the workplace scenario-based approach we used to develop our model. We conjecture that the 31 scenarios which showed some cultural differences could be good starting points for discussion.

Understanding the influences of culture is understudied. People are a major component of information systems and people’s attitudes to technology, knowledge codification and sharing are shown in other studies to be influenced by culture (e.g. Ardichvili et al. 2006; Chow, Deng and Ho 2000; Michailova and Hutchings 2006). From an IS practitioner’s point of view, culture is particularly relevant to knowledge management. For example, understanding cultural influences across the organization, which may vary not only between offices in different countries and states but also within the same geographic location will have implications for the design and implementation of strategies such as the viability of using: email for knowledge sharing, the role of Communities of Practices and group decision support systems and other team-based activities such as system development and project management. Similarly, while diversity is seen as essential for innovation, a past-oriented (Kluckholn and Strodtbeck’s 1961), collectivist and ascription oriented culture may be less inclined to diverge from what has been done in the past or question what the group wants, particularly senior members of the group or accept new group members. Management will need to understand the basis of this reluctance and ensure that the new team members are appropriately integrated into the ingroup perhaps through formally organized social events or team building activities, known as managed socialization (Moitra and Kumar 2007). One strategy is to work with existing ingroups and knowledge intermediaries while new intra-organizational groups are formed to facilitate knowledge sharing (Michailova and Hutchings 2006). Ely and Thomas (2001) found that diversity of itself does not necessarily bring benefit. An integration and learning perspective was seen to be the key to success by providing rationale, guidance and motivation to deliver sustained and maximized benefits from diversity. Lau and Murnighan (1998) found that the key to handling diversity was to understand the faultlines within a group so that they could be understood and managed. Cultural differences potentially pose a fault-line and thus understanding the differences can assist in managing and
composing groups. Harrison et al (2002) discusses the notion of deep (psychological) versus shallow (demographic) diversity. By bringing deeply embedded differences and similarities to the foreground, including our culture-based belief systems; can promote deep level diversity leading to better social integration and resulting in better performance (Harrison et al 2002). Our study which reveals differences in the ways employees may put their knowledge into action and how ways of thinking and behaving can be aligned to cultural influences can promote appreciation of deep diversity.

In our study we take the common view of ‘multiculturalism’ to mean people from different nationalities/countries/ethnic backgrounds and a multicultural organization to mean its employees come from a wide range of cultural backgrounds. To find interesting patterns of knowledge usage behaviour, similar types of cultural groups may need combining. For example, while we believe the United States, United Kingdom, Australia, Canada and New Zealand have different cultural traits it will be much harder to find differences in behaviour as the differences within these countries is probably at least as great as the differences between the nations. On the other hand if we compare these Anglo countries with Latin countries such Italy, France, Spain, Portugal, Argentina, Brazil, Chile, etc. differences are expected to be noticeable. Indeed when it comes to acting upon the range of behaviours, for example with respect to knowledge management practices and policies, it would not be feasible to try to accommodate each individual ethnic group. The fact that we were able to identify patterns of behaviour by combining ethnic groups supports this approach. While not explored in this study, smaller groupings, say four rather than two cohorts based on ethnic background, could reveal even stronger patterns, but with fewer numbers the validity would be reduced.

In answer to our research questions we were able to find patterns in the responses of ICT workers on the basis of their cultural background identified via languages spoken at home. Understanding culture in the not so distant past, promoted tolerance and assisted trade. Understanding culture in the increasingly multicultural organizations and societies of today is no longer an outward looking concept. Nowadays awareness of our own culturally-influenced attitudes and behaviors and those of the people we work and live with is essential if we are going to survive. Education and training can ensure that we “know” the same things, but our culture will influence how we value, interpret, utilize and share that knowledge. Similar to techniques used to help employees to evaluate their own personality, leadership and/or decision making styles and those of their colleagues in order to work together more effectively, we recommend that organizations train their employees, managers in particular, to understand and recognize cultural differences to improve human resource, technology and knowledge management practices within an organization. Identification of responses to workplace scenarios can contribute to this understanding.

Abstract

One manifestation of today’s globalization is a new type of work environment where employees who are living in different parts of the world regularly engage in collaborative activity. Because these workers are socialized in different cultural environments, an important research issue is how to understand workers behaviors and effectively manage in this global workplace were workers communicate on a daily basis but do not meet each other and may not even know the life styles of their team members. Based on an ethnographic analysis of GLOBALIS, a multinational firm in the financial sector with IT solution centers in the US, Ireland and India, this paper presents a conceptual model of how culture was impacting the behaviors of global teams at GLOBALIS. In this model the behaviors of globally team members is primarily governed by corporate norms, project requirements and workplace culture. National culture, which has been identified in cross-cultural research as a key factor in global work, is just one of many demographic variables like age, education, professional standards, inter-relationships among sites, etc. that impact workplace culture. Thus, this paper reinforces the current multi-faceted view of culture as a set of forces that impact values and behaviors and it also clarifies some of the clouded opinions on whether or how national culture differences impact today’s globally distributed work.

Keywords: Global Work, National Culture, Corporate Culture, Project Culture, Professional Culture, Workplace Culture, Time, Offshore Outsourcing, Ethnographic Case Study, Survey Research.
1 INTRODUCTION

One manifestation of globalization is the movement of multinational firms across their countries’ geographic boundaries in order to access qualified labor pools, tap into hubs of talent, reduce costs through wage differentials, and achieve proximity to customers, thereby becoming truly global in their operations. This movement is changing the way in which work is performed. In this new form of work organization, employees routinely work with team members who reside in other nations. This new way of working is made feasible by advances in information and communication technologies (ICTs). ICTs enable workers to interact, communicate and coordinate their work across great distances, such as is found in virtual global software development teams.

While ICTs are a necessary condition for such work, it is by no means sufficient by itself. While human determination, commitment and innovation have yielded success, distance has shown to contribute complexity to the communication, coordination and control processes in global software development (Herbsleb et al. 2000). Because workers live in different countries and thereby are socialized in different national cultures, investigation of the role of culture in global IT work is an important research topic (Borchers 2003, Chand et al. 2007, Cramton & Webber 2005, Galliers 2003, Galliers 2008, Krishna et al. 2004, Symons & Stenzel 2007; Walsham 2002). Notwithstanding, there are many views on the role of national culture in global IT work that vary from ‘culture does not matter’ to ‘the success of global projects requires a keen understanding and management of cultural differences’ (Carmel & Tjia 2005).

Even though culture is a frequently used term, there is no commonly agreed upon definition regarding specifically what it means (Straub et al. 2002). In daily usage the word culture is associated with observable things such as food, language, literature, music, art, etc. that characterize a community or a group. At the country level we quickly get into trouble with this ‘observable things’ view of culture. For example, is it appropriate to say that India a country with 15 major languages in use, conflicting religions and many races has a uniform national culture? Sir John Strachey who had spent many years as a member of the Governor-General Council in India observed that “Scotland is more like Spain than Bengal is like the Punjab (Guha 2007). This observable diversity does not mean that India does not have a unifying essence. This example of India just points out that the observable things view is insufficient to fully capture the concept of national culture.

Edward T. Hall (1959,1981), a pioneer in the field of cross-culture studies, conceptualizes culture as a means of communication through “silent languages.” He identified five silent languages of cross-cultural difference, namely the use of time, physical space between people, attitude toward material goods, friendship and bounding, and forms of agreement. His thesis is that one can use these silent languages to highlight the cultural differences among groups, communities and countries. For example, on how societies used time Hall observed that Americans think of time as linear and discrete, are monochromic and tend to do one thing at a time, adhere to schedules, believe that meeting deadlines and keeping appointments is important, and they consider keeping someone waiting to be a sign of disrespect. On agreements, Hall observed that Americans do not rely on communication that is deeply embedded in cultural context and therefore they tend to negotiate contracts that are explicit, complete, and literal.

Geert Hofstede, a Dutch academic widely known for his pioneering research on culture, surveyed 116,000 employees of IBM, a large multinational company, spread across fifty countries and three regions and two points in time (Hofstede 1980, 2001). The questionnaire items measured work-related values. Factor analysis of the responses grouped the questions into four categories that he titled as Individualism-Collectivism, Power Distance, Uncertainty Avoidance and Masculinity-Femininity.
Later he added a fifth dimension of culture. When he grouped the responses by countries for each of these dimensions and mapped the responses to an index value between 0 and 100, the country indexes revealed differences between countries along these dimensions.

Hofstede built his theory of culture (Hofstede 1980) based on this study. His key finding was that country-based differences persisted among the responses of the IBM workforce despite the ‘strong’ corporate norms of IBM. To explain this finding Hofstede defined culture as “the collective programming of the mind that distinguishes the members of one category of people from another” and this collective programming of the mind occurs through the socialization processes. This definition frames culture as a set of norms and values that people are socialized into, while growing up, by their family, neighborhood and the schools.

Schein’s (1985) sees culture represented as the layers of an onion. The outer layer is what people generally associate with culture, namely the observable things related to behaviors such as arriving late to events, maintaining leisure time completely separate from work time, the inability to say no, etc., and artifacts such as language, food, literature, etc. The middle layer refers to the norms and values which a community holds. The norms define how to act and what is considered right or wrong, and values tell what is considered good or bad. The core represents the underlying assumptions. According to Schein, to understand the root causes underlying behavior or values, the underlying assumptions have to be surfaced.

Grounding their analysis on social identity theory, Gallivan and Srite (2005) argue that culture should be viewed as a richly layered set of forces that go beyond national culture dimensions and corporate culture norms in shaping individuals’ beliefs and actions.

Divergent conceptions of time, based on national cultural differences, are frequently cited as a fundamental barrier to collaborative work (Hall 1959, Hall 1983, Cusner & Brislin 1996, Olson & Olson 2003). Perhaps one reason why time is so often cited is because divergent adherences to schedules and deadlines are so readily observable, and thus reportable. Also, in the business and IT world, time is a crucial variable in defining whether a project is successful and/or on time. In terms of cultural differences as to how time is perceived, the more distant a culture is seen to be geographically and normatively, the greater the expected difference. This means that in teams that are globally dispersed, time is assumed to be a critical problem in developing collaboration.

This paper explores the role of culture in global work by investigating the use and attitude towards time by the employees of GLOBALIS that were distributed across multiple sites in the US, Ireland and India. Our study is exploratory in the sense that the examination of the IT unit of one multinational firm cannot stand for the national cultures of US, Ireland or India. Further, the results we derived based on an empirical analysis of IT workers cannot automatically be generalized to other occupational groups. Thus, what the inductive analysis of this study provides is a nuanced understanding of the sub-cultures and factors that affect workers’ behaviors in global work.

In the next section we describe the research site, the data sources and our research methodology. After this we present our ethnographic and survey data that is used later to construct and synthesize the conundrum of culture layers into a new model of how these different layers of cultures impact global work. The paper ends with a discussion of the implications of this model and the future research that are needed to place this model on a sounder footing.

---

1 In subsequent work with Chinese scholars, Hofstede added a fifth dimension called short-term v. long-term orientation
2 RESEARCH SITE, RESEARCH METHODOLOGY AND DATA GATHERING

Over the last twenty-five years GLOBALIS, a Fortune-500 firm in the US, has successfully launched and operated multiple IT software and systems services facilities, called solution centers or sites from now on in the paper. Today, GLOBALIS has solution centers in multiple cities in the US, in Ireland and in India. Although GLOBALIS has considerable experience in establishing solution centers and is well aware of industry’s best practices for dealing with issues and problems of geographic dispersion: distance, time zone differences, cultural differences, loss of communication richness, etc., it is facing difficulty in unifying these sites into a cohesive community. The data used in this paper was collected over a span of three years.

We interviewed forty employees of GLOBALIS that included six senior management personnel, six project managers and twenty-eight workers associated with the four projects. These interviews occurred in both individual and group format and most of the interviews happened in person. Each interview lasted approximately one hour in length. These interviews were semi-structured and conversational in nature, and they covered a range of topics related to GLOBALIS’ global delivery systems.

We made repeated visits to the onshore and offshore sites associated with the project. During these visits, we also observed the nature of the work associated with the project, especially meetings and other situations where people from the various sites interact with one another. The Ireland sites were visited in 2003 for one week, and again in 2006 for another week. The India sites were visited over ten days in 2006. During the course of the project, the sites in the New England area were visited intermittently in order to attend meetings, conduct interviews, and deliver reports.

We observed eight engagement managers monthly video-conference meetings over a period of ten months, first six at the US site, seventh at one of the Ireland sites and the eighth at one of the two sites in India. We monitored two team meetings conducted via conference calls between the team leader in the US and testers in India. We also surveyed the workers associated with the four projects we tracked. The team members on these four projects were distributed across the New England sites, Dallas, Texas, Galway, Ireland and Bangalore, India. In addition, we made six management presentations of our findings at the headquarters site in US, in Dublin and in Gurgaon, and received valuable feedback.

Unlike intercultural communication research, which imposes a cultural framework on the interactions, and assumes that the source of problematic interactions is cultural, we were interested in “what more” (Garfinkel 1996) could be accounted for outside of the corpus of literature and research methodologies associated with the study of globally distributed work teams. Thus, we were not looking for the impact of national culture on virtual team collaboration per se. We were not assuming that the work process was problematic. Rather, we were interested in what emerged from the project, rather than trying to confirm previous studies or testing existing theory. In this way, we were following a workplace studies approach abstaining from broad a priori application of theoretical concepts and opting instead for a detailed analysis of in-situ social order (Suchman 1987, Orr 1996, Luff et al 2000).

Our analysis is based on the following four data gathering situations: engagement-managers monthly video conferences, cross-cultural training course, survey of attitude and use of time and our visits of the sites in Ireland, India and the US.

2.1 Monthly Video Conference Meetings

When we started our study, GLOBALIS had just made a decision to establish a new solution center in Bangalore and was engaged in defining and implementing a new global delivery process (GDP). We attended six monthly engagement managers meetings at the headquarters (HQ) of GLOBALIS in the New England region in the US. They were two hours meetings that started at 8 AM eastern standard
time. The management teams at Dallas, Dublin and Gurgaon were connected to these meetings via a video interface. The Dublin and Gurgaon sites were always on the meeting agenda, but their role was relegated to making presentations on the status of their projects, resources and issues. When we observed the same meeting from the Dublin and Gurgaon sites, we noticed that the Dublin and Gurgaon participants would put their audio part on mute, in effect cutting them off from the dialog taking place at the HQ site. Twice these monthly video conferences started late because the video equipment at the HQ site malfunctioned.

When we probed why the Dublin and Gurgaon sites mute their systems, we found that whenever anyone at the remote sites speaks, the camera focuses on that person and the face of the speaker appears on the television screen in the meeting room at the HQ site. This would happen with slightest utterance of a sound such as someone sneezing. To avoid disturbing the conversation, the Dublin and Gurgaon sites would mute the audio portion of their systems.

We observed that every video conference meeting was “run” by a manager at the HQ site, meaning time was kept from HQ, the meeting began from HQ, the agenda was followed or altered from HQ, etc. Questions asked from the distributed sites tended to be clarification questions, while the questions from HQ were accountability questions, (why something was not done, project delays, employee allocations, etc.). We never observed accountability questions raised by people at the distributed sites. Thus, accountability was a uni-directional practice originating from HQ.

In addition, all meetings were scheduled to start at 8 AM eastern standard time in the US. This meant that it was 1:00pm in Ireland, 7:00pm in India, 7:00am in Texas and 6:00am in Utah. Thus, people in New England were beginning their workday with a meeting, while workers in Ireland were having their day interrupted and people in Texas, Utah and India had to work outside their normal work hours. This is an indication of who has to adjust to whom. But more significantly, the people at the headquarters behaved as the decision makers and the people at the remote site behaved as vendors, suggesting an unequal relationship among the sites.

We also observed that the people at the two Indian sites did not understand at least 40% of the discussion taking place among the participants in the meeting room at the HQ site. This was partially because of the quality of the audio signal and partially because they did not understand the accent and were not fully cognizant to the implications of the issues being discussed. Furthermore, the participants in the HQ meeting room often used humor and jokes to convey their positions or even displeasure, and most of this humor did not carry over because most Indian were not familiar with the common American expressions.

In summary, our video-conference observations suggested a hierarchical relationship among the sites and the expression and usage of the English language in the US made it hard for the Indian participants to understand the video conference conversation.

2.2 Cross-Cultural Training

GLOBALIS contracted with a consulting company to train their employees on how to do business with India. This training was a one day program where managers were exposed to generalized traits and characteristics of Indian culture while developing an awareness of their own culture. We attended this training program and found that like most cross-cultural training programs, the focus of this training was on exposing the American workers to those cultural traits of Indians that were different from Americans such as American society is very individualistic and Indian society is group-oriented; Americans are egalitarian and Indians are very hierarchical; Americans view time as linear whereas time in India is cyclic and event driven; American are monochromatic, that is, they prefer to work on one task at a time, and Indians are polychromatic and they often engage in multitasking; etc. No equivalent training was given to US managers on doing business in Ireland. More significantly, the Irish managers were never given any training on doing business in India. On the other hand, when we interviewed the Indian workers, we found out that they were given a short 3 hours program on working with US. Unfortunately, the people we interviewed could not remember much about that
training except that they were told not to use “but” in their email communications with US workers and managers.

When we asked the workers whether national culture differences impact their work, the response was always “they did not see national culture playing any significant role.” However, when we walked into the cafeteria for lunch at a New England site we noticed that all the workers from India who were in the States for a training program were sitting on one table whereas their American counterparts were distributed on other tables away from their Indian visitors. The exception was one Indian woman trainee who was sitting with other American women workers. When we asked the male Indian workers why they did not socially mix with their American colleague at lunch time, their response was that they did not know enough about the American pop culture to engage in informal chit chat. When we asked the Indian female worker who was sitting with other American women what they talked about, she said that since she was getting married soon, the conversation dwelt on weddings in India and in the US and how the bride dresses, etc.

Although workers in the US, Ireland and India told us that their work suffers from many communication problems but none of these workers attributed any of those problems to culture differences. However, the managers felt that cultural differences were really impacting behaviors. We present three stories, one by Scott, who was a project manager at one of the New England sites, the second by Seamus, a project manager at one of the Dublin site in Ireland and the third by the site manager, Alka, in India.

Scott was managing a team of US and Irish workers working on a critical project. Late in the project life cycle new team members from India were added to the project as additional resources to keep the project on schedule. Scott observed that the new team members from India were not as responsive and prompt as the original team members. After attending the cross-cultural training Scott realized that because time in Indian culture is elastic, the Indian team members may not fully grasp the project’s sensitivity to deadlines and schedules. To remedy this situation, he said he micro managed the Indian team but could not improve the behavior.

Seamus was the manager of a team which consisted of Irish analysts, architects and integrators and Indian software engineers and testers. The project involved upgrading of an existing system for an old valued customer, and the Irish team members had extensive knowledge of the problem domain and the current system. Seamus asked the Indian team to start coding from a set of incomplete specifications. The Indian team refused. Seamus was very frustrated and he complained to us that the Indian workers are too process-based and they don’t understand the relationship culture of GLOBALIS. This is an example of a communication conflict that has been framed in terms of professional cultures.

During our conversation with the site manager, Alka, in Gurgaon, India we inquired whether she had more information on the content of the three hours of cross-cultural training provided to the Indian workers. She did not know the details and she asked us to tell her what we have heard from our interviews. We told her that people do not remember the details except that they were being trained to communicate more directly. We suggested that because Hall (1981) had identified US to be a low-context culture, the training course may be focusing on teaching how to engage in direct and detailed communications. Alka mentioned that one source of communication difficulty is that ‘we Indians have difficulty saying No’ and that often leads to ambiguity and misunderstanding. We asked her to provide us an example. She tried to explain this in the following manner. When my counterpart in the US tells me that Alka I have given my word to the customer that the new system will go live on October 1, are you sure you can meet this deadline? Alka feels that even when she knows that it will be hard to meet the deadline, she cannot just say no and instead her response will be “Jack, you know it is hard to predict all that can happen when you are doing software development, especially when the technology we are using is new. But you know us, we are committed and will do our utmost to make the deadline.”
2.3 Attitude and Use of Time Survey

Using a well-tested time-at-work questionnaire (Schriber & Gutek 1987) which is shown in Table 1, we surveyed the GLOBALIS employees who were engaged in the four projects we tracked. Respondents indicated their level of agreement on a five point Likert scale (Likert 1932) with each of the twenty-five statements based on their perceptions of what was most typical within their organization.

Table 1-Time-at-Work Questionnaire

Figure 1 on the next page shows the mean values for each of the four temporal constructs which are aggregated for the whole company and by each country. On the schedule and deadline dimension the mean values for US, Ireland and India are 4.11, 4.26 and 4.13. This indicates that, irrespective of the differences in the national cultures, GLOBALIS workers in the US, Ireland, and India all proclaim the same orientation to schedules and deadlines. Similarly, the mean values on punctuality for the US, Ireland and India are almost identical, thus indicating that punctuality at GLOBALIS is also valued with the same uniformity across the global sites in these three countries.

The work time/non-work time boundary construct is a measure that attempts to assess how far work interferes with personal life. A mean value of 2.87 on the time boundaries dimension being less than 3.0 suggests that GLOBALIS workers perceive a good work/life balance at their work place. The mean value for both the US and India is 3.08, while the mean value for Ireland is 2.71. This indicates that work/life balance is perceived to be slightly better by Irish workers in comparison to those at the US and Indian sites.

The awareness of time use construct measures the extent to which workers plan and manage their use of time. A mean value of 2.38 suggests that the work environment of GLOBALIS is such that workers cannot always plan and control their use of work time. The mean values of 2.20, 2.39 and 2.45 for workers in the US, Ireland and India respectively would indicate that, irrespective of location, workers believe they have difficulty in planning and controlling their work time.
Figure 1 - Temporal Dimensions by Nationality

In summary, schedule and deadlines are uniformly valued and taken very seriously by GLOBALIS workers across geographic boundaries, punctuality is valued equally across these globally distributed worksites, and Irish workers report a stronger work/life balance than US and India workers. It should be mentioned that we had stratified the responses on project type, age, and job-level, and that data will be presented later when we will synthesize these diverse findings into a unified culture model.

2.4 Visits to GLOBALIS Sites in India, Ireland and US

Because these observations are varied we have identified each with a label.

2.4.1 Observation 1 - Punctuality

When we visited the sites in India, we experienced punctuality and an awareness of time. For instance, while the cross-cultural training on India observed that Indian culture has an “elastic” view of time, meetings in India always started promptly at the assigned time, unless of course we were the ones who were running late. In other words, there was no moment at which we were significantly delayed because of a lack of time sensitivity. We had the same experience at all the other sites of GLOBALIS.

2.4.2 Observation 2 - Age & Tenure

During our ten day visit to the GLOBALIS sites in India, we were immediately struck by how young the GLOBALIS employees in India were. We discovered that the average age of the Indian employees was in the mid-twenties and roughly 90% of the employees had less than 2 years of experience with the firm. These Indian workers had to interface with US employees who are typically 10 to 15 years older than them and who have over 10 years of experience with the systems, application and the firm. We even came across American GLOBALIS employees who had worked on the same project over the span of their career in the organization.

2.4.3 Observation 3 - Chit-chat

At the two Indian sites it was readily apparent that the workers engaged in a lot more chit-chat than what we saw at any of the sites we visited in the US. Even while working people talked over the booths, and the chit-chat was often embedded with work talk where someone would ask a questions and receive an answer from someone else. We estimated that if the work time / social time divide in the US is 80% to 20 %, work time/ social time divide in India is closer to 60% and 40%.
2.4.4 Observation 4-Attrition

GLOBALIS has been successful in recruiting experienced IT staff in India, with most having started their careers with an Indian IT firm (such as Infosys, TCS, Satyam, Wipro, etc.) with many moving to a US IT firm (e.g., IBM, Microsoft, Oracle, Motorola, Hewlett-Packard, etc.) in India as their second IT job. They were attracted to GLOBALIS in order to gain domain knowledge of financial systems and technologies. These people came to GLOBALIS expecting to work directly with the clients. In addition, we were told that the expectation in the IT market place is such that a new employee expects to move to project leadership position in two years, and if s/he is not sent to the US for training or system implementation within two years of joining the firm, then his or her career is perceived to be in a crisis. A lack in any of these expectations often leads to the worker to leave for career aspirations and opportunity with another firm, making attrition a real issue.

2.4.5 Observation 5- SLAs

A manager in US told us that he gets complaints from his staff about the poor quality of work done in India but when he talks to the manager in India he is presented with the service level agreement data that shows the Indian site is meeting the agreed SLAs. We saw an example of this dichotomy during our India visit. We observed how a customer support staff in Bangalore handled a customer call from a US customer. The support staff had real difficulty understanding the name of the customer and took at least 10 minutes to find the record of the customer. We could anticipate the customer was frustrated but the support staff continued repeating the script. Then suddenly the phone went dead and the support staff entered this as a satisfactory closed call. It is possible the customer was frustrated and may have decided to call back again hoping to catch another support staff, but our support person closed the call, indicating that the customer query was resolved.

3 UNPACKING CULTURE

Our time-at-work survey of GLOBALIS workers found that the attitudes towards punctuality and deadlines and schedules were uniform across US, Ireland and India. This finding is not aligned with the common perceptions of the attitude of Indians towards time. For example, observing the Indians who live in the US, Acharya (2008) states “Although many Indian Americans have achieved considerable professional success ... one thing we do not seem to learn is the concept of time. Except for activities related to one’s profession – where one has to be on time or lose a job – there is absolutely no regard for appointed time in other non-professional or social activities. We seem to think that all activities start on Indian Standard Time, and not on announced time.”

Acharya recognizes the casual attitude to punctuality in Indian culture, but he also points out that in the workplace this attitude changes. Within the cultural frame our time-and-work survey finding is consistent with Laurent’s (1986) argument that adherence to corporate norms can modify behaviors that may be embedded in national culture. Our attitude-toward-time survey suggests that any study of how culture impacts worker behaviors in global virtual work must include the analysis of corporate culture.

We surveyed the same 137 employees to assess GLOBALIS’ culture, using the instrument developed by Sarros et al (2002). It profiles corporate culture across seven dimensions: Competitiveness; Emphasis on Reward; Innovation; Performance Orientation; Social Responsibility; Stability and Supportiveness. As shown in Table 2, all seven dimensions received a mean score above 3.0, indicating that GLOBALIS employees report placing importance to all seven dimensions. The mean values for the US, Ireland and India individually are also greater than 3.0, and no significant statistical difference was observed in five of these seven culture dimensions. We can therefore conclude that GLOBALIS’ corporate values are uniform across its work sites.
### Table 2-Culture Profile Summary

The diffusion of GLOBALIS’ corporate culture across sites could be a reason why GLOBALIS employees indicated in our survey uniform valuing of the temporal dimensions of time across countries. This would suggest that GLOBALIS’ corporate norms are modifying the temporal attitudes that are embedded in national cultures. However, as observed by Scott and described earlier in the data gathering section that the actual behavior of the Indian software engineers who were added late to a project he was managing does not match the self-reported finding of the change in attitude toward temporal dimensions.

Furthermore, our chit-chat observation (observation) is indicating that the work time / social time divide behaviors at GLOBALIS sites are aligned to the observed national culture differences (Manrai and Manrai 1995). In addition, our interview data is showing (a) a high-context / low context communications styles exist at GLOBALIS and (b) differences in the professional cultures between the Ireland (more customer-oriented) and India (more process-oriented) sites.

Thus, an important research question is: how to reconcile these conflicting observations and findings associated with the study of workers behaviors in global work. Prior research (Huang et al. 2003, Straub et al. 2002, Myers & Tam 2002; Gallivan & Srite 2005) have recognized this conundrum as layers of cultures that impact behavior in global work and they have warned against using national

</table>
culture as a sole operationalization of culture to explain global workplace behavior. This paper will next unify this culture layers conundrum.

3.1 The Concept of Workplace Culture

The co-location of workers at each work site generates a workplace culture which is simply a shared understanding of norms, practices and values. Because the workers are co-located, behaviors and norms are visible to each other and there is more opportunity to engage in informal chit-chat leading to behavioral knowledge sharing. Thus, proximity and visibility enables a form of cohesion among the workers at a site that we are calling as the workplace culture. We will analyze GLOBALIS’ data further to shape and sharpen the workplace culture construct and demonstrate its role in analyzing behavior in global work.

3.1.1 Analysis of Chit-chat observation

When we visited the Bangalore site we noticed workers in groups of two or three talking in the canteen at all hours during the work day. During our visit to the Gurgaon site, we observed continual small talk among the adjacent workers during work hours as well. This behavior was markedly different from that which we observed at the US sites: there, we rarely saw workers chit-chatting during work hours. While undoubtedly some level of small talk occurred, it did not appear to be at the level we observed in India. Furthermore, in the US, the people whom we interviewed came to meet us at the assigned time and their body language indicated that the interview should end at the allotted time. Seemingly, the workers at the US sites went straight back to their cubicle or office right after the interview. We also noticed workers at the US sites walking to the coffee machine, mostly during the morning hours, and always carrying their cup of coffee to their workplace. In contrast, the workers in India, including American managers who were there on temporary assignment, did not seem to be in a hurry to return to their work after scheduled interviews.

These observations are consistent with what Brislin and Kim (2003) call the task and social time variance among cultures during the workday. Manrai and Manrai (1995) studied this phenomenon empirically and found that in big cities in the US, the task time/social time divide is 80:20, while in India, Nepal, Malaysia, and some Latin countries, it is often 50:50. We initially attributed this behavior to national culture differences. Later, at one of our visits to a New England site, we observed a set of Indian workers from the Gurgaon site (who were stationed there for three months in the US for training), behaving similarly to the US workers: they neither engaged in small talk while working nor chatted at the coffee machine at odd hours. This would indicate that, irrespective of their national culture, people readily adapt to the norms and behaviors of the workplace. This led us to further examine the concept and role of workplace culture.

Cramton and Webber (2005) report that the local contexts across which global virtual teams operate are important and they impact communication and coordination across sites. These studies remind us that greater emphasis needs to be placed on studying how culture and communication manifest themselves in specific contexts. Examples of local context in global work are: travel to and from the worksite, accessibility to the communications infrastructure, local holidays, language proficiency and accents, and cultural differences. Our task time / social time divide observation has identified the existence of a workplace culture that impacts workers’ behaviors, irrespective of their national culture orientations.

3.1.2 Analysis of Age and Experience observation

One US GLOBALIS manager told us that, “When I’m asked a question in a meeting, my modus operandi is to generate a conversation by asking the group what they think about the issue before giving an answer.” When this manager used this approach with his Indian subordinates in Bangalore, “no one spoke up.” Apparently, according to him, “this is common Indian worker behavior that US managers and workers encounter.” At the cross-cultural training course we attended, the US
employees reported that Indian workers “are meek and do not push back”. Other stereotype traits pointed out in this course were: “Indians can’t say ‘no’”, and “Indians have a laid-back attitude toward time”. In summary, both the US managers and workers at GLOBALIS have observed and/or encountered many of these behavior patterns in their interactions with Indian workers.

During our ten day visit to the GLOBALIS sites in India, we were able to investigate these issues directly. We observed that the average age of the employees in India is in the mid-twenties, with roughly 90% having less than two years’ experience with the firm. These Indian workers have to interface with US employees who are 10 to 15 years older and who typically have over ten years’ experience with the systems, applications, and the firm. It is not unusual to find American GLOBALIS employees who have worked on the same project throughout their career in the organization. The Indian workers at the Indian sites are not only young, but were recruited from technical IT firms and lacked the application domain knowledge in the finance sector. They behaved like typical new employees. Thus, many of the behaviors attributed to national culture traits may just as easily be attributed to age and experience. For example, as discussed earlier Scott observed that the new Indian workers added to his project were not as prompt and responsive as the original US and Irish workers. When we talked to these Indian workers we learned that GLOBALIS has many databases with a complex system of access rules and the Indian workers, being new to the project and lacking domain knowledge, were not given direct access to these databases. As a consequence they had to discover who had access and then request them to access and transmit those files. This took time and gave the impression to Scott that these Indian workers were not prompt and responsive.

3.1.3 Observation regarding Process versus Relationship Behavior

In our data section we reported earlier that Seamus, a manager at an Ireland site, told us that when he asked the Indian software engineers to start coding from a very general set of requirements, they refused until the requirements were formally specified. Seamus complained that the Indians were being too process-oriented and they did not understand the customer orientation of GLOBALIS.

Because the software development industry in India is invested heavily in capability maturity certifications and people change jobs often, the IT work culture in India is predominantly process-focused. Since GLOBALIS’ recruiting strategy in India is to recruit only experienced people, its workers at the Indian sites arrive after having socialized in process-based, matured software organizations. Thus, GLOBALIS’ recruiting strategy in India and the professional software culture of the Indian IT industry is responsible for the process-focused software professional culture (Cougar et al. 1990) of GLOBALIS in India.

3.1.4 Analysis of video-conferencing observations

Our video conference observations brought out that GLOBALIS sites are not all equal. The sites in the New England region are in the core and Ireland and India sites are clearly on the periphery in terms of decision making. This was underscored by all the project managers being stationed in the US. While some global teams are currently managed by personnel located in Ireland, India does not currently “own” any projects. Thus, the very organizational distribution of work, while speaking of integrated teams conveys the message of hierarchical stratification. This perspective was reinforced in the training sessions being taken by the Americans (who were being trained to manage relationships), and the Indians (who were being trained to do the work). The video-conference interactions brought out the Indian managers at the Indian sites of GLOBALIS, even though they worked for the same company, viewed their American counterparts as their clients or bosses. This was underlined by their previous work experience. Since the vendor model dominates the Indian IT landscape, it is not surprising to see this perspective being adopted by GLOBALIS’ Indian employees. Thus, the Indian workers were struggling to see themselves as team members, a struggle that was enhanced by the age and experience differential between the Indian and US offices. One could say that the workplace culture of the Indian sites is vendor-oriented, and in a vendor-oriented culture, it is difficult to push
back or say ‘no’ directly, especially when being trained to provide a service. This may be a reason why the workers at the Indian sites use a high-context communications style.

Bringing these observations together, we see that certain cultural attributes are related more to the characteristics of the worksites than due to national or corporate culture. They substantiate the existence of workplace culture. The workplace cultures we observed at GLOBALIS can be summarized as follows:

- The work culture at the Indian sites of GLOBALIS is process-based
- GLOBALIS’ work culture in Ireland is more customer-oriented
- Because GLOBALIS employees at the Indian sites view their US and Irish colleagues as clients, GLOBALIS’ Indian sites culture is vendor-oriented
- Although the task time / social time divide at GLOBALIS match national culture traits, it is part of the workplace culture because of the unconscious adaptation of local practice by visitors from other sites.

As discussed above, age and experience, professional standards and certifications, and client/vendor orientation all combine to impact workplace culture.

3.2 Towards a new model of culture in global organizations

Our investigations of attitude and use of time at GLOBALIS suggest that, to understand the role of culture in today’s global work, the national culture construction of culture is insufficient. Rather, corporate and workplace cultures need to be incorporated into the mix. This is consistent with the findings of Perlow and Weeks (2002) and Huang et al. (2003). Perlow and Weeks noted that behaviors of software engineers doing the same type of work in the US and India reflect the combined influence of national, occupational, and organizational layers of culture in the two settings. Huang and colleagues noted different organizational subcultures at work in their study. We integrate these concepts and offer a new culture model of global work in multinational firms such as GLOBALIS, shown in Figure 2. Workplace culture is a key construct and, as argued above, it depends upon a variety of environmental factors, including age and experience of the workers, industry standards and certifications, and differing client/vendor relationship perceptions at different sites.

The addition of project culture in the model is based on our survey data. The responses were stratified on following variables.

- Nationality - US, Ireland, and India
- Project - Bank of America, FMD, PACE, and STARS
- Position - non-management, lower management, middle management, top management
- Age - 20-29, 30-39, 40-49, 50-59

Figure 3 presents the survey participants’ rating based on the four projects. The variation in the mean values (4.59, 4.09 and 3.75) for the four projects in the schedule and deadline dimension in Figure 3 implies that meeting schedule and deadlines are not only uniformly valued across sites, the level of importance assigned to schedule and deadlines depends of on the nature of the project. This suggests that project characteristics impact workers behaviors.
4 IMPLICATIONS AND DISCUSSION

Although culture investigations in global IT work have been an important area of research, the focus often has been on attributing behaviors to national culture differences (Ramingwong and Sajeev 2007, Symons and Stenzel 2007, Krishna et al. 2004, Borchers 2003, Walsham 2002, Heeks et al. 2001). We will review some of the findings of earlier research using the lens of our proposed culture model in global work.

Using Hofstede’s dimensions of national culture, Ramingwong and Sajeev (2007) conclude that the risk of the ‘mum effect’ (or code of silence) is higher in Asia (higher power-distance, lower individualism-collectivism index and higher long-term orientation) than in the West. Our time-use investigations showed that people tend to comply with organizational norms and values, and therefore,
worker behavior would be driven by visible actions of the organization (such as the firing of a whistle blower) rather than workers’ inherent proclivity to the mum effect. Similarly, since the client/vendor relationship impacts workplace behavior, the ‘mum effect’ will also be moderated by the culture of the workplace. In summary, our culture model of global work suggests that an analysis of the ‘mum effect’ must take into account the impacts of corporate and workplace cultures.

After a chance reading of Hofstede’s (1980) book *Culture’s Consequences*, Borchers (2003) began to see how Hofstede’s culture dimensions were playing out in the behaviors among team members in the US, India and Japan. For instance, Borchers reasoned that the difference in behaviors between the US and Indian workers during a ‘bug fixing’ phase on a project was due to Indian culture having a lower value on Hofstede’s individualism-collectiveness index in comparison to the US, and that this enabled the Indian developers to form close interpersonal bonds within the team.

There are, of course, other potential causes for the behavior of the Indian team, which are not considered by Borchers, and do not necessarily relate to Hofstede’s analysis. During our investigations of global work at GLOBALIS, we noticed that the Indian software developers working for multinational firms belonged to a narrow band of Indian culture. Most of them were educated in English-speaking high schools and grew up listening to Western popular music, popular literature and movies. It is this identity with Western pop culture and their youthfulness that can be seen to separate them from Indian society in general and to seed the kind of bonds of friendship that Borchers observed in the Indian software team members. This high degree of social solidarity, often cemented through shared social activities, may be what is fueling their collaborative work rather than simply belonging to “Indian culture.”

Scholars on global work who have explored research-driven best practices for effective management of global software teams (Krishna et al. 2004, Walsham 2002) frame cultural barriers to global coordination on societies’ distinct ways of working. As a result, they attribute observed behaviors in the workplace to national culture differences alone. For example, British managers in an outsourcing relationship with a particular Indian software supplier noted that Indian programmers would not voice criticism in face-to-face meetings but would sometimes send their opinions in email messages after the meetings had disbanded. This behavior is attributed to Indian culture where ‘deference to authority’ is valued.

Again, there are alternative explanations that can be posited upon closer examination, utilizing different analytical lenses. For example, we observed that a number of the Indians we interviewed could not converse fluently in English. Borchers (2003) observed that because of certain Japanese workers’ inability to communicate fluently in English, they preferred to communicate through emails. Thus, a possible reason for some of the Indian workers not voicing criticism in face-to-face interaction could be their inability to effectively converse in English. Furthermore, these Indian employees often had far less experience on the projects, had less time in the company, had little or no domain knowledge, and were interacting with American team members who had been involved in the project from the outset. All of these factors may well have contributed to a ‘following’ versus ‘leading’ approach to team interactions.

Heeks et al. (2001) offer an interesting example of cultural dissonance. Apparently project leakage in a UK firm Sierra, called UK-Sierra here, was typically 2 to 3 percent and in its wholly-owned offshore development center in India (India-Sierra), it was between 25 to 30 percent. Conflict arose between UK-Sierra and India-Sierra regarding definitions of leakage. At UK-Sierra, leakage was measured in terms of time spent versus time planned. They reported that “from the Indian staff’s perspective, deadlines mattered but how much time was spent did not, and they felt UK values were insensitive to Indian conditions.” Because the authors analyzed this issue based on their view that “players in this global game still retain cultural values rooted in a particular locale,” (ibid., p. 59), Heeks and colleagues framed the conflict in terms of differences in cultural values between UK and India.

In our study of attitude towards time and its use at GLOBALIS sites in the US, Ireland and India, we saw no evidence to suggest that ‘meeting deadlines’ is a particularly Indian cultural value. Rather, it
was a corporate value of GLOBALIS with which the Indians complied. Also, we observed that local working conditions (such as lack of domain knowledge or of tacit knowledge) cause delays and interfere with the promptness of Indian workers. It is hard to say that the definition of leakage in UK-Sierra is based on certain British values, but it is clear that measures used in one corporate environment may not transfer across geographic boundaries, especially when they make workers look bad. Thus it may not be appropriate, certainly not in all cases, to attribute national culture differences to be the cause of dissonance.

Irrespective of their worksite location, GLOBALIS workers felt that national culture is not an overriding factor in distributed workplace collaboration. However, GLOBALIS managers in the US, Ireland and India all reported that national culture differences matter greatly. Besides the contradictory perceptions between workers and managers regarding the role of culture in global work, we also observed uneven management actions with respect to culture training at GLOBALIS. For example, GLOBALIS’ management contracted with a consulting company to train their US employees on how to do business with India. This training consisted of a one-day program where managers were exposed to generalized traits and characteristics of Indian culture while developing an awareness of their own US culture. We attended this training program and found that, like most cross-cultural training programs, the focus was on exposing the American workers to those cultural traits of Indians that were said to be different from Americans. Attitude and use of time was one of the topics covered. It is perhaps instructive to note that the Irish and Indian managers were not given a similar cross-cultural training opportunity. Our interviews with the Indian workers indicated that some had been given a short, three hour introduction to working with US colleagues, but the people we interviewed could not remember much about this training other than they should not use the word “but” in their email communications with US workers and managers.

During our monitoring of global conference calls during our study we observed that any time someone joined a conference call five minutes or so late, they apologized. Since this appeared to be so irrespective of the location of the participant, we concluded that, in the culture of GLOBALIS, five minutes of tardiness for a conference call is considered significant and requires an apology. As an aside, when we took a class of American students to Bangalore, India, the five Indian industry speakers we had invited to speak to the students were all well over half an hour late for their lectures, yet none of them apologized to the class. Does this suggest that in Indian culture being tardy to a formal event by half an hour is not considered significantly late, but that Indians in GLOBALIS have been acculturated to the company culture? In any case, these observations tend to confirm Edward Hall’s (1959) finding that punctuality is cultural at some level, and Laurent’s (1986) argument that adherence to corporate norms may modify behaviors embedded in national culture.

The purpose of these examples has been to illustrate that the current conceptualization of cross-cultural analyses based on the traditional view arising from Hofstede, namely that workers in global work retain cultural values rooted in national culture, can result in inappropriate attributions (Osland & Bird 2000). Myers and Tan (2002) found wide usage of ‘national culture’ models by many IS researchers, resulting in narrow, simplified perspectives on the effects of national culture. Their review of the IS literature on national culture shows how the concept of national culture was taken for granted by many IS researchers. They criticized the conceptualization of national culture models proposed by Hofstede and other researchers. They proposed a research agenda inviting researchers to develop better lenses through which to move beyond simplistic treatments of national culture in order to investigate the dynamic and complex effects of cross-cultural diversity for the management of today’s global organizations. This study has been an attempt to move the field in the direction proposed by Myers and Tan (2002) and Gallivan and Srite (2005). Our model of culture provides a more nuanced and refined framework to study the impact of cross-cultural differences on global work. Next we will discuss the research directions needed to place our model on a firmer foundation and the research approach needed to move the field forward.

First, most empirical studies in the IS and Software Engineering literatures on global work and global virtual teams have tended to focus almost entirely on national culture differences, primarily on two of
Hofstede’s culture dimensions, namely Power Distance and Individualism/Collectivism. Trompenaars and Hampden-Turner (1997) proposed a set of seven culture dimensions and two among these are same as Hofstede’s. More recently, Gupta and House (2004) proposed nine dimensions of culture which, unlike Hofstede’s, are rooted in theory and they are: Performance Orientation; Assertiveness Orientation; Future Orientation; Human Orientation; Institutional Collectivism; Family Collectivism; Gender Egalitarianism; Power Distance, and Uncertainty Avoidance. These provide a more finely grained approach that is worthy of further consideration. Thus, we argue that there is a need to develop a richer understanding of how these culture dimensions affect global interactions and work.

Second, as argued by Huang and colleagues (2003), the role of corporate culture, and corporate subcultures, in global work requires much more serious consideration. Although there is extensive literature on corporate culture and adoption and use IT in organizations (Gallivan and Srite 2005), the learning from these studies have not been incorporated in the study of global virtual work.

Third, the construct of workplace culture is crucial for a more comprehensive understanding of the factors that impact global work, yet there is little research on this construct in the IS literature. Since our conceptualization of workplace culture is based on the study of just one multi-national firm, the contextual variables we have identified need to be validated in other settings.

Finally, one cannot just engage in traditional survey research alone to build theory (Galliers 1992); a pluralistic approach is required (Mingers 2001). We would further argue that, for the theory to be robust, it must be rooted in practice. Because global work is a relatively new phenomenon, an ethnographic study is needed to uncover the factors that may be affecting behaviors in global virtual work with the findings being used to develop hypotheses for theory testing.

Abstract

Many companies consider and undertake outsourcing of their software-development activities. Often information systems development is outsourced to vendors in different cultures or with a different level of software-process maturity. Recommendations for managing such outsourcing arrangements typically involve that client and vendor should increase interaction, learn more about the culture of the other part, communicate more, form partnerships, and the like. We have studied a client that did the opposite with a successful outcome. Based on a case study we lay out the story of how interaction between client and vendor on purpose was minimised. What mechanisms were used? What worked and what did not? We conclude that minimizing interaction can be a viable strategy to follow when clients face large cultural and maturity inequality in offshoring their software-development activities.

Keywords: Offshore outsourcing, Culture, Maturity, Minimal-interaction strategy, Extra costs.
1 INTRODUCTION

Information systems (IS) outsourcing can be defined as the practice where an organization purchase goods or services “that were previously provided internally” (Lacity et al. 1993). Many companies consider and undertake outsourcing. It has been estimated that global software outsourcing is going to reach $260 billion by 2009 (Vitharana et al. 2007). The documented benefits of IS outsourcing have been reduction of time and cost, increased quality, improved business performance, and increased ability to concentrate on the core of the business (McFarlane et al. 2004). Recently, outsourcing to another country – so-called offshoring – has become popular because large numbers of technically skilled developers are being educated in countries such as India where wages are low compared to Western Europe and North America, in which skilled developers are in short supply. Offshore outsourcing is defined as “the subcontracting of an activity by a client organization to an independent service provider working from an overseas destination” (Vlaar et al. 2008) or simply as “inter-country outsourcing” (King et al. 2008).

While geographic distance is, thus, a defining characteristic of offshore outsourcing, the challenge is not geography as such but overcoming communication bottlenecks, knowledge asymmetries, psychological dissociation, and socio-cultural differences. General recommendations to manage collaboration at a distance include establishing common ground at the outset and distributing tasks such that only loosely coupled tasks are allocated to different sites (Olson et al. 2000). For offshore outsourcing two specific challenges are that the client and the vendor often have very different cultures and are at very different levels of maturity with respect to their software development processes. To handle these challenges it is frequently recommend to increase interaction, learn more about the culture of the other part, communicate more, form partnerships, or the like (Bhat et al. 2006; Hendry 1995; Krishna et al. 2004).

In this study, we analyse a company that did the opposite, namely minimized interaction between client and vendor, and with a successful outcome, in the sense that they just decided to renew their contract with a large Indian vendor; on the same terms as for the last four years. This approach is contrary to the prevalent recommendations in the literature, and we consider it of interest to study this anomaly. In doing so our research question is: Is minimal interaction between client and vendor a way to overcome cultural and maturity inequality in offshore outsourcing?

The next section sets the context for our study by describing related work on offshore outsourcing, culture and maturity. Section 3 accounts for the method we used in our empirical study, and Section 4 introduces the client and vendor organizations. Section 5 analyses the client’s minimal interaction approach to offshoring and identifies the mechanisms established to succeed with this approach. Section 6 discusses how the minimal interaction approach has affected the client’s software-development activities and at what costs.

2 OFFSHORE OUTSOURCING

Carmel and Agarwal (2002) propose four stages of offshore sourcing of information systems development. An organization is at the first stage if it is still an offshore bystander. While there may be a variety of reasons for remaining at this stage, more and more organizations choose to proceed to one of the subsequent stages. Organizations at the second stage have started experimenting with offshoring, for example through pilot projects, and often their motivation for offshoring is unavailability of onshore developers rather than a proactive focus on offshore possibilities. Loaded wages for skilled Indian developers at 30-50% of onshore wages in Western Europe and North America is an important motivator for offshoring, but rarely realized at this stage. One reason for this is that the stage is transitional; when some experience has been gained and cost savings start to occur, organizations move to the next stage. At the third stage organizations are characterized by a proactive cost focus. A typical recommendation at this stage is to restrict offshoring to non-core and structured
tasks, such as construction based on detailed specifications (e.g., Cusick et al. 2006). Often, onshore project managers receive targets specifying that a certain percentage of the developer hours on their projects should be offshore developer hours. At least one study finds that onshore staff tended to perceive offshore developers as cheap worker-bees who could be ordered around (Levina et al. 2008).

At the fourth stage organizations no longer view offshoring as simply a source of low cost work but have adopted a proactive strategic focus. The strategic objectives pursued at this stage include access to new markets and offshoring of entire projects from requirements through to support, also of projects involving innovation and new product development. The best offshore practices described by Bhat et al. (2006) appear to be directed solely at this fourth stage and focus on achieving shared goals, culture, processes, and responsibilities for client and vendor.

While the vast majority of research approaches offshoring from the client’s point of view, some studies do investigate vendors’ views of offshoring (e.g., Bhat et al. 2006; Oza et al. 2005). A theme common to client and vendor research is asymmetries in knowledge and experience. These asymmetries concern, among other things, the business domain, typically with the client in possession of business knowledge and the vendor less so (e.g., Levina et al. 2008), and development processes, typically with vendors that have more structured development processes than clients (e.g., Oza et al. 2005). Technical knowledge exhibits another type of asymmetry in that the vendor typically employs a large pool of technically skilled developers while this resource is scarcer onshore.

The top risks associated with offshore outsourcing include lack of top management commitment, miscommunication of requirements, inadequate user involvement, failure to manage end user expectations, and poor change control (Iacovou et al. 2008). These risks do not appear to be specific to offshoring but rather to apply to information systems development in general (cf. Schmidt et al. 2001). Some of the top risks associated with offshoring are, however, specific to offshoring, including language barriers, lack of offshore project management know-how by the client, lack of technical or business know-how by the offshore team, and failure to consider all costs (Iacovou et al. 2008). Many client organizations have expected cost reductions from their offshoring arrangements due to the lower offshore wages but have not fully understood all the costs involved in outsourcing (Barthélemy 2001). Dibbern et al. (2008) identify specification costs, design costs, knowledge-transfer costs, coordination costs, and control costs as the five main categories in which clients face extra costs when projects are offshore. The five categories of extra costs relate to the less effective possibilities for communication between client and vendor and the resulting degradation in their mutual awareness of each other’s work and day-to-day activities.

2.1 The role of culture

Hofstede (2001) defines culture as “the collective programming of the mind that distinguishes the members of one group or category of people from another”. Hofstede’s work shows that even within a single organization, national groups of employee exhibit different cultural characteristics. These characteristics have been specified in terms of five cultural dimensions: power distance, uncertainty avoidance, individualism/collectivism, masculinity/femininity, and long-/short-term orientation (Hofstede 2001). It appears that managers in organizations chronically underestimate the magnitude and importance of cultural differences (Hofstede et al. 2005).

Prior surveys indicate that national culture is a leading cause of problems in the offshoring of services (Metters 2008). Metters (2008), for example, refers to a survey where 60 executives involved in offshoring information technology (IT) services cited “cultural differences” as the most important problem in relation to offshoring. Also, Terdiman and Berg’s (2001) framework for evaluating a potential offshoring country has “cultural issues” as one of three main areas. The interest in nearshoring is another indication that similar cultural characteristics, such as ways of doing business, are considered important to outsourcing decisions (Carmel et al. 2007). In contrast to nearshoring, offshoring typically implies profound cultural differences between client and vendor. Never the less one can find countries that may be remote but culturally close such as Great Britain and Australia.
In the concrete Denmark and India (the client and vendor countries of this study) differ along several of Hofstede’s cultural dimensions but in particular with respect to power distance – defined as the extent to which the less powerful members of institutions and organizations expect and accept that power is distributed unequally. In India power distance is very high, in Denmark very low (Hofstede 2001). Consequently, in the Danish business culture, rank and title are less important than in India where hierarchical forms of behaviour are expected. In Denmark subordinates are expected to speak up and offer suggestions; in India superiors and seniors enjoy more respect, and decisions tend to be top-down. This affects, for example, communication styles and ownership of results (Schomer 2006).

Recommendations for handling cultural differences in offshoring arrangements include facilitated communication sessions (Dubé et al. 2001), building consensus on norms for meetings and deadlines (Paré et al. 1999), and other efforts to establish a shared culture (Bhat et al. 2006).

2.2 Maturity and software process improvement

Maturity models are used to improve the performance of organisations, processes, technology, and people. The Capability Maturity Model (CMM) is a framework characterizing a five-step path for software process improvement (Paulk 1995). The path describes key processes and goals at each of the five levels. An organization has to meet the goals at one level to reach the next. For example, to go from the basic level 1 where behaviour is characterized by being ad-hoc and intuitive to level 2, you need to achieve the goals incorporated in six key process areas: requirements management, subcontractor management, project planning, project tracking, quality assurance, and configuration management. CMM became so popular that a large number of other models using the same five-step path were invented, including People-CMM, Integrated Product Development CMM, Systems Acquisition CMM, and Testing Maturity Model. Finally a large number of the CMM models were summoned in CMM-integrated – or just CMMI (Ahern et al. 2003; Chrissis et al. 2003).

In relation to offshoring, it is noteworthy that India has embraced CMMI. Four countries in the world have used the CMMI model extensively: Australia, India, Japan, and the US (IndiaExpressGroup 2003). The highest level of maturity is level 5, and a few years ago 80% of all the companies in the world at level 5 were from India (Mohnot 2003).

In Denmark only one or two companies have reached level 5 (cf. Pries-Heje et al. 2008), and the majority of Danish companies are at level 1. Thus, when Indian and Danish organizations enter into offshoring arrangements there may be huge maturity inequalities between them.

3 METHOD

Our empirical study is a case study based on interviews in one Danish organization. The case study is single-case and embedded (type 2) according to the typology by Yin (1994, p. 39). We have not obtained data from the vendor. Thus, the empirical data are restricted to a client-side perspective on offshoring. One of the authors has worked with the organization since 2003, and has carried out several assessments and training sessions in the organization from 2003-2007. We believe that it is fair to claim that this author has extensive knowledge on how software development is carried out in the organization.

Concerning offshore outsourcing, however, the case study reported here took place in 2008 and was carried out by both authors. We conducted an initial interview with three staff involved in the client’s offshoring at the managerial level. During this interview we got an overview of the client’s offshore-outsourcing history and identified seven persons for in-depth interviews. The interviewees comprised persons involved in or responsible for (1) the start-up of the offshoring activities, (2) the entire course of offshoring activities, (3) the offshoring contract, (4) the offshore development centre, (5) concrete offshoring projects and certification of offshore staff, and (6) improvement of the client’s development processes; and (7) an offshore coordinator recently returned from a long-term placement at the vendor.
The seven in-depth interviews were loosely structured by an interview guide addressing:
- The offshoring arrangement between client and vendor, and its evolution
- Client-vendor interactions at the levels of the offshore agreement, projects, and individual staff
- The creation of a project identity in projects involving offshoring
- The coordination of such projects
- Initiatives undertaken to facilitate offshoring and the lessons learned from them
- Issues relating to differences in the cultural background of onshore and offshore staff

In addition, the interviewees were asked to reflect upon the factors critical to the client’s experience with offshoring. This part of the interviews was based on a walkthrough of Iacovou and Nakatsu’s (2008) ten-item list of top offshoring risk factors.

The interviews were conducted in meeting rooms at the client’s premises, except one interview which for practical reasons was conducted at the authors’ university. The initial interview was documented in written notes; the in-depth interviews were audio-recorded, and subsequently an extensive written record of the main points was produced. The written record included selected quotes, but the interviews, which lasted 1-2 hours, were not transcribed verbatim. The interviews were analyzed by reading through the written records several times, noting issues stated in individual interviews and patterns emerging across interviews. These issues and patterns were then grouped into themes, resulting in the analysis presented in this paper.

4 THE EMPIRICAL SETTING

The client is a Danish organization in the financial sector. It has approximately 850 employees, some 450 of which are directly involved in the development of IT systems. The client has for 40 years developed and hosted services for the Danish banks, particularly with regard to payment solutions. The financial sector is characterized by high volumes of safety-critical transactions and, thereby, a need for efficient and secure systems. Moreover, the financial sector is dynamic with changes in national and, increasingly, international legislation forcing revisions of systems, with mergers and acquisitions among banks necessitating integration or redesign of systems, and with considerable competition among providers of financial services creating a continual pressure for the development of new services.

After an early, unsuccessful attempt with outsourcing in the late 1980s, the client refrained from further attempts during the next decade. In 2000 the client started offshoring to India, and in 2002 they started working with their current vendor. The vendor is an Indian software-development organization, which employs over 8000 software developers and has years of experience as an offshore-outsourcing vendor of financial and other services. While the vendor has been certified at CMM level five since 2002 and CMMI since 2006, the interviewees estimate that the client is at CMM level 1 or 2. The collaboration between the client and the vendor has been going on for six years, and it has been decided to renew the current contract when it expires by the end of 2008.

The client’s rationale for entering into an offshoring relationship was to increase its capacity. This is stated by several interviewees, who also state that thanks to this increase in capacity the client has been able to carry through projects it would otherwise have been unable to take on.

5 OFFSHORE OUTSOURCING WITH MINIMAL INTERACTION

When setting up an offshore arrangement some interaction is required to negotiate the terms of cooperation, write a contract, and start working together (Willcocks et al. 2006). In the phase following – the operating phase it has been called (Cullen et al. 2006) – there also needs to be some interaction; the salient question is: how much? At one end, we can talk about minimal interaction. That is, just enough to make things work. One could say that minimal interaction is about paying as little transaction cost (Williamson 1979) as possible. Minimal interaction also entails that as few changes as
possible are made in the client’s and vendor’s internal processes. It should be noted that when one reduces transaction costs the remaining interaction will look as being more intensive at particular contact points. At the other end, we can maximize interaction trying to come as close together as possible. This may involve more communication, more learning about the culture of the other part, trying to level or balance maturity, forming a partnership, and maybe even blur the distinction between a client and a vendor.

5.1 Keeping distance

An illustrative example of minimal interaction is project A in the Danish organisation we are studying. This was the first project the client offshored to the vendor. The project, which lasted three years, consisted of converting an existing system to another platform. That is, the existing system in itself comprised a complete and, by definition, fully accurate specification. Such a task involves little analysis and design compared to programming. This characteristic of project A was the main reason it was chosen for offshoring, and it implied that the client could specify the project very accurately and very easily. This made the project very suited for the client’s minimal interaction strategy because minimal interaction could be attained at low risk.

Also, project A was only economically feasible for the client if it could be offshored. The project showed that the vendor had the technical knowledge required to make the conversion. Very few errors were detected during testing, and some of them turned out to be errors in the “specification”; that is, hitherto unnoticed errors in the old system.

After having completed project A, it was decided to set up a more permanent relationship between the client in Denmark and the vendor in India. It was at this point that the idea of minimized interaction really came into play. A manager says: “The point of departure is that they are vendors. They are not employees. They are a vendor like an external company we cooperate with. The idea was to establish it out there [i.e., at the vendor], so that they can maintain their culture and keep working the way they are used to; and people here [i.e., at the client] work in their way. Actually, reducing the need for intercultural interaction to as little as possible was part of what I was trying to accomplish.”

5.2 Exchanging people

The client has made use of two mechanisms for exchanging people to accomplish offshoring projects while maintaining minimal interaction. Both mechanisms involve intensive interaction but for selected people and selected periods of time. First, offshore developers have been on placements at the client to work with their onshore colleagues. This mimics how new onshore IT developers acquire business knowledge, but in addition to improving the offshore developers’ business knowledge it has also facilitated the general relationship between onshore and offshore staff. However, the placements require that onshore staff has the necessary time for communicating and interacting with the offshore developers; and the placements temporarily cancel the economical effect of offshoring because the offshore developers get onshore wages while they are onshore.

Second, the client has placed an offshore coordinator at the vendor. The few onshore employees who have had this position have been at the vendor on long-term placements. The offshore coordinator has a mediating role involving frequent phone contact with client staff, with whom they are well connected, and participation in project meetings with vendor staff. Collaboration between the offshore coordinator and vendor staff is face-to-face, thus avoiding the limitations of communication and collaboration at a distance and providing more opportunities for becoming aware of cultural and maturity issues in need of attention. Periodic onshore visits have been necessary for the offshore coordinators to maintain their network among the client staff. Moreover, the vendor may occasionally feel that the presence of the offshore coordinators transgresses the client-vendor boundary.

Apart from these two mechanisms, an effort has been made to motivate offshore developers to work for the client for a longer period of time. In the Indian offshore-outsourcing industry it is customary
that IT developers move into the management ranks after only a couple of years as developers. This is very different from the career path of Danish developers, who often work a decade or more as developers in the same business area. This cultural difference threatens the client’s minimal interaction strategy, because the continuous renewal of offshore developers implies that most of them will have insufficient business knowledge. The client has therefore aimed to make their relationship with the vendor sufficiently interesting for offshore developers to make it attractive for them to stay for a long period of time. The onshore placements of offshore developers have been effective in this regard.

5.3 **Exchanging knowledge**

The client has set up business courses at the vendor. The courses have been run by visiting onshore staff and by some of the offshore developers that have been on onshore placements. In some areas of the client’s business, the courses form an entire certification program, which ensures that offshore developers have a basic understanding of the business area for which they develop systems. While the offshore developers are not at a level of business understanding comparable to the onshore staff, their improving business understanding increases their ability to work autonomously and decreases the amount of interaction they need to have with the client.

The courses and certification programs are an attempt to exchange knowledge in concentrated packages and to several offshore developers at a time. This is considered preferable to frequent ad hoc interactions, which are complicated by the geographical separation. Extensive ad hoc interaction is also seen as time consuming, especially to the client, and therefore as contrary to the intention of shifting work from the client to the vendor. A manifestation of this is that a single point of entry has been enforced when offshore staff needs to communicate with onshore quality-assessment staff. This has been decided to protect the majority of the onshore staff from becoming engaged in too many, time-consuming communications. In this case it appear that the client has been more concerned with not making offshoring unpopular among its onshore staff than with providing the offshore staff with access to needed knowledge and the opportunity to gradually build a network.

Restricting access to needed knowledge in order to minimize interaction creates problems because it prolongs the period during which business knowledge is unevenly distributed between client and vendor. As an example, the present assessment of project B – a large, ongoing offshore project – is that it has been hard to strike the proper balance between technical and business development. The project requires both technical and business knowledge, but the uneven distribution of knowledge entails that the vendor, which is involved in the project with a massive 300-400 person years, often has only the technical knowledge. In working on project B, the vendor proceeds on the basis of its technical knowledge and remains unaware of some of the issues that might warrant business considerations. The client is at too great a distance from the vendor’s work to spot such issues and has not been able to specify them up front. As a consequence opportunities for business considerations are unintentionally bypassed, and project B becomes to an excessive extent about technically reprogramming a system.

5.4 **Developing software in two places with minimized interaction**

Today the client uses the vendor in India on a regular basis. Project B provides an interesting example. This project consists of converting a standalone system into a service available to many systems. The client considers such moves toward a more service-oriented architecture crucial to enable reuse across systems and to enable flexible assignment of the development of individual services to onshore or offshore groups with the ability and capacity to take them on. A main reason for completely reprogramming the system is, however, that the existing system has evolved over a long period, and due to extensive changes in the staff working on the system nobody any longer has a comprehensive overview of the programming code. Moreover, the documentation is not trusted to be up-to-date. Thus, it has become exceedingly difficult and costly to make revisions of the system (cf. Naur 1985). The capacity and lower price of the offshore vendor compared to onshore developers make it feasible to solve these difficulties by reprogramming the system from scratch.
However, turning a system into a service is not merely a technical task but also requires considerable business understanding to know the applications to which a service is relevant and the differences in what these applications require from the service. To overcome this challenge the client decided to apply use cases (Cockburn 2000; Jacobson et al. 1992). At first, some of the offshore developers that had been on placements at the client, but had returned to India, were asked to lead the writing of use cases in India. It was agreed to use a writing style with four abstraction levels with the first being mostly business oriented and the fourth very technically oriented. But when the results came in, the more business oriented use-case levels just consisted of pointers to lower levels, and the client discovered that it took way too much effort to review the very detailed technical use cases at the fourth level. Thus, that way of dividing work did not minimize interaction. In a second round, business staff at the client was taught to write use cases. These upper-level use cases were then given to the vendor who wrote the technical levels. This proved to minimize interaction much better.

6 DISCUSSION

Cultural differences between client and vendor are an inherent characteristic of offshore outsourcing. For offshoring to India it is also common that the vendor’s development processes are at a higher maturity level than the client’s development processes (Levina et al. 2008; Vlaar et al. 2008). The case investigated in this study concerns whether such inequalities can be handled by minimizing the interaction between client and vendor.

6.1 Costs and challenges of minimal interaction

In the section above we mentioned project A as an example of minimizing interaction. While the project was successful in the sense that the offshoring arrangement produced a high-quality system, it was restricted in the sense that only a modest part of the activities of a full project were performed by the vendor. The entire project A was offshored to the vendor, but project A was special in the sense that it consisted almost entirely of programming. In this sense project B is a better example of the client’s minimizing interaction strategy, because a larger amount and variety of development activities were offshored to the vendor. Figure 1 shows how work has been divided between the client and the vendor. In the beginning the bottleneck of this model was in the middle. It was difficult to offshore enough coding activities to the vendor and test the quality of the produced code. Today the bottleneck has moved to the front and back ends of the process. About 400 people are ready to work at the vendor site, starting from business oriented use cases and delivering integrated code ready for acceptance. The hard part now, tells a manager at the client, is to get the business people to write enough, high-quality use cases – that is, to decide and specify how they want the business processes to be.

The main limitation of the client’s approach has been that in order to minimize interaction with the vendor it has become necessary to perform considerable extra work. This work is required to enable the vendor to take on tasks in spite of its limited business knowledge. The extra work consists of preparing tasks for offshoring, preparing the vendor for working in the client’s application domain, and assessing the quality of the vendor’s work. In the terminology of Dibbern et al. (2008) this extra work corresponds to specification costs, knowledge-transfer costs, and control costs. While the knowledge-transfer activities and certification programs are intended to gradually make it possible for the client to offshore also the specification of systems and the assessment of work products, the currently offshored activities are somewhat biased toward programming. Thus, the client is succeeding in offshoring programming but, at least currently, at the cost of extra work on other activities. Compared to previous, onshore development the client’s activities have shifted toward the start and end of the development process, see Figure 1.
This shift has important consequences for the client. First, it implies that the client is to a considerable extent doing work in order not to have to do work. The amounts of extra work have not been fully foreseen, and cultural differences entail that the extra work is perceived differently by client and vendor. For example, the vendor organizes activities partly from the implicit perspective that hours are cheap and capacity large, but this perspective is defective when some of the hours (e.g., control activities) are to be performed by the client. It is an ongoing learning process to identify and reduce areas of extra work but also to realize that offshoring is increasing the amount of some of the client’s tasks. Second, the extra work may exceed the capacity of the client staff and thereby prevent the client from offshoring as much work as the vendor would be able to perform. While the bottleneck that initially motivated the client to offshore was perceived as a shortage of programming capacity, it may now emerge as a shortage of capacity to specify systems and control work products. This way, the uneven distribution of business knowledge may be the factor that limits the client’s minimal-interaction approach to offshoring, making a reduction of the knowledge asymmetry central to continued success with this approach. Third, the tasks of the client staff are changing. This implies that client staff increasingly needs a different mix of competences with more focus on business understanding and abilities to facilitate the formulation of requirements, the transformation of requirements into system specifications, and the follow-up on whether developed systems match business requirements. Some client staff may welcome this change of focus; others may be reluctant to give up time for programming in favour of activities at which they feel less proficient and comfortable.

6.2 Conway’s law

Conway’s law (Conway 1968) states that “organizations which design systems … are constrained to produce designs which are copies of the communication structures of these organizations.” Thus, the communication bottleneck between client and vendor in offshoring arrangements will lead to system designs that reproduce this structure. Conway concludes that flexibility of organization is central to effective design. Flexibility is needed to be able to adjust the organizational structure to a system.
architecture that matches the needs of the use situation. Because designers’ understanding of these needs will likely evolve during the development process, flexibility of organization is required throughout the development process, not just when projects are set up.

Conway argues that especially for large systems the required flexibility is rarely present and that the structures of large systems therefore tend to disintegrate during development. This disintegration is the result of a three-step process. First, when designers realize that a system will be large they are tempted to assign too many people to the project. This temptation is exacerbated by access to a large pool of development staff, as is typical in offshoring. Second, in a large project the communication paths must be restricted in order to avoid that communication consumes all people’s time, as exemplified by the single point of entry enforced between offshore staff and the client’s quality-assessment staff. This causes the communication structure to disintegrate. Third, Conway’s law ensures that the disintegration of the communication structure will be reproduced in the system structure, which therefore also disintegrates. This argument appears pertinent to offshoring because the client gets access to the vendor’s large pool of development staff and because the communication between client and vendor is already restricted by their physical separation (e.g., Herbsleb 2007; Herbsleb et al. 1999).

In projects A and B we can clearly explain part of what we see by using Conway’s law. Project A, for example, complied with Conway’s law by reproducing the organizational separation between an onshore group with business knowledge and an offshore group with technical knowledge in the system: The system was completely rebuilt technically but remained completely unchanged functionally (as it was planned). This was not a problem for project A itself, because it was the client’s first offshore project and a lot was learned from it. However, project B gives some indication that the client’s aim of eventually offshoring entire projects from requirements to implementation is still hampered by the uneven distribution of business knowledge. This makes communication about business knowledge a central bottleneck because it leads to missed opportunities in the offshore-developed systems.

7 CONCLUSION

In October 2008 while we were making interviews in the Danish organisation it was decided to renew the contract with the vendor without changing anything but the ending-date of the contract. Thus, the way the interaction had worked between client and vendor was considered a success. We have shown in this paper that the strategy followed was one of minimizing interaction. Concretely, we have shown how keeping distance, exchanging people, and exchanging knowledge can be used to develop software in a way that minimizes interaction. It should be noted, however, that achieving minimized interaction requires a lot of work. It is not a cheap solution; the price (and time) invested by the client was larger than expected.

We conclude that minimizing interaction can be a viable strategy to follow when clients and vendors face large cultural and maturity inequality in offshore outsourcing.

Acknowledgements

This work has been supported by the Danish Agency for Science, Technology, and Innovation through its funding of the SourceIT project. We wish to thank our colleagues in the SourceIT project for inspiring discussions and master-thesis students Sofia Knudsen and Magnus Hansen for their support in documenting the interviews. Special thanks are due to the interviewees for their openness and their willingness to take part in our study in spite of their busy schedules.

Abstract

Product counterfeiting is a growing problem worldwide, threatening the health of consumers and reducing company profits. By detecting and intercepting counterfeits before they reach the customer, the problem can be mitigated. In this paper, an approach to detect counterfeit items based on their claimed history is presented. The necessary data is provided by tracking infrastructures that enable the recording and retrieval of movements of individual items in the supply chain based on unique identifiers assigned to products. If the movement history of an item deviates from the movements of genuine items that have been learned before, a warning about a potential counterfeit is issued. Counterfeiter activities that are possible in a tracking enabled environment are modelled and the capability of the proposed approach to detect these strategies is assessed.

Keywords: Anti-Counterfeiting, Authentication, Supply Chain, RFID
1 INTRODUCTION

Counterfeiting is growing in terms of industries and countries affected, as well as the number of fake goods seized by customs each year. The OECD (2007) estimates that the international trade in counterfeit products was up to 200 billion $ in 2005. Products subject to counterfeiting range from luxury handbags, sneakers and liquor to plane spare parts and pharmaceuticals. A counterfeit is any product that infringes intellectual property rights such as trademarks, patents and designs. This includes items produced in factory overruns - by the same manufacturers that produce genuine products during normal working hours - although they do not differ in appearance from genuine products.

Each counterfeit that is sold to a customer affects the rights holder negatively. Potential consequences range from reducing the sales of genuine products and affecting brand value to disappointed or even physically harmed customers (OECD 2007, Staake et al. 2008). Rights holders attempt to minimize the negative consequences by implementing anti-counterfeiting measures that aim at cutting off counterfeit supply and increasing the number of detected counterfeits. Product authentication approaches, i.e., methods that aim at deciding whether a product is counterfeited or genuine, enable stakeholders such as customers, customs and supply chain partners to check products and contribute thus directly to an increased counterfeit detection rate. Moreover, the higher the detection rate, the less profitable is the business for the counterfeiter as revenues decrease with each detected counterfeit, while counterfeit production costs persist. For each counterfeiter organization there is a detection rate that reduces the profits to zero and drives the counterfeiter out of business. Additionally, as profits decline, counterfeiters might target products that are less well protected and thus promise larger profits. This contributes to decreasing the supply of counterfeits.

Traditional authentication approaches, e.g., the check of holograms, base authentication on something an item has. Authentication can also be based on something an object did in the past (Stajano 2002). With the advent of item serialization – facilitated by radio-frequency identification (RFID) technology - and tracking infrastructures, history information about individual items is available. Serialization means that each item is assigned a unique identifier (UID) that can be stored on an RFID tag attached to the item. Suitable readers are deployed in the supply chain. When an item passes, an event is created that contains UID, time, location and further context information. Tracking infrastructures then enable the storing and sharing of events between companies. To illustrate how this information can be used for authentication, assume that product #123 was seen in Paris at 12:00 h, followed by a sighting in Tokyo at 12:05 h. As item #123 cannot physically have moved over this distance in such a short period of time, it can be concluded that the item is carrying a duplicated serial number and is therefore probably a counterfeit.

While the potential of tracking for counterfeit detection has been recognized (Koh et al. 2003; Staake et al. 2005; Inaba 2008), few concrete methods have been suggested so far. The general difficulty is to specify rules operating on the item history that accurately distinguish between counterfeit and genuine products, while keeping the specification effort manageable. The research question is thus how to design a counterfeit detection approach based on tracking data that addresses these requirements. The approach proposed in this paper learns rules governing the behaviour of genuine items from available tracking data, thus eliminating the need for manual specification. The warning about potential counterfeits is based on anomaly detection. The research thus contributes to the general aim of developing methods and systems for analysing tracking data to support business decisions (Asif & Mandviwalla 2005; Curtin et al. 2007).

The research method pursued is reflected in the structure of the paper: In the next chapter, related work is reviewed and shortcomings are identified. Chapter 3 gives an overview of item tracking and the proposed authentication approach while chapter 4 presents the methods for learning and counterfeit detection in detail. To evaluate the approach, a model of counterfeiter behaviour in a
tracking enabled world is developed and utilized to assess the detection capabilities of the approach, before concluding and suggesting areas for future work.

2 RELATED WORK

A large share of authentication approaches in use today are based on adding a hard to imitate, artificial feature to the product, e.g. holograms, printing in colour-changing ink or chemical markers (OECD 2007). Authentication with these approaches requires special equipment, expertise or can only be performed one product at a time. As the counterfeit detection rate depends not only on the detection capability of an approach, but also on the check rate, i.e. the fraction of products that are actually checked, approaches that do not allow for bulk authentication in the supply chain will usually result in lower detection rates.

With the advent of RFID technology, cryptographic authentication approaches that make use of the computational capabilities of RFID tags have been proposed (Juels 2006). Cryptographic authentication cannot be performed with low-cost RFID tags as they have only very limited processing power. Once a method has been devised to perfectly imitate a security feature – for instance by hacking cryptographic RFID tags - the approach is no longer secure and counterfeits become undetectable.

Some proposed authentication approaches utilize item serialization, i.e. the fact that each genuine item was assigned a UID during manufacturing. It was proposed to check the validity of the serial number of products against a database of all serial numbers assigned during manufacturing (Lei et al. 2005; Johnston 2005). In the context of tracking infrastructures, this approach was suggested to be used for pharmaceuticals (Koh et al. 2003). Drawbacks of this approach include the low protection against UID copies and the possibility of counterfeiters to skim the database for valid numbers.

When more tracking data is available, the full product history can be made accessible and checked by the prospective buyer for plausibility (Staake et al. 2005). Some types of plausibility rules are suggested by Illic et al. (2009). For specifying individual rules, background knowledge and manual input is required, e.g. the maximum allowed item stay time per location must be configured. The drawback of these approaches is the effort imposed on the user for rule specification and decision.

Few approaches have been proposed that learn rules from available data. It has been suggested to learn which product transitions between any two locations are plausible (Illic et al. 2009, Lehtonen et al. 2007). By considering only two locations, these rules are not precise enough to detect some counterfeit types. The approaches use a probabilistic decision function that classifies items as counterfeit if the observed movements are infrequent. This poses a problem if genuine items perform unusual movements. The Hidden-Markov-Model based approach by Lehtonen et al. (2007) detects counterfeits based on similarity with previously detected counterfeits, but does not adapt well to new counterfeiter strategies.

The counterfeit detection approach proposed in here extends on previous work by learning rules from tracking data, but adds precision by considering the full context information contained in events, event timing, and the full sequence of events instead of two consecutive events. The decision will be based on the discovery of anomalies in event sequences. The concept of anomaly detection has been applied in fraud and computer intrusion detection. In both domains, anomalies caused by fraudster activity are sought among sequences of events, e.g. credit card transactions, phone calls, or system calls (Bolton & Hand 2002). Fraud or intrusions are detected by identifying deviations from previously learned profiles (Forrest 1997; Hilas & Sahalos 2005). A main difference to counterfeit detection is that these systems operate on continuous event streams, while a product has a lifecycle and the corresponding event sequence has a beginning, end, and a regular structure determined by the underlying business processes.
3 OVERVIEW OF TRACKING-BASED COUNTERFEIT DETECTION

3.1 Serialization and Tracking

Serialization and tracking infrastructures are necessary prerequisites for tracking-based counterfeit detection. The UID may be stored on an RFID tag attached to a product, facilitating the simultaneous identification of multiple items without line of sight. However, tracking is not limited to RFID tagged products, and in principle any technology able to provide UIDs can be employed, e.g., printed 2D-barcodes. To enable tracking, suitable reading devices need to be distributed in the supply chain that capture events when items pass. The attributes to be contained in an event are usually determined by the tracking infrastructure. For example, the attributes (UID, time, location, business step) specify a simple event format. An event instance contains values in the domain of each attribute, e.g., (123, 12:00 h, Paris Shop A, Sale). In a business setting, further useful attributes include the organizational unit, associated business transactions, lifecycle information, and aggregation with other products. The captured events are submitted to a local database – the repository - for future reference. A tracking infrastructure provides methods for finding and assembling the events pertaining to a specific item, which are usually distributed over multiple repositories and even multiple companies.

The trace of an item is defined as the sequence of all events containing the item UID ordered by their timestamp. The trace may not only contain information about the physical movements from location to location, but also about the underlying business processes and the actions performed. This is illustrated by the traces of two sample products in Table 1. Both items are produced in Lyon and then delivered to a distribution centre in Paris. While item #123 does not pass the quality control and is therefore disposed of, item #126 is shipped to a retailer and subsequently sold to a customer.

Table 1. Sample traces of two items represented in an event format that contains the two context attributes location (represented by city and facility) and process step.

Serialization and tracking are not yet in widespread use, although trials of limited scope are performed. However, some product types, e.g., luxury watches or plane parts, already carry serial numbers and proprietary systems are used to track them over their lifecycle. Standardization of tracking infrastructures is under way, most notably in the context of the EPCglobal framework, a set of standards targeted at enabling an interorganisational, distributed tracking infrastructure based on globally unique identifiers (EPCglobal 2007b). Part of the framework is also a specification of an event format suitable for a business context (EPCglobal 2007a). Government mandates requiring serialization and tracking for high risk products such as pharmaceuticals might further foster the adoption of tracking based systems (e.g. FDA 2004).
The event format presupposed for the proposed counterfeit detection approach is generic in so far as only a UID, timestamp and at least one recurring attribute is required. The approach is thus independent from a specific standard such as the EPCglobal framework and can be adapted to the event format utilized by any tracking system that fulfils these basic requirements.

3.2 Components of the Authentication Approach

An overview of the components of the proposed anti-counterfeiting approach and the data flows between them is given in figure 1. The model learner takes as input a set of sample traces from the tracking repository and infers from them the rules according to which items move. The output is a model of the supply chain containing all rules. The learning step can be repeated periodically to update the model with current traces. For every product type, a separate model should be constructed, so that the trace of a handbag is not compared to traces of car brakes. The Electronic Product Code (EPC) standard contains the product type identifier as prefix in the UID, followed by the actual serial number of the item (EPCglobal 2007b). For all products identified by EPCs and UIDs constructed in a similar manner, the product type is directly available from the events.

The quality of the learned model depends on the quality of the traces contained in the sample. The sample must fulfil the following requirements:

- The traces should cover all potential product movements, including legitimate exceptions in product routing or process execution, as well as seasonal variations.
- All traces must belong to genuine items, otherwise the movements exhibited by counterfeit products will later be accepted as normal.

To fulfil the first requirement, the sample size must be chosen large enough and cover a sufficiently long period of time. Furthermore, commonly used data cleansing techniques aimed at filtering out outliers and exceptions based on low observation frequencies should not be applied. The problem of separating events triggered by legitimate users from events generated by intruders is well known from the intrusion detection domain. But unlike intrusion detection, which operates in the virtual space, counterfeit detection deals with actual physical objects. This allows for authenticating items with non-tracking based approaches, e.g., relying on security features or expert judgement. It is also possible to send designated test items from the manufacturer through the supply chain, authenticating them at each read point, and basing the sample on their traces. Only traces of items confirmed to be genuine should be admitted to the sample. Another possibility to ensure that only traces of genuine items are contained is to visualize the model with a suitable representation (e.g. Illie et al. 2009, Hoffman et al. 2008) and have it inspected by an expert.

The decider takes the trace of the product to be authenticated, the learned model and possibly also the position at which the authentication is performed as input. Position information is required because items might also be authenticated at intermediate points in the supply chain. In fact, every capturing of an event may be coupled with authentication, thus leading to a high check rate. This allows to intercept counterfeits early, before they reach the customer. The position information can be supplied by the user, the reading device or by an authentication service. The decider compares the trace reported by the item to be authenticated with the supply chain model (up to the authentication position) and computes the authentication result. If a mismatch is found, the item is a potential counterfeit and a warning is issued. If no anomaly is detected, the trace is reported to be plausible. These cautious results are justified because even for plausible traces, it cannot be guaranteed that the item is genuine. Likewise, deviating traces might be caused by errors, e.g., wrong item routing and need not necessarily be caused by counterfeiting activity. The detailed algorithms used by the decider and the model learner are presented in the next chapter.
4 AUTHENTICATION APPROACH

4.1 Representing Item Movements

The supply chain model shall in a general yet precise way describe the movements of genuine items. The movements as represented in tracking data are characterized by

- the events contained in the trace,
- the sequence of events, and
- the timing of events in the trace relative to each other.

Before describing how the model is constructed from sample traces, it will be described how each of these three concepts is represented.

The attributes specified by an event format can be divided into recurring and non-recurring attributes. The values of recurring attributes can be expected to be observed for further items, while the values of non-recurring attributes have a limited lifespan. The UID – bound by the lifetime of an item - and the event time – being monotonically increasing – are non-recurring. In the above example (table 1), the attributes location and process step are recurring. As their values are determined by the underlying business processes and the design of the supply chain, the values can be expected to be observed also for future items. The set of recurring attributes can be determined by the user (as this is necessary only once per event format) or automatically by scanning the sample traces for attribute values recurring over the sample period. A unique combination of values of recurring attributes will be called a station. Examples of stations are (Lyon Plant A, Production) or (Paris Distribution Centre A, Receiving). Each event maps to exactly one station, while a station represents many different events.

To accurately represent an event, its position in the trace and prior events must be considered in addition to the attribute values contained. Take for example a process in which items are shipped from a central distribution centre to shops, and, in case they are not sold, sent back to the distribution centre and shipped to outlet centres. Some items will pass the shipping ramp - the station (Paris Distribution Centre A, Shipping) - twice, but depending on the position in the trace, the legitimate next event will vary, being either the reception at a shop or at an outlet centre. Therefore, the concept of a node is introduced to represent an event at a specific position in the trace. Each node references a station that indicates which attribute values are contained in the event represented by the node. Multiple nodes (representing events at different positions in the trace) may reference the same station.

The ordering of events in a trace is represented by transitions between nodes. A transition is a directed arc from a start node to a successor node. The timing of events relative to each other is given by the difference in the timestamps of two consecutive events in a trace. The time is therefore a property of
the transition between event representations. When considering multiple items that share the same transition in their traces, the average, minimum and maximum *transition times* are computed for the transition.

4.2 Constructing the supply chain model

Given stations, nodes, transitions and transition times as building blocks, a model of the legitimate behaviour of items in the supply chain can be constructed from a set of traces of genuine items. Put shortly, the model is built up by transforming each trace into a sequence of nodes connected by transitions and then merging sequences sharing the same prefix together. The resulting model is a tree shaped directed acyclic graph containing nodes and transitions, and an additional look-up table mapping the nodes to stations. The model represents all prior observed sequences of movements of genuine items.

The graph is initialized with a root node and a terminal node. The root node is a common predecessor of all nodes representing potential first events in traces. The root node connects for example the traces of items produced in Lyon and items produced in Tokyo. The terminal node serves as a common end node for all traces. It is needed to mark the potential last events so that the completeness of traces can be checked.

Each trace in the input set is processed in the following way: If the station corresponding to the current event is not yet contained in the model, the station is created and added. Starting with the root node of the graph as the current node, it is tested whether the station corresponding to the current event is referenced by one of the successor nodes. Successor nodes are all nodes to which a transition exists. If such a node is found, the average, minimum and maximum time of the transition between the current and the successor node are updated with the difference between the timestamps of the last and current event from the trace. If no suitable successor node is found, a new successor node referencing the station corresponding to the current event is created. A transition between the current and the successor node is added and the transition times are initialized. As long as there are more events in the trace, the successor node then becomes the new current node and the next event from the trace is processed. If the last event of a trace is reached, a transition to the terminal node is added to indicate that the trace ends at this point.

Figure 2 presents a sample supply chain model learned by this algorithm. Stations are labelled with characters, while nodes are labelled with consecutive integers. The model has the following properties: All direct successors of the root node represent valid start events of traces, the predecessors of the terminal node represent valid last events. The transition from node 8 to the terminal node indicates that \((A, B, F, B)\) is a valid trace. Although the node pairs 4:5 and 8:9 reference the same stations, the preceding nodes 3 respectively 7 influence not only the transition times between stations B and D, but also the set of valid successor events (represented by E respectively G). It is important to note that events may not only have implications for the directly following event, but also on events that happen at any later point in time. These higher level dependencies (spanning multiple events) are commonly found in supply chains. For example, an unpacking event is only valid if items have been packed earlier. Nodes 12-14 showcase a potential repetition of events. By representing events as nodes it is possible to determine how many repetitions are allowed (maximum 3 in the example) and how transition times may change with the number of repetitions.
4.3 Item Authentication

The decider classifies a trace as plausible if its trace conforms to the supply chain model. If this is the case, a similar trace has been observed for a genuine item, rendering the item in question unsuspicious. For a trace to conform to the model, the following conditions must be fulfilled:

- All events in the trace must be valid, i.e., for each event the corresponding station must be contained in the model
- The events in the trace must form a valid sequence, i.e., there exists a path in the graph on which all stations corresponding to events in the trace are connected by transitions
- The trace must be complete, i.e., the path starts at the root node and ends at the terminal node
- The timing of events in the trace is plausible, i.e., the time difference between any two events is within reasonable boundaries of the time span observed for the corresponding transition

If any of these conditions is violated, the item is classified as a potential counterfeit. The four types of mismatches are illustrated in figure 3. The completeness condition needs to be relaxed if an item is authenticated at an intermediate point in the supply chain. For example, if all traces represented by the model end at a shop, but an item is authenticated at a distribution centre, it will unjustifiably be classified as counterfeit. Therefore, if no information about the authentication context is available, the test for a trace ending with the terminal node may be skipped. In case some information about the authentication context is available, transitions from all stations matching with this context to the terminal node should be added temporarily to the supply chain model. The context information may correspond directly to a station, e.g., authentication is performed at the reader located at (Paris Distribution Centre A, Shipping) or only to some attribute values contained in a station, e.g., (?, Sale).

The decider processes the current trace as follows: For each event, the corresponding station is computed and searched in the look-up table. If the station is not found, the item is classified as potential counterfeit. Starting with the root node in the model, a node referencing the current station is searched among the successor nodes. If no such node exists, the item is again a potential counterfeit. If a valid successor node is found, the difference of event times of the last and current event is compared to the corresponding transition time. We propose to check whether the event time difference is smaller than the minimum or greater than the maximum transition time, each extended by a small margin to account for minor variations in event timing. The extension may, e.g., be set to 10% of the difference.
between average time and minimum time for the lower bound and to 10% of the difference between maximum and average time for the upper bound. If all tests are passed, the successor node becomes the new current node and the next event is processed. If the last event in the trace is reached, it is additionally tested whether a transition from the current node to the terminal node exists.

### 5 EVALUATION

The information about counterfeiter strategies and the routes on which counterfeited items are put on the market is limited due to the clandestine nature of the operations. To assess the detection capabilities of the proposed approach, it is moreover necessary to systematically explore the possibilities of counterfeiters in tracking enabled supply chains, for which the available data is not suitable. A model of the potential counterfeiter activities is therefore suggested, the effect of the behaviour on item traces is analyzed and used to evaluate the detection capabilities of the proposed approach. In future work, it is planned to computationally verify the results of the analysis by simulating the modelled counterfeiter strategies and normal supply chain operations and assessing the detection capability.

Suppose all items of a certain type are equipped with UIDs and a tracking infrastructure covering the supply chain is in place. The first challenge for the counterfeiter is to obtain UIDs for the counterfeited goods. One option is to completely omit the UID, but this strategy should be easily detectable during authentication. For actually obtaining a UID, the options include guessing identifiers, transferring the UIDs of genuine products to counterfeits or copying the UIDs found on genuine products. If identifiers are guessed randomly, the resulting UID may in rare cases be a duplicate of a valid UID, but most likely it will be invalid, i.e., no genuine item carrying the same UID exists. To transfer UIDs, counterfeiters may remove RFID tags from genuine items and reapply them to counterfeits, or they may seek access to UIDs of disposed products and reuse them. Any UID found on a counterfeit will have at least one of these properties: it is invalid, has been transferred or is duplicated.

The counterfeited items must be distributed, either by injecting them in licit channels or by distributing them outside of the legitimate supply chain, for example by smuggling, selling on flea markets or through online shops. For the resulting item trace, it is important whether there are read points on the path of the item or not. Illicit distribution channels are likely to contain no read points and thus be invisible, while licit channels can be assumed to be visible. The combined effects of UID and distribution strategies on traces will now be analyzed. The various scenarios are illustrated in figure 4.

An item with an *invalid UID* that is traded completely through invisible channels has no trace. This can be detected immediately. Items with invalid UIDs that are injected in the licit supply chains will appear suddenly after the injection point (figure 4a). Some events at the beginning of their trace are missing and the trace will fail the completeness check as the first event in the trace is not a successor
of the root node in the model. However, if a counterfeiter manages to inject counterfeits in the licit channel before the first event is usually captured – which is most likely in the production facilities of genuine items – and it is ensured that this manipulation does not distort the further routing of the item, the resulting trace will fully correspond to the model and the counterfeit will not be detected. If distortions surface later in the trace (not only in terms of location but also in terms of wrong business steps or missing transaction information) the counterfeit will also be detected (figure 4g). An additional check for UID validity offered by the rights holder and strict number management can mitigate this threat.

In case a counterfeit carries a transferred UID (valid and unique), the events in the trace were triggered by the movements of two items: Up to the point in time when the UID was removed, the events were created for a genuine product and the beginning of the trace will conform to the model. After that, the counterfeit carries the stolen UID. Depending on the distribution of the counterfeit, the following possibilities for the continuation of the trace exist: If the counterfeit is distributed outside visible channels, the trace ends early (figure 4b). Unless the last captured event was a valid terminal event, the completeness check will fail. If the counterfeit is injected in the licit supply chain, the sequence of events will only be valid if the counterfeit directly replaces a genuine item, the time needed for the product exchange does not lead to a time threshold violation and the manipulation does not lead to distortions on the future path of the counterfeit. If the injection is not a direct replacement but takes place further upstream (figure 4c), downstream (figure 4d) or in another branch of the supply chain (figure 4e), the model will contain no transition allowing this sequence of events. If the replacement leads to an exceeded transition time, invalid transitions or events later in the trace (figure 4g), it will also be detected.

If counterfeits with duplicate UIDs are distributed through invisible channels, they can be detected as long as the trace of the genuine item carrying the UID is not complete (figure 4a). If the duplicates are injected in the licit supply chain, the trace that is retrieved for the UID is a mix of all sub-traces created by the multiple items carrying the same UID (figure 4f). As soon as the first item with a copied UID is injected in the supply chain, this will result in an invalid trace as a transition between the last event captured for the genuine item (from which the UID was copied) and the first event triggered by the counterfeit is missing. However, if the counterfeiter manages to inject the counterfeit at exactly the station where the next event for the genuine item is expected, the injection will remain undetected, but only as long as the genuine item does not arrive at this station. As soon as the genuine item triggers the next event, the trace becomes invalid as a transition is missing and the counterfeit can be detected at the next sighting. Note that in this specific case, a genuine item will be classified as counterfeit. As counterfeiters will probably put the same copied UID on many items, it may be acceptable to misclassify one genuine item if this allows detecting mass copied items.

![Figure 4](image_url)

**Figure 4. Consequences of counterfeiter strategies on trace data**
From this analysis follows that a wide range of potential counterfeiter activities result in traces that deviate from the traces of genuine items and can thus be detected by the proposed approach. Only few options are open to counterfeiters to “construct” traces for counterfeits that are indistinguishable from the traces of originals. Moreover, each of these remaining options requires considerable effort in terms of knowledge and access to the licit supply chain.

Tracking based authentication enables a high check rate compared to traditional authentication, as automated event capturing can be combined with authentication and, in case of RFID, this can be done for many items simultaneously. The possibility to check items by their UID might also be extended to end customers, further increasing the check rate. The detection capability of the approach for low effort strategies such as identifier guessing without access to the licit supply chain is given, as well as the capability to detect the strategy most prevalent today - the distribution through illicit channels. Additional safeguards such as random inspection of inconspicuous goods, investigation of the sources of detected counterfeits facilitated by tracking data and UID validation may help in limiting the number of counterfeits that cannot be spotted with the proposed approach. In combination with a high check rate, this may result in detection rates that are high enough to drive counterfeiters out of business or make them target more vulnerable products. In any case, tracking based counterfeit detection will raise the bar for counterfeiters and each detected counterfeit decreases the overall negative consequences of counterfeiting.

6 CONCLUSION AND OUTLOOK

In this paper, a counterfeit detection approach based on item serialization and tracking was proposed. Rules governing the behaviour of genuine items are learned from available tracking data. The traces of items to be authenticated are compared to these rules and a counterfeit warning is issued if no match with a rule is found and the trace is thus distorted. By modelling the potential behaviour of counterfeiters in a tracking enabled environment and analyzing the consequences of these actions on item traces, it could be shown that the approach is able to detect a large share of the modelled strategies. It was also analyzed which strategies are undetectable by the suggested approach as they result in traces that are indistinguishable from the traces of originals. These strategies have in common that they require prerequisites from the counterfeiter such as access to the licit supply chain and knowledge about the current location of items. It was argued that the combination of the detection capability and the attainable check rate may lead to favourable counterfeit detection rates, particularly in comparison with traditional authentication approaches.

As some organization are already tracking items or are preparing to do so in the future, they may wish to consider the suggested approach to discourage counterfeiting of their products. Organizations that are affected severely by counterfeiting might assess the suitability of the approach for their specific context. Of particular importance is the trust that companies have in their supply chain partners, their expected willingness to participate in such an approach, as well as the current and expected future strategies of counterfeiters.

It was demonstrated that counterfeit detection is a problem that is in principle amenable to information technology support, but before tracking based counterfeit detection can be applied in practice, many questions remain to be answered. A major concern that could not be addressed in this paper is data sharing in the supply chain. Organizations are generally reluctant to reveal fine-grained and potentially sensitive business data as contained in tracking events. Data access is a prerequisite for model learning and authentication, so a challenge is to enable these functionalities with minimal or no divulgence of critical information. To address this issue, concepts from the area of privacy preserving data mining and secure multi party computation may be assessed. Furthermore, mechanisms for avoiding high false positive rates are required, as a large share of genuine items for which a counterfeit warning is issued might hamper the practical applicability of the approach. Given current rates of read errors in RFID based systems, issuing a warning for any deviation might be a too harsh decision criteria in real world operations and the decision logic may be further refined to account for this requirement.
Operator models need to be developed, e.g., a service hosted by a trusted third party, the tracking infrastructure provider, or a distributed model learning by every supply chain participant. The enforceability, cost and benefit distribution in various supply chain settings might also be explored. How the approach can be extended to end customers, the security implications of this step and user acceptance of a mobile or web based authentication system are further areas of interest.

The proposed tracking based authentication approach might prove to be a useful complement to traditional authentication approaches. Given item serialization and tracking are in place as prerequisites, the proposed approach may help to increase security in the supply chain and to lessen the negative consequences on health and finances caused by counterfeiting.

Abstract

The potential of Radio Frequency Identification (RFID) for increasing supply chain efficiency has been repeatedly stressed by practitioners and researchers alike. The cross-company usage of RFID applications can only work if the collaborating companies agree on the syntax and semantic used. EPCglobal, an international industry consortium, has specified a stack of specifications that enable a standardized identifier to be stored on the RFID tag and all object related data to be kept on the network. Such a standardized concept does not yet exist to store object related data on RFID tags. To minimize the coordination effort as well as the emerging interoperability or integration problems and, therefore, also guarantee wide-spread adoption of the data-on-tag approach, it is advisable to build on existing standards for the storage of data on RFID tags. In this paper, we recommend applying the ISO 13584 standard for parts libraries (PLIB). We conceptualize how to use ISO 13584 to store data on RFID tags and use a case study on a kitchen furniture manufacturer, which uses RFID tagged components in a cross-company application with its suppliers, to develop a scenario for the storage of data on RFID tags.

Keywords: RFID, Data-on-Tag, Standardization, ISO 13584, PLIB.
1 INTRODUCTION

The potential of Radio Frequency Identification (RFID) for increasing supply chain efficiency has been repeatedly stressed by practitioners and researchers alike (Niederman et al. 2007). The most widely spread practice of using RFID tags on components, products and logistical units as they move through the supply chain follows the GS1 EPCglobal approach (EPCglobal 2007) of storing only an identifier on the tag and all related data in the supply chain participants’ information systems (either using the official EPC or a company specific ID). The main advantages of this approach are the facts that RFID tags are relatively cheap if they only have to store an identifier and do not need memory for user generated content; that it is easy to standardize the identifier, e.g. on the basis of the European Article Number (EAN), which is uniquely assigned by GS1; and that there is no need to encrypt a simple identifier because the access to the data on the network is restricted.

On the other hand, there are several factors that support storing data on the tag (Günther et al. 2008, pp. 143-144). The first factor addresses the need for fast data access – when the IT infrastructure must meet real-time requirements and bottlenecks happen during back-end queries. For such cases, data on tags may help ensure quick access to the required information. The second factor concerns the dependency of the business process, including production, on the back-end system. Storing relevant data on the tag can help production to be kept up without being connected to the back-end system – at least temporarily. The third factor refers to the reliability of the back-end system: storing data on the tag facilitates decentralization and helps avoid single points of failure. This can be relevant if the existing IT infrastructure is not optimized for reliability, e.g. if no redundant system is in place.

The advantages described for both approaches for data storage serve as the disadvantages for the other concept at the same time. But especially because of the differences, Diekmann et al. (2007) claim that these methods are not antithetic but complementary and should be integrated into a consolidated approach; this guarantees that the relevant data is always accessible. In their work, two case studies that employ a combined data-on-network and data-on-tag approach were presented.

When extending RFID applications to inter-organizational processes, the standardization of data formats and data content becomes crucial (Hasselbring 2000). For the data-on-network approach, researchers and companies respectively founded the Auto-ID Center and EPCglobal consortium and have developed the Electronic Product Code (EPC) to uniquely identify physical products (Brock 2001). The data format specification includes a 96-bit code with a fixed, 8-bit header. The standardization of data content is achieved by relying on existing standards (e.g. the Serial Shipping Container Code). The most famous usage of this EPC combines the European Article Number (EAN) with a serial number for each object.

The cross-company usage of data on RFID tags can also only work if the collaborating companies agree upon the syntax and semantic used. Standardization initiatives have taken the first steps in this direction. The German Association of the Automotive Industry (VDA) published a recommendation about the usage of RFID for container management in the automotive supply chain (VDA 2008). The syntax in the user memory is specified by the alternation of data field identifier and value. The semantic of the data fields (IDs, description, data type, etc.) are described in a table in the recommendation, e.g. vehicle identification, maximum quantity of parts, purchase order number, etc. A similar approach for tracking tyres individually has been proposed by the Automotive Industry Action Group (AIAG). In this recommendation, the auto-industry-specific data such as the global location number that identifies the facility where the tyre is made; the tyre cure date and the country of origin should be stored in the user memory (RFID Journal 2005).

Both recommendations to store data on RFID tags will minimize the coordination effort as well as the emerging interoperability or integration problems for all companies in the automotive industry that want to introduce these kinds of applications. However, many different, possibly competing standards for numerous applications within and across industries are not desirable; therefore, to guarantee the
The widespread adoption of the data-on-tag approach, it is advisable to build on existing standards for the storage of data on RFID tags.

In this paper, we recommend applying the part libraries (PLIB) standard ISO 13584. This standard has been widely discussed as a reference model for developing product classification systems and standardized property lists (Leukel et al. 2006b). Major industry consortia have incorporated this standard into their specifications for B2B data exchange (e.g. BMEcat 2005), product classification systems (e.g. eCl@ss, UNSPSC) and property dictionaries (e.g. DINsml). Implementing the PLIB concept for the storage of data on RFID tags promises to avoid heterogeneity and maximize interoperability in cross-company RFID applications.

In Section 2, we conceptualize the usage of ISO 13584 for storing data on RFID tags. A case study of a German kitchen furniture manufacturer is applied in Section 3 to develop a scenario for the storage of data on RFID tags. The company took part in a joint research project on using RFID tagged components in a cross-company application with its suppliers. Finally, Section 4 concludes the paper.

2 PROPERTY-BASED CONCEPT OF ISO 13584

For our purpose, Part 42 of ISO 13584 (ISO 1998), which describes its conceptual model, is of primary interest. ISO 13584 was originally developed to describe technical product data, i.e. functional and physical characteristics, on the basis of unambiguous, semantically well-defined, globally unique properties. Its usage for commercial product data has been proven as well (Leukel et al. 2006a). To describe how the conceptual model of ISO 13584 has to be implemented, the definition and usage of properties have to be distinguished.

2.1 Definition of ISO 13584-compliant properties

The goal of defining ISO 13584-compliant properties is to make them available and accessible in standardized online dictionaries. For instance, the German Institute for Standardization (DIN) Properties Dictionary (http://www.dinsml.net) is based on ISO 13584. That means that each property:

- is identified with a global unique identifier;
- is described with a set of mandatory and optional attributes (e.g. description, unit, data type), which are specified in the ISO 13584's information model;
- is assigned to a set of references to product classes which define context the properties can be used;
- was defined following a standardized process.

The number of properties in the dictionary is continuously growing. Any company can submit new properties to the standardization procedure to be included in the dictionary. The read access to the online dictionary is free of charge, but companies that want to use it without restriction have to purchase a license. This license includes the passing of the properties used to other companies that are involved in their business process (e.g. suppliers and customers). When describing products on the basis of properties, it can happen that the property values are dependent on each other. For instance, if a liquid is described with the property “volume”, it depends on the temperature of the liquid. The property “temperature” is called the condition in this context. To solve this issue, ISO 13584 defines three different types of properties: non-dependent properties, dependent properties and conditions.

2.2 Usage of ISO 13584-compliant properties for the storage of data on RFID tags

RFID technology in supply chain management can be used to track components, finished products or logistical units (e.g. containers, pallets, cases). These objects have certain characteristics which might be stored on their respective RFID tag. Following ISO 13584, all data have to be expressed in form of property-value pairs. This information has to be very precise, e.g. concerning meaning of the property.
or unit of the value, but to minimize the amount of data storage needed on tags, only the ID of the standardized property (which includes this precise information) and the value should be stored.

Figure 1. Logical model for property usage in XML Schema format

When storing these property-value pairs on tags, the syntax and semantic layers have to be distinguished. Semantically, all three different types of properties have to be supported; therefore, it is not enough to provide only the property id and value for a property: for a dependent property, the reference to the value of the condition has also to be given. One option for this usage of property-value pairs is described in Figure 1, which uses a graphical representation of an XML Schema. The reference to the value of the condition is called “PropertyConditionIDRef” in this model.

To illustrate the usage of the three different types of properties, the example in Figure 2 shows the independent property “colour” and the dependent property “optical density”, which is dependent on the condition “optical glass type”. The representation format follows the model in Figure 1.

Although we have used an XML format based on the developed XML Schema to describe the semantics of using property-based product descriptions, it is not necessary to utilize this format as the syntax. The main disadvantage appears when comparing the payload of this short example with the XML element names etc. – which make up 91% of the characters and symbols – which are not essential for the content.

2.3 Benefits of using ISO 13584

Standards in general contribute to the harmonization of interfaces between heterogeneous systems and, for this reason, increase interoperability. This may result in decreasing coordination efforts and wider usage. In the context of storing data on RFID tags, besides the technical interoperability, data interoperability is of great importance. Typical problems include the following:

• data could be misinterpreted because the information is not understandable;
• different data models could describe the same information;
• and different information could have the same description in individual data models.

For the mapping between different data models, a high coordination effort is needed to overcome these problems, if it is at all possible.

From another point of view, competing standards do not solve this issue if companies do not know which standard they should choose. In information systems literature this is known as the standardization problem (Westarp et al. 2000). The different standardization efforts introduced in Section 1 for the usage of RFID in the automotive industry highlight this problem.

The property based concept of ISO 13584 addresses both problems. First, the standardized properties are precisely defined according to the ISO 13584 data model, which includes language independent verbal definitions as well as additional information regarding units, data types, etc. This results in easier data exchange via standardized interfaces, higher data quality, and a reduction of data redundancy (Pohn 2006). Second, using ISO 13584 implies following a bottom-up approach because with properties small pieces of information are standardized and so can be applied to very different
circumstances. Other standardization initiatives (e.g. AIAG and VDA) can create their own standards based on these standardized properties. In this way, ISO 13584 is not competing with other initiatives and, even more importantly, with the EPCglobal approach.

Figure 2. Example for the usage of different types of properties

2.4 Extraction of ISO 13584-compliant Properties

If a company chooses to use ISO 13584-compliant properties for a certain use case, the properties usually do not have to be developed from scratch. The existing data sources in the companies’ information systems about the object under investigation have to be taken into consideration. Data models provide a useful basis for the identification of properties because the attributes describing an entity in an ER diagram or a class in a UML class diagram can often be transferred into a property, while associations between entities or classes refer to the type of property (dependent, independent, etc.). A methodology for extracting properties from an XML Schema has already been developed by Leukel et al. (2006a).

Once the required properties are determined, the corresponding properties in the property dictionary have to be found. Three cases could appear in general: first, a corresponding property in the dictionary exists and the semantic of the usage is the same. In this case, the property ID from the dictionary and the values from the existing instances can be used without further processing. Second, a corresponding property in the dictionary exists, but its property definition differs in usage, e.g. about data type or measurement unit. Here, the property ID from the dictionary can be used if the instances can be
transformed into the required semantic. Finally, the company could require properties that have not been defined in the dictionary yet. This is highly dependent on the type of object, e.g. some industries are more actively working together with the dictionary operator. In this case, the new property should be created in the dictionary. As already mentioned in Section 3.1, this creation has to follow a certain standardization process that has several phases (initiation, evaluation, etc.), which takes 25 weeks at most.

3 CASE STUDY OF A GERMAN KITCHEN MANUFACTURER

Wellmann GmbH & Co. KG (Wellmann) based in Enger, Germany, is a kitchen manufacturing specialist. Founded in 1953 by Gustav Wellmann, the company was taken over by Alno AG in 2003. In its supply chain, Wellmann’s position is that of the Original Equipment Manufacturer (OEM). The structure of its suppliers is very heterogeneous and varies from small factories to industrial producers and logistic service providers. The kitchens produced are offered by several retailers – mostly under their own brand names. The business goal of Wellmann is to provide high quality, complete kitchens on schedule for competitive prices, despite numerous variants and a high share of individual and special parts.

This case study covers all processes, including procurement and production, that are relevant for introducing RFID at Wellmann. This introduction is currently being analyzed in a joint research project by the company and two universities and is being partly financed by the German Federal Ministry of Economics and Technology. The implementation of RFID in Wellmann’s logistical and production processes is done in several successive steps. In the initial steps, only parts with the most critical logistical importance (Strassner 2005), i.e. parts of high value, are tagged with RFID transponders. These are kitchen cupboard fronts that are custom ordered; produced by an external supplier; and delivered just-in-time for assembly at Wellmann.

3.1 Scenario description

The production of cupboards with fronts follows a structured process that consists of ordering parts, picking parts, drilling fronts, assembling components and assembling whole cupboards. The process starts with a customer who plans his or her kitchen at a retailer which in turn creates a custom order for Wellmann. As soon as the route planning for the custom orders is finished, the orders for the externally sourced parts are automatically placed by Wellmann’s Enterprise Resource Planning (ERP) system once a day to all affected suppliers. Each position in the electronic order is always associated to its corresponding position in the custom order. In this case study, we focus on fronts, which can either consist of wood or glass. Glass fronts are either framed in wood on all four sides or only have wood on the top and bottom. The combination of individual dimensions, different types of handles and other characteristics makes the production of cupboards with fronts vary greatly.

Parts are moved through the factory in special containers, which are identified with a unique twelve digit Transport Group number (TG number). Within this container, the parts are identified with a twelve digit Transport position number (TG position number). Additionally, each part is identified with a twelve digit Transport order number (TA number). All numbers are newly assigned before each production step. To control all production steps, the numbers of all objects are stored in Wellmann’s ERP software. The data model for identification numbers is depicted in Figure 3.

![Figure 3. UML model describing the identification scheme](image-url)
The supplier produces the fronts ordered and supplies them just-in-time when the assembly of the kitchen is scheduled. The delivery of the fronts is scheduled for two working days before the cupboards are sent to the customers. The supplier prints a delivery note, which contains only the TG number and the supplier’s delivery note number as a bar code. Additionally, all parts are listed with their corresponding TG position numbers, TA numbers and characteristics (e.g. dimensions and colour). On an attached negative delivery note, all parts from the order that could not be delivered are listed in the same way. Besides these delivery notes, each front has a label attached that contains the TA number for its first processing step as a bar code and the description of its characteristics as well as its production and delivery date.

When the fronts are received at Wellmann, the receiver first scans the TG number on the delivery note or the TA number off of a label attached to one of the fronts. With either of these possibilities, the list of ordered parts is received from the ERP system and displayed. To check the completeness of the delivered parts, the receiver can scan the barcodes (TA number) of each front label and compare the lists. Additionally, the receiver could enter the TG position numbers or the TA number of the parts that have not been delivered into the system. The receiving process is finalized by storing the delivery note number in the ERP system. This triggers a rescheduling of the downstream activities, where the undelivered fronts are removed from further processing steps.

For further processing, the fronts have to be buffered directly in front of the next work station. In this case, the fronts are drilled at a CNC (Computer Numerical Control) jig boring machine. Each bore program is retrieved from a central server over the network and always relates to one special front. This program determines the bore template as well as the depth of the drill holes and the components that have to be assembled (e.g. hinges and cushion for the doors). During the production of one batch, which consists of several front containers, changes with the bore program might occur. For this reason, the boring machine is loaded with programs once a new container arrives; therefore, the TG number barcode of the container is scanned from the picking list that was created for this work step. The operational sequence of the boring programs depends on the position of the fronts in the container; therefore, the picking process of fronts into the container has to be done very accurately. If there is one front missing, the bore program for this front has to be removed manually. The operator, who equips the machine with fronts, removes the missing front by selecting the position on the display of the CNC machine. Because the machine works automatically after the operator has equipped the machine with the custom fronts from a container, mistakes have a great effect on the overall process if they are destroyed. In such a case, a complete delivery of the kitchen to the customer at the scheduled time is not possible any more.

After this processing step, a new picking list is printed. This contains the next processing step, the container ID (TG number) and lists the fronts in this container (TG position and TA numbers). After each processing step, this data is retrieved from the ERP system. Additionally, the completion of the processing step is recorded. This acknowledgment is necessary because the production order has to follow the planned and scheduled production process. After the acknowledgement in the ERP system, the next processing step is unlocked.

For the transport to the following processing step, the fronts are put into a new container, which depends on the type of cupboard and the new TG position numbers that are assigned for their following processing step. At the final working station, the fronts are assembled with their bodies that have the same TG position number. The bodies are delivered on an assembly line. For a smooth process, the sequence of the fronts plays an important role again, to avoid the downtime of the assembly line. Cupboards whose fronts have not been delivered have to be set aside. The bodies are buffered until the fronts are produced and provided.

3.2 RFID Process Benefits

In contrast to barcode technology, RFID offers the possibility to simultaneously identify several objects without contact, without line of sight and without human interaction. For these reasons, two
general effects are achieved: first, manual effort can be decreased (e.g. faster receiving and shipping processes); and second, costs incurred due to errors (e.g. at the boring machine) can be reduced.

The general potential from using RFID at Wellmann can be achieved with the data-on-network approach; however, in the production environment where components are tagged and not consumer products, the usage of the EPC is not suitable. Instead, the TA number, which is assigned by Wellmann and pushed to the supplier, is stored as a unique identifier. All manual process steps described in the scenario above are positively affected by the introduction of RFID: the registration of fronts at the receiving business step, the manual deletion of missing fronts at the boring machine as well as the control of the fronts’ sequence. An automatic matching of front and bore program ID helps reduce costs incurred by errors (the higher price for emergency orders for fronts, etc.) and reduce the risk that a kitchen can not be completely delivered to the customer.

Additional to the benefits that can be reached with the data-on-network approach, there are advantages to Wellmann by storing data on the RFID tag. First, the data related to the processing step can be accessed without connection to the network. Second, the bore programs for the boring machine including the specific parameters and characteristics of the fronts can be stored on the transponder. These bore programs can be accessed directly before a front is processed. Furthermore, the completion of the processing step, the retrieval of the following steps and the printing of this plan can be omitted when all necessary data are stored on the RFID tag. The processing progress can be stored on the tags as well as a trigger to release it for the following processing step. In case of a failure or breakdown of Wellmann’s local network, the production is not affected.

For Wellmann’s supplier in this case study, the introduction of RFID in cooperation with Wellmann offers benefits, too. Certainly, the supplier also benefits from the reduction of manual effort (e.g. the shipping process and creation of delivery notes). Additionally, the conflict potential in the transferring of title and risk can be reduced.

Wellmann wants to establish a standardized approach for storing data on RFID tags instead of developing a separate solution with every business partner. Although the prototype described in this case study encompasses only the business relationship to the front supplier, it is Wellmann’s intended target to expand the RFID solution to other suppliers, logistic service providers and retailers. Those, in turn, work together with other manufacturers and will benefit from a standardized approach as well. Searching for a prospective solution not exclusively for this use case, Wellmann chose to store the data on RFID tags in the form of ISO 13584-compliant properties.

![Figure 4. UML diagram showing the objects' characteristics](image)

### 3.3 Extraction of ISO 13584-compliant properties

The effects of the RFID introduction described in the scenario above affect the existing processes only. In this case study, RFID does not act as an enabler for new processes with a transformational effect (Straube et al. 2007); that is why all relevant data that should be stored on RFID tags are
implicitly contained in the current business processes and should be extracted from them instead of being newly created. To define the properties compliant to the ISO 13584 specification, at least the name of the property, the type of the property and the data type have to be extracted. Further information, such as IDs and units, can be manually added later. The needed information can be found in the information model of Wellmann’s ERP system.

The processing steps of the fronts, which are the objects of investigation in this case study, are receiving, producing and assembling. The identifiers related to the fronts as well to the containers the fronts are transported in have already been described in Figure 3. Considering this information model, the RFID tag is put on the fronts, which means that the TA number and TG position number can be extracted as properties (compare Table 1). Because of the association of the class fronts to exactly one container, the TG number can be added as a property as well. Attention has to be paid to the “one or more” association to the processing steps. This indicates that all three properties are not unambiguous, but depend on the ID of the disposition number of the processing step. For this reason, the disposition number builds the condition for the tree dependent properties.

Further characteristics of fronts and their related objects are depicted in Figure 4. In this information model, coming from the class front, all other classes are connected with an association multiplicity of exactly one. That is why no dependent properties have to be created because of multiplicities in the class diagram. Other dependencies (e.g. glass type and density) have to be manually detected. The attributes of the class front can be extracted as independent properties along with their corresponding data types. The attributes of the related classes can be extracted as well, but if the names of the attributes are not unambiguous for the front, the class name has to be added to the property (e.g. cupboard length). The extracted characteristics are shown in Table 1.

The properties of the bore program for the fronts can be extracted from Wellmann’s manufacturing execution system. In general, there exist two options: first, the whole bore program could be stored as one property that has the data type BLOB (binary large object). Second, the properties for the bore program can be extracted from the bore program. The bore program is encoded in PrimeFact’s XNC format (Smeerdijk 2006). The subset of this XML Schema, which is used by Wellmann, is depicted in Figure 5. The ISO 13584-compliant properties are extracted with the methodology proposed in Leukel et al. (2006a) and added to Table 1 (where the attribute SubProgram is renamed to bore program ID).

*Table 1. Extracted ISO 13584-compliant properties*
3.4 Prototypical Implementation

To realize the RFID project at Wellmann, special requirements and challenges have to be considered. First, only one type of RFID tag has to be used for applications in logistics and production. A combined approach of the data-on-tag and data-on-network concepts has to be applied. Second, passive RFID tags are preferred over active ones because of the price differences. For the data-on-network approach, RFID tags according to EPC Gen 2 (ISO/IEC 18000-6) in the UHF frequency range have succeeded in the market and should also be used at Wellmann for this reason.

Nevertheless, most RFID tags that comply with these specifications are only produced with the 96 bit memory for the EPC. For the reasonable usage of the data-on-tag approach at least 1024 bits of additional memory is necessary. The additional cost of this type of RFID tag is currently about 20 Eurocents. Individual companies have to decide for their own RFID business cases whether such a solution is economically reasonable or not. In the case of Wellmann, between 20,000 and 30,000 fronts, which are the subject of investigation in this case study, have to be tagged each year (253 working days). The extra costs of 5000 Euro per year at Wellmann can be justified by the reduction of costs incurred due to errors at the boring machine. Assuming that only 25% of the ca. 5 cupboards per day (1265 per year) that are mis-bored can be saved from errors, which saves about 20 Euro per cupboard for recycling, material and extra logistics, the annual savings add up to 6325 Euro. The qualitative benefits, such as the reduced dependency on the backend system and the number of additional satisfied customers, can be added, but it is not so easy to evaluate them monetarily. In this costs consideration, only the extra costs and savings of using a combined data-on-tag and data-on-network approach were considered, not general RFID benefits and the costs for implementation, maintenance and training.

To prepare for the introduction of RFID at Wellmann, technical tests in the laboratory were first conducted with RFID tags with 512 bits of extra memory. Later on, RFID tags with 1024 bits were chosen because of the needed memory as already stated above. For this prototypical implementation, a proprietary syntactical format – following the VDA recommendation (VDA 2008) with a separator – was chosen to store the data on tags. Since the ISO 13584 standard, which is recommended in this paper, only covers the semantics layer, further research on the syntactical layer is necessary.

4 CONCLUSIONS AND OUTLOOK

A company that considers the introduction of RFID technology has to develop a business case and calculate the related costs and benefits. The business case determines which of the following three scenarios to pursue: (i) the RFID tag stores the identifier only and all object-related data is stored externally (typically a networked databases); (ii) all object-related data is stored on the RFID tag; or (iii) one uses a hybrid approach using both paradigms for different applications. Due to various reasons, for the company described in the case study the hybrid approach is appropriate.

If companies want to use RFID technology in a cross-company application, standards have to be considered. For the data-on-network approach, the EPCglobal standards provide an appropriate solution. A standard for the data-on-tag concept had been missing.

In this paper, we recommended using ISO 13584 for the standardized storage of data on RFID tags. A standard in general contributes to the harmonization of interfaces between heterogeneous systems and, for this reason, increases interoperability, data quality and reduces data redundancy. The properties in our approach are precisely defined according to the ISO 13584 data model, which includes language independent verbal definitions as well as additional information regarding units, data types, etc.

We have shown that using ISO 13584 is a suitable approach for the data-on-tag concept by presenting a case study from Wellmann, a German kitchen manufacturer. Within this case study, we explained how the properties were extracted from the existing information models. For the processes under
consideration, all necessary data could be transformed into independent, dependent and conditional properties. Thus, at least for this application ISO 13584 is appropriate.

The next steps for a successful implementation of ISO 13584 consist of standardizing those properties that have not yet been standardized in the DINsml property dictionary. Subsequently, and after gaining experience with RFID technology, the scope of the application will be expanded.

Although we used a single case study approach in a very specific industry, the goal of using ISO 13584 is that the approach can be used for all other industries and RFID applications. This is because using ISO 13584 implies following a bottom-up approach. With properties, small pieces of information are standardized and can be applied to different circumstances. In this case study, we applied them to the production of custom ordered kitchen cupboards. Other standardization initiatives (e.g. AIAG and VDA in the automotive industry) can create their own standards for certain applications (e.g. container management and theft prevention) based on these or other standardized properties.

Abstract

Ubiquitous information technologies like RFID allow for immediate, extensive and fine-grained capture of real world information. Scalable and efficient networks for exchange of this vast amount of information amongst companies are crucial for the economic exploitation of benefits of ubiquitous information technologies. Existing networks bear several limitations like risks of single-point-of-failures or bottlenecks, unequally distributed power and burdens as well as inflexibility through stringent structures and formats. In particular there is a need for improving the scalability of solutions and ensuring autonomy of network participants. In this paper we introduce a Peer-to-Peer-based architecture for exchanging distributed information, which are shared among participants of a supply chain facilitated with ubiquitous information technologies. This architecture builds on the well-established EPCglobal standards, but can be implemented as an autonomous network. Unlike other architectures it does not need central coordination mechanisms, because it is based on self-organizing Peer-to-Peer protocols. We argue that our architecture supports business processes especially of small and medium-sized enterprises better than other architectures. We provide a discussion about requirements for solutions and a simulation-based analysis of the proposed architecture.

Keywords: RFID, Peer-to-peer networks, Supply chain management, Ubiquitous systems
INTRODUCTION

Ubiquitous information technologies merge the virtual world with the real world in a seamless way, making embedded information and computing capabilities available anytime and anywhere (Weiser 1991). Gathering real world information with ubiquitous IT enables precise monitoring and controlling of physical objects, their current state, whereabouts, movements and their environmental conditions. Radio Frequency Identification (RFID) is a basic and mature ubiquitous IT, which is applied to automatically identify individual objects and to link related individual information. It has already been thoroughly tested and is in actual use in several companies. Case studies (Fosso Wamba et al. 2008, Loebbecke 2007) as well as analytical studies (Bendavid et al. 2008, Lee & Özer 2007) document its potential both to improve efficiency of business processes, their management and controlling, and to facilitate new services and concepts within the scope of an integrated Supply Chain Management (SCM) (McFarlane & Sheffi 2003, Angeles 2005). Examples are track and tracing of products, automatic inventory and item-level product lifecycle management. Still, RFID systems for SCM, which reach beyond a single organization’s boundaries, are not yet widespread (Gaukler & Seifert & Hausman 2007).

While the decrease of production costs for RFID tags and readers is mainly dependent on technological advancements, the cost-benefit-ratio of the whole system is influenced by design and configuration of the system architecture (Asif & Mandviwalla 2005). A prominent solution is provided by EPCglobal (EPCglobal 2007), a comprehensive framework for standardized, integrated deployment of RFID in supply chains. EPCglobal and other existing solutions for interorganizational RFID systems still bear limitations. Among the main limitations are inefficient, centralized system structures and unbalanced powers between participants (users) and solution providers. Upcoming streams of information may not be manageable by these solutions or become very costly. Central coordination entities could turn out to be bottlenecks or even be attacked by offenders. Furthermore, those entities may also misuse their power. Joint adoption of RFID across the supply chain is still considered unfavorable by many companies. These conditions call for pursuing research in the field of interorganizational ubiquitous IT systems (Ngai et al. 2008, Curtin & Kauffman & Riggins 2007). Therefore we discuss network system architectures and propose a new architecture aiming at overcoming existing limitations. Our architecture enables companies to efficiently exchange locally stored information, captured by RFID systems, over an interorganizational, decentralized network. Our research focuses in particular on adoption of ubiquitous IT by small and medium-sized enterprises (SME).

The remainder of this article is structured as follows: In section two we shortly describe the use of ubiquitous IT in SCM, existing approaches like EPCglobal and related work. The next section comprises our proposal for an architecture based on the Peer-to-Peer (P2P) paradigm. This architecture is then discussed concerning conceptional requirements especially of SME. Further on, a preliminary prototype is presented and tested by means of computational simulations. Finally we conclude with key findings, recommendations, limitations of our work and an outlook to further research.

BACKGROUND

SCM aims at the integration of business processes alongside the whole supply chain in order to increase global competitiveness through flexibility and responsiveness (Bowersox & Closs & Cooper 2007). Information systems play a major role for the integration across the supply chain (Gunasekaran & Ngai 2004). The deployment of RFID supports real-time, ubiquitous monitoring of the integrated supply chain, by making item-level information, e.g. product history and whereabouts, visible for all participants (McFarlane & Sheffi 2003). Other ubiquitous IT like environmental sensors or embedded
systems allow for even richer information services alongside the supply chain, e.g. cold chain monitoring or self-routing packages.

2.1 Supply chain RFID systems

An RFID system commonly consists of three components: Transponder (tag, label), reader and a backend system. A globally unique identifier for item-level identification of physical supply chain objects is needed to allocate information related to individual objects (Främling & Harrison & Brusey 2006). The Electronic Product Code (EPC) builds the identification foundation of the EPCglobal framework. It is an identifying code for objects tagged with RFID, similar to the traditional EAN for barcodes, but on item-level instead of object-class-level. The EPC consists of a header, filter, partition, manager master number, object class and serial number. The first three parts contain format and processing information (e.g. format type and length of object class number). The manager master number indicates the tag owning organization. Each organization that wants to use EPCs on its products has to acquire a master number. In the US and in Europe the EPC is the commonly used identifier. Other identifiers for item-level RFID concurrently were developed and are also in use (e.g. uCode in Japan).

Because memory capacity on tags is limited, extensive information is stored in backend systems connected to the RFID systems by networks (Diekmann & Melski & Schumann 2007). Through RFID-based information services business partners can immediately inform each other about any supply chain event information (e.g. “Packet 88 was shipped in Honolulu at 12:31 UTC”) at time of occurrence and on item-level. Business process information flows can thus be automated, enabling supply chain participants to react to events in near real-time.

To allocate new or unknown services or look up changed service interfaces, the network system has to provide service discovery functions. The EPCglobal infrastructure provides core services to paying members of the EPCglobal network. One of the core services is the EPC Object Name Service (ONS) root. This service is administrated by the company VeriSign and is needed for search of EPC Information Services (EPCIS) offered by other participants of the network. The ONS root links address entries, by leveraging Internet Domain Name Service (DNS), to the manager master number of the organization, which provides the EPCIS. The holder of the master data number may operate local ONS and hierarchically link to further EPCIS or ONS. Non-certified EPCs or object identifiers of different formats cannot be processed by the EPCglobal network. Another core service is the Discovery Service. It is not completely specified yet, but will allow for search on item-level in the future. All core services are implemented and controlled by central authority of the EPCglobal organization. Disadvantages of the hierarchical structure and the centralized implementation of EPC core services are limited scalability and expandability, bottleneck and single-point-of-failure problems, unbalanced loads in the network, disabled self-organization and participants’ loss of control and power. The characteristics of the EPCglobal architecture may be one reason for low adoption of RFID supply chain systems. Companies refuse to join the exclusive club and to pay fees while the system still is in development (Kürschner et al. 2008).

Efforts of EPCglobal and others are under way to improve and amend the framework. An open RFID service discovery with an alternative EPCglobal-like ONS root was brought up by Afilias for discovery of participants’ local information services. Fabian and Günther (2007) elaborate security issues of EPCglobal and recommend geographically distributed name services. Other approaches bypass EPCglobal’s network by developing completely new frameworks. One of those is DIALOG, in which identification of objects follows the scheme ID@URI (Kärkkäinen & Ala-Risku & Främling 2003). Here the address (URI) of information resources is deposited directly on the object’s tag. This approach is quite flexible, but requires additional procedures for tagging, memory capacity on tags and administrating information resources stored at the URI.
2.2 RFID systems based on Peer-to-Peer networks

Requirements on scalability and efficiency of interorganizational RFID systems inspired efforts to create distributed solutions which support real decentralized coordination. Decentralized coordination is regarded as the more appropriate way to face challenges of managing complex supply chain processes in dynamic environments than centralized coordination (Amaral & Uzzi 2007). The concept of P2P networking is aligned to decentralized coordination in large networks of participants, who interconnect to exchange resources (Schoder & Fischbach & Schmitt 2005). Advantages of P2P systems for interorganizational applications are scalability, reduced risks of central bottlenecks, direct transactions, self-organization and failure resistance.

A special type of P2P networks, called structured or Distributed Hash Table (DHT) -based P2P networks, relies on hash table based communication protocols, which can guarantee efficient scalable and reliable information exchange (Risson & Moors 2006). In DHT-based P2P networks each information resource is stored as a key-value-pair and can be looked up with the key, which is an identifying name of the information resource (e.g. a file) mapped to a keyspace. Responsibility for the key-value-pairs is distributed fairly among peers. Each peer is responsible for a specified range of key-value-pairs and stores an address table with a confined number of known peers (neighbors) for routing purposes. Requests for storage or looking up of information are handled by routing those to a neighbor peer, whose hashed identifier is closest to the key in the keyspace. By this means it is ensured, that requests reach the responsible peer after a deterministic number of steps. Joining and leaving of peers is handled dynamically through intelligent repair mechanisms of address tables.

Summing up the current state, interorganizational RFID systems are centralized or proprietary and bear risk of performance weaknesses. Trying to face this, Wakayama et al. (2007) presented a product tracing system, which combines information service discovery using DNS according to EPCglobal with DHT-based service discovery. The major weakness of their approach is the chain-linking of address entries. If participants are not available, chains are broken and information can thus not be retrieved properly. Therefore, pursuing their idea, our architecture aims at efficient routing of information within a self-organizing, scalable, fully decentralized network of autonomous peers, without chain-links.

3 PROPOSED DESIGN OF THE P2P ARCHITECTURE

In this section we specify the design of our P2P architecture for service discovery of ubiquitous IT-based information services provided by participants within supply chains. We start with the description of object identification based on EPC or other identification schemata. Then we will illustrate the processes of providing and of querying information within the network. Lastly we explain the interoperability with EPCglobal.

3.1 Object identification

To identify an object tagged with RFID, a unique name has to be stored at the RFID tag memory. For RFID-based identification of objects the EPC provides a standardized name schema. For an open approach we regard it necessary to include any variants of identifiers in use or desired by applying companies, for instance hardware serials on RFID tags. A hashing function allows the publishing of information assigned to an object by using the hash value of any kind of object identifier. The hash value is mapped to a distinct location (one responsible peer and a predefined number of replication peers) in the network, from where participants can retrieve the entry directly by lookups using the object’s identifier as search key. Object identifiers and participants’ service addresses can be treated separately and multiple address links can be linked to one identifier.
3.2 Providing information to network participants

All RFID-based information generally remains in the participants’ local systems. Only meta-information is made publicly available through stored entries in the network. Two main entry types are distinguished: PublisherProfiles and PublicationRecords. A PublisherProfile defines the interface for an information service of a participant, who provides object information for other participants. It consists of the type of service (e.g. SOAP or EPCIS) and the service address (e.g. URI of the SOAP internet interface). Once an object identifier was captured by a company, it may publish information on that object within the network. For each object there is one PublicationRecord stored in the network. A record comprises a list of RecordEntries, and each RecordEntry consists of a reference to a PublisherProfile and optional information about the entry (e.g. type of event). Optional information is time of the capture event, object identifiers (children) that were aggregated to this object identifier (e.g. a container), a parent identifier, and additional, unspecified data. Each PublisherProfile and each RecordEntry has an expiration time, after which it will be deleted to prevent the network from storing too much or outdated data. Figure 1 shows classes and attributes of publication data, which is stored in the network. The segregation of profiles and records allows for separate update of each. In SCM systems records are potentially updated much more often than profiles. Furthermore, additional certificates or other authentication and authorization data may be stored in the profile.

A participant who wants to provide information sends a RecordEntry together with the object identifier to the P2P network. It will be replicated (depending on the configuration of the peers) and stored in the network. The participant’s profile will be published if it had not yet been published in the network or if he wants to update it.

3.3 Discovery and query of object information

The search for information is either accomplished directly with object identifiers or indirectly with queries, if a relevant identifier is unknown respectively is sought for or if other attributes are relevant for the search, e.g. date of entries. Direct search is simple and can efficiently be carried out in a DHT-based P2P network by taking the object identifiers as keys and looking up the keys in the DHT-keyspace. In contrast, complex query processing in P2P networks is a challenging task. Because in a fully decentralized DHT-based P2P network there is no participant who knows the entire network, an indirect query without an identifying key has to be resolved using distributed indices (Harren et al. 2002). If complex queries should be supported, indices have to be updated subsequently to each publication or periodically.

In addition to query processing the network also offers a publish/subscribe mechanism to realize event driven supply chain management. Information can then be pushed to interested participants immediately after capturing it. The mechanism allows participants to create a topic, subscribe to a topic or publish information linked to a topic, which automatically is sent to all subscribers of that topic. The topic subscriber group is also used for access and publishing restrictions by password.
Technically a topic corresponds with a sub-network of subscriber peers, which is in the same way self-organizing as the basic P2P network.

3.4 Interoperability

The proposed architecture offers interoperability with other systems like the EPCglobal network or ERP systems. Information to be published just has to be linked to any kind of object identifier and the publishing participant has to have or create a PublisherProfile. This means, the participant has to operate an information service at an address that is reachable by his supply chain partners. Figure 2 shows the components of the proposed architecture and how it could interoperate with EPCglobal. RFID reader events are processed by reader systems and middleware (which are provided e.g. by ERP software vendors) and then passed to our system as either binary data stream, XML or through data bases like mySQL. The system then extracts meta-information and publishes it in the DHT-based P2P network. On the other side, a query application can directly lookup meta-information of an object identifier or query meta-information through complex queries by sending a RecordEntry, where all determining attributes (e.g. event time) are filled and sought attributes are left blank. It then receives PublisherProfiles of participants which provide the appropriate information. By calling the service address given in the PublisherProfile, the query application can finally retrieve the information, e.g. from an EPCIS.

Figure 2. Components of the architecture and its interoperability with EPCglobal

4 DISCUSSION OF CONCEPTIONAL REQUIREMENTS

Conceptional requirements on supply chain RFID systems are manifold, depending on application context, supply chain and individual company needs. A detailed discussion regarding EPCglobal can be found in Kürschner et al. (2008). SME play a major role in implementing integrated supply chain RFID systems. On the one hand, as manufacturer, assembler or supplier of (pre-) products SME are in charge of tagging objects with RFID and of providing item-level information first (Gaukler & Seifert & Hausman 2007). On the other hand, SME can often act and operate very flexible, because of lean processes and organizational structures. Therefore, good alignment with innovative ubiquitous IT systems is attainable for SME. Despite that, SME still hesitate, e.g. in Germany 2007 only 3 % used RFID, but already 18 % of large companies (Martzahn & Renner & Pols 2007, p. 32). The following discussion will shed light on requirements of users, with focus on SME.

4.1 Scalability

Internet DNS root server process up to 48 billion queries per day (VeriSign 2008, p. 4). Upcoming item-level information systems will impose significantly higher volumes of information and queries. Furthermore, analogue to the Internet, benefits from RFID increase with amount of users due to
network externalities (Curtin & Kauffman & Riggins 2007, p. 95). Scalability is therefore most important for supply chain RFID systems. It ensures that companies are not restricted but can extensively interact with many business partners. Strong partnership networking is especially crucial for SME.

Based on DNS EPCglobal is organized hierarchically, and it is arguable whether centralized core services (like ONS root and discovery service) are capable of managing future loads. In a DHT P2P network there is no central bottleneck and with hashing algorithms information load is distributed equally. The search for entries with a DHT lookup receives a guaranteed answer even at high number of participants and communication loads. Also a limited response time can be guaranteed. Responses to searches and complex queries either contain the requested information (i.e. the appropriate PublicationRecords) or a Null-answer, if no one yet has published the sought information. DHT protocols like CAN, Chord, Pastry or Tapestry process lookups within $O(\log N)$ steps in networks with $N$ peers (Risson & Moors 2006). The required address tables for routing the lookups only occupy $O(\log N)$ storage space.

### 4.2 Security

Access to and authenticity of supply chain data, which participants insert into the network, should be secured. In centralized systems security mechanism can easily be implemented through authorization of participants and control of data by the authoritative organization. On the other hand, the central authority may abuse its power, because it can take over control about data streams and network access. Furthermore, it is an obvious target for attacks.

In distributed systems other security means are feasible. Authorization can be realized by a public key infrastructure (PKI) and a trusted third party, which offers and validates certificates of participants. An alternative solution is the web of trust (Datta & Hauswirth & Aberer 2003), where authentication of participants is confirmed not by a certifying authority but by other participants. Furthermore, data should be encrypted and transported over public infrastructures via secure protocols like SSL.

DHT-based P2P networks are self-organizing and therefore capable of self-healing after dynamic joinings and leavings of participants or other disturbances - up to some degree (depending on the configuration e.g. of replication mechanisms). Within the networks there is no single point-of-failure, which would be a potential target for internal or external attacks. As long as there is no large group of malicious actors, the network is robust. Besides that, all peers are autonomous and have equal power and control over their own data.

### 4.3 Flexibility

Existing IT infrastructures of SME may not be well equipped, which hampers exploitations of RFID benefits, e.g. because information is not utilized to advance internal information processes. Therefore solutions should be flexible and allow for customized implementation. Dynamic business relationships and supply chain structures should also not be absorbed by static network structures. The ability to quickly respond to changing situations is notably essential for SMEs.

Most interorganizational RFID systems are bind to fixed structures, like the hierarchical infrastructure of EPCglobal, and to special naming schemata for object identifiers, like EPC or ID@URI. But dynamically changing business environments and especially the internal flexibility of SME, e.g. in adapting to customer needs, require flexible systems. Therefore, our network is not bind to any fixed structure. It is capable to handle dynamic groups of participants, and any character string may serve as a key for information provided within the network. For instance, serialized data from XML documents can easily be exchanged in the network. In this way, existing e-business standards (like AS2, ebXML, eCl@ass) can be included with small efforts. This allows for individual configurations by participating companies when they implement such a system and integrate it into their existing SCM or ERP.
systems. The absence of a hierarchical structure supports flexible connections and enhancements. A distributed P2P system as proposed may be operated as a sub-network or a separate private network. In contrast, the EPCglobal architecture requires the establishment of dedicated instances, which operate core services and ensure unique naming.

### 4.4 Autonomy

Often SME are exposed to the power of major customers, who put pressure on them to implement systems suiting only customers’ needs. In the past years large companies, for instance Wal-Mart, mandated suppliers to adopt RFID (Soon & Gutierrez 2008). But sustainable adoption of ubiquitous IT will only be successful, if a company has internal motivation. Provided solutions should support SME in using RFID independently from others. This, of course, holds true for all other companies as well.

The participants of a P2P network are independent from each other and from any organizing instance. There is no central server, whose breakdown would block network transactions or become a bottleneck reducing efficiency and scalability. It is nearly impossible for individual instances to gain control over the network. Costs of implementation and operation of the systems are fairly distributed among all participants. There is no fee which has to be paid to an infrastructure operator. To lower the barriers, an interorganizational RFID system should allow for lean and incremental implementation. It should not cause or intensify dependencies on other organizations. Participants of EPCglobal are bind to the core service infrastructure, which is operated by a commercial US company (VeriSign), as well as to the hierarchical network and fixed data structure. Our architecture is compliant with EPC standards and can be used in combination with EPCglobal or other systems, but it is not bind to the EPC.

### 4.5 Costs and benefits

Major barriers for adoption of RFID are high investment expenditures and unclear benefits (Angeles 2005). Many cost-benefit-analyses are concentrating on costs of RFID tags and readers - but costs for tagging procedures, process reengineering and reorganization, system integration and user training have to be taken into account (Smith & Konsynski 2003). As manufacturer or supplier SME suffer from cost-benefit-asymmetry, because they bear the costs of tagging, while large retailers take credit e.g. for better customer service and lower inventory. In addition, SME are deterred by the complexity of system rollout and integration. After employment of RFID systems the flood of information has to be managed and that often requires well-planned process reengineering. SME traditionally lack capital, time and competencies to accomplish these tasks successfully. Assigning consulting firms or service providers adds even more to the cost-side.

EPCglobal grounds on a complex framework, initially driven by interests of retailers and large corporate groups. Each participant has to pay a periodic subscription fee. In contrast, an open P2P network will be free of charge, because there is no authority to charge it. Despite that, adoption costs and benefits are hard to be determined, because they strongly depend on individual design choices and organizational factors (Dutta & Lee & Whang 2007, p. 646). But within complex supply chains a P2P-based solution encourages a fair approach.

### 5 SIMULATION-BASED ANALYSIS

Supply chains are complex systems, whose investigation is known to be difficult in many respects (Harrison 2007). Under these circumstances computational simulations provide a good method for the study of supply chain systems (Terzi & Cavaliere 2004). Our simulation-based analysis may set an initial point for subsequent empirical studies. By this means we can test the large-scale performance of our P2P system with affordable efforts. After shortly explaining the prototype and setup we will discuss selected results.
5.1 Prototype

The prototype is based on the generic DHT-protocol Pastry (Rowstron & Druschel 2001a), which allows creation of a P2P network as a self-organizing, fault-tolerant overlay in the internet. Pastry routes messages between peers based on a 128-bit hash-value ring provides load balancing and leverages peers’ routing distances in the underlying internet for improved efficiency. Furthermore, we deploy the Pastry application PAST (Rowstron & Druschel 2001b) for hash-based, distributed storage and retrieval of data in Pastry networks. The prototype is implemented in Java and uses the open source Pastry implementation FreePastry1. In addition to the direct search with hashed object identifiers we added two exemplary types of queries: (1) Entries published by a specific participant, and (2) entries of a specific date.

5.2 Simulation setup

The simulation is conducted with a network of \( N \) participants. After bootstrapping the participants stochastically publish RecordEntries. Each participant publishes his PublisherProfile at first entry publishing. The probability of publications per preconfigured time interval \( \text{interval} \) is defined by a parameter \( p_{\text{pub}} \). Participants search (based on hashed EPCs) and query information in the network stochastically with probability \( p_{\text{look}} \) per interval. When receiving answers, they also lookup PublisherProfiles of received RecordEntries.

To examine the ability of flexible self-organizing, we introduce dynamic factors. The probability for leaving and joining of randomly picked participants is given by \( p_{\text{join}} \) and by \( p_{\text{leave}} \). The parameter \( rep \) determines the number of replications which are stored for each entry in the network.

In each simulation experiment we measured the actual dynamics \( \text{dyn} \) (numbers of participants leaving and joining the network per interval), the actual number of activities \( \text{act} \) (publications and lookups) per second, and failures \( \text{fail} \), and the average time till responses \( t_{\text{resp}} \) (excluding failed ones) in seconds. A publication or lookup activity is counted as failure, if there is no respond from the network after a preconfigured timeout (default 30 seconds). A Null-answer is not counted as failure, but as correct response.

5.3 Selected results

During the simulation runs we varied the input parameters for network size, replication, publishing and querying, joinings and leavings. The default time interval was set to 100 milliseconds. We run each experiment with at least 200,000 activities. Table 3 shows some selected results.

There were no significant differences in response times in different network sizes. The responses took 0.27 to 0.63 seconds on average. Moreover, failure rates were not significantly higher in larger networks. In small networks, e.g. with 500 participants, no failures appeared. Failure rates in low dynamic networks did not exceed 0.007 \%. In networks with dynamics of 5 \% of peers joining or leaving each minute failure rates increased slightly, but only up to 0.013 \% (experiment 7 in table 3). The replication factor naturally had an impact on failures. On the one hand, more replications led to lower failure rates, down to 0 \%. On the other hand, more storage capacity is used. But no observable influence on response times could be observed. Storage size for records ranged from less then 1 to a few 100 KB per peer. This obviously depends on amount and expiration time of published data. The used bandwidth for communication was not measured. Simulations of Haebeleren et al. (2005, p. 6) showed that the general overhead for Pastry consumed a bandwidth of 1-10 KB/s at maximum.

6 CONCLUSIONS

6.1 Lessons learned

The challenge of implementing RFID systems alongside the supply chain is not trivial and the design of appropriate network architectures is crucial. This article aimed at proposing a P2P architecture to meet general demands for ubiquitous IT systems and some special requirements of SME. To overcome limitations of existing approaches we introduced decentralization of supply chain RFID systems. Good scalability and flexibility are major advantages of decentralized architectures. Sophisticated DHT protocols provide a highly efficient base for distributed supply chain RFID systems.

We illustrated our DHT-based P2P architecture and explicated conceptional requirements with special regards to SME. Further on we presented results of simulation experiments with our prototype for large-scale networks. The results indicated short response times and self-organizing capabilities to handle dynamic participant structures as well as prevention of failures.

6.2 Limitations

This work is still in progress. The prototype is no fully-fledged software and real-life tests still have to be conducted. Advanced security mechanisms are not implemented, but Fabian and Günther (2007) describe P2P-based security mechanisms, that can be applied for supply chain RFID systems. The proposed architecture is not meant to replace existing solutions, but to enrich and amend their further development. With our work we want to give design hints for more fair and scalable implementations.

6.3 Recommendations

Companies should thoroughly analyze available supply chain RFID systems before they start implementation. If they do not want to be dependent on global solution providers and to constrict their flexibility, decentralized architectures should be considered in particular. Nevertheless, technical standards like the EPC have to be taken into account for any interorganizational RFID implementation. SME without in-depth RFID knowledge can use support of consultancies and research institutes, but may keep in mind, that more scalable solutions provide more future potential.
6.4 Future research

Next parameters of the simulation model will be refined on the basis of empirical data taken from analysis of information and material flows in real supply chains. Empirical evaluation and scientific discourse are further steps of our research. With a refined simulation setup and an advanced prototype, we may predict future information flows within RFID-based supply chains and assess the suitability of different architectures more precisely. It is worthwhile to find out, how structures and dynamics of supply chain systems are affected by large-scale adoption of ubiquitous IT. Several alternative solutions will be available concurrently. It is necessary to pursue research on the design and quality of various solutions.

Abstract

A new kind of Web-based application, known as Enterprise Mashups, has gained momentum in the last years: Business users with no or limited programming skills are empowered to leverage in a collaborative manner user friendly building blocks and to combine and reuse existing Web-based resources within minutes to new value added applications in order to solve an individual and ad-hoc business problem. Current discussions of the Mashup paradigm in the scientific community are limited on technical aspects. The collaboration and the peer production management aspects of the Mashup development have received less attention yet. In this paper, we propose a reference model for Enterprise Mashups which provides a foundation to develop and to analyse grassroots Enterprise Mashup environments from a managerial and collaborative perspective. By following the design science research approach, we investigate existing reference models and leverage the St. Gallen Media Reference Model (MRM). The development of Enterprise Mashups is structured by market transaction phases similar to electronic markets. The user roles, the necessary processes and the resulting services are modelled according to the views of the MRM. By means of the SAP Research RoofTop Marketplace prototype we demonstrate the application of the designed reference model for grassroots Enterprise Mashups environments.

Keywords: Enterprise Mashups, St. Gallen Media Reference Model, Design Science, Electronic Markets.
1 INTRODUCTION

1.1 Motivation and Problem Scope

The process of development of Web-based business applications follows usually the typical process of software development involving first assessment of user requirements followed by a long process of development and testing. The functionality of the resulting application is actually a compromise of user requirements, as not all user requirements can be considered. As a result, there is a long tail – a term first coined and popularized by Chris Anderson (2004) – of many specific and heterogeneous user requirements or dynamically changing user requirements that are not covered by the IT department (Carrier et al. 2008, Hoyer and Stanojevska-Slabeva 2008).

A possible solution for this problem could be a new development paradigm, known as Enterprise Mashups, which integrates the users from the business units characterized by no programming skills in the software development process (Cherbakov et al. 2007). At the core of the paradigm are two aspects: First, empowerment of the end user to cover ad hoc and long tail needs by reuse and combination of existing software artefacts; and second, broad involvement of users based on the peer production concept. According to Yochai Benkler, who coined the term peer production, “it refers to production systems that depend on individual action that is self-selected and decentralized rather than hierarchically assigned” (Benkler 2006). Thereby, the creative energy of large number of people is used to react flexible on continuous and dynamic changes of the business environment. Instead of long-winded software development processes, existing and new applications are enhanced with interfaces and provided as user friendly building blocks.

Existing research efforts focus mostly on technical aspects like the development of Mashup tools – i.e., IBM Mashup Center (formerly IBM QED Wiki, IBM Mashup Hub, IBM Damia), Intel Mash Maker, Microsoft Popfy, and Kapow Mashup Server, which enable easy integration of available components - or underlying technical concepts and principles - i.e., Maximilien et al. (2008), Yu et al. (2008), Hoyer et al. (2008). The discussion from a collaborative and peer production perspective is still missing in the scientific community discussing the implications, challenges, but also the potential benefits and limitations of the Mashup paradigm in the enterprise context. Important questions from these perspectives are: Who is involved in the Mashup development and what are the roles of the different players in particular of the software development department and the business units? What are the necessary processes to enable and support community building and collaboration?

The goal of this research paper is to fill this gap by designing a reference model which integrates the collaborative and community aspects and can serve as a framework to structure the development and analysis of Enterprise Mashup environments. The general research questions guiding this study are to model the roles and relationship of the interacting users as well as to interlink community and technical aspects within grassroots Enterprise Mashup environments.

1.2 Research Design: Design Science applied

For answering the research questions motivated in the previous section and characterized by a practical nature, engaged research is needed in order to provide rigorous solutions. Design science research aims at solving practical and theoretical problems by creating and evaluating IT artefacts indented to solve identified organizational problems (March and Smith, 1995, Hevner et al. 2004, Peffers et al. 2008). Artefacts represent the final result of a design process. They can be characterised as constructs, model, methods, or instantiations (March and Smith, 1995).

To come to rigorous and relevant research results, we draw upon on Peffers et al. (2008) to specify the subsequent phases of the design science research process applied:
• **Problem Identification and Motivation.** In the motivation, we specify the specific research problem, show the practical relevance and justify the value of a solution. Based on the problem scope, we derive the research questions guiding this paper.

• **Define the Objectives for a Solution.** In the second chapter, we infer the objectives of a solution from the problem definition and knowledge of the state of art. In particular, chapter two defines Enterprise Mashups, analyses existing reference models by means of a literature review and presents the St. Gallen Media Reference Model.

• **Design and Development.** In chapter three, we leverage the St. Gallen Media Reference Model (MRM). As observed by Legner (2008), Hoyer and Stanoevkska (2008), and Carrier (2008) the peer production of Enterprise Mashups has many similarities to electronic markets: Available components are classified and offered by providers and potential consumers search for the most suitable ones and if required pay for the usage. Thus, the required support should enable the matching of supply and demand in a way similar to conventional market phases (knowledge, intention, contract/design, and settlement). We apply these market phases to model the roles and the relationships between the interacting users according to the layers of the MRM.

• **Demonstration.** For demonstration of the designed artefact, we apply the reference model in order to develop the SAP Research Rooftop Marketplace. In particular, we structured the requirement and software design phases according to the reference model for Enterprise Mashups.

The results of each of the above activities are presented in the remaining parts of the paper. Finally, the last chapter closes with a brief summary, limitations of the conducted research and an outlook to further research.

2 RELATED WORK AND OBJECTIVES OF THE SOLUTION

2.1 Enterprise Mashups – Definition and Characteristics

In literature, the exact definition of Enterprise Mashups is open to debate. In this work, we refer to the following definition: “An Enterprise Mashup is a Web-based resource that combines existing resources, be it content, data or application functionality, from more than one resource in enterprise environments by empowering the actual end users to create and adapt individual information centric and situational applications” (Hoyer et al. 2008). By simplifying concepts of Service-Oriented Architecture (SOA) and by enhancing them with the Web 2.0 Philosophy of peer production, Enterprise Mashups focus generally on software integration on the user interface level instead of traditional application or data integration approaches (Daniel et al. 2008). In contrast to SOA that is characterized by high technical complexity of the relevant standards and requiring specialists’ technical knowledge, the simplified Enterprise Mashups enable the integration of the end users with no or limited programming skills in the development process.

The relevant architectural components of the Enterprise Mashup paradigm are resources, widgets, and Mashups (Hoyer et al. 2008) and can be structured in an Enterprise Mashup Stack comprising three layers (see figure 1): **Resources** represent actual contents, data or application functionality that are the core building blocks of Mashups. They are encapsulated via well-defined public interfaces (Application Programming Interfaces; i.e., WSDL, RSS, Atom, etc.) allowing the loosely coupling of existing resources – a major quality stemming from the SOA paradigm. These resources are provided by enterprise systems or by external Web providers (i.e., Amazon, Google, etc.) and are created by traditional developers who are familiar with the technical development concepts. The layer above contains **widgets** which provide simple user interaction mechanism abstracting from the complexity of the underlying resources. For example a widget “Customer Data” might provide results for a predefined query requesting the data for all customers of a sales manager. The creation of these widgets can be done by consultants or key users in the business units who understand the business requirements and know basic development concepts. Finally, end users with no programming skills...
are able to combine and configure such visual widgets according to their individual needs, which results in a **Mashup**. For example, the sales manager wires the "Customer Data" with a map to show the location of the customers.

![Enterprise Mashup Stack (Hoyer et al. 2008) - Meta Model and User Roles](image)

**Figure 1.** Enterprise Mashup Stack (Hoyer et al. 2008) - Meta Model and User Roles

The first key driver of the Enterprise Mashup paradigm is the **lightweight composition style** by reusing existing building blocks in new ways. The Enterprise Mashups paradigm separates between the wiring and piping composition as depicted in Figure 1. The piping composition integrates heterogeneous resources defining composed processing data chains concatenating successive resources. Aggregation, transformation, filter, or sort operations adapt, mix, and manipulate the content of the underlying resources. The visual composition of input and output parameters of widgets on the Mashup layer is called wiring (i.e. the output parameter address of the customer widget is connected to the input parameter of the map widget). In addition to this lightweight composition style, the **mass collaboration principle** is the second key driver. The willingness of users to offer feedback to the Mashup creator, who may be unaware of problems or alternative uses, directly contributes to the adoption of the Mashup and can foster its ongoing improvement (Hoyer et al. 2008). Another important contribution of users is the inclusion of their Mashups in the available pool of components. The willingness of users to provide their Mashups for further reuse increases the number of available components.

### 2.2 Reference Modelling

Despite the popularity of the term reference modelling since the 1990s, there is still no single meaning connected to this term and it is used to designate different approaches. By analysing various definitions, Fettke and Loos (2007) identified the following three main characteristics of reference models: First, **best practices**. A reference model provides best practices for conducting business. Second, **universal applicability**. A reference model does not represent a particular enterprise or system, but a class of domains. Hence a reference model is valid for a class of domains. Third, **reusability**: They can be understood as blueprints for information systems development. Thus a reference model is a conceptual framework that could be reused in multitude of information system projects. Modeling guidelines (Becker et al. 1995) and evaluation criteria of reference models (Frank 2007) are discussed in the scientific community.

In general there are two approaches for creating reference models: either by observing many instances available in practice and extracting common elements into a reference model or by leveraging and adjustment of existing reference models. The first approach is suitable when a sufficient number of instances are available. The second approach might be a suitable option when the underlying phenomenon is not well researched yet, but similarities to other phenomena can be revealed. As
Enterprise Mashups are a recent development there are not proven good practices yet that can be applied for reference model extraction. Thus, the second approach was applied: existing reference models were checked if they fulfil the requirements of Enterprise Mashups environments.

By means of a literature review and by applying the classification framework of Braun and Esswein (2007), we analysed existing reference models that are relevant for the Enterprise Mashups paradigm. Gartner proposes a practitioner reference model that specifies the technical architecture components in Enterprise Mashup environments (Bradely 2007). A practitioner reference model of Forrester uses a similar layer structure like Gartner and the presented Enterprise Mashup Stack. In addition, a phase model is integrated specifying the inputs and information flow (Young 2008). First, the actual content provided by the IT department is provisioned for the Enterprise Mashup environment from both internal and external resources. Second, users from the business units use a so-called Mashup composer to arrange and combine content, as well as determine a visualization paradigm. Third, the mashable components are managed by a Mashup life-cycle manager and shared with others to use in new Mashups if desired. Even though both reference models provide first technical structures of Enterprise Mashup environments, a multi-view concept integrating the managerial perspective is missing. The existing reference models miss in particular support for the collaborative aspect of Enterprise Mashups development and do not provide sufficient support for the peer production process. In order to integrate the different aspects (community, processes, or technical), a multi-view reference model is necessary.

Another specific characteristic of Enterprise Mashup environments is their similarity with electronic markets. Enterprise Mashup environments need to provide besides support for easy integration of software artefacts also support for efficient management and matching of supply and demand for Mashup components. Legner (2007) describes the trading of Web Services according to market transaction phases. Carrier et al. (2008) put the discovery and sharing of mashable elements in the center of the development process to reuse existing assets in new combinations.

In summary, a comprehensive reference model for Enterprise Mashups is required that on the one hand considers technical requirements regarding the easy integration of mashable components and on the other hand support for matching of supply and demand for required Mashups based on the market paradigm. We will incorporate these findings by leveraging a scientific multi-view reference model (The St. Gallen Media Reference Model) that has its roots in electronic markets and that has already been applied successfully for modeling electronic markets (Schmidt and Lindemann 1998), m-commerce communities (Stanoevska-Slabeva 2003), and cross-company electronic collaborations (Schroth and Schmid 2009).

### 2.3 St. Gallen Media Reference Model

The St. Gallen Media Reference Model (Schmidt and Lindemann 1998) provides a framework for specifying IT infrastructures. Under the term medium, we understand platforms based on information and communication technologies, i.e., communication spaces of "social interaction which allow the participant to meet and which embed them in a common physical, logical, and socio-organizational structure" (Schmidt 1997). The media reference consists of two dimensions: The horizontal dimension contains the four phases of a market transaction whereas the vertical dimension is built of four views.

The four view layers structures the different successive interaction goals of the participating agents. The **community view** describes the participating agents, their roles and the organizational structure defining the relationships among roles together with their obligations and rights. The **interaction view** refers to the relevant processes and is based upon the underlying services. The **service view** comprises all services in the four market phases that need to be available on the platform. The four services are: First, the **knowledge phase** is which information about offered services and knowledge and the media platform itself is acquired. Second, the **intention phase** in which agents signal their intentions in terms of offers and demand. Third, the **contract phase** where agents negotiate legal binding contracts and finally the **settlement phase**, in which agents act according to the negotiated contract using the
platform’s settlement services offered for this purpose. Examples of services in the service view are electronic product catalogs in the knowledge phase or payment services in the settlement market phase. Finally, the infrastructure view contains communication protocols and standards which comprise the groundwork for the implementation of services.

3 DESIGN: REFERENCE MODEL FOR ENTERPRISE MASHUPS

As elaborated in the previous chapter, we leverage and adjust the existing St. Gallen Media Reference Model due to its similarities to electronic markets and due to their successful application for managing communities. The driving force is the transfer of typical market transaction phases to the development of software artefacts to address the specific requirements of Enterprise Mashups. In addition to the two dimensions (views and phases), we introduce the architectural Enterprise Mashup Stack as a third dimension of the reference model for Enterprise Mashups as depicted in Figure 2.

Starting with the knowledge phase, available mashable components (Mashup, widget, resource) are classified, rated and explained in different ways to the agents of the Enterprise Mashup environment. Concepts from the Web 2.0 philosophy, like rating, tagging, or recommending are integrated for browsing through the Enterprise Mashup medium. During the intention phase, the concrete offers are provided in a structured manner including the payment mode, the price as well as the delivery conditions. In the contract (design) phase, users select the right mashable component based on the provided information, configure it according to their preferences and combine it with other components. Finally, in the settlement phase the Enterprise Mashup is executed.

In the following, each view of the model is described and modelled by using the well-known conceptual modelling languages Unified Modeling Language (UML), Business Process Modelling Notation (BPMN) and Fundamental Modelling Concepts (FMC).

3.1 Community View

To describe the interacting and connected agents as well as their tasks and roles, we refer to the following interaction model well known in Service-Oriented Architectures (Papazoglou 2003) but also in electronic markets (Legner 2007): A provider develops and publishes a mashable component via an intermediary, where a consumer can find it and subsequently may compose and consume it. As
depicted in Figure 4, the interaction between consumers and providers is always managed by the intermediary. The tasks of the three agent roles are described in the following:

- **Provider.** A provider implements and hosts a Mashup component (resource, widget, or Mashup) which encapsulates the actual content or knowledge. To promote their provided functionalities, the provider annotates the component with relevant information and publishes it to the intermediary through which the component description is published and made discoverable.

- **Intermediary.** An intermediary mediates between providers and consumers similar to electronic marketplaces (Legner 2007). In contrast to traditional SOA-based implementations like UDDI or ebXML, novel forms of intermediaries are currently about to emerge which improve navigation, transparency, and governance. They monitor continuously the parameters (such as availability or response latency) and provide performance metrics and other evaluation results which may be used by the consumers to select the right Mashup component.

- **Consumer.** Based on the available information of a mashable component, a consumer is able to retrieve and compose Mashup components according to his individual preferences. Consumers take also over the role of annotating Mashup components by tagging, recommending, or rating them. The consumers also contribute to the community base of widgets by providing their created and adapted Mashups back in the community pool.

![Figure 3. Agents in the Enterprise Mashup Community.](image)

A critical success factor for Enterprise Mashups is a broad potential user group, familiar with the technology and willing to use it in their daily operational environment. Users from the business units are able to create their own component and provide it to the community (Hoyer and Stanoevska-Slabeva 2008, Carrier et al. 2008). In this sense, users can take over both agent roles (consumer and provider). For example, a sales manager can publish his created Mashup combining different widgets (i.e., the customer and map widget) to the community. One of his colleagues can reuse and consume the Mashup immediately without the involvement of the IT department. The creation of more complex widgets and the adaptation of existing backend services are in responsibility of the developer from the IT department (provider role). Additionally, the IT department takes over the intermediary role. The Mashup components itself are located within the enterprise boundaries (i.e., my sales orders) or are sourced via external Web providers. The foundation of the richness of Enterprise Mashups applications is based on the seamless combination of corporate internal and external information sources. News feeds, a map or a credit cart checking Web Services can be combined ad-hoc with the internal customer data. The continuous growing numbers of available Web-based resources can be observed by the two intermediaries Programmableweb.com or Seedka.com.

### 3.2 Interaction View

Figure 4 depicts a simplified process in BPMN describing the interaction between the three agent roles as presented in the community view before. The detailed interaction process can be found in Hoyer and Stanoevska-Slabeva (2009). According to the findings of section two, the interaction process itself is characterized by permanent loops between the converging design and runtime phases. The need to
adapt the operational environment ad-hoc leads to adding, removing, or replacing existing mashable components. In the following discussion of this paper, we focus on the Mashup layer.

Figure 4. Interactions between the three Agent Roles (Mashup Layer).

After registering to the Enterprise Mashup environment, consumers (i.e. the sales manager) are able to discover the community and member profiles. By means of examples in form of short videos, the benefits of the Enterprise Mashup environment are demonstrated to potential users. Only if a huge amount of users are convinced of using the environment, it will exploit its actual potential. By discovering the catalogue of mashable components (in this case widgets), consumers are able to select a widget based on extensive information provided by the provider, intermediary as well as the consumers. Reviews, recommendations, and ratings of colleagues help for selecting a component. In case the consumer accepts the underlying business model (costs, payment model, consumption licence, etc.) of a widget that is defined by the provider, he can compose the component with others by connecting the input and output parameters of the widgets. In contrast to the classical software development, the design of ad-hoc applications uses real resources and no demo systems. In this sense the consumption in the settlement phase differs only from the hidden configuration capability in contrast to the design phase. In case a new business situation comes up, the consumer shifts quickly to the design or intention perspective to adapt the individual operational environment.

3.3 Service View

Based on the described interaction process, we derived the required services for the process steps. According to the role of the intermediary mediating between consumers and providers, the IT department is responsible to act as a service intermediary (Hoyer and Stanoevska-Slabeva 2008). Because business users focus on solving daily business problems in the sales or accounting department and not on creating or adapting their operational environment, Enterprise Mashup platforms have to hide the complexity from the users. The figure below depicts the related services to implement the interaction process by using the Fundamental Modelling Concepts (FMC) notation. In contrast to the technical oriented UML notation, FMC focuses on human comprehension of complex systems.

The growing number of available mashupable components requires adequate discovery services for retrieval purposes. According to the user context (profile, preferences, social network it belongs to) relevant widgets are presented to the consumers who are able to select the relevant Mashup component. Sharing of information, experiences and knowledge within the community is a key driver for Enterprise Mashups. Besides the default semantic annotations (functional and non-functional

---

1 http://www.fmc-modeling.org
qualities) defined by the provider, consumers are able to tag, recommend, or rate the mashable components. A catalogue manages all this information for widgets, Mashups, and users. The design of the widget components (wiring) is handled by the composition service that accesses the catalogue for the required information. As mentioned already before, good enough solutions lead to a converging design and run time. That implicates a direct integration between thes two services. From consumer perspective, no traditional deployment exists. They design their operational environment and execute it immediately. During the execution phase, the Enterprise Mashup environment monitors and protocols the usage of the mashable components. Based on the aggregated statistics resulting in popularity, availability or error rate information, consumers and providers get additional information to select or adapt a component or to publish a new one. Additionally, the accounting of the environment usage is calculated by this data. To administrate and monitor the performance of the Enterprise Mashup environment, the IT department needs adequate services to manage the running system.

Figure 5. Services of Enterprise Mashup Environments (FMC Notation).

3.4 Infrastructure View

In contrast to existing applications (i.e., MS Excel or MS Access) created and managed by business units to address ad-hoc requirements, the technical infrastructure of Enterprise Mashups environments are managed and provided by the corporate IT department. Independent if the users from the business units act as consultant (widget layer) or as end user (Mashup layer), they are able to integrate easily their local resources encapsulated by Mashup components. Consumer-oriented Mashup environments like iGoogle, Netvibes, or Facebook consume mostly light weight Web-based resources sourced via RSS, ATOM, or JSON. Instead Enterprise Mashup environments integrate resources from legacy systems as well. Currently, the major vendors of enterprise systems like SAP, Oracle, or Microsoft enable their applications to service-oriented platforms which are based on established standards. For example, SAP provides more than 1500 so-called enterprise services described by WSDL. However, besides standardized Web Services, the implementation of first Mashup prototypes in Enterprise Mashup environments shows the relevance to integrate other resource types as well, i.e. XML files, data bases, or RPC.

Due to the open and Web-based character of Enterprise Mashups, wide accepted standards or protocols are required. This includes technical standards for the visual composition (piping and wiring) but also standardized accounting methods.
4 DEMONSTRATION – SAP RESEARCH ROOFTOP MARKETPLACE

This section is devoted to apply and demonstrate the design artefact by means of the SAP Research Rooftop Marketplace platform (Hoyer et al, 2009). It represents a prototype which allows the creation and adaptation of Enterprise Mashups according to the individual and heterogeneous needs. We used the designed reference model to develop the prototype by following the marketplace and collaborative character as elaborated in this paper. Thereby, the reference model structured the requirement analysis and the transfer to the technical specification of the platform.

![SAP Research Rooftop Marketplace](image)

**Figure 6. SAP Research Rooftop Marketplace.**

The SAP Research Rooftop Marketplace itself is a Web-based application based on AJAX (Asynchronous JavaScript and XML) and is internally available to all SAP employees without installation. In this sense, the platform is provided by SAP Research acting as an intermediary. By using a Single Sign On (SSO) login process, users (provider and consumer) are able to register to SAP Research Rooftop automatically. After defining the individual user profile, users are able to discover the Mashup community which provides information about Enterprise Mashups in general as well as features and demonstrations (videos) of the SAP Research Rooftop tool in specific. A catalogue allows the discovery of the provided Mashups and widgets. Besides the browsing of predefined categories, the user is able to select top rated, most popular or latest widgets. Each widget is annotated by extensive information provided by all three agent roles (see figure 6). The actual consumer is able to rate, to tag, or to recommend a widget. In case a user has created an Enterprise Mashup, he is able to send a link to his colleague who can consume immediately the component. On the other side, providers can specify a default description and the business model (i.e. the costs) of a widget. The SAP Research Rooftop Marketplace platform itself (intermediary) monitors the consumed widgets and Mashups continuously (i.e., popularity and availability) and provides the information to the consumer and provider.
The composition of widgets is depicted at the bottom of the figure above. The customer data widget is wired with a map by connecting the input and output parameter (orange line) represented by the red bullets on the left (input) and the blue bullets right (output) side of the widget. The configuration and information of a widget can be easily accessed by clicking on the info button of the widget. It allows that the consumer can directly contribute to the community by rating or tagging a widget without changing to a different view which covers the knowledge/intention phase. According to the described marketplace and collaborative characteristic of Enterprise Mashups, the SAP Research Rooftop Marketplace platform integrates these two market phases. The figure above at the bottom right indicates the available information of the “Customer Data” widget and how a consumer can add easily a rating and comment to a widget.

Coming back to the composition environment, the real data of the “Customer Data” widgets are displayed already at the design time as depicted in the figure. If the user selects a customer (Siemens in Munich, Germany) in the widget, the address is updated in the map (in this case Microsoft Virtual Earth). So, there exist no separation between the design and runtime within the SAP Research Rooftop Marketplace prototype. By shifting to the runtime view, only the configuration capabilities like adding new widgets are logged.

5 CONCLUSION

The aim of this paper is the design of a reference model for grassroots Enterprise Mashups environments serving as foundation to develop and structure Enterprise Mashup environments. In order to achieve this, we follow the design science methodology. After defining the main terms related to Enterprise Mashups and reference models, we presented a designed reference model for Enterprise Mashups by leveraging the St. Gallen Media Reference Model. Thereby, we took advantage of the observed and identified similarities to electronic markets and collaborative characteristics. Instead of following the traditional software development phases (requirements, specification, development, testing and deployment), we propose the structure of market transactions. The roles, required services, and relationships between the interacting agents (provider, consumer and intermediary) were modelled. By means of the SAP Research Rooftop Marketplace, we demonstrate the application of the designed reference model for structuring the development of an Enterprise Mashup environment.

What is still missing is a broader application of the reference model for Enterprise Mashups in other areas and its further verification in an iterative design cycle (“Design as a search process”) according to the design science methodology (Peffers et al. 2008, Hevner et al. 2004). Further research will deal with the application of the reference model to structure further Enterprise Mashup environments. In particular, we have applied the reference model in the frame of the EU funded FAST/EzWeb project (http://fast.morfeo-project.eu) that covers the Mashup and widget layer.

The designed reference model for Enterprise Mashups provides furthermore only a first generic framework that helps to understand the organizational and managerial challenges of the Mashup paradigm in enterprise environments. Besides the structuring of requirements for the development of Enterprise Mashup platforms, the generic reference model has to be extended and operationalized with unhandled managerial aspects. The loosely coupled user-friendly building blocks both from internal and external IT systems require also a governance, quality, and security concept defining who is able to access a widget. The inclusion of these aspects would provide a more detailed and different models of the community and interaction view.

Abstract

Different approaches on how to implement or deploy enterprise resource planning (ERPs) systems exist. Although virtually nobody really doubts importance of ERPs for running a business today, there is a sentiment regarding their implementation – both in terms of time and money. In this paper we investigate relationship between factors influencing selection of a specific implementation approach and companies’ ability to stay on budget when implementing ERPs. The question is: whether factors influencing implementation approach then affects to what extent ERP system implementation costs exceed planned costs for implementation. The questionnaire research, focused on this issue, was conducted in Denmark, Slovakia and Slovenia. Dependent variables were percentage of actual ERP system implementation costs and staying on budget vis-à-vis the planned costs and budgets. The independent variables were implementation approach, country, company size, information strategy, representation of the IT department on board level, and number of implemented modules. Main conclusions are that number of modules influences selection of implementation approach and companies with information strategy are more likely to stay on budget. However, implementation approach does not significantly influences implementation costs and clear relationships between factors influencing selection of implementation approach and costs for ERP implementation could not be found.

Keywords: Enterprise Resource Planning (ERP), IS Investments, Implementation, Empirical Study.
1 INTRODUCTION

Enterprise resource planning (ERPs) systems consist of an integrated set of programs that provide support for core business processes, such as production, input and output logistics, finance and accounting, sales and marketing, and human resources. An ERP system helps different parts of an organization to share data, information to reduce costs, and to improve management of business processes (Aladwani, 2001). Wier, Hunton, and HassabElnaby (2007) argue that ERP systems aim to integrate business processes and ICT into a synchronized suite of procedures, applications and metrics which goes over firms’ boundaries. It can be stated that the success of ERPs to a high extent depends on its implementation. It can also be stated that implementation or as often also labelled deployment is a complex and costly endeavour.

So, although virtually nobody really doubts their importance for running business, there is a sentiment regarding ERP implementation – both in terms of time and money. Cunningham (1999) reports from an investigation of 7500 IT projects conducted by Standish Group in 1998 which discovered that 45% of them were late or over budget. According to the only publicly accessible Standish Group report on ERP implementation projects (Standish Group, 1995) actual cost of projects was, on average, 214% of what small companies planned, 182% of what medium companies planned, and 178% of what large companies planned and took 2.39 times longer than small companies intended, and 2.02 times longer than medium companies intended, and 2.30 times longer than medium companies intended. There are, definitely, several contributing factors to staying on budget and on time. However, in this paper, the question is if different approaches for implementation result in different outcomes when it comes to costs for ERP implementation.

The research question is whether factors influencing implementation approach then affect to what extent ERP system implementation costs exceed planned costs for implementation in European context, which is characterized by, for instance, fixed price policy. It can be stated that cost of implementation is an important part of total cost of ownership (TCO), and therefore it is important to know how large is the disparity between actual and planned total cost of implementation of ERP systems, and how different factors influences costs for ERP implementation. The rest of the paper is as follows: the next section discusses ERP system implementation approaches. The section after that describes the research method and how data were collected and analyzed. The following presents the results of the analysis regarding relationships between the variables and whether the organization stays on budget or not respectively what percentage they spent on implementation related to the budget. The penultimate section then discusses limitations and suggests future research. Finally some conclusions are presented.

2 ERP SYSTEM IMPLEMENTATION APPROACHES

In the paper, implementation is defined as the way how organizations systematically integrate ERPs into the specific organization. This can be done in different ways and that is what we mean with implementation approach. Implementation approach is defined as a systematically structured approach that aims at integrate selected ERP system into the workflow of an organizational structure (http://en.wikipedia.org/wiki/Product_software_implementation_method) One way to distinguish between different implementation approaches is to look into changes in the organization and when these changes take place. This can be described as piecemeal versus concerted implementation (Robey, Ross and Boudreau, 2002). The difference between these two is that in the piecemeal implementation the ERP is implemented first and then changes in the organizations business processes are implemented. The concerted implementation approach means that the ERP and changes in the business processes are implemented at the same time. These different approaches could be related to IT/IS strategy and it could be suggested that if the organization has a formalized information strategy
that probably influences what ERP implementation approach that the organization select. It can also be related to business process reengineering (BPR) (Davenport, 1993; Hammer and Champy, 1993) which has a clear focus on restructuring both the organizational structure as well as the used information system (IS) structure, and it can be stated that this makes the change from the earlier structure of legacy system complex. It is, therefore, interesting to see what influences organizations when they select a specific approach for implementation.

McGillcuddy (2007) states that there is a difference between size of the organization when it comes to the time it takes between the organization starts to implement an ERP to its implemented ERPs go live. The claim is that small businesses have a shorter time than midsized and large organizations. This statement builds on data presented in a report from the Aberdeen Group. In that report it is said that 86% of small enterprises achieved their first go live milestone within the first year, in midsized enterprises the same happened in 64% of the implementing enterprises and when it comes to large enterprises just 47% of them reported that they experienced the first go live milestone within a year. It could be asked if this means that small organizations more often implement ERPs as a big bang approach and that the bigger the organization is, more likely they select a slow phased implementation approach.

In this study, we distinguish between three types of implementation approaches: slow phased, pilot project and big bang implementation. In the literature, there exist two general approaches for how ERPs are implemented, which were popularized in the mid-1990s (Mabert, Soni and Venkataraman, 2003; Markus, Tanis and Van Fenema, 2000b): (1) the “big bang” approach and (2) the phased implementation approach. The “big bang” is an implementation approach that means that the entire organization starts to use the new ERP at the same time. The big bang probably has been planned for a long time and the specific ERP have been adjusted and to some extent tested before the actual big bang, but, what happens is that the organization decides on a specific date for when the ERP should be taken into usage. When that specific day then comes, data are transferred from the old legacy system and all users start to use the new system. This can then be compared to the phased implementation approach. The differences between these are that the phased means that some parts of the organization start to use the new ERP and after a while the next part starts to use it and so on. The phased implementation can be phased in different ways, it could be that, if the organization is situated at different locations, a specific location starts, or it could be that a specific user group starts and so on. The major difference between these two approaches is probably the time it takes. The big bang approach means definitely a shorter time for the roll-out in the entire organization. The phased implementation approach takes longer time, but it is not sure that it takes so much longer time from the first decision on adoption of a new ERP to the time it is in full use. It could be that the big bang implementation approach demands a longer time period for preparing before the big bang. However, it can be stated that although phased implementation is time consuming, it involves less risk compared to the “big bang” approach (Scott and Vessey, 2000). Recent research has also revealed that the phased implementation tends to involve less reengineering efforts.

Parr and Shanks (2000) state that there is a need to further describe implementation approaches into a taxonomy if being able to investigate ERP implementation. They suggest a taxonomy describing three different implementation approaches which they label: Comprehensive, Middle Road and Vanilla implementation. However, in our view this categorization is more related to earlier decisions such as deciding on what ERP package to adopt and/or deciding on if going for “best practices”. But the taxonomy suggested by Parr and Shanks have an interesting further categorization when they talk about characteristics related to each approach in the framework. The characteristics are: 1) physical scope, which means if implementation is made at several places, 2) BPR scope, which consider to what extent reengineering is considered, 3) technical scope, which is about to what extent the adopted ERP is modified, 4) module implementation strategy, considering two different strategies for implementation of ERPs modules, 5) resource scope, which is about the time and budget scope for the implementation. In this paper, the most interesting characteristic from Parr and Shanks to investigate further is the module implementation strategy. What they state about this is that there exist broadly
two different decision points in the module implementation strategy. The first decision is about whether the ERP should be implemented as a skeleton or with full functionality and the second decision is then if the implementation should be done module by module integration to legacy systems or all ERP modules implemented and then integrated to legacy systems (Parr et al., 2000). The latest described approach – all ERP modules implemented – can be compared to big bang implementation while the other one could be compared with phased implementation. Parr and Shanks state that phased implementation, is less risky, but more resource intensive, while the big bang implementation is precarious but a less time consuming option. According to Basoglu et al. (2007), big bang implementation creates adoption problems in the long run, and the reason they state for this is that organizations, when implementing big bang, spend less effort in adjusting the software and the organization to each other. Because of the advantages of a phased implementation, it was of our interest also to figure out how exactly companies approach this issue and what it is that makes an organization select a specific implementation approach. This and the inspiration from (Bernroider and Leseure, 2005) was the reason for splitting the phased implementation into slow phased-in implementation approach (one module at a time) and a pilot project implementing (one module followed by all other modules in one step). Although one could try to divide big bang implementation into two, as e.g. (Madapusi and D'Souza, 2005) did, it could also confuse respondents.

3 DATA AND METHODOLOGY

This exploratory paper is based on a questionnaire survey, conducted in Denmark, Slovakia and Slovenia in May and June 2007. Questionnaire forms accompanied by cover letters were mailed to randomly selected companies. Lists of addresses and information about the number of employees were retrieved from CD-Direct in Denmark, and from respective Statistical Bureaus in Slovakia and Slovenia. In each country, 600 questionnaires were sent to small, 300 to medium enterprises, and 300 to large companies. The number of questionnaires mailed to small companies was double the number of medium and large companies because small companies constitute the highest proportion of companies and based on our personal experience, they are less likely to respond. In total, there were 223 responses (21 from Denmark, 112 from Slovakia, and 90 from Slovenia) out of 3600 mailings, i.e. the response rate was 6.2%.

Respondents were to answer what the actual total cost of ERP system implementation was – whether it was less than planned, as planned, or more than planned. In case that the total implementation cost did not match the planned one, they were asked how many percent less or more they actually spent on implementation. There were 120 responses, which compared actual and planned implementation costs (and provided all required information on independent variables) and 114 provided enough input to calculate the actual percentage. Independent variables were implementation approach, country, company size, representation of the IT department on the board level, information strategy, and number of implemented modules. The questionnaires were sent to companies in Denmark, Slovakia and Slovenia, so therefore one of the independent variables is country. The implementation approaches were big bang, phased-in, and a pilot project implementation. In the analysis, we have analyzed small, medium and large companies. The definition, which we used, stated that companies from 10 to 49 employees are considered to be small, companies from 50 to 249 employees are considered to be medium-sized enterprises, and companies having 250+ employees are considered to be large companies. This definition is consistent with how the European Commission (European Commission, 2003) defines SMEs. Regarding the independent variable information strategy, this should be understood as that the organization has a formal information strategy. Representation of the IT department on the board level means that there is a CIO or alike director for IT on the board level. Therefore, it will be described as CIO in Figure 1-5. Regarding modules, we asked if they implemented modules for (1) finance and controlling, (2) human resources, (3) manufacturing and logistics, (4) sales and distribution. So the figure used for the analysis is not the overall number of modules but the number of the abovementioned groups covered by implemented modules.
In this paper, three relationships were investigated with the aim of finding if and how the factors: CIO, country, company size, information strategy, and number of modules influence costs of ERP implementation in the form of actual costs compared to budgeted costs. This is done by first exploring whether the factors influence selection of a specific ERP implementation approach. This is then followed by exploring whether a specific implementation approach influences companies’ costs when they implement ERPs. The final relationship investigated is then if the factors have a direct influence on companies’ costs when they implement ERPs.

In the first relationship (if factors influence selection of implementation approach) the independent variables: country, company size, CIO, information strategy, and number of modules are investigated with the aim of finding if there exists any relationships between them and the dependent variable implementation approach. In this context, implementation approach is described as being a strategy for implementation that can be done in three different ways: big bang, slow phased, and pilot project. The result of this is shown in figure 2.

The second relationship investigated is then whether a specific ERP implementation approach influences costs of the ERP implementation. This is done from the independent variable implementation approach described as either slow phased, big bang or pilot project implementation. The result of this exploration is shown in Figure 3.

The final relationship is then an investigation whether the independent variables CIO, country, company size, information strategy, and number of modules influence costs of ERP implementation in the form of actual costs compared to budgeted costs. The result of this is presented in Figure 4, which shows the results related to staying on budget, and in Figure 5, which shows the results related to percentage spent. What they both present is how the suggested factors influence actual ERP system implementation cost vis-à-vis planned costs. The first relationship looks into how many companies did not exceed their planned budget. There were only three Slovenian companies, which spent less than planned; they were merged with companies, which spend exactly the amount they planned, since both can be classified as staying on budget. The second relationship investigated focuses on the percentage spent compared to the planned amount.

Regarding the methodology, logistic regression was used for the analysis of the first relationship, analysis of variance (ANOVA) and chi-square test for the second one, and ANOVA and logistic regression for the third one. Multivariate approach was used in both ANOVA and logistic regression.
Additionally, binomial test was used to test if there is a significant difference between the percentage of companies that stayed on budget and 50%; Tukey-Kramer multiple-comparison test was used to identify differences between individual instances of independent variables; t-test and Wilcoxon signed-rank test were used to test if there is a significant difference between the average ratio of actual ERP system implementation cost vis-à-vis planned costs and 100% (i.e., companies spending exactly according to plan). Results of the statistical tests are commented on confidence level $\alpha = 0.05$.

4 RESULTS

In the study, the overall results of the question about selection of implementation approach are the following: 28.5% said they used a slow phased implementation, 20.8% used a pilot project for implementation, while 50.7% used the big bang implementation. The result in our study shows a significant (p-value < 0.001) difference between the percentages and results presented by Palanisamy (2007). The result of our study is as such interesting to compare with statements about the IT productivity paradox (Brynjolfsson, 1993; Brynjolfsson, 2003; Carr, 2004; Hitt and Brynjolfsson, 1996) and statements about the risk of big bang implementation (Parr et al., 2000; Scott et al., 2000). It is also interesting to think about software vendors and distributing partners when analyzing this. It can, definitely, be stated that the way ERPs are implemented, depends on the vendor’s suggestion and since they suggest and provide tools for big bang implementation, it is not that strange that 50% of implementation is done in that way. However, there could also be other factors involved and the idea was to investigate if and how country, company size, CIO, information strategy, and no. of modules influences selection of implementation approach. The results of this are summarized in Figure 2.

![Figure 2 Exploring the relationship of factors influencing selection of ERP implementation approach](image)

The first factor investigated is whether country as such has any influence on selection on ERP implementation approach. The three country investigated are Denmark, Slovakia, and Slovenia. These three countries show definitely some cultural differences and therefore we were interested in whether they differ in what ERP implementation approach that are selected. The result of how country influences selection of implementation approach is shown in Table 1.

Table 1 does not show any significant difference between countries regarding selected implementation approach. There is a small difference when it comes to the percentage of big bang implementation between Denmark and Slovenia, where Denmark shows the highest number of big bang implementation. Otherwise the results are in line with the overall results on ERP implementation approach. It would be interesting to further investigate whether the difference in percentage of big bang implementation is a cultural difference between the three countries. An initial hypothesis on this could be that Slovak and Slovenian companies are more used to work with long time planning and therefore in higher degree go for the slow phased and pilot project implementation in relation to
Danish organizations. It may be assumed that subsidiaries of multinational companies, regardless of location, will have to use the same ERP system and the same implementation approach as selected by headquarters, thus independent from the county, in which a subsidiary is located. On the other hand, the number of multinational companies should be small enough to influence the investigation of relationship between the country and the selected implementation approaches.

*Table 1 Relation between country and selected implementation approach*

In the questionnaire, there was no specific question about size of organizations, this information was instead collected from other sources and linked to each response. The organizations were divided into the following size groups: large, midsized, and small using the measure of number of employees. This means that large is when the organization has 250+ employees, midsized 50-249 employees, and small when the organization has less than 50 employees. From the perspective of selection of ERP implementation approach, the size of the organization is of interest. Our basic thoughts about this are that if it is a small organization then it would go for the big bang implementation, and the reverse would then account for large organization. The rationality for this statement would be that a small organization does not have so many users so it would therefore be easier to do a big bang implementation. In the large organization it would be more risky to do a big bang implementation and therefore would it be possible to suggest that slow phased ERP implementation is more often used.

The result from the questionnaire related to organizational size is shown in Table 2.

*Table 2 Relation between organizational size and selected implementation approach*

There is no difference between large, mid-sized, and small organizations when it comes to which approach is most commonly used, and as shown in Table 2 the most commonly used approach is big bang. However, percentage of big bang as used implementation approach decreases with the increasing size of organization. This means that percentage of slow phased implementation is higher in small organizations than it is in large organizations. In one way it could be said that this is strange since it should be easier to do a big bang implementation in a small organization and less risky than in a large organization. One potential explanation to the result could be that implementation approach depends on implemented ERP system, and this could mean that in for instance large organization SAP is more commonly implemented and it could be that the implementation approach is influenced by what ERP that is implemented. Another possible explanation could be that large organization have resources available to do some kind of test implementation which they after having done decide on roll-out in a big bang implementation. This would then mean that they do a big bang implementation after doing a sort of parallel test implementation. For small organizations it can be suggested that they do not have the resources to do that and since the potential impact of a failure of a big bang implementation is smaller they maybe more often directly goes for big bang ERP implementation.
According to Bernroider et al., (2005), who used the same three types of implementation strategy, in small and medium enterprises (which they merged together), the most often used implementation approach was big bang, the second implementation approach was slow phased, the least used was pilot study. In large companies, the most often used implementation approach was big bang, the second implementation approach was pilot study, and the least used was slow phased. Our results are in line with Bernroider’s results but it differs to some extent when it comes to percentage of pilot project and slow phased implementation in large organizations. Unfortunately, although there are several studies conducted in the U.S., such as Madapusi et al. (2005), although investigating only two general implementation strategies – big bang and phased-in, but they cannot be compared to these outcomes, since the definition of a company size differs significantly between the U.S. and European Union.

We aimed to investigate if presence of IT professionals in the board of companies influences the selection of ERP implementation approach. In order to do that we asked if the IS/IT division were represented at board level in the organization. In the paper, we describe representation in the board as having a CIO. The reason for asking about representation at the board level was that this may for instance influence selection of ERP implementation approach. It could be suggested that if there is representation of IT/IS at board level then the risk of implementing ERP as big bang would be considered in more depth and from that it would be possible to state that a higher level of pilot project and slow phased implementation should be the case. The result of this question can be seen in Table 3.

</tbody>
</table>

Table 3 Relation between presence of CIO and selected implementation approach

The results on representation of the IT department at the board level do not show any significant results regarding relation to selection of implementation approach. There is a small difference between the slow phased and pilot project if the organization have a CIO or not, but if summing up slow phased and pilot project and comparing the sum with the big bang implementation approach no difference is seen. The result is to some extent a surprise since it does not show any difference whether the IT department is represented on board level or not on selected implementation approach. Further research may include a deeper investigation of CIOs – their educational background (field of study), risk adversity, leadership style, possibly also related factors like organizational culture and structure and size of IT department. The latter and cooperation between business and IT staff may be related also to information strategy.

In the questionnaire, it was asked whether the organization has an information strategy or not. The answer on this question is rather complex to interpret since having strategy or not could be seen from the perspective of whether the strategy is formalized or not. However, our intention with this question was to distinguish between if the organization has a written formal strategy or not. From the extent of having a formalized strategy or not the idea is then to investigate if it influences selection of a specific ERP implementation approach. The result of this is shown in Table 4.

<td>35%</td>
</tr>
</tbody>
</table>

Table 4 Relation between information strategy and selected implementation approach
The results from the analysis show that there are no big surprises in whether the organizations have a formal information strategy or not in relation to selected implementation approach. There is a higher extent of slow phased implementation in organizations without formal information strategy, which could indicate that these organizations does not have that clear perspective on whether they should fully implement the specific ERP. However, it could also be that they have a clearer perspective of what they aim at and therefore takes longer time for the actual ERP implementation and focus more on adjustment of the specific ERP as well as adjustment of specific business processes.

The numbers of modules used for the analysis are actually numbers of the groups of processes (finance and controlling, human resources, manufacturing and logistics, sales and distribution) covered by implemented modules, not the overall number of modules.

*Table 5 Relation between no. of modules and selected implementation approach*

There is a significant difference between companies with 2 and 3 modules. The difference is namely in pilot project and big bang implementations. Both groups use slow phased approach in about the same percentage of cases but companies with two modules much more often go for pilot project implementation and companies with three modules choose much more often big bang implementation.

The model for investigation the relationship between implementation approach and ERP implementation costs is shown in Figure 3.

*Figure 3 Relationship between implementation approach and ERP implementation costs*

In order to test relationship between the actual percentages spent vis-à-vis the planned implementation costs and selected implementation method, ANOVA was used. The averages on percentage spent for each implementation approach are shown in Table 6.

<tr>
<td>No</td>
<td>24%</td>
</tr>
</tbody>
</table>

Table 7 Relation between staying on budget or not in relation to implementation approach

There is no significant relationship between the chosen implementation approach and staying on budget. Since there is no clear relationship between the chosen implementation approach and implementation costs, we decided to add additional variables into the model.

There is a significant relationship between staying on budget and having a formal information strategy. Companies with formal information strategy seem to be more likely to stay on budget (74.2 %) than companies without information strategy (59.3 %). Overall, 67.5 % of companies stayed on budget; this percentage is significantly different from 50 % (p-value < 0.001), i.e. more than one half on companies actually manages to stay on budget.

Figure 4 Findings from analyzing the first relationship

When analyzing the second relationship, data were transformed into percentages and these percentages were then analyzed. Findings about the second relationship are summarized in Figure 5.

Figure 5 Findings from analyzing the second relationship
ANOVA identified a significant relationship between the percentages of actual spending compared to planned one and information strategy. Companies with a formal information strategy were less over budget (104.2 %) than companies without one (111.3 %).

Overall average was 107.3 %. There is a significant difference between the overall average of 107.3 % and 100% (no disparity between planned and actual costs). P-value is smaller than 0.001 regardless whether t-test for difference between mean and value, or Wilcoxon signed-rank test for difference in medians is used.

Based on the results, it can be summarized that companies with formal information strategy are likely to spend about 7 percentage points less than companies without information strategy. It suggests that ERP system vendors need to be sensitive to companies without information strategy, since these have either wrong expectations of costs or lack technical skills beneficial for ERP system implementation. However, there are also other explanations that are worth mentioning and these are the following. Firstly, it could be that companies with formal strategy are better on making a budget and take more serious in the task of doing that. Secondly, it could also be that they are better in constructing a clearer contract with the implementing partner. Thirdly, it could also be that they have a better control over overall costs and thereby are better in calculating the implementation budget. Fourthly and finally, most likely have organizations with a formal information strategy a clearer view over what they want and thereby do not so many “surprises” show up during the implementation.

5 KNOWN LIMITATIONS AND FUTURE RESEARCH

There are two known limitations of this paper, which are actually inherent for most of questionnaire surveys – response rate and reliability of data. Usually, there is an average response rate of 10 % expected in questionnaire surveys. But a response rate of 80 % and less (that is a case of almost all questionnaire surveys) can already lead to biased results. We tried to overcome the problem by sending out 3600 questionnaires and hoped that the autoselection would not depend on the questions asked. In our opinion, we achieved it, since the percentage of companies being over budget (i.e. ones, which would be more likely to complain about their bad experience) is only 32.5 %, i.e. less than 45 % (which included also projects going over time) mentioned in Cunningham (Cunningham, 1999), and surveyed companies were only 7.3 % over budget, i.e. much less than 114 % for small, 82 % for medium, and 78 % for large companies mentioned in the Standish Group (Standish Group, 1995) report. Regarding the reliability, it is not possible to check it without being allowed to look into accounts and to talk to people involved in the implementation, which would provide insight necessary to understand the accounting data.

Regarding the implementation approach, one could also consider additional factors, such as size of the system, its complexity, organizational hierarchy, and extent of the coverage.

The future research should look into what caused additional costs. For example, customization of ERP is a crucial, lengthy, costly aspect of the implementation of ERP systems (Gefen, 2002). Studies have shown that many organizations exceed their budgets due to the need for more customization than they originally planned (Markus, 2000; Markus, Cornelis and Paul, 2000a; Swan, 1999). Besides customization, companies often run into higher than expected costs for temporary and overtime labor, re-skilling, and training during the implementation process (Markus, 2000; Markus et al., 2000a; Sumner, 2000).

Last but not least, it might be useful to investigate whether additional costs arose because of the misalignment (the gap between the standard version of the ERP system and the organization) or was it spent in order to increase benefits. Investigation of both total costs of ownership and total benefits of ownership might provide a different angle for looking at expenditures.
6 CONCLUSIONS

To sum up, although not all companies manage to stay on budget when it comes to ERP system implementation, the situation in investigated European companies is not too critical. It can be evaluated from two points of view. First, about two thirds of companies still manage to stay on budget. Secondly, companies exceeded their budgets only by 7.3% on average. A contributing factor for Danish, Slovak and Slovenian, i.e. European, companies staying more-or-less on budget is the prevalent fixed price policy for ERP implementation projects in Europe. So, the findings might be generalized in European context but definitely not for the U.S., where effort-based pricing policy is prevalent. A formal information strategy implies more comprehensive planning, so there should be also smaller discrepancies between the plan and the reality. It was found out that the chosen implementation approach does not influence the ability of the company to stay on budget with implementation costs. The research also pointed out that selection of the implementation approach depends on number of modules, which are implemented.

Abstract

We question the strategic potential of EMPs to bring a competitive advantage to their users: their nature and the main differentiating factors that progressively appear over time.

Based on three case studies in the retail, automotive and MRO (Maintenance, Repair and Order) industries, conducted from 2002-2007, we more thoroughly describe where buyers and suppliers perceive strategic advantages in the eValues brought by EMPs. We classify these strategic opportunities according to Porter (1980) and Wiseman’s (1985) typologies: differentiation, cost, innovation, alliance/power gains and growth. Finally, we explore how these different factors have evolved over time in users’ perceptions.

The paper brings an in-depth and longitudinal empirical study of EMPs specific competitive advantages in each industry.

Keywords: Electronic marketplace (EMP), competitive advantage, strategic information system, inter-organizational information system (IOIS), information systems (IS), purchasing, supply, eValues, electronic catalogues, electronic auctions, sourcing, integration, standardization.
1 INTRODUCTION

During the last ten years, electronic marketplaces (EMPs) have been progressively adopted in industrial and service activities. Emarketservices study (Zällh, 2005) points out 52 significant EMPs in 17 industries based on two criteria: reputation and significant global traffic. If EMPs survival since 1999 proves that these intermediaries bring different types of eValues to their users, it is still not clear whether EMPs will only be transactional inter-organizational systems (IOIS) or whether they will hold a strategic potential both for their users: buyer and supplier organizations.

The literature demonstrates the different types of eValues brought by EMPs but does not say if these eValues can bring a competitive advantage to their users. More precisely, we will focus on the following questions: do EMPs drive differentiator factors to suppliers and buyers? What types of eValues could be considered as a competitive advantage? How do these strategic factors evolve over time from 2000 to 2007? Are there differences in these advantages according to the type of industry? What are the long-term competitive advantages that EMPs will provide to buyers and suppliers in their industry?

In the first section, we bring back EMP characteristics and their challenges in purchasing and supply chains. Then, we show the different types of eValues in EMPs. Thirdly, we summarise what the literature tells about the emergence of a competitive advantage in EMPs. In the second section, we present our research methodology. In the third section, we present our results and conclude with a discussion.

2 LITERATURE REVIEW:

2.1 The EMPs: definition, characteristics and challenges for purchasing and supply chains

In an organizational perspective, EMPs can be seen as intermediaries between buyers and suppliers devoted to answering purchasing and supply chain needs. They can also be defined as inter-organizational information systems (IOIS) that interact to create, store, transform, and communicate data between buyers and suppliers.

Behind the term EMP, there are actually a number of different business models, that is to say strategic positioning and models of revenue. Different criteria to classify EMP business models appear in the literature. Kaplan and Sawhney (2000) distinguish EMPs that focus on exchanging MRO (Maintenance, Repair and Operations) products and services like Hubwoo with those that focus on more strategic goods directly linked with manufacturing processes (like WWRE and Supply On). In the same connection, Barratt and Rosdahl (2002) highlight “vertical EMPs” that offer their services to a single industry like WWRE and Supply On, with “horizontal EMPs” that offer their services to all types of industries. Soh and Markus (2002b) go further by proposing three criteria to represent EMPs landscape according to the value proposition of the EMP, the product/market positioning and the value of activities. Finally, the e-business literature aimed at EMPs distinguishes two main types of eValue in EMPs: transactional EMPs aimed at executing exchanges and collaborative EMPs aimed at

---

1 In this article, we will mention buyers and suppliers to talk about organisations being in a position of buyer or seller/supplier in the EMP. We are not directly talking about individuals working as purchaser or seller.
encouraging collaboration between participants (Mahadevan, 2003). In this paper, we will focus on the differences between EMPs positioned in different industries and types of activity.

Whatever its business model, the EMP’s essential purpose is to provide an answer to the purchasing and supply challenges summarized by Carter et al. (2000). They highlight the challenge of electronic commerce to improve communication processes, performance metrics to assess suppliers, sourcing tools to help supplier identification and selection globally, the choice to internalize or externalize MRO purchasing, and the general evolution of exchanges around large-scale buyer and supplier companies. They conclude by describing the increased use of IT in purchasing and supply to reach these challenges.

2.2 The nature of electronic eValues in EMPs

Different types of eValues are brought by EMPs with different ways of classifying these eValues. The literature generally presents two main origins of eValues. The main benefits gained by technology are mentioned by Malone, Benjamin, and Yates (1987). They assert that electronic interconnections will bring three main benefits to markets: electronic communication will accelerate data transportation generating cost reductions; electronic matching will improve sourcing; and electronic integration will facilitate process coupling. In the same vein, Bakos (1997) concludes that IT diffusion in electronic markets will bring price transparency to buyer organizations and increase their knowledge of supplier organizations cost structure. IT will also make it easy to compare standard offers between different suppliers. Finally, IT will bring cost reductions linked with negotiations and transportation.

In an empirical perspective, Kambil and Van Heck (1998) attribute different IT benefits to electronic auctions; they facilitate supplier identification and price negotiation and they improve the coordination of logistic flows. Moreover, IT increases the richness of data exchanged and brings processes that reinforce regulation control. Hence, IT reduces opportunism risks and provides the capacity to track flows as arguments to avoid conflicts.

On the other hand, eValue is described though the role of electronic intermediaries in an industry characterized by its structure and specific needs. Kaplan and Sawhney (2000) highlight aggregation (the capacity to bring many buyers and sellers under the same roof) and matching (an optimized encounter between offer and demand to minimise negotiated prices) as the two main EMPs’ eValue. Aggregation is particularly interesting in the case of a fragmented industry whereas matching serves to reintroduce competition in oligopolistic industries to reduce negotiated prices. The effect of EMPs on industrial structures are not known yet: whereas Malone et al. (1987) predict a reduction of vertical integration with a “move to the market” others such as Clemons and Row (1992) state that electronic exchanges will bring a “move to the middle” with an increase of middle-sized companies connected through electronic networks. Amit and Zott (2001) focus on asset complementarities (Han et al. 2005), innovation synergies, the nature of the participants and the exchanged mechanisms (structure), and finally the governance defined as the interaction rules. Actually, EMPs can be considered as strategic networks (Gulati, Nohria, Zaheer, 2000), that is to say « stable interorganizational ties which are strategically important to participating firms. They may take the form of strategic alliances, joint ventures, long-term buyer-supplier partnerships, and other ties (Gulati et al. 2000: 203). In addition, these networks are characterized by the opportunity to share risks and generate economies of scale (Katz, Shapiro 1995; Shapiro, Varian, 1999), to share knowledge (Dyer, Singh, 1998), to facilitate access to the market (Kogut, 1998), to reduce information asymmetries and to improve coordination. Finally, these networks highlight the key role played by suppliers and customers to create value (Afuah, Tucci, 2001). Rayport et Sviokla (1996) also develop the concept of a virtual value chain where eValue is created by the way of combining informational with physical value chains. Kambil and Van Heck (1998) illustrate this capacity in the Dutch flower industry.
It appears that there are many different nature of eValue in the e-business context but no consensus on its source. eValue is partly made by technology, and partly made by the services provided by EMPs through their intermediation. If the process through which eValues is generated in EMPs is difficult to catch, it is yet possible to catch sight of the types of eValues that will be diffused in all organizations and the ones that will bring a competitive advantage to their users.

2.3 Dynamic evolution of eValues in EMPs: from a transactional value to the emergence of a competitive advantage

One of the key questions in evaluating EMPs impact on markets is to know whether these IOIS will bring a competitive advantage to their users. Will EMPs be a trend or will they shape long-term exchanges in the digital economy?

Information systems (IS) for competitive advantage are defined as IS that drive or formulate the organization’s competitive strategy in order to provide it with (or maintain) a competitive advantage (Wiseman, 1985). In this perspective, IT may be used to help the organization produce at lower cost, to differentiate itself from its competitors, or to identify and concentrate on a particular market segment (Porter, 1980; Porter, Millar, 1985; Clemons, Row, 1991). Porter and Millar (1985) also incorporated the concept of value with the previous meanings of strategic impact. An IS would have strategic impact if it had the potential to add value to a product or a service in at least one stage of the value chain. Moreover, considering all the supply chain of IOIS, IS will provide a competitive advantage if it modifies the structure of the industry, improves the position of the firm, or creates new business opportunities. In the same path, Rackoff and al. (1985) develop the theory of strategic thrusts to identify strategic IS opportunities. Strategic thrusts are major competitive moves (offensive or defensive) made by firms to use IT to create a competitive advantage. The authors identify five strategic thrusts: differentiation, cost, innovation, growth and alliances. In this paper, we will identify the latest with the capacity for suppliers or buyers to gain power in the chain (Cox, 2003).

In this paper, we will cross this framework to the resource-based-view (RBV) theory. This theoretical framework seems to be particularly interesting in analyzing the strategic potential of EMPs (Ordanini, 2005; Wernerfelt, 1984) considers that the growth of a company depends on its capacity to identify and exploit resources that may give high profits. The identification of these resources partly relies on the capacity to exploit markets’ inefficiencies. Barney (1991) shows that a firm’s competitive position is based on resources that it is able to control. In order to sustain a competitive advantage, the resource should be valuable, rare and difficult to imitate or substitute.

Jelassi and Enders (2005) question the capacity of EMPs to generate a competitive advantage for buyers. Some EMPs competitive advantage factors have yet been highlighted in the literature. Soh and Markus (2002a) question the capacity for EMPs to drive collaboration between buyers and suppliers as a potential competitive advantage. Ordanini (2005) identifies nine effects of participation in a digital exchange: process cost reduction, time saving, quality of process, purchasing cost reduction, increased number of suppliers, increased number of customers, sales growth, information and knowledge, partnership and cooperation. Further on, Ordanini (2006) summarizes three main factors that bring an advantage to EMP buyers: standardization, business process integration and IT negotiation tools to aggregate suppliers. Soh et al. (2006) show that price transparency should be the main advantage provided to buyers by EMPs using eAuctions. However, some EMPs do not provide this transparency to buyers in order to attract sufficient suppliers to be able to obtain a critical mass in exchanges. Then, they offer buyers “compensatory benefits” such as information content and IT change management. Before that, in the next section, we will present our methodology.
3 METHODOLOGY:

This investigation is based on three in-depth multiple case studies on EMPs made from 1999-2007: WWRE (World Wide Retail Exchange) in the retail industry, Supply On in the automotive industry and CC-Hubwoo in all types of industries to exchange indirect goods and services. These case studies included interviews conducted with the managers of each EMP, but also with their users, buyers and suppliers. Case studies (Yin, 1994) are applicable when control over events is not needed and when there is a focus on contemporary events and multiple-level analysis. Case studies permit the analysis of many variables.

Previous studies in EMPs provide us with an understanding of each EMP business model. We use these interviews to sum up the initial value proposition of each EMP in order to better analyze the strategic potential of EMPs perceived (Davis, 1989) by their users. We suppose that users were the best positioned stakeholders to have an objective view of the strategic potential of EMPs - hence avoiding the biases of the marketing discourse of EMP managers who have to justify their value to their buyer and supplier customers.

In this research, we focus on users and analyze 28 semi-structured interviews of buyer and supplier organizations: 9 in WWRE, 10 in Hubwoo and 9 in Supply On. In these organizations, we interviewed different profiles of managers: IS managers, Purchasing managers in buyer organizations, Sales managers in supply organizations, Supply Chain managers, and CEOs. We also use secondary data documents such as cases studies and interviews shown on EMPs web sites, roll out documents, users return on investments analysis.

We process data in two steps. Firstly, we use N’Vivo in order to codify the competitive advantage factors enhanced by buyers and suppliers according to Porter’s (1980) typology: differentiation, cost, innovation, alliance/power gains and growth in bold in Table 1). To do so, we first transcribe interviews and codify them in tabulars. We link “differentiation” factors when they were presented by interviewees in comparison with their competitors with key words or meanings such as competitive advantage, success key factor, and unique resource. Besides, we complete the “Innovation” factors codified according to a previous typology (Authors, 2006).

Secondly, we explore the evolution of the frequency of these different items over time. To do so, we note the number of items that appear during the different key periods of the evolution of EMPs: their start and survival period from 1999-2002, the consolidation of EMP business models from 2003-2005 that correspond to the consolidation of the advantages perceived by users, and finally, the stabilization of their activity since 2005. We also enrich this frequency approach to all paragraphs that describe the dynamic evolution of the perceived value brought by EMPs. This longitudinal analysis helps us to identify the orientation of the strategic potential of each EMP, as well as differences between industries. Thirdly, we use these case studies to highlight the strategic potential of EMPs that progressively appear in user discourses.

4 CASE STUDIES:

4.1 WWRE in the retail industry:
WWRE was founded in 2000 with the main middle-sized retailers worldwide (Tesco, Ahold, Kmart, Casino, Auchan etc…) with the exception of Wal-Mart and Carrefour. The former decided to develop its own IT tools in a proprietary mode, whereas the latter decided to join GNX – Global Net Exchange), which became a competitor for WWRE. Since 2000, with the overloading of customer mass consumption in Europe and US and the increased competition between suppliers in new markets such as China, retailers encounter difficulties in maintaining their margins. The industry is then looking for other growth opportunities such as mergers and management and organizational innovations. WWRE is then created, with I2 and Ariba as IT partners, to boost B2B exchanges.

Historically, the retail industry is one of the most advanced in electronic linkage. As an example, EDI covers 90% of exchanges between retailers and their main suppliers and is recognized to have provided major improvements in delays, reduction of data mistakes (Holland, 2003). However, the lack of IT integration between suppliers and retailers leads to numerous mistakes in the supply process (notably orders). The industry tends towards synchronizing the informational and physical supply chains for the logistics delivery (Rayport, Sviokla, 1996). The purchasing process has been managed with traditional face-to-face negotiations in central purchasing departments. WWRE initially offered a large set of IT tools and services covering the whole exchange process. Finally, users only adopted e-RFX, e-Auctions and e-Catalogues.

As summarized in Table 1, buyers see three main differentiation factors in WWRE. First, EMPs accelerate the use of electronic auctions with price gains. Second, they recognize the promising potential of global data synchronization in future transaction gains. Third, they already include knowledge management gained by shared returns on experience on the implementation of IT tools between members. The latest is shared with suppliers’ perspective. Suppliers also describe WWRE as a customer-oriented IS that incites them to orientate their sell-side information systems according to customer needs. The EMP initiates privileged links with retailers that may turn out to be lock in benefits in the future.

Cost gains are shared between buyers and suppliers and seen as directly linked with their participation in EMPs. The intermediary improves data standardization and quality as well as the standardization of the supplier communication process. Finally, the EMP favors resource mutualisation between members and hence reduces investments to manage electronic exchanges.

Another strategic potential is the innovative dimension of the EMP. For retailers, innovation lies in the capacity to easily compare supplier offers thanks to process standardization or even to access international supplier data bases owing to the EMP partnership. Besides, by facilitating retailers with tools such as eAuctions or more collaborative ones such as CPFR (Collaborative Planning, Forecasting and Replenishment), EMPs bring fuzzy relational modes with suppliers from collaboration to hard competition. Finally, the reporting tools of EMPs provide retailers with decision-making tools helping them to know the products that bring higher sales and margins in stores. In addition, suppliers highlight the improvement of data quality through synchronization. This leads suppliers to better control the information sent to retailers. Suppliers also mention the fuzzy relational modes as a risk factor in exchanges.

Alliance and power gains to retailers characterize the main strategic potential of WWRE. First, retailers build alliances with other retailers to have a lobbying activity, for instance on the choice of standards at an international scale. The EMP also provides middle-sized retailers with an international dimension, as it is the case for Casino or Auchan. Finally, the fuzzy supplier relationship management is seen as a weapon (Wiseman, 1985) to empower retailers’ position in the chain. In this context, some suppliers also make alliances with other suppliers to serve their own interests.

EMP participation is recognized to bring growth both for retailers and suppliers. Retailers’ main gains lie in electronic auctions in a short-term perspective and data synchronization in a long-term
perspective. For suppliers, the EMP is not mentioned as a factor of growth in itself, but since 2005 all interviewees are convinced of its strategic potential.

How do these strategic factors evolve over time?

The initial interviews in 2002 showed that the buyers and suppliers who were willing to participate in the EMP initially did not have a clear vision of the strategic impact of EMPs. The initial approach was to consider the different tools proposed by the intermediary without being able to foresee the strategic potential such as the implications for supplier relationships or alliances with other retailers. Retailers see EMPs as a way to adopt IT tools for purchasing and supply chains: “Initially, the objective of WWRE was to adopt common tools between retailers, without any more vision” (Retailer). Hence, the main gains expected were transactional: cost reduction, process reengineering (Davenport, 1993), and technological communication with suppliers.

Progressively, between 2003 and 2004 the main items are linked with the innovative potential of EMPs and the first alliance agreements emerge in discourses in 2004.

Finally, at the beginning of 2005 and after the stabilization period of their revenue model, the EMP is seen as way to obtain a competitive advantage. Growth arguments are kinked with the EMP IT tools. Some of them, such as eAuctions, are seen to have brought short-term competitive advantages between 1999 and 2003 when all retailers adopted eAuctions tools in their daily activity, initially in indirect goods (household appliances, bins) and then in food products (vitamins, vegetable bins, corns). In addition, long-term growth perspectives appear with the progressive implementation of an international global data synchronization network, connecting retailers and their suppliers, with the same standardized product and supplier data, necessary for the implementation of electronic catalogues. “We consider global data synchronization as the technological foundation of the business relationship with retailers with potential applications to electronic tenders, promotion management, and product assortment in stores” (Retailer). Other collaborative tools such as CPFR and software for shared visibility of supplier promotions in stores may be the third IT tool generation. Here again, whereas WWRE initially in 2000 highlighted collaboration as a key strategic advantage of the EMP, this advantage is still to be realized.

4.2 Supply On in the automotive industry:

Supply On was founded in 2000 in Germany by Bosch, ZF, Ina and Continental to manage B2B exchanges of direct goods and services in the automotive industry. In the 1980s, manufacturers were really manufacturing vehicles and assembling parts, only dealing with a few Tier 1 suppliers. This situation evolved in the 1990s with an increasing number of parts and technical issues in car manufacturing that led manufacturers to externalize to Tier 1, and then Tier 2 part of the engineering and assembly lines. In 2000, Tier 1 suppliers were in charge of dealing with a higher engineering and supply chain complexity as well as an increased number of communications with their own suppliers. Today, the industry is characterized by close business links between vehicle manufacturers and Tiers 1 suppliers, but also, to a lesser extent, by links between Tier 1 and Tier 2 suppliers. This is also a call to drastically improve B2B coordination and communication processes in the whole chain owing to adapted IOIS.

In 2008, Supply On links more than 65000 Tier 1 suppliers with Tier 2 (and possibly other smaller suppliers), that represent 75% of the top automotive suppliers in different areas of activity such as electronic, pneumatic, metals, turned and mill parts (Supply On internal report, “We make our global supplier management easy”, 2008).
With the help of support services such as training and a hot line, the main value proposition of Supply On is presented by the company in three areas: engineering and sourcing (Business Directory, eAuctions tools), supply Chain (EDI, Web EDI and inventory collaborative tools (VMI)) and Supplier Relationship Management Quality: (supplier performance assessment. These tools are electronically integrated since 2006.

Let us compare the evolution of the strategic potential of Supply On as perceived by buyers and suppliers over time.

From the buyer perspective, the main **differentiation factor** is **sourcing**. Supply On helps buyers to find new suppliers, specifically when they are looking for competences they do not have in their portfolio, in order to manufacture new commodities. Since 2006, Supply On has reinforced its supplier portfolio by opening an international desk in China (Shanghai) and near the historical American manufacturers in Detroit. In addition, they highlight the fact that the EMP brings a **knowledge management** competitive advantage to buyers by giving them the opportunity to share experience with industrial experts on the implementation and use of IT tools. Finally, Supply On recently offers an **integrated platform** for some tools: between RFQs and eAuctions or between Tier 2 performance monitor and the Problem Solver tool. The supplier perspective is more focused on a sales approach: the EMP brings them a competitive advantage when it effectively offers the opportunity to **get new sales contacts**, and even more increase their market share “a concentrated fair reduced in a monitor” (Tier 2 Supplier). In addition, the EMP is also seen as high value when it brings suppliers **access to the right purchasing contact** in the Tier 1 buyer company. However, only a few suppliers that have privileged relationships with the EMP, recognize these differentiator factors.

Arguments on **costs** are similar between buyers and suppliers. They agree on the fact that Supply On helps them to standardize data (notably the product norms and specifications) and the communication process. It also decreases IT investments by mutualising resources. Finally, suppliers highlight the IT integration as a main advantage in order to directly register customer tenders in their systems, and then, compress the time process execution.

According to buyers, the main **innovation factor** lies in the capacity to easily compare Tier 2 supplier offers thanks to data and process standardization. The EMP also facilitates their decision-making process by providing higher transparency on supplier performance: firstly by being able to share a common Tier 2 supplier database that involves different departments concerned in the Tier 1 company (purchasing, quality and operations) that previously did not open their frontiers from one to another; secondly by linking Tier 2 service commitments to their real performance on time, quality and delivery. Buyers also play on fuzzy supplier relationships by using at the same time eAuction tools and collaborative ones such as VMI. On the other hand, Tier 2 suppliers highlight, as the main advantage, the capacity to technically integrate customer data in their IS. However, they deplore the fuzzy relationships that buyers impose on them, especially when they do not have any unique engineering competence in the market.

Finally, buyers are quite discrete on the capacity of Supply On to create potential **alliances** with other buyers with a view to gaining more knowledge on supplier performance, with shared sourcing policies. Whereas some of them assert this will not happen, others mention the potential emergence of these alliances in the future.

**Growth** is only perceived through the IT tools like eAuctions to buyers, when they get direct returns. Accurate numbers are not communicated by interviewees. Buyers and suppliers both mention the immaterial gains in being able to share knowledge through the marketplace.

How do these strategic factors evolve over time?
The initial strategic advantage of Supply On since the beginning in 2000 rapidly appeared to be sourcing, including eAuctions, but most of all the content of a Business Directory that provides Tier 1 suppliers with unknown low-cost and efficient suppliers. However, if the initial value proposition of Supply On was oriented through engineering (map exchanges and product design), there have been a few advances in this area as Tier 1 suppliers, following the choice of vehicle manufacturers, have decided to exchange through portals with their own manufacturers or Tier 2 suppliers.

Between 2003 and 2004, the business directory and document manager increased the number and quality of its data to become recognized as a unique advantage in the market. Hence, Supply On’s business model strengthened its value proposition by offering long-term benefits to participants. Finally, IT tools aimed at improving the supply chain have been progressively adopted by users since 2004, at the request of buyers, when they sufficiently perceived the process standardization proposed by Supply On. Finally, tools aimed at improving Supplier Relationship Management Quality have revealed their full potential in the field since 2005. By offering the possibility to link supplier assessment to real time supplier performance (based on quality, time and service delivery), and by opening frontiers inside buyer departments (purchasing, quality, operations), they are considered to bring high growth potential in the future.

4.3 Hubwoo: an EMP that deals with MRO goods and services in multiple industries

Hubwoo is a French EMP founded in 1999 with SAP as one of the main shareholders. This EMP offered new opportunities to improve the demand to order delivery cycle, and then managed in paper and fax mode. Hubwoo used to put together suppliers providing electro components, electrical devices, stationery, all goods and services that generally support buyers’ activity known as MRO. The industries that manufacture MRO are characterized by small to middle-sized companies around the world. These companies deliver a wide variety of goods and services where the main value lies in linked services such as low prices, reduced time delivery, reactivity to customer demand and stock capacity.

This industry contains several intermediaries as these suppliers generally sell their products to distributors who concentrate their offer on paper or in eCatalogues, offering joint promotions to large customers in all types of industries. Hence, distributors have been direct partners to EMPs who have helped them to go through the digital economy. As an example, an international distributor and supplier in the EMP generated 30% of its total revenue in Europe through e-Commerce in 2007 and over 60% in Asia. The growing presence of e-Commerce in these exchanges implies a heavy dependency of the industry on data processing and communication systems.

Hubwoo proposed to coordinate the implementation of eCatalogues with the list of major suppliers of indirect goods and services of each buyer, by choosing the same data standards and process agreements. After a technological learning period to create and implement eCatalogues, buyers developed new relational modes with their suppliers and generally reduced their supply base: they first incite them to increase their price transparency; standardize their offer and sometimes enlarge it to answer the needs of their customers. In exchange, buyers offered them mid-to-long-term contracts (2-3 years). In 2005, Hubwoo introduced electronic billing in exchanges.

Let us compare the evolution of the strategic potential of EMPs perceived by buyers and suppliers over time.

In the buyer perspective, the main differentiation factor deals with sourcing. EMPs provide a set of IT tools and services that first allow access to international supplier data bases such as Global Sources,
and then facilitate **supplier comparisons**. A consequence of the use of EMPs and e-procurement is a “consolidation of negotiated contracts on a few suppliers able to serve global market” (Buyer). In the supplier perspective, the main differentiation factor deals with the technological edge provided by IT with the capacity to offer high quality content to customers, such as a unique and up-to-date view of the product offer.

Arguments on **costs** are similar for buyers and suppliers. They agree on the fact that EMPs contribute to reduced costs due to data standardization and quality, mutualisation of technological investments and maintenance, and finally standardization of the communication process around the purchasing and supply chain.

According to buyers, the **innovation factor** deals with the capacity of IT to gain visibility on internal expenses before the accountability stage and finally to improve supplier IS in customer expectations. Innovation also accelerates the process order execution and initiates the opportunity to pilot purchasing and supply flows. Relational modes with suppliers are also impacted with the introduction of fuzzy relationships from collaboration to hard competition. This leads to source large-sized suppliers able to serve international markets. IT then makes it possible to apply these negotiated contracts internally - owing to the structuring power of technology that restricts the choice of suppliers to order. IS act as a Big Brother tool able to control buyer behavior so that only contracts that have been previously negotiated via eCatalogues are ordered, this is the “structuring power of eCatalogues easily exclude suppliers from markets, in the day-to-day habits of operational buyers, when they are not selected in long-term contract partners” (Buyer). By doing so, the EMP contributes to aligning the whole organization on the best price negotiated: “when the group has decided to buy Dell, all the entire company effectively makes its orders to Dell” (Buyer).

On the other side, suppliers highlight the fact that participation in EMPs forces them to orientate their IS towards customers’ needs. As an example, they have to synchronize their electronic catalogues according to the EMP standard format or process communication. These modifications help them to accelerate their capacity to integrate customer data in their back ends. Finally, by being the ones able to exchange electronically, for instance by mastering electronic payments, suppliers become pioneers in IT; that leads them to lock in the marketplace. Process standardization helps them to reduce data errors, accelerate product time delivery and hence to improve their cash flows. Finally, eCatalogues are considered as positive innovations due to their capacity to be an up-to-date show window for their products, and accelerate the pace of time delivery. Despite these benefits, suppliers deplore the fuzzy relationships enhanced by suppliers with eCatalogues.

**Growth** is recognized both by buyers and suppliers. For buyers, the main benefit lies in prices, due to the capacity of the EMP to leverage negotiated volumes by bringing together the purchasing needs of different subsidiaries of the same company. Suppliers just begin to see return on investments by recovering, as incumbents, the market shares of their competitors that were excluded from eCatalogues. Most of them see a growing part of their business through EMPs and electronic channels in the future. The main benefit of these exchanges is to come with the IS integration between the EMP and their supplier IS.

How do these strategic factors evolve over time?

Here again, it is interesting to notice that the strategic advantage factors highlighted by suppliers and buyers do not correspond to the initial announced EMP’s value proposition: “we did not get return on investments where we initially expected to” (Buyer).

When the EMP started in 1999, Hubwoo basically communicated on the following three main advantages: the improvement of the communication process with emphasis on administrative tasks (organizational cost reduction in processing orders), content (data standardization and improvement of
the quality of data) and economic gains. We qualify these factors of improvements as “transactional” as they refer to reduction costs on technology or processes. Actually, buyers do not have an accurate view on cost cuts due to the EMP. However, they all recognize eValues such as differentiation factors as sources of competitive advantages, innovation, alliances/power gains or global growth.

Since 2004, the strategic eValue of Hubwoo appears to be the great visibility that eCatalogues bring in internal purchasing expenses, the control on purchaser behavior as well as power gains for buyers. For suppliers, there is still uncertainty over whether EMPs will help them to differentiate from their competitors with the lock in effect and the technology control. It is too early to see what is coming next: some suppliers think EMPs will bring them a strategic advantage whereas others do not. EMPs will have a contrary effect, by avoiding their differentiation.

</table>
5 DISCUSSION:

In this discussion, we will first compare the main competitive advantages that emerge in the different industries (See Table 1) and complement it with an overall vision of the evolution across industries of the following criteria: the dynamic evolution of IT tools, the eValue with higher frequency of items, a summary of the specific needs of each industry and finally an evaluation of the strategic potential of these eValues using Barney (1991)’s framework. Second, we will highlight the specific competitive advantages that EMPs bring in each industry. We will then conclude on the impact of EMPs and electronic exchanges on the structure of each industry.

Some factors are common to all EMPs. Others are specific to the needs of each industry.

There are three main differentiating factors in all EMPs: sourcing and knowledge management are common to all of them whereas data synchronization is specific to the retail industry. In terms of frequency of items, sourcing has the most impact in the automotive industry as this industry was one of the first to use supplier content to evaluate supplier performance through metrics. MRO industrial suppliers and buyers hold before all the capacity of the EMP to help them to provide returns on experience (implementation and adoption of best practices). The retail industry is the only one that has already started to build a global standard for product and supplier databases thereby creating a worldwide network. This was also possible because WWRE managed to link the main retailers with the major suppliers, contrary to Supply On which only connects smaller players. It is a long-term project that will connect the key players of the industry through a standard and future interoperable IOIS.

All industries benefit from cost reductions owing to data and process standardization, resource mutualisation, EMP change management and the objective to tend towards fully-integrated applications. However, this advantage appears to be short-term and is not going to differentiate one competitor from another, but to improve the whole collective marketplace.

The main innovation factor lies in new ways of managing the supplier relationship in the exchange, combining aggressive IT tools such as eAuctions with more collaborative ones such as CPFR, with the same supplier. This combination of IT tools introduces fuzzy relationships that renew the way purchasers deal with the supplier portfolio. Bakos (1997) prediction that IT will bring higher price transparency is actually limited to buyers through eAuctions. Transparency in buyer-supplier relationships has to be considered as a complex variable used to choose the suppliers allowed to enter
into the EMP (Soh et al. 2006). Hence, IT will not automatically facilitate access to the market (Kogut, 1998), especially for little-sized companies. In addition, the visibility provided by EMPs on supplier performance worldwide will enlarge the way purchasers assess their supplier from a local territory to the globe.

In all case studies and knowing that the EMPs studied are buyer-controlled, power gains clearly appear on buyer sides, in both the purchasing and supply processes. Buyers gain visibility on supplier practices, data and performance.

Finally, several factors of *growth* are mentioned: some of them can be qualified as short-term gains (price gains with eAuctions) whereas others are described as long-term gains. We further discuss the way we should consider long-term competitive advantage in EMPs with the help of RBV.

**What are the specific competitive advantages brought by EMPs in each industry, according to their structure and needs?**

The initial benefits for the *automotive industry* lie in price gains with the diffusion of eAuctions as well as cost reductions due to the improvement of the exchange process (Howard et al., 2006). These gains were short-term as all automotive players, irrespective of whether or not they belong to an EMP, now include eAuctions and process reengineering in their negotiation, whether they belong to an EMP or not. From 2000-2004, the focus was on improving the supplier and product business directory. According to interviewees, this sourcing tool is relatively rare, difficult to imitate or substitute. In addition, the supplier performance metrics appears to be relatively advanced considering that the retail industry, for example, has not yet obtained value in this area. Thus sourcing appears to be a long-term competitive advantage provided by EMPs in the automotive industry by implementing global sourcing systems (Mol, Koppius, 2002), including low cost countries, some of them offering rating functionalities based on performance metrics (Carter et al., 2000; Kleijnen J., Smits M., 2003). This leads us to conclude that EMPs bring an aggregation value (Kaplan, Sawhney, 2000) by reducing the fragmentation in the base of suppliers. That will probably bridge the gap between the oligopolistic structure of the retail industry to the one of the automotive industry and hence orientating the market to a “move to the middle” (Clemons, Row, 1992). In addition, since 2004, buyers have asserted that Supply On also provides value with IT tools in delivery and stock management processes. This drives cost reduction in the short to middle-term perspective. The next step will be to improve coordination and cost cuts derived from the IS integration of the EMP with its users. IS integration between Tier 1 and Tier 2 suppliers has always been a source of value in automotive supply chains (Clemons, Row, 1993).
In the retail industry, initial benefits were similar to those in the automotive industry: cost reductions due to process reengineering, improvement of communication, gains in prices owing to eAuctions. The sourcing value extents matching (Kaplan, Sawhney, 2000) not only on price gains but also on the capacity to deal globally, being able to exploit the specificity of local markets and cultural needs. However, these eValues have been progressively imitated by all retailers and suppliers, even if they do not belong to an EMP. The main competitive advantage brought by the EMP is global data synchronization with an improvement on product and supplier data quality and accuracy. The capacity to have high data quality in their own IS will soon allow buyers and suppliers to develop different collaborative tools such as promotions management, shared planning, stock inventory based on stores’ sales. Besides, buyers and suppliers will be able to better control the data that is sent outside their IS. This improvement in data quality and purchasing and supply IS control appears as a rare and difficult to imitate resource. Hence, suppliers and buyers who benefit from this competence will also benefit from a long-term competitive advantage. Considering the yet oligopolistic structure of this industry, we assert that electronic catalogues are not used to gain aggregation as in the automotive or MRO industries but to improve the communication and coordination all along the supply chain.

Finally, the acceleration of the restructuring of the configuration around a few large-scale retailers with electronic exchanges questions the evolution of power gains in the chain. The power gains from which buyers presently benefit as a middle-term advantage will depend on the capacity of suppliers to take advantage of IOIS to strengthen their positions. In the same connection, network alliances (Gulati et al. 2000) initiated between buyers in 2005 may bring long-term advantages if they manage to use these coalitions to their advantage without being accused of collusion.

For purchasing and supply, the final step will be to reach fully-integrated and agile IS able to coordinate and communicate in the whole supply chain, from the upper food supplier in the chain, to the different warehouses and finally, stores that directly connect to end customers. An increased visibility in the supply chain is also urgently needed to guarantee healthy products and customer protection in the case of food crisis. However, before 2000, IT linkage was limited to demand to order processes and began to reach the purchasing process with eAuctions.

The case of MRO industry is similar to the automotive and retail industries as initial gains (2000-2002) were linked to cost reduction. The EMP brought high value in accelerating change management and supplier roll out by trying to concentrate widespread suppliers in the same database format. From the start, Hubwoo has also greatly contributed to improving supplier and product data content as content was a condition to exchanges through eCatalogues. Here again, and according to interviewees, this content is relatively rare, difficult to imitate or substitute. If the supplier performance metrics is not so advanced in MRO industries as in the automotive industry, the latter will probably greatly improve the optimization of stock inventory which are notably sent to automotive customers. Hence, supplier and product content can be considered as a long-term competitive advantage. Finally, the
main long-term competitive advantage that is recognized to the EMP is the capacity to offer a **fully-integrated platform** able to make links between tenders to order delivery. **Integration** is also expected to reach supplier and buyer IS back ends. Such integration is considered to be relatively difficult to imitate or substitute and hence, considered as a long-term competitive advantage for users that will help to better manage supplier stocks. Finally and in the near future, these tools will probably be used to assess suppliers and compare their offers apple-to-apple. The EMP will then become a rating intermediary and this questions the evolution of power gain in the chain (Webster, 1993) as well as the evolution of the structure of this fragmented industry. As the MRO industry is part of the suppliers of the automotive industry, and as it is still more fragmented than the automotive industry, we anticipate that the MRO industry will follow the same path of the automotive one and will totally benefit from an aggregation value (Kaplan, Sawhney, 2000).

In conclusion, some eValues are common to all of them: cost reduction, standardization, communication process reengineering, price gains, mutualisation and power gains.

In addition, EMPs drive different types of competitive advantage according to the needs and structure of each industry: sourcing, supplier performance metrics and IT integration in the automotive industry; global data synchronisation, internal increased control of purchasing and supply IS and alliances in the retail industry; supplier and product content and a fully-integrated platform in MRO industries.

Looking at the dynamic evolution of EMP eValues, we can highlight **three main conclusions**.

First, EMPs should not only be considered as transactional IOIS aimed at driving cost reductions. They also reveal other types of long-term competitive advantages (Ordanini, 2005) that are larger than an improved collaboration in the chain. Whereas collaboration is generally presented as the main advantage of EMPs (Mahadevan, 2003), our cases show that collaboration is actually a long-term perspective that will be possible with the integration of IOIS from buyers to suppliers. However, the differentiator factors highlighted bring further questions such as the evolution of alliances and power gains in a fully-integrated supply chain between suppliers and buyers, but also in supplier-buyer relationships.

Second, following the example of EDI (Webster, 1995), EMPs have initially brought value to supply processes with the development of eCatalogues and, since the beginning of the 1990’s, EMPs brought value in the purchasing process with eAuctions and eTenders. We do consider this as an historical evolution of the value brought by IOIS from supply to purchasing processes.

Third, the eValue of EMPs are directly connected with the needs and structure of each industry. EMPs help us to imagine the evolution of global electronic markets connected through global IOIS. The example of the retail industry may foreshadow the evolution of global electronic markets around an
oligopolistic configuration that excludes little-sized companies from global and finished products of inter-organizational exchanges. Are the automotive and MRO industries going to follow the same path or are they going to create different industrial configurations and benefits from eCommerce?

6 CONCLUSION:

In this paper, we describe the dynamic evolution of eValues provided by EMPs to buyers and suppliers. We analyze these eValues according to the needs of the automotive, retail and MRO industries. Using both Wiseman (1985) and RBV theoretical frameworks, we discuss what types of eValues could be considered as short to long-term competitive advantages.

Our results first highlight that EMPs were initially introduced to gain transactional value such as cost reduction, mutualisation, standardization, process reengineering. Then, they progressively revealed their strategic potential in several directions: buyer-seller relational modes, alliances, sourcing, product and supplier content and global data synchronization. Hence, we highlight similarities and contrasts on how suppliers and buyers play with the strategic opportunities of EMPs in their exchanges. Finally, we show that this strategic potential of EMPs differs according to the strategic positioning of EMPs (on direct or indirect goods and services) and according to the specific needs of each industry. The dynamic description of three case studies helps us to foresee the evolution of the structure of these industries through the development of eCommerce.

As a continuation of this research, we could consider analyzing the risks perceived by users (Kumar, Van Dissel, 1996; White et al. 2007) and see whether they endanger the strategic factors highlighted in this study. In addition, we could more thoroughly explore how the position of buyers and suppliers in the chain and their stakeholder salience (Howard et al., 2003) may explain their capacity to take advantage of the strategic advantages highlighted.

Abstract

We argue that types of Simmelian-tied employee dyads (dyads embedded in three-person cliques) influence organizational justice perceptions, and knowledge sharing within and across organizational boundaries through virtual workgroups. We study the interaction between employees’ advice and friendship ties, shared interpersonal, interactional, procedural and distributive justice perceptions, and the types of knowledge shared from a social network perspective. We predict that Simmelian-tied advice and friendship dyads influence justice perceptions, and in turn knowledge sharing. Compared to Simmelian-tied advice dyads, we suggest that Simmelian-tied friendship dyads were hypothesized to be strongly associated with congruent distributive, interpersonal, and interpersonal justice perceptions. Congruent procedural justice perceptions were likely to be associated with both Simmelian-tied advice and friendship ties. We hypothesized that distributive, procedural, and informational justice perceptions were likely to be shared across formal organizational boundaries through strong friendship ties. We also predicted that positive congruent procedural, interpersonal and informational justice perceptions influenced expert knowledge sharing while congruent distributive justice perceptions influenced product knowledge sharing.

Keywords: Simmelian Ties, Advice Ties, Friendship Ties, Social Network Analysis, Organizational Justice; Knowledge Sharing.
1 INTRODUCTION

Research shows that organizational justice perception, or how employees perceive fairness, influence performance-related work outcomes such as job satisfaction, organizational commitment (Aryee et al., 2002), performance (Kim & Mauborgne, 1997; Colquitt et al., 2002), and work motivation (Colquitt, 2002). Justice research in recent years has shifted from the individual perspective to the congruent perceptions of groups using social structure, influence, and interaction (Lind et al., 1998; Van Den Bos & Lind, 2001; Colquitt et al., 2002; Colquitt, 2004; Roberson, 2006a; Roberson, 2006b).

Several studies point to the impact of formal (Schminke et al., 2002; Ambrose & Schminke, 2003) and informal (Chia et al., 2006; Shapiro et al., 2008; Fang & Shaw, 2008) organization structures upon justice perceptions. Field network studies further confirm that justice perceptions not only transmit via social structure but also possess the ability to influence peers (Lamertz, 2002; Umphress et al., 2003).

This research is grounded on the notion of justice perceptions as a contagion (Degoey, 2000), such that individuals seek and provide justice perceptions based on uncertainties, past experiences and social structure. Our study adds to the current literature in three ways. First, we seek to extend and clarify existing studies to address the influence of strong social ties on congruent justice perceptions between employees. Second, we examine the ability of justice perceptions to endure across organizational and geographical boundaries. Finally, we consider the impact of congruent justice perceptions on knowledge sharing, an outcome of work performance.

2 THEORY AND HYPOTHESES

The manner in which employees seek advice or friendship leads to the emergence of informal ties (as opposed to formal ties, e.g. departments). These ties carry a myriad of organizational implications, such as knowledge sharing (Krackhardt & Stern, 1988; Tortoriello & Krackhardt, 2008) and social influence (Gibbons, 2004). As organizations adopt virtual workgroups, ties possess the ability to span and influence perceptions across local and geographical boundaries (Krackhardt & Stern, 1988).

Justice perceptions are not formed in isolation; rather, they are subject to the influence of social interaction. Through existing ties and referents of injustice (Kray & Allan Lind, 2002), employees exchange and process justice information (Chia & Fang, 2005; Chia et al., 2006; Fang & Shaw, 2008) to determine whether they were subjected to unfair treatment or as a means to avoid potential injustice. However, research involving the influence of ties on justice perceptions had yielded inconsistent results (Lamertz, 2002; Umphress et al., 2003; Roberson, 2006b).

![Figure 1: Proposed Research Model](image-url)
This study aims in part to integrate and empirically examine these issues in the virtual workgroups of a knowledge-intensive organization. We also aim to study the knowledge sharing outcomes of such congruent justice perceptions, an area current literature is relatively silent about (Kim & Mauborgne, 1997; Lin, 2007). Therefore, we attempt to bridge these gaps by formulating a research model (Figure 1) and subsequently grounding the hypotheses in the literature.

2.1 Organizational Justice Perceptions

Justice perceptions of employees hold crucial implications for managers and organizations (Simons & Roberson, 2003). In our study on knowledge sharing, related outcomes include citizenship behavior (Nichoff & Moorman, 1993; Lavelle et al., 2007), job satisfaction (Wesolowski & Mossholder, 1997), rule compliance, commitment, and helping behavior (Colquitt et al., 2001). In order to distinguish the myriad of outcomes associated with justice perceptions, these perceptions have been distinguished as distributive, procedural, interpersonal, and informational (Colquitt, 2001).

Distributive justice perceptions refer to the fairness and equality of outcomes relative to one's contribution (Colquitt et al., 2001). On the other hand, procedural justice perceptions consider the process fairness or the ability to voice one's opinions during the decision process (Lind & Tyler, 1988) represent the cornerstone of procedural justice (Folger & Cropanzano, 1998). Interpersonal justice refers to whether individuals are treated with dignity and respect, while informational justice considers the completeness of processes and outcomes explanations (Colquitt et al., 2001).

2.2 Social Influence and Justice Perceptions

Sensemaking (sharing and clarifying perceptions) within groups serves as a source of social influence, leading to congruent perceptions of behavior and group norms (Salancik & Pfeffer, 1978). In the organization, justice perceptions are shared among colleagues to voice concerns and clarify ambiguities to determine fair outcomes and treatments (Degoeij, 2000; Folger & Kass, 2000; Van Den Bos & Lind, 2001; Lamertz, 2002). For example, group ratings of justice perceptions were more significant compared to the individual (Lind et al., 1998; Van Den Bos & Lind, 2001; Roberson, 2006b), especially in highly interdependent groups (Colquitt, 2004).

We draw from social network analysis to examine this social heuristic phenomenon. Social network analysis provides insights into informal structures such as group cohesiveness (Gruenfeld et al., 1996) and relationships (Krackhardt & Kilduff, 2002). Early applications of social network analysis found evidence for congruent procedural and interactional (comprising of interpersonal and informational) justice perceptions between dyadic (2-person) and triadic (3-person) relations (Lamertz, 2002; Umphress et al., 2003; Chia & Fang, 2005).

These early network studies suggest that unambiguous work outcomes of distributive justice are not subject to social influence. However, this is contrary to later laboratory studies (Roberson, 2006a; Roberson, 2006b). We attempt to clarify social influence on justice perceptions within groups by utilizing the concept of Simmelian ties and distinguishing between different types of relationships.

2.3 Simmelian Ties

A Simmelian-tied dyad (Krackhardt, 1995) is a regular dyad embedded in a triad. While a strong dyad may foster congruent perceptions, a Simmelian-tied dyads enforces such perceptions by introducing three properties: (1) enforcing group interests through outvoting (2) reducing individual bargaining power (3) encouraging cooperation through mediation by a third party.

By utilizing the Simmelian-tied dyad, the complexities of studying groups are stripped away while retaining essence of the group by considering the common third-party common. This allows us to examine the associated influence, constraints and interactions. Simmelian-tied dyads offer opportunities for sensemaking and clarifying issues with similar others (Festinger, 1954; Krackhardt & Kilduff, 2002), forging shared perceptions and agreement. Related outcomes include increased
cognition of workplace relationships (Krackhardt & Kilduff, 2002), knowledge access (Tortoriello & Krackhardt, 2008), and social support spanning organizational boundaries (Krackhardt & Stern, 1988).

2.4 Advice and Friendship Ties

Informal relationships play an important role in the organization (Krackhardt & Hansen, 1993). For example, strong workplace friendship influences shared values (Gibbons, 2004). This study concentrates on two types of social ties: advice and friendship. Advice ties concerns with which individuals approach for work-related advice (Podolny & Baron, 1997), while friendship ties consider with whom individuals share perceptions, experiences and rely for social and political support (Coleman, 1990; Krackhardt & Kilduff, 1990).

Strong advice ties lead to organizational learning (Biele et al., 2008), information sharing, and performance (Verbeke & Wuyts, 2007), while friendship ties transmit affect and emotion, transcending boundaries such as demographics (Plickert et al., 2007), fostering congruent perceptions (Gibbons, 2004). Therefore, information transmitted over advice and friendship ties have the ability to reinforce justice perceptions in varying ways (Umphress et al., 2003; Chia & Fang, 2005).

2.5 Simmelian Ties, Social Influence, and Justice Perceptions

We have addressed the social influence effects of Simmelian ties, the characteristics of advice and friendship ties, and the existing justice research. We now attempt to integrate these factors.

Distributive justice perceptions are associated with objective, work-related outcomes (e.g. pay). While laboratories studies report congruent distributive justice perception through sensemaking (Roberson, 2006a; Roberson, 2006b), earlier network studies suggest the contrary. The unambiguous nature of distributive justice perception do not seem to provide avenues for sensemaking and social influence, and the objective work outcomes led earlier studies to associate this perception with work-related ties (Lamertz, 2002; Umphress et al., 2003; Chia & Fang, 2005).

We argue that distributive justice perceptions are susceptible to social influence through friendship ties rather than advice ties, particularly through Simmelian-tied friendship ties. While distributive justice perceptions work outcomes are objective and unambiguous, individual favorability perceptions of these outcomes remain highly personal and subjective (Sweeney & Sweeney, 1992; Sweeney & McFarlin, 1993; Colquitt et al., 2001). Sensitive and subjective perceptions subjected to sensemaking and social influence (Klein et al., 2001), particularly between strong friendship ties associated with trust and concern (Verbeke & Wuyts, 2007). Thus, we propose that compared to regular friendship dyads, Simmelian-tied friendship dyads are likelier to form congruent distributive justice perceptions.

Hypothesis H1. Compared to regular friendship dyads, Simmelian-tied friendship dyads are more likely to share congruent distributive justice perception.

Procedural justice perception is associated with the ability to voice concerns and appeal against work decisions. Compared to distributive justice perception, procedural justice perception concerns subordinate-leader exchanges and supervisor evaluation (Colquitt, 2001), which are of a less personal nature. Such perceptions are likely to be exchanged among friends in the workplace and workgroup members who may not necessarily be personal friends.

Recent studies found that work and friendship dyads exchanged and accepted procedural justice perceptions amongst themselves (Chia et al., 2006), while Simmelian-tied work dyads and groups were found to share congruent procedural justice perception (Van Den Bos & Lind, 2001; Lamertz, 2002; Colquitt et al., 2002). However, these findings have been met with inconsistency. In another study, friendship but not advice dyads shared procedural justice perceptions (Umphress et al., 2003).

We suggest that while regular advice and friendship dyads exchange and accept procedural justice perceptions, these do not necessarily mean that each individual receive other's justice reports as their own personal views. Reports of secondhand justice information may be seen as less reliable and biased compared to their own experiences (Van Den Bos & Lind, 2001). This issue may be mitigated in a
Simmelian-tied dyad, as justice perceptions may be reinforced with the presence of the third party.

Interpersonal justice perception is often associated with the subordinate’s evaluation of the supervisor (Colquitt, 2001). The sensitive nature and consequences associated with the interpersonal perceptions of supervisors means that close friends who share empathic concerns, social support, and trust are likelier to exchange such information compared to regular colleagues. Informational justice perception addresses the transparency work-related processes and outcomes (Greenberg, 1993). Considering that informational justice perception also deal with sensitive information such as treatment bias, we expect that like interpersonal justice perception, informational justice information is exchanged among close, trustworthy friends (Chia et al., 2006). Similarly, we predict that these notions will be further reinforced within Simmelian-tied friendship dyads.

In the context of our study, we aim to investigate if positive perceptions of procedural, interpersonal, and informational justice perceptions are likelier to promote greater levels of work performance and in turn motivate expert knowledge sharing. Explicit expressions of injustice have been proposed to be more susceptible to social influence and sensemaking (Shapiro et al., 2008). Therefore, in the absence of explicit sharing of injustice among Simmelian-tied dyads, we propose that it is also likely for Simmelian-tied individuals to share positive levels of these justice perceptions.

**Hypothesis H2a.** Compared to regular advice dyads, Simmelian-tied advice dyads are more likely to share positive congruent procedural justice perception.

**Hypothesis H2b.** Compared to regular friendship dyads, Simmelian-tied friendship dyads are more likely to share positive congruent procedural justice perception.

**Hypothesis H3.** Compared to regular friendship dyads, Simmelian-tied friendship dyads are more likely to share positive congruent interpersonal justice perception.

**Hypothesis H4.** Compared to regular advice dyads, Simmelian-tied friendship dyads are more likely to share positive congruent informational justice perception.

### 2.6 Workgroups and Justice Perceptions

Formal organization structure comprise of boundaries such as different workgroups, departments, and spatial locations. Depending on the type of informal ties, the increased use of virtual workgroups allows ties to span across boundaries, opening access to new information and perspectives (McEvily & Zaheer, 1999; Burt, 2004). For example, strong friendship ties spanning boundaries encourage cooperation and remove hindrances (Krackhardt & Stern, 1988).

Employees a part of virtual workgroups may have ties that span multiple countries and departments. This increases opportunities for employees to access and compare justice perceptions. We suggest that while colleagues may seek justice perceptions across boundaries (Chia et al., 2006), close friends forge congruent perceptions. Close friends demonstrate emphatic concern and support for unfair treatment in each other (Coleman, 1990; Krackhardt & Kilduff, 1990), fostering similar attitudes (Gibbons, 2004). However, colleagues place more importance on self-interests (Verbeke & Wuyts, 2007), particularly if they are from different workgroups.

Not all perceptions endure across physical boundaries. Interpersonal justice perceptions are oriented toward individual supervisors and not the organization as a whole. Perceived interpersonal justice by an employee does not apply to his/her friend with a different supervisor, and therefore do not necessarily lead to congruent interpersonal justice perceptions. By contrast, distributive, procedural and interpersonal justice perceptions may propagate across boundaries.

Close friends are likely to empathize and reinforce organization-oriented justice perceptions, such as distributive justice (Cropanzano & Ambrose, 2001). For example, an employee in location A expresses pay dissatisfaction to a colleague-friend in location B. While both employees may have different initial perceptions, both may conclude that the organization did not treat employees as equals and thus unfair. Alternatively, the employee in location B may convince the friend in location A
otherwise, or not at all. The presence of a third friend will aid in reinforcing a particular position.

Procedural and informational justice perceptions involve the ability to appeal injustice and the degree of transparency across the organization. The relative ambiguity of these justice items also prompt employees in virtual workgroups to seek out perceptions to reduce treatment uncertainties, such as the case of procedural justice (Hakonen & Lipponen, 2008). Like distributive justice, procedural and information justice perceptions are also organization-oriented rather than being supervisor-specific. Thus, it is possible that organization-oriented perceptions will endure across boundaries.

Hypothesis H5a. Simmelian-tied friendship dyads are likely to share distributive justice perceptions across distributed workgroups.

Hypothesis H5b. Simmelian-tied friendship dyads are likely to share procedural justice perceptions across distributed workgroups.

Hypothesis H5c. Simmelian-tied friendship dyads are likely to share informational justice perceptions across distributed workgroups.

2.7 Justice Perceptions and Knowledge Sharing

Knowledge sharing within the organization may be defined as the exchange of information, expertise or feedback (Cummings, 2004). While knowledge sharing has been recognized as crucial to organizational success, equally important is the type of knowledge shared. Product knowledge (e.g. documentation) saves time while expert knowledge (e.g. advice and experience) improves work quality and performance (Haas & Hansen, 2007). Employees were found to regard expert knowledge as their own and product knowledge as organizational property (Constant et al., 1994). Thus employees are obligated to share product and not expert knowledge (Jarvenpaa & Staples, 2000). Distributive justice perception is associated with commitment, citizenship (Aryee et al., 2002), and compliance behavior (Kim & Mauborgne, 1997). Unlike other perceptions, distributive justice perceptions do not induce counterproductive work behavior (Jones, 2008). Also, individuals sharing similar perceptions (such as of the organization) are likely to be closer and familiar with each other, sharing resources to solve problems (McPherson & Smith-Lovin, 1987; Gruenfeld et al., 1996; Umphress et al., 2003). Therefore, we suggest that individuals who share congruent distributive justice perceptions will be inclined to share product knowledge in order to get the job done.

Hypothesis H6. Congruent distributive justice perceptions will be positively related to product knowledge sharing.

Positive procedural justice perceptions allow employees the ability to voice concerns and influence decisions about their work. This encourages volunteering, helping, and discretionary service behavior (Kim & Mauborgne, 1997; Colquitt, 2001; Simons & Roberson, 2003; Spitzmüller et al., 2006). This motivate individuals fulfill more than the basic job requirements to share expert knowledge (Kim & Mauborgne, 1997; Spitzmüller et al., 2006), and contribute to the community (Wasko & Faraj, 2000). Interpersonal justice perception concerns the supervisor (Colquitt, 2001), and also encourages work performance akin to procedural justice perception (Simons & Roberson, 2003; Roch & Shanock, 2006; Jones, 2008). Similarly, informational justice perception instills voluntary performance-oriented behavior through trust and transparency (Colquitt, 2001; Turel et al., 2008; Ellis et al., 2009).

As procedural, interpersonal, and informational perceptions are related to employees are treated, recognized (Constant et al., 1994), we predict that positive perceptions will allow employees to share expert knowledge. Unlike distributive justice however, negative perceptions of procedural, interpersonal, and informational justice lead to counterproductive work behavior (Jones, 2008). We suggest that employees are likely to withhold utilizing expert knowledge in their work to sabotage work quality if they harbor negative perceptions of procedural, interpersonal, and informational justice items. Therefore, such individuals would be in a position to share and reciprocate expert knowledge only if they hold to congruent positive justice perceptions.
Hypothesis H7. Positive congruent procedural justice perceptions will be positively related to the expert knowledge sharing.

Hypothesis H8. Positive congruent interpersonal justice perceptions will be positively related to expert knowledge sharing.

Hypothesis H9. Positive congruent informational justice perceptions will be positively related to expert knowledge sharing.

We have discussed the effects of Simmelian-tied dyads on congruent justice perceptions, and the effects of congruent justice perceptions upon knowledge exchange. We noted that with Simmelian-tied dyads, there are greater trust, shared cognition and congruent perceptions. Considering that such strong ties between employees foster like-mindedness and congruent perceptions, these similarities in turn encourage work performance (Phillips et al., 2004) and knowledge exchange (Levin et al., 2002). Thus, we hypothesize that congruent justice perceptions mediate the relationship between Simmelian-tied dyads and knowledge sharing.

Hypothesis H10. Congruent justice perceptions mediate the relationship between Simmelian-tied dyads and knowledge sharing.

3 PROPOSED METHOD

3.1 Research Participants

We will conduct this research within virtual workgroups in a global knowledge intensive organization. Within each workgroup, members are both co-located and distributed across different continents and time zones. Communication occurs over mediums such as face-to-face meetings, and emails. The collaborative nature of these workgroups allows us an appropriate setting to execute our study.

3.2 Measures

Advice and Friendship Dyads. To capture reciprocated advice dyads, respondents will be asked to whom they provide and seek work-advice. To capture reciprocated friendship dyads, respondents will be asked whom they consider a personal friend (Krackhardt & Kilduff, 1990; Shah, 1998). A reciprocated advice dyad existed only if person \( i \) gives to or seeks advice from person \( j \), and vice versa. The same applies to a friendship dyad. This gives us the raw advice and friendship dyads.

Simmelian-tied Advice and Friendship Dyads. A hypergraph matrix illustrating every instance in which a respondent is tied to every other respondent is derived from the raw dyadic matrix obtained from the survey. From this hypergraph, the matrix of Simmelian ties is then derived to determine which respondents are Simmelian-tied (Krackhardt & Kilduff, 2002).

Workgroup Membership. To study whether Simmelian-tied dyads transmit justice perceptions within and across organizational and geographical boundaries, workgroup membership are used. We consider workgroup boundaries of members who span geographical boundaries.

Justice Perceptions. Shared justice perceptions refer to the congruence in distributive, procedural, interpersonal and informational perceptions within a Simmelian-tied dyad. Congruent perceptions within a dyad are measured by taking the absolute difference in the rated perception. The measures are adapted from Colquitt’s (2001) four-factor justice model to fit the organization. All of the items were measured using a 5-point Likert-type scale (1 = strongly disagree).

Knowledge Sharing. The degree of knowledge shared by each respondent to another respondent will be measured by indicating the frequency and type of knowledge shared over different mediums. Frequency is measured over a Likert-type scale (1 = never and 5 = several times a day).
Control Variables. We include three other variables to eliminate alternative explanations for our hypotheses. Different job hierarchy may alter justice perceptions, e.g. managers may not be open in communicating or expressing fairness perceptions to subordinates. We also control for organizational tenure. New employees may not attune to the organizational dynamics, while long-staying employees may have accepted certain practices as a norm. Finally, we control for individual centrality, which have been shown to increase the social influence of interactional justice (Umphress et al., 2003).

3.3 Study Design and Procedures

The independent variables, mediating variables, dependent variables and control variables will be collected through an online survey. The moderating variables will be gathered by the organization. The network survey will contain a list of study participants to capture the respondents’ social and communication structure. As we are examining the influence of congruent justice perceptions and reciprocal knowledge sharing within dyads, we adopt a dyadic level of measurement and analysis.

The network survey will request each respondent to note to whom they turn to for work-related advice and whom they consider friends. From this set of responses, raw advice and friendship matrices will be generated. We will utilize a social network analysis package, UCINET 6 (Borgatti et al., 2002), to calculate advice and friendship Simmelian-tied dyads. A similar procedure will be used to calculate reciprocated knowledge-sharing dyads.

Distributive justice perception congruence will be calculated by taking the negation of the absolute difference of each rated response pair. This generates a matrix where a higher value between each pair signifies greater congruence. This procedure will be repeated to generate matrices of the differences in job hierarchy and tenure for each pair. Positive congruent procedural, interpersonal, and procedural justice perceptions will be calculated by generating a matrix for each justice. Positive justice perceptions between each pair will be marked with a 1, or otherwise a 0 will be given.

In line with existing dyadic studies (Umphress et al., 2003), we will adopt quadratic assignment procedure analyses to perform bivariate correlations as this procedure demonstrated the ability to remain unbiased despite the autocorrelation of network data (Krackhardt, 1988). Hypotheses testing will be conducted with a multiple regression quadratic assignment procedure analysis.

4 CONCLUSION

Our research proposed a theoretical model utilizing congruent justice perceptions as a mediator between Simmelian-tied dyads and knowledge sharing. This study sought to address the limitations and conflicts found in existing studies to examine how social structure may potentially influence justice perceptions between employees.

The effects of congruent justice perceptions on organizational outcomes were also examined, which may potentially differ from the effects of individual justice perceptions. For example, in situations of perceived injustice, a dyadic perspective demonstrated that helping behavior might still occur between close, like-minded individuals, whereas a purely individual perspective may not yield contribution behavior toward the organization. We also attempted to explain between fulfilling minimum job requirements and discretionary behavior through congruent justice perceptions. This is particularly crucial for organizations attempting to motivate their employees into sharing and utilizing their expertise and to achieve greater levels of work performance.

This study also attempted to explain how justice perceptions might propagate across local and distal boundaries within the organization. The ability for justice perceptions to carry throughout the organization potentially holds important implications for managers and decision-makers. For example, there may be a greater need for uniformity in making and executing decisions across the organization regardless of location to eliminate perceptions of bias.
There is much room for future research. Future studies might consider the effects of other factors that may potentially affect the flow of justice information such as network size (Fang & Shaw, 2008), small world networks (Shapiro et al., 2008), and external ties (Umphress et al., 2003). Issues such as culture may also need to be readdressed in the context of justice perceptions in virtual workgroups. The interactional effects between different justice perceptions through the use of fairness theory (Colquitt et al., 2005) or fairness heuristics theory (Van Den Bos & Lind, 2001) may also reveal greater insights into how congruent justice perceptions are formed and influence outcomes.

As organizations increasingly rely on useful knowledge and adopts greater use of distributed workgroups, there is a greater need to understand the concepts and mechanisms underlying the interactional effects between informal structure and justice perceptions upon the individual contribution behavior.

WEB-ENABLED BOUNDARY SPANNERS AND THEIR ROLE IN THE KNOWLEDGE FLOW NETWORK

Abstract

No organisation, no matter how large, can remain totally reliant on the stocks of new knowledge it generates itself. In order to keep abreast of the latest scientific and technological developments, R&D organisations must continuously import knowledge from beyond the organisations boundaries. How does this external knowledge which is critical to success then become absorbed and integrated into the firm? Our paper addresses this question through the lens of the influential technological gatekeeper theory. Drawing on social network analysis (SNA) and interview evidence from a medical devices R&D group, we find that the gatekeeper role is still vital, but no longer needs to be performed by a single individual. Instead, the modern R&D group can keep abreast of the latest technological advances through a combination of Web-enabled internal and external communication specialists. A unique contribution this paper makes to the IT-enable social network literature is the development of an updated conceptual framework of how the gatekeeper role is performed in the modern R&D group.

Keywords: Web Technologies, Socio-Technical, Technological Gatekeeper, Boundary Spanners, R&D.
1. INTRODUCTION

Research and development (R&D) intensive firms must keep abreast of and adapt to the latest scientific and technological developments in order to remain competitive. Increasingly, however, knowledge vital to the firm’s competitive advantage is located outside the firm’s boundaries (Chesbrough 2003). How does this external knowledge which is critical to success then become absorbed and integrated into the firm? A large body of literature exists which highlights the importance that both formal and informal social networks play in transferring knowledge within and between organisations (Allen and Cohen 1969; Allen 1977; Hansen 1999; Wenger, McDermott et al. 2002; Assimakopoulos and Macdonald 2003; Wasko and Faraj 2005; Su, Mark et al. 2007). However, the rapid adoption of Web technologies in recent years is challenging our extant understanding of what constitutes a social network. Today, not only can a person be a member of close, face-to-face social networks, but he or she may also participate in numerous Web-based collaborations comprising thousands of globally dispersed unknown and anonymous individuals. Research is needed to inform organisations of how business value can be generated from the interplay between the social and technical aspects of these socio-technical systems (Parameswaran and Whinston 2007). Thus, the purpose of this exploratory paper is to address this research gap by examining how external knowledge is accessed through Web-based channels and personal contacts and then disseminated throughout the R&D group.

To fulfil our purpose, we turn to the concept of the technological gatekeeper (Allen and Cohen 1969; Allen 1971; Allen 1977; Tushman and Katz 1980; Katz and Tushman 1981; Tushman and Scanlan 1981). Through decades of innovation research, the role of the gatekeeper has proven to be a critical factor in understanding the performance of R&D organisations as gatekeepers have served as key nodes in the innovation process – acquiring, translating, and disseminating external knowledge throughout the R&D organisation. The question arises, however, as to how the role and tasks of the gatekeeper are changing due to the ability of every professional in an R&D organisation to quickly and easily access external knowledge through Web-based channels. Thus, after a review of the seminal literature on gatekeepers as well as of the relevant IS literature, we develop the research question: how have Web technologies impacted the technological gatekeeper’s tasks of acquiring, translating, and disseminating external knowledge? We then present our results from a case study of a medical device company in Ireland in which we collected social network and semi-structured interview data. Finally, the paper presents an updated gatekeeping conceptual framework and concludes with the implications of our findings on research and practice relating to organisational knowledge and learning.

2. THE TECHNOLOGICAL GATEKEEPER

R&D groups are the drivers of innovation in high-technology firms. In order for the group to sustain itself, the literature on R&D innovation emphasises the importance of acquiring a diverse and novel body of knowledge from beyond the organisation’s boundaries (Allen 1977; Tushman 1977; Aldrich and Herker 1997). The acquisition of external R&D knowledge helps the firm to build its ‘absorptive capacity’ (Cohen and Levinthal 1990) and will serve as the seeds for future technological developments (March and Simon 1958; Leonard-Barton 1992). A rich stream of research throughout the 1970s and early 1980s examined the processes through which scientific and technological knowledge enters the R&D group. This particular stream was headed by MIT’s Thomas Allen and his seminal book Managing the Flow of Technology (Allen 1977) documents over a decade’s worth of studies with some of the largest American R&D corporations. Using social network analysis techniques, Allen discovered that knowledge of the latest scientific and technological developments entered the R&D group through a two-step process. Not every R&D professional was directly connected with external sources of knowledge. Instead, a small minority had rather extensive contacts and served as sources of knowledge for their colleagues. These individuals were termed ‘technological gatekeepers’ (Allen and Cohen 1969; Allen 1971; Allen 1977; Tushman 1977; Allen, Tushman et al. 1979; Katz and Tushman 1981; Tushman and Scanlan 1981) as they act as the conduit through which knowledge of external technology flows into the R&D group. A more formal
definition explains that technological gatekeepers are those key individual technologists who are strongly connected to both internal colleagues and external sources of information (Allen and Cohen 1969; Allen 1977; Tushman and Scanlan 1981).

It is logical to assume that direct communication between R&D professionals and external sources of knowledge would be a more efficient knowledge integration mechanism than a two-step process. However, studies have found that widespread direct contact by all project members is not an effective method for transferring technical knowledge into a project from external sources (Katz and Kahn 1966; Allen 1977; Tushman 1977). The reason for this phenomenon relates to task specialisation and the evolution of local norms, values and languages that emerge as a result (Tushman 1977). Not every individual has the ability to understand contrasting coding schemes and misinterpretations are likely to occur if one communicator is without knowledge of the others local coding scheme (Cherry 1965).

Thus, scholars have argued that specialised boundary spanners are required to facilitate the transfer of knowledge across intra and extra-organisational boundaries (Tushman 1977; Tushman and Scanlan 1981; Bouty 2000; Teigland and Wasko 2003; Cross and Parker 2004). The technological gatekeeper is one such boundary-spanner who mediates between the local R&D Group and the world beyond the firm’s boundaries. Allen and Cohen (1969) noted when studying gatekeepers in the R&D division of a large aerospace firm that "...if one were to sit down and attempt to design an optimal system for bringing in new technological information and disseminating it within the organisation, it would be difficult to produce a better one than that which exists". The inference is that there is an association between gatekeepers and higher performance, however, no empirical data existed until the early 1980s when a number of studies advanced Allen’s original gatekeeper concept by examining the relationships between the existence of gatekeepers and project performance for different types of tasks (i.e. research work vs. development work). Tushman and Katz (1980) and Katz and Tushman (1981) found that development projects with gatekeepers were significantly higher performing than those without gatekeepers. Thus, development projects are higher performing when external communications are monopolised by a small number of individuals.

Given the vital role which gatekeepers perform in development projects, it would be useful for R&D managers to be able to identify these individuals. While there is no pre-requisite checklist that an individual has to conform to, the literature does provide some clues to recognising those performing the gatekeeping role. The original studies of Allen and Cohen (1969) and Allen (1971;1977) suggest that the gatekeeper is a highly competent technical performer who is likely to be a first line supervisor. Seldom were gatekeepers found with fewer than five years organisational experience as it takes time to develop one’s communication network. They are genuinely interested in keeping abreast of developments in their technology domain and knowledge of their specialty is deep as opposed to wide-ranging. They tend to read the harder-literature (e.g. scientific journals), present more papers at technical conferences, and maintain long-term relationships with colleagues outside their own organisation. The gatekeeper’s principle contribution comes by way of the translation that they can perform (Allen 1977). The gatekeeper can convert knowledge gained from journal papers and personal contacts into terms that are understandable by members of the local R&D group. It is because of this ability and their technical competence that they are frequently sought out by their colleagues.

The gatekeeper concept has received modest attention since the early 1980s, presumably because the likes of Allen, Katz, and Tushman ploughed the field so thoroughly and left little for other scholars to explore. In recent years however, interest in the concept has been reignited, particularly in the IS field. The gatekeeper existed in a time when it was a difficult and time consuming process for the average R&D professional to acquire knowledge from beyond the company’s boundaries. The past decade has borne witness to major advances in ICT and particularly Web technologies. What these advances have changed is the ease and speed with which employees at all organisational levels can access and disseminate knowledge (Teigland and Wasko 2003; Whelan 2007). With a PC and an internet connection, a knowledge worker can join computer-supported social networks to seek solutions, share expertise, and discuss ideas with like-minded individuals far beyond the reach of their
local social network of friends, contacts, and colleagues (Wasko, Faraj et al. 2004). Recent ethnographic research by Su, Mark et al. (2007) has found that throughout the working day knowledge workers constantly switch between multiple social networks, all of which are a complex mixture of formal and informal, face-to-face and computer-mediated, intra-organisational and extra-organisational, and work-related and private interactions. Yet, we have a limited understanding of how the interaction between the social and technical aspects of practice-based networks impact the knowledge flow network. We address this gap by examining how Web technologies have impacted the gatekeeper processes in development focused R&D:

**RQ:** How have Web technologies impacted the gatekeeper’s tasks of acquiring, translating, and disseminating external knowledge?

We have specifically chosen to examine the impact of Web technologies as an earlier pilot study by some of the authors (Whelan and Donnellan, 2008) found that the key communication technologies used by R&D engineers to acquire and distribute technological information were websites, search engines, and email. Hence, our definition of Web technologies centres on these applications. For the purposes of this study, we define Web technologies as “Web-based communication technologies, such as websites, search engines, and email that enable the easy exchange and retrieval of digitized content.”

### 3. METHODS

For the purpose of our research, case study methods are appropriate as the objective of the study is theory building (Eisenhardt and Graebner 2007), there is a need to focus on contemporary events (Benbasat, Goldstein et al. 1987; Yin 1994), and the phenomenon of interest cannot be studied outside its natural setting (Yin 1994). In order to compare with the original high-technology engineering gatekeeper studies, we have collected data from MediA, a medical device firm who have requested to remain anonymous. The case study setting is further described below.

#### 3.1 Case Setting - MediA

MediA is an American multinational that has been in the medical device business for over 25 years with an annual turnover of $8.3 billion. MediA employs approximately 4,200 people in Ireland. The company has advanced the practice of minimal-invasive medicine by providing a broad and deep portfolio of innovative products, technologies and services across a wide range of medical specialties. The company employs approximately 3,000 R&D engineers, scientists, and technicians worldwide. While the majority of these are based in the US, an R&D group comprising 76 professionals are co-located in MediA’s Irish subsidiary (referred to as Group A in the rest of this paper). While a high level of collaboration exists between the Irish and US R&D bases, Group A is largely a stand alone entity. Both the Irish and US groups are design owners of certain products, and it is the responsibility of each group to advance those designs. Group A is organised on a functional basis into four specialist subgroups – Drug Eluting Stents, Test Method Development, Vascular, and Stent Delivery Systems. Each of the four subgroups has a technology brief which relates to a specific part of the product design.

#### 3.2 Data Collection and Analysis

Data were gathered from Group A between the months of February and March 2008. The data collection methods are summarised in table 1.

*Table 1 Data Collection Methods*
Phase 1 involved analysing the flows of knowledge into and around Group A using social network analysis (SNA) techniques. SNA or sociometry is an established social science approach of studying human relations and social structures by “disclosing the affinities, attractions and repulsions between people and objects” (Moreno 1937). SNA views social relationships as nodes and ties which can be illustrated visually and mathematically. As such, it can provide an x-ray into the inner workings of a particular network. With this tool, important patterns become visible, the relationships between people can be better understood, the health of a group can be assessed and, the people playing key roles within the group can be identified (Cross and Parker 2004). In recent years, SNA has found increasing use as a structured way to analyze the extent of informal relationships that exist within various formally defined groups (Cross, Nohria et al. 2002). However, despite the knowledge intensive nature of R&D, SNA of the R&D function remain relatively rare (Allen, James et al. 2007).

The purpose of phase 1 was to identify the ‘stars’ of the knowledge flow network. To collect these data, all group members were asked to complete a short online questionnaire on their internal and external communications. To measure internal communications, we used the question asked by the original gatekeeper scholars – ‘Please identify which work colleagues you discuss technical issues with at least once a week?’ The choice of once-a-week frequency is purely arbitrary although it does represent a fairly heavy degree of consistent communication (Allen 1977). To measure external communications, respondents were asked to indicate how often they used three sources of external knowledge: personal contacts, internet, and academic publications. An earlier pilot study by one of the authors at MediA indicated that these three knowledge sources were the most frequently used by R&D professionals when acquiring knowledge from outside the company. We used the SNA software package UCINET (Borgatti, Everett et al. 2002) to illustrate the knowledge flow network in Group A.

In phase 2, we conducted semi-structured interviews with selected members of Group A. Interviewees were selected based on the SNA results from phase 1. The objective of the interviews was to explore how the use of Web technologies impacts the acquisition, translation, and dissemination functions of the technological gatekeeper. Group A members were categorised as being a gatekeeper, an internal communication star, an external communication star, or a non-star. Following the approach of (Allen 1977; Tushman and Katz 1980; Katz and Tushman 1981), this study operationalised gatekeepers as those individuals who were in the top fifth of both the internal and external communication distributions. Internal stars were operationalised as those individuals in the top fifth of the internal communication distribution but outside the top fifth of the external communication distribution. The reverse applies for external stars. To get a non-biased view of how knowledge flows around the R&D group, we interviewed a sample of gatekeepers, external stars, internal stars, and non-stars. Care was also taken to ensure that all levels of the formal group hierarchy were represented in the interviewee sample. All interviews were conducted face-to-face and ranged in length from 30 minutes to 75 minutes. In addition, all interviewees gave permission for the interview to be recorded. The procedures outlined in the dramaturgical model (Myers and Newman 2007) were adopted in order to ensure that high-quality interviews were conducted. Interview data analysis was performed using the NVivo software package and followed established inductive qualitative methods: coding, data categorization, and pattern identification (Miles and Huberman 1984; Eisenhardt 1989; Yin 1994).

4 FINDINGS

4.1 Social Network Analysis

Figure 1 illustrates the flow of technical knowledge into and around Group A. The nodes in the diagram are the individual members of the R&D group and the lines represent the flow of technical knowledge between them. The external stars are represented as triangles. The size of the triangle is reflective of how well connected that individual is to external knowledge sources. For example, Node 52 is the biggest triangle as this individual is the most frequent user of external knowledge sources.
Nodes 23, 33, 42, 46, 60 and 75 did not complete the questionnaire hence the reason they are isolated on the left. Nodes 2, 18, 21, 41, 56 and 69 completed the questionnaire but are also isolates because they have no reciprocated interactions with another group member. The overall reciprocation rate in Group A was 64%.

![Figure 1: Group A’s Knowledge Flow Network](image)

The SNA data reveals that only 4 members (or 6%) of the group can be classified as technological gatekeepers. The gatekeepers of the group are nodes 5, 9, 11, and 54. Rather than relying on single individuals to both acquire and disseminate external knowledge, the SNA evidence shows that one set of boundary spanning individuals acquire external knowledge, and a largely different set of individuals disseminate this knowledge around the group. The relationship between node 62 and node 66 can be used to demonstrate this process. Node 62 is an external communication star. This individual is well connected to external knowledge sources but is not very well connected internally. Node 62 acquires external knowledge and communicates this to node 66. Node 66, on the other hand, is well connected internally and can distribute this knowledge around the group through his or her many connections. In fact, many of Group A’s external communication stars have low levels of internal communication, hence the reason why they are located on the periphery of figure 2. The average number of reciprocated internal interactions per week in Group A is 4.343. Nine of the 14 external communication stars fall below this level.

Where do the external stars acquire their knowledge from? The Web was by far the most widely used source with 79% of external stars using this knowledge source at least once a day. 29% reported consulting academic publication while only 21% would consult an external colleague on a daily basis. Thus, knowledge from beyond the company’s boundaries is acquired by the external communication
stars who predominately use the Web to acquire this knowledge. This knowledge is then passed to the internal communication stars who distribute that knowledge around the R&D group.

4.2 Semi-structured Interviews

External Knowledge Acquisition

The SNA of Group A reveals that external knowledge flows into the group via external communication stars who predominately use the Web to acquire this knowledge. There are a number of specific medical technology websites which these external stars access in order to keep up-to-date with developments in the field. For example, cvpipeline.com is one website that many of the external stars identified as being a good source of external knowledge. Cypipeline.com is a subscription based service that promotes itself as “a new online database solution that keeps you up to date with emerging companies, products, technologies, people, and clinical studies in the fast-changing cardiovascular market” (www.cvpipeline.com). One theme in the interviews with Group A’s external stars focused on the benefits that websites such as cvpipeline.com offered over traditional sources of external information e.g. conferences and journal articles. As is reflected in the following quotation, the prime advantage of the Web relates to the ease with which technical professionals can keep abreast of the latest developments in the industry:

I would use the internet quite a bit. For my own development I use it to keep up-to-date with new technologies, new medical device developments. Recently I subscribed to a [trade] magazine…which I think is very good for providing information on new technologies and new medical devices outside. I think another good source of information would be attending conferences…but I think that can be got through the internet. You’d get current information, very up-to-date. I think the internet is a great source of information in that way…it’s there at your fingertips and it’s just a matter of using Google. But subscriptions to magazines, attending conferences, attending procedures over in the hospital and watching the ‘docs’ do their stuff…they can all be good sources of information too.

The external communication stars interviewed not only scan their own industry for the latest developments, but also monitor advances in related industries like electronics and pharmaceuticals. Some of the best innovations in the medical devices field have actually come from other industries. This is explained by one of the gatekeepers. He highlights in the following quotation that the Web provides him with access to a broader range of external information and this is used to stimulate more and better ideas:

There would be a lot of overlap between what we do, and say, the electronics industry. The physicists and electronic engineers in companies like Intel have been coming up with ideas and solving problems for years and the medical device industry has said “Oh, hold on a second now, that could be very useful in this application”. Inkjet technology for example…Hewlett Packard has developed that technology down to such precise detail…inkjet technology is actually being used now for injections in low dosages onto the tiniest medical devices that you can think about. The internet keeps you in touch with those industries. You might see some new drug delivery system treating some obscure disease that had nothing to do with our industry. You find out that they took X and Y and sorted the problem out. Now we can try a similar approach with our problem. [The internet] stimulates a thought process rather than sorts something out for you there and then.

External Knowledge Translation

A number of interviewees commented that it took a number of months working at the company for them to become familiar with the technical jargon and abbreviations unique to Group A. In order to be usable by Group A, knowledge acquired from the external environment needs to be translated into a form consistent with these local norms. However, as is evidenced in the following quotation from an
internal star, these contrasting coding schemes create a problem when communicating with external contacts:

*It’s mind blowing how much jargon we have – not jargon – more abbreviations. We have abbreviations for everything. I’d say within the [this] R&D group, there is probably no real misinterpretation of abbreviations. People usually understand what you mean when you say something like that. However, when you go outside R&D – if I was talking to customers, which I do sporadically, probably about once or twice or three times a year…it’s like I’m talking a completely different language. The jargon and abbreviations are needed but they can be a barrier.*

The analysis of the interview data reveals the existence of a small number of individuals who perform the knowledge translating function for Group A. These individuals are frequently sought out by their colleagues, hence the reason they are also likely to be internal communication stars. One interviewee, Chris1, acknowledged that many of his colleagues often consult with him when they have discovered novel external information. The analysis of the SNA questionnaire reveals that while Chris is one of the most connected people internally, he has very low exposure to external sources of knowledge. Chris is a senior person in the Group A and has 13 years experience in the medical device field, eight of those with MediA. The knowledge translation discussions he has with his colleagues are almost always conducted face-to-face and focus on figuring out if and how outside knowledge can be used by Group A. While he believes that his colleagues consult with him because of the formal reporting structure, he also suggests that he has certain skills which are useful for translating external information. In the following quote, Chris explains these skills. As he is well connected internally, he has the ability to see the bigger picture within the wider R&D group, and he understands how external knowledge needs to be modified in order to fit into that bigger picture:

*So anything mechanical related...people would probably run it by me just to make sure it makes sense. The reason for that is probably – I wouldn’t say it’s my technical expertise – there are a lot of people in the group that would burn me in terms of pure technical expertise. My skill sets would lie in that I know a little about a lot of different things, and I probably have a good appreciation for how they all fit together into the overall picture. We do have people who are bond experts, who are crimping experts, who are balloon experts, [but] they probably wouldn’t have as good an appreciation for the impact that something new would have on other people...whereas I probably would have that visibility. The skill set I have – other people probably don’t have that.*

While the Web is the most widely used source of external information, there is a realisation within the group of the need to be selective when gathering web-based information. There are no guarantees that information sourced from the Web is truly accurate. The medical device industry is highly regulated and the information used to produce these products has to be documented for FDA and EU inspection. Popular websites like wikipedia are extremely convenient for explaining a particular topic however, anyone in the world has the potential to edit a wikipedia article. Thus, the reliability of this information is always open to question. One internal communication star acknowledges that while wikipedia is frequently used as an information source, the validation of this source information is an important process. Group members cross-reference web-based information against other data sources to check its validity:

*I’ve heard comments where people talk about something like wikipedia [but] you have to be careful with it. I suppose I’m guilty of it myself – it’s just convenient, you just pull the information. If it’s just for illustration purposes it’s not a problem. But if it’s something where you’re probably going to rely on this as a source to make a decision or to go and use it in support of a submission to a Regulator, then yes – clearly you have to go and check the source of the information. And we do enough cross referencing, reviewing or peer reviewing*

---

1 Fictitious name

Proceedings ECIS 2009
of our internal documents, and that in itself is the catch for it. We go look for a source document.

External Knowledge Dissemination

Through a combination of social and technical means, the internal communication stars disseminate and integrate novel external knowledge into Group A. Email is the bedrock of the internal communication system. Many of the interviewees suggest that they easily receive over 50 emails per day. Group A has a very clear hierarchical structure and the flow of knowledge tends to follow the chain of command. The following quotation from an internal communication star provides evidence that the pattern of email traffic conforms to the formal organisational chart:

We have a lot of distribution lists. We all have functional managers and they have managers. So I report to my boss. He may have 5 or 6 engineers and a number of technicians in his group – he distributes to us. I’d have a couple of technicians reporting to me and I’d keep them on a little distribution list. I’d have 3 or 4 people I work with outside the area – my peers – on another list. It just goes on and on. So my manager’s boss, he would have all of us in stent delivery on his distribution. Everyone has their own little tiers of it.

Email is the primary system used to alert colleagues to new information from outside the company. However, there is an expectation that only the more senior people in the group should be sending out these emails. There is a feeling among the younger and less experienced members of the group that any external knowledge they discover would not be accepted by their colleagues if they tried to distribute it themselves. Instead, they usually ask an internal communication star to distribute that knowledge around the group on their behalf. The process of disseminating novel external knowledge usually begins with the internal star sending an email with the attached information to the group members they know would be interested in that information. The email will include one or two sentences explaining why the sender believes the attached information is relevant to the receiver. If the information is of interest to that individual, they then return to the internal communication star and have a face-to-face discussion about how that information can be used by the group. An example of this process is provided in the following quote from a non-star:

The information would go up the chain and then fed back down. During the week, one of the members of our group found an interesting external training course, sent an email to the functional manager who was my boss as well, and the manager sent it out to all our extended teams saying, “We’ve just found this, if we’re interested, please come back to me”. The same applies with new recruits from universities…they may have spent a lot of their last year or two in conferences. They may have exposure to new developments that people here may not have known about. They would communicate that to the functional manager, and the manager will then feed it out to everyone.

While email is used to distribute external knowledge, face-to-face discussions are needed in order to figure out how to make use of that knowledge. The consensus among the interviewees is that it would be virtually impossible to perform the work of the R&D group without face-to-face interaction among peers. R&D work in the medical devices sector is very technical in nature. Email is useful for alerting people to external developments but a discussion about that knowledge through email is cumbersome. For this very reason, group members frequently travel to their sister site in the US. In fact, when engineers are being interviewed for positions in R&D, it is explained to them that travel is part of the job. Face-to-face time is a vital component of the group’s work. This is highlighted in the following quotation from an internal communication star. He explains that integrating new knowledge into the group requires face-to-face discussion:

You can only truly understand something new if the other person asks questions and you reply straight away, so that you can address their needs straight away...whereas in e-mail you can’t do that. You do need face-to-face time. You can do a certain amount over email and the phone but you have to build up that face-to-face rapport. What happens is once you build up
that face-to-face rapport, people get the measure of you. They understand what your convictions are, where your strengths are, how you behave – or misbehave – and how to manage that.

5. DISCUSSION

This paper asked the question “How have Web technologies impacted the technological gatekeeper’s tasks of acquiring, translating, and disseminating external knowledge?” While we find that the gatekeeping tasks are integral to the R&D operation, we also find that these tasks no longer need to be performed by a single individual. Gatekeepers do exist, but they are rare. When Allen (1977) first formulated the theory, the gatekeeping role could only be performed by a single individual because technical communications were predominately oral based. Among other skills, the traditional gatekeeper needed excellent social networking abilities in order to effectively acquire and disseminate knowledge orally. While other R&D engineers may have wanted to perform the gatekeeping role, the lack of these social networking skills possibly impeded them. Combining the results of this study with the literature, an updated conceptual framework of the gatekeeper concept is illustrated in figure 2. We acknowledge however that the framework is a simplistic representation of an extremely complex process.

![Figure 2 An Updated Gatekeeping Conceptual Framework](image)

The framework explains that outside knowledge is largely brought into the R&D group by external communication stars. External stars primarily use the Web to scan and acquire their knowledge. External knowledge is then presented to the ‘go-to’ people of the R&D group – the internal communication stars. As well as translating the knowledge into a form that can be used by the group, the internal star also validates that the outside knowledge is accurate and reliable. Knowledge validation is an important step in the knowledge integration process for the modern R&D group but it is not discussed in the original gatekeeper studies. The process of disseminating novel external knowledge usually begins with the internal star sending an email with the attached information to the group members they know would be interested in that information. The email will include one or two sentences explaining why the sender believes the attached information is relevant to the receiver. If
the information is of interest to the receiver, they then return to the internal communication star and have a face-to-face discussion about how that information can be used by the group. It is through this discussion that learning occurs and the knowledge becomes internalised (Nonaka 1994).

6. CONCLUSION

The findings of this paper are of benefit to both theory and practice. We contribute to the advancement of the gatekeeper theory into the 21st century. We show that the gatekeeper role has fragmented, enabling it to be performed by Web-enabled boundary spanners and internal communication specialists. This study should be of particular interest to the IS community. Practitioners are increasingly aware that innovative knowledge is located beyond the boundaries of their firm. This study finds that the Web is a vital tool for accessing this knowledge and that certain people exist who have the innate ability to find relevant knowledge on the Web. It will be increasingly important for R&D firms to find people with the right blend of social and analytical skills. We have also identified some negative aspects to the Web-enabled R&D group that managers will need to be aware of. Firstly, with so much information freely available on the Web, verifying the accuracy and reliability of this information is becoming a critical step in the knowledge integration process. Managers will need to ensure that proper verification procedures are in place. Secondly, an interesting finding was the existence of certain individuals who constantly send FYI emails to their R&D colleagues. Rather than enhancing knowledge flows, the actions of these individuals are seen as a hindrance. The FYI phenomenon could become a significant problem if group members become overloaded with irrelevant messages and end up not reading the important messages.

We see two additional areas for future research. Firstly, while our findings make a unique contribution, they are based on only a single case study. For the purposes of generalisability, future research studies should examine multiple R&D groups in differing industries. Secondly, our findings show that the gatekeeping role can be performed by a single individual or by a combination of internal and external communication specialists. Future research needs to examine which of these routes is most effective for R&D project performance.

Abstract

This paper sets the basis for a research project focused on collaborative social network’s genesis and dynamics. It introduces a research framework for the empirical investigation of a network focused on the design of a shared artefact, the so-called "Web services Architecture". Our hypothesis is that network artefact’s characteristics, seen as the final outcome of a collaborative process, influence and drive the genesis and the structure of the social network that is designing it. We embraced this view in order to avoid a limitation of the traditional perspectives that consider the network structure as exogenous and stable. We consider the reciprocal influence between the artefact and the social network structure, with a phase in which the desired artefact may shape the network genesis and a phase in which the emergent network’s structure may drive the artefact design.

Keywords: social network genesis and dynamics, design network, Web services, coordination, boundary object
1 INTRODUCTION

This paper sets the basis for a research project focused on collaborative social network’s genesis and dynamics. This work aims at the empirical investigation of a social network collaborating in the design of a shared artefact, the so-called "Web services Architecture" (WsA).

We named "design networks" those social networks that exist in order to design an artefact, like technical standards or open source software. We are interested in verifying whether the characteristics of the network artefact, seen as the final outcome of a collaborative process, may influence the genesis and the structure of the design network that is producing it. The traditional causal relationship between network structure (often seen as the independent variable) and network outcome (often seen as dependent variable) may be reversed in design networks: in our case, the (desired) characteristics of the artefact (WsA) may influence the genesis, the structure and the activities of the collaborative network. We therefore hypothesize that one important factor in the genesis of a design network is its fit with the designed outcome (i.e. the network artefact). If our intuition is correct, there could be situations in which the process of design a specific object (with certain characteristics) rather than another one (with different characteristics) shapes and influences the genesis and the dynamics of the social network committed to design the artefact.

The network artefact here investigated is the WsA, a rapidly emerging standard architecture recently defined by the W3C standardization consortium for distributed componentized software applications over the Web (Alonso et al. 2003). The WsA is a set of guidelines enabling any system to remotely access and use software components as “Web services”. The “Web services” concept is a relevant innovation, attracting significant investments in the software industry. The use of the Web services makes it possible to assemble a software application with several independent parts (software components), each accessible over the Web. Using Web services, programmers can compose a "virtual" software application like a puzzle, by accessing the different pieces (Web services) over the Web, independently of their physical location. In principle, many different (and incompatible) implementations of Web services may be possible: standardized architectural guidelines are therefore crucial to ensure true compatibility and interoperability of systems based on Web services by different vendors.

Within the W3C consortium, more than 40 different companies all over the world collaborated for a two-year period toward the definition of this artefact, with weekly teleconference meetings, mailing lists and conferences. The company experts collaborated not only to harmonize different technical specifications, but also to actually face difficult technical issues including not only compatibility, but also security, privacy and reliability of the overall system. The entire standardization process is therefore in the same time a negotiation process (aiming at finding a common definition) and a design process (aiming at solving complex technical issues and devising innovative use scenarios).

With the help of social network analysis techniques and tools, we are here interested in exploring the complex web of network relationships between the actors during negotiation and design of the artefact "WsA". More specifically, we are interested in verifying whether the characteristics of the final outcome of the collaborative process, may actually influence the structure of the network that is producing it.

In comparison with the mainstream literature on social network analysis, this study has two main peculiarities: 1) it is focused on design networks, i.e. social networks aimed at the production of an artefact like open source software or standard technical specifications; 2) it is investigating the influence that the network outcome could have on the network genesis and structure (and not only the opposite relationship as traditionally analyzed by literature).
2 THEORETICAL BACKGROUND AND CONTRIBUTION

Traditional social network analysis (SNA) was originated in Social Psychology, and then applied to several different fields and levels of analysis, including for example inter-firm relationships, using categories and concepts like centrality, structural equivalence and clique analysis (Grandori & Soda 1995). Typically, SNA investigates how the characteristics and the structure of the network may influence the organizational or economic outcomes. For example, some organizational studies discuss the role of relationships in generating innovation (Ahuja 2000) and competitive advantage in markets (Gulati, Nohria, & Zaheer 2000); others focus on the influence of social networks on knowledge creators and spreaders (Singh 2005). In Granovetter’s works (Granovetter 2005;Granovetter 1973) a thorough analysis is proposed on social networks, and why and how they may influence economic outcomes like hiring, prices, productivity and innovation. The same interest emerges from several economic studies, both theoretical, like (Rees 1966) and (Montgomery 1991), and empirical, like (Calvo-Armengol & Jackson 2004), showing the effects of social networks on employment and wage inequality or (Rauch 2001), discussing the role of social and economic networks in international trade. We recognize that the traditional perspective network structure drives outcome is crucial for the understanding of the network relevance and effects, but we also suggest that – particularly in design networks - the outcome itself (i.e. the artefact) may play a key role for the emergence and the genesis of the network structure of a successful collaborative project.

The debate about the endogenous or exogenous nature of the changes in the structural network’s characteristics is still open. The attention of the researchers have been captured by the intangible aspect of the relationships between nodes and had not investigated any influence that the object itself, often only considered as the results of the network activities, could have on the network dynamics. Instead, our perspective, though recognizing the influence of the network structure on the outcomes, is based on the idea that the network artefact can influence the network genesis and dynamics, especially for creative design activities. This approach not only aims at throwing new light on antecedents of social network emergence and dynamics (Carugati & Bolici, 2006; Virili 2003); it is also an answer to a call for more research focusing on IT artefacts and on their direct influence on organizational processes (Orlikowski & Iacono 2001).

In order to give a contribution to this emergent research area, we will address the following research question: does the desired outcome of a specific design project (i.e. the artefact) influence the genesis and the structural characteristics of the network? In particular, we are asking: how do the characteristics of the artefact influence the design process? How do they eventually shape the actors positions, roles and relationships in the network? Answering to these questions would mean not only showing how the artefact could shape network structure and dynamics, but also covering some ground towards showing how the artefact itself may play a crucial and central role in the overall coordination of the design process.

The contribution of this research work is thus twofold: it shows the role of the working standard definitions (the social network outcome) in influencing the genesis and structure of a design network; it sets an empirical ground for further analysis of artefact-centered coordination processes in design networks.

3 METHODOLOGICAL SET-UP

In the W3C consortium, there is an “activity” for each technology being standardized. For each activity there may be several workings groups, each one focused on the production of a technical specification. Our analysis is focused on the WsA Working Group, which has the objective to define the technical specifications of a standard architecture for the Web services activity. Every working group has one or two leaders. There are two modalities of interaction: mailing list or group meetings – they can be either face to face (F2F) or distributed (technology mediated)--. The charter document
specifies that "to be effective every working group should have from 10 to 15 active participants". The F2F meetings don't have a predetermined frequency; they are settled by the group leader according to the matters to be treated, to the deadlines and the opportunities of co-location of side events (e.g. conferences, other W3C meetings). The distributed meetings are scheduled at least once a week (twice when required by the deadlines). The participation to the F2F meetings is limited, on invitation of the group leader. Guests or external experts may be occasionally invited.

4 DATA SET DESCRIPTION

All these forms of discussion and negotiation (mailing list, F2F meetings and teleconferences) are recorded, and the scripts are publicly accessible via the working group Web site. This collection of documents, eventually integrated with external information sources like specialized press articles and news, is illustrated in Fig. 1 here below. All the teleconference scripts and the public mailing lists are available for analysis on the W3C web site.

Fig. 1. Structure of the design process and – on the right – the empirical traces left.

The available data sources for the WSA activity are: deliverables, meeting records, mailing lists and the external sources (like technical magazines and newspapers). The published deliverables include: the WS Architecture and the supporting documents (requirements, glossary, usage scenarios, service life cycle, and ontology). For each document all the previously published releases are accessible, together with the list of the modification intervened. For example, the first official version of the Web services architecture was published in November 2002, followed by two major updates in May 2003 and February 2004. The editor copies are also available: the first editor copy of the Web services architecture is dated June 2002, and was followed by updates in August 2002, March 2003 and July 2003. There are about fifty meeting records per year (on average the meetings were held once a week); they are usually written or edited by a scribe nominated for each session. The working group mailing list, during the period from February 2002 to February 2004 (25 months), collected 6895 messages,
with an average of about 276 messages per month. The two “hottest” months were July 2002 (546 messages) and January 2003 (516 messages); the “coldest” were November and December 2003 (32 and 86 messages, respectively). Moreover, the working group created two temporary task forces that produced proposals on specific issues. The Management task forces produced four deliverables; the Security task force produced one deliverable. The task forces mailing lists are also available for consultation.

4.1 Exploratory data analysis

The strategy for initial data analysis was the following: 1) selection of an appropriate data sample for text analysis; 2) exploratory analysis of the relationship network-artefact, based on initial text labeling.

1) Sampling - The document sample initially selected for this preliminary analysis, was formed by the weekly teleconference scripts for the first year of activity of the working group. It is about 45 scripts, dating from February to December 2002, representing about half of the whole standardization period, focusing on the initial phases design giving birth to the first four drafts of the standard architecture. At the end of this year the standard was already at an advanced stage of design.

2) Labelling and first exploration of the meeting notes - The very first information we looked for was about text size and text authorship for the discussions documented in the scripts. To this aim we had to label more than 4,500 text passages, assigning an author name to each of them. The textual labelling was done with the software “NVivo” version 2.0 (Gibbs 2002).

Text size can be measured as number of text passages, or as number of characters, words, etc. The distribution along time of text sizes, measured as number of text passages is shown in Fig. 2 below.

The graph illustrates the evolution over time of the textual discussion reported in the scripts of the weekly teleconferences and of the four face to face (F2F) workshops in April, June, September and November. The four peaks of the F2F meetings are due not only to the higher number of participants, but also to the length of the conferences (2-3 days of a F2F conference against 1-2 hours of a teleconference). Moreover, considering the distribution of the authorship in the sample data set, grouped per company, it is quite evident that some companies (and some subject) like Sun (26% of total communication) or WW Grainger (11%), participated in the process much more intensively than others, like Oracle (4%) or Chevron (5%).
3) **Mail selection** - In order to have different data sources we also investigated the mailing lists coordinated by the W3C consortium and open to discussion with the public. Thus we analyzed all the emails exchanged between Feb. and Dec. 2002. Moreover we decided to group by the emails along the same time scale adopted for the meeting notes. Thus, our first analysis was to count the number of email exchanged between two direct communication events (F2F or teleconference).

As shown in Fig. 3, our preliminary evidences indicate periods of intense email exchange followed by period of relatively low interaction (min. 22, max. 182 emails, for periods of around 7 days).
Comparing the email volumes and the number of text passages in teleconferences or in F2F meetings (Fig. 4) we can have a detailed representation of the communications between the different actors along the design phase. 

A preliminary finding that emerges from this activity is that the two channels of communication (emails and teleconference/F2F) seem to be complementary. When direct communication is maximum (e.g. April 10th, June 13th, September 12th, November 14th), the email exchange drops off. Similarly, the picks in the email exchanges (7-14 March, 2-9 May, July, etc) correspond to period without any meeting or teleconference.

4) Artefact analysis - The subsequent analytical step has been the selection and the analysis of pilot episodes related to a specific part of the artefact. We selected the first five most relevant parts of the artefact in terms of volume of communications. The analysis about these components of the artefact is presented in section 5 and the design activities related to a specific part of the artefact (the “security” requirement) is described in section 5.1 based both on the F2F and teleconference meetings and on the exchanged emails.

4.2 Strategy and issues for further analysis

The author-based text labelling phase discussed above was useful to trace an overall picture of the data set. The subsequent steps would be: 1) drawing the social network; 2) exploring the relationship between the social network structure and the characteristics of the artefact. Both these steps present crucial methodological issue to be faced.

Social network analysis is often based on detecting and representing the number of direct communications (links) between actors (nodes). However, in our research domain, also the simple task of defining and representing direct communication presents intriguing problems. How do you consider a teleconference? Is it a discussion one-to-many or many-to-many? Is it enough to take part to the
meeting to be considered a node of the network (any actor is exposed to all the messages exchanged in the teleconference) or is it better to require some form of active response to draw a network node? A discussion is often triggered by the intervention of one actor, with responses by one or several actors that may not be immediately and automatically connected to the original one. Methodologies for automatic detection of the network are under study (XXX 2009, removed for anonymity); in the meanwhile, a sensible option in the exploratory phase is to manually trace down the flux of conversation for selected episodes deciding on a case-by-case basis.

Another relevant empirical issue is how to investigate the relationship between the characteristics of the artefact to the structure of the network. Which characteristics might be relevant? How to detect and measure them?

*Fig. 5. Hierarchical classification of design activities as related to the artefact – part 1.*
Fig. 6. Hierarchical classification of design activities as related to the artefact – part 2.

Figures 5 and 6 above show a classification of some of the main activities of the design network as detected by the grounded theory analysis of the Telcon and F2F scripts.

We started our exploration by classifying the artefact (the WsA) and the related activities according to the most important architectural documents, one for each different type of deliverable to be issued by the design group.

The following parts were evidenced:

- The goals/requirements list (activities under code 3.2.1)
- The architectural document (activities under codes 3.2.3 and 3.2.9)
- The issues list (activities under code 3.2.4)
- The glossary document (activities under code 3.2.5)
- The usage scenarios (use case) document (activities under code 3.2.7).

Within each of these parts the hierarchy of sub-entities with the related activities is partially shown in the figures. The activities under code (3.2.2: Discussion on how to design WsA) are about the design method and can be referred to in general to all the parts above.

We are now investigating the differences and similarities on network structures that emerge around each object. We may expect to identify differences in the network structures according to differences in the designed outcome/artefact. At the same time we should notice a similar network structure for those objects that present similar characteristics.
5 DATA ANALYSIS AND DISCUSSION

The WsA design network under analysis in the selected sample period (between February and December 2002) consists of 66 persons belonging to 46 companies, collaborating for the design of the Web service Architecture standard in the W3C environment. According to our hypothesis we expect that (sub)networks with different structures may emerge according to the specific characteristics of the (sub)artefact under development.

Therefore, the attention is here focused on the (eventually) different sub-networks of WsA, each one working on a specific part of the artefact (i.e. architectural document, use cases, glossary, architectural requirements). We expect that similar artefacts will drive the emergence of similar network (both in its genesis and structure) and that objects that strongly differ for their characteristics will lead to different network dynamics and structures.

A preliminary analysis of the data set shows that the most active artefacts (those with a high number of communications between actors) present different network structures. We are able to report at this stage an exploratory matrix, accounting for the number of text passages attributed to each actor and relative to a specific category (Fig. 7). We select the first five artefacts for number of communications: artefact A (3.2.9.8 “ARCH document/F2F40 arch disc-revis”; 164 messages); B (3.2.152 “goals-requirements/20 DAR 6_1-13 security”; 160); C (3.2.9.9 “ARCH document/Management Task Force”; 147); D (3.2.1.43 “goals-requirements/discussing reqrmnts doc voting res”; 119); E (3.2.9.2 “ARCH document/F2F outline of arch”; 115).

</table>

Fig. 7. Communication matrix of teleconference and F2F meetings. Columns report the actor codes; rows the artefact codes illustrated above in Figures 5-6. In each cell the number of text passages for each actor/artefact combination is shown.

The sub-artefact codes (A, C, E), evidenced in grey, are part of the architectural document (code 3 2 9). The codes (B and D), evidenced in orange, are part of goals/requirements list (code 3 2 1).

The matrix cells report the text passages produced by each actor in reference with each object. The cell colours are lighter for lower volumes of communication, darker for higher volumes.

Actor #16 was very active for the artefacts B (28% of all the communication about the artefact) and D (48%) but he was less active for the other artefact (only 15% of his communication has focused on artefact A, C and E). Artefacts B and D seem to be driven by the activity of few persons compared with artefacts A, C and E. In details, if we consider the amount of communication between the most active actor for every artefact we have that they represent the 26% for A; 51% for B; 27% for C; 59% for D and 40% for E. So, the communication for artefacts B and D result to be much more concentrated than for the others.
5.1 Artefact analysis. 3.2.1.52 design task: security

As a further exploratory step, in this section we focus on a specific (sub)artefact. We selected the most relevant artefact for volume of communication (3.2.1.52 - the "D-AG004 Security" requirement) and then we investigated all the direct communications (F2F, teleconference) or emails related to it. We will then try to replicate this analysis to different artefacts and than to compare these results in order to test our original hypothesis about the role of the network outcome in network genesis. Our hypothesis will be confirmed if similar artefacts present similar network structures and if different artefacts present different structures. Thus, this section will focus on D-AG004 Security artefact as a debated artefact inside the WsA distributed group.

*D-AG004 Security* is a specific part of the Web services Architecture Requirements (3.2.1.52), it "addresses the security of Web services across distributed domains and platforms” and it “enables privacy protection for the consumer of a Web service across multiple domains and services”. During the sample period there have been 164 text passages in the minutes regarding this specific topic and several threads.

*Minutes* - Analyzing in details the minutes of the (physical and virtual) meetings, it emerges that few actors lead the discussion on the security requirement. In details, actor 13 is the most active (23 txt passages) followed by actor 91 (22), 51 (21), 17 (20) and 21 (13). Thus more than the half of the communications on the security requirement (86/164) is conducted by four actors. After them, there are three actors (8, 11 and 87), each with 10 passages and others with few communications. In total, only 16 actors participate in an active way to this discussion (around 24% of the group members). Considering the organization as level of analysis, W3C is leading the discussion with around 20% of the communication, followed by Sun (around 15%) and Thompson Corporation (14%). The group of interest composed by Microsoft, IBM and BEA does not often comment on this requirement (17 passages; around 10%). The security requirement appears to be immediately interesting for the group. In the first meeting (06 February 2002) there are 10 different members pointing at the security issue as a crucial requirement that should be designed. The second meeting (14 February 2002) has already the security as an issue in the agenda (point “e” and initially AG006) and in the first WsA Requirements Document (29 April 2002) the security is already well identified as D-AG004 Security and decomposed in two specific sub-parts (D-AC006 and D-AC020); this classification is the same of the final release of the WsA Requirements (11 February 2004).

*eMails* - In order to identify the relevant emails for this specific topic, we have investigated the mailing list repository for the period considered in this analysis (2002). As result for a searching with the keyword AG004 we have identified 69 mails. However in the initial period the “security” requirement have been identified with the tag AG006. Thus we have analyzed all the emails with either the keyword AG004 or AG006 in order to identify those in which the security topic was debated. Non pertinent emails selected by automatic search were manually spotted and removed.

At a preliminary view, the tendency to centralize the discussion of this requirement among few actors seems to emerge also in the mailing list. This finding is in line with similar results in different distributed context, as the open source development teams that seem to be founded on solo-work into a shared and collaborative environment.

6 PRELIMINARY CONCLUSIONS

Summing up the contribution, we can consider this paper as a first attempt to analyze a well known phenomenon (social networks) from a different perspective. We embraced this challenging path in order to avoid a limitation of the traditional perspectives that consider the network structure as exogenous and stable. Instead, in our perspective, we consider the reciprocal influence between the artefact and the social network structure, with a phase in which the desired artefact may shape the network genesis and a phase in which the emergent network’s structure may drive the artefact design.
These two phases may be iterative along a collaborative project life. Further investigation may uncover relevant patterns and factors of the process, advancing our knowledge of design networks and contributing to new methods and perspectives in social network analysis.

In conclusion, this article is illustrative, rather than confirmatory. It is desirable to continue the study, moving forward to a deeper data analysis in which structural measures of the social network (cohesion, homogeneity, connectedness, centrality) will be conducted. Moreover, the study should also take into consideration a more detailed literature review and the possible overlapping with other research streams, as collective actions or common resources.

Abstract

In the information age, enterprises base or enrich their core business activities with the provision of informative services. For this reason, organizations are becoming increasingly aware of data quality issues, which concern the evaluation of the ability of a data collection to meet users’ needs. Data quality is a multidimensional and subjective issue, since it is defined by a variety of criteria, whose definition and evaluation is strictly dependent on the context and users involved. Thus, when considering data quality, the users’ perspective should always be considered fundamental. Authors in data quality literature agree that providers should adapt, and consequently improve, their service offerings in order to completely satisfy users’ demands. However, we argue that, in service provisioning, providers are subject to restrictions stemming, for instance, from costs and benefits assessments. Therefore, we identify the need for a conciliation of providers’ and users’ quality targets in defining the optimal data quality level of an informative service. The definition of such equilibrium is a complex issue since each type of user accessing the service may define different utilities regarding the provided information. Considering this scenario, the paper presents a utility-based model of the providers’ and customers’ interests developed on the basis of multi-class offerings. The model is exploited to analyze the optimal service offerings that allow the efficient allocation of quality improvements activities for the provider.

Keywords: Data Quality, Efficiency, Service Offerings.

1 INTRODUCTION

Enterprises increasingly focus their business strategy on information management, since an effective use of organizational data can have a considerable impact on business decisions and provide high benefits. Furthermore, information can be often exploited to offer additional and valuable services to external customers. Informative services manipulate raw data and produce information products (Ballou et al. 1998). In order to evaluate the service effectiveness and thus the ability of the provided information to meet both the organizational and users’ (customers) requirements, it is then possible to consider data quality theories. Data quality is a multi-dimensional concept that evaluates the suitability of data to the tasks for which they are required, and thus to the users that access them. Data quality can be assessed by means of different dimensions, whose definition and evaluation are strictly dependent on the context and users involved. For this reason, the users’ perspective has been always considered fundamental in data quality. Consequently, literature contributions have always focused their attention on the definition of methodologies and methods that support providers in the achievements of data quality targets that would completely meet users’ needs. Quality management mainly suggests the adoption of the Zero Defects approach that consists in setting targets to the highest quality values (English 1999). However, if the organization follows a zero defects approach in areas which do not need it, resources may be wasted. Moreover, reaching the highest quality values might lead to quality improvement that the organization may not be able to afford. In fact, it is necessary to consider that
providers have their own requirements in provisioning services and many times the complete satisfaction of users’ requirements is not convenient since costs are greater than benefits. Hence, the Zero-Defects approach to data quality management is often excessive, since it does not consider that the data quality improvement is not a trivial task and in some cases it requires very expensive projects, which are not always feasible for the service providers. Generally, we argue that it would be better to adopt an approach that fixes data quality targets on the basis of a conciliation of providers’ and users’ needs. The definition of this equilibrium is a complex issue since, for each provided information, we can have different utilities depending on the type of user that accesses it. Considering this scenario, the paper presents a utility-based model of the providers’ and customers’ interests developed on the basis of multi-class offerings. The model is exploited to analyze the optimal service offerings that allow the efficient allocation of quality improvements activities for the provider.

The paper is organized as follows. Section 2 reviews the literature on similar contributions. Section 3 presents the main useful concepts for data quality management and shows the model for the definition of the users and providers quality targets. Section 4 presents the model of the provider and users’ utility functions in a data service scenario and discusses the issue of optimal data quality level definition in informative service offerings.

2 RELATED WORK

The identification of service offerings that define the most suitable quality targets that contemporarily satisfy providers and users’ needs is a research issue that can be generally related to the identification of quality level agreements. This is a new open issue in the data quality field, as well as in the broader field of Service Oriented Computing. Here, the Service Level Agreement (SLA) is defined as a binding contract which formally specifies end-user expectations about the solution and tolerances, i.e., it is a collection of service level requirements that have been negotiated and mutually agreed upon by the information providers and the information consumers. In fact, providers define some service levels as a fixed combination of their specific capabilities on a set of quality dimensions that are also considered by the users to define their targets. If providers’ capabilities and users’ needs are not immediately compatible, a negotiation phase is required in order to find the most suitable conciliation between providers’ and users’ quality targets. In this field, there are several languages proposed for the definition and monitoring of the SLA such as WSLA (Keller and Ludwig 2002) or WS-Agreement (Ws-Agreement Framework 2003). WSLA allows providers to define quality dimensions and to describe functions to evaluate them. Furthermore, it provides monitoring of the parameters during operations and invocation of recovery actions when contract violations occur. Similarly, WS-Agreement provides constructs for advertising the capabilities of providers and creating agreements based on creational offers, and for monitoring agreement compliance at runtime. Once the service capabilities description is provided, the selection of the most suitable service is enabled by the definition of the users requirements. The SLA definition starts from provider capabilities and users’ requirements specification and defines all the condition of the service provisioning.

In the data quality field, quality requirements are focused on a set of criteria able to define the suitability of a data set for the process in which it is involved. Data quality is a multi-dimensional concept and the data quality literature provides a thorough classification of data quality dimensions, even if there are discrepancies on the definition of most dimensions due to the contextual nature of quality. The six most important classifications are presented in (Wand and Wang 1996, Wang and Strong 1996, Redman 1996, Jarke et al. 1999, Bovee et al. 2001, Naumann 2002). By analyzing these classifications, it is possible to define a basic set of data quality dimensions including accuracy, completeness, consistency, timeliness, interpretability and, accessibility, which represent the dimensions considered by the majority of the authors (Scannapieco and Catarci 2002). The assessment of these dimensions reveals the ability of a data collection to meet users’ needs.

In the literature, data quality users’ requirements have been mostly used as one of the driver for the identification of the most suitable data source (e.g., Scannapieco et al. 2004). Users’ requirements have been sometimes translated into utility functions. In (Even and Shankaranarayan 2007), utility
functions have been used by supporting multiple assessments of quality, each within a different usage context. Utility functions have been also used to alleviate the problem of data fusion in the presence of inconsistencies, for example in combining different versions of the same data (Motro et al. 2004). As already discussed in the Introduction, in the data quality field, the provider perspective has been scarcely considered. Data quality agreements issue has been only addressed in quality-constrained data provisioning (Missier and Embury 2005). Missier and Embury (2005) propose a framework for the definition of formal agreements between the provider and the customers. Focusing on the completeness dimension, they also provide an algorithm for dealing with constraints on the completeness of a query result with respect to a reference data source.

In our work, the approach can be considered innovative since providers capabilities are not fixed at priori. In fact, we primarily consider the users’ requirements and we assume that the provider capabilities are functions of the current quality level of their IT services and of the costs related to the improvement activities needed to satisfy users requirements.

3 THE SERVICE PROVISION AND DATA QUALITY REQUIREMENTS SPECIFICATION

A business process can be composed and executed by means of IT and physical services. The former are services that are responsible for data manipulation and that aim at generating and providing useful information. The latter are business services that are composed of physical activity that cannot be made automated (e.g. delivery of goods). In this paper we focus on the first type of services and we characterise them by considering functional and non-functional requirements. Since the output provided by IT services is information, the quality of such services can be mainly evaluated by considering data quality dimensions.

In our model, in the data quality assessment phase, we consider the quality dimensions introduced in the previous section and define an aggregate measure of data quality level ($q_c$) by using a weighted average, that is:

$$q_c = \sum_{i=1}^{N} w_i \cdot dq_i$$

(1)

where $w_i$ are the weights that denote the importance of the single dimension $dq_i$ for the user or the provider and $N$ is the total number of the considered criteria. In order to use this model, we make the main assumption to consider the quality dimensions independent of each other.

If the assessment results reveal that the provider sources are characterized by an insufficient data quality level, the adoption of quality improvement techniques should be considered. Improvement methods are distinguishable in data-oriented and process-oriented techniques. The former focus on error detection and correction, whereas the latter aim at identifying and correcting the activity in the process responsible for the error. Therefore, data-oriented techniques are characterized by low investment costs and short term benefits, whereas process-oriented techniques imply a very high investment cost, even though they are likely to provide long-term benefits. Process-oriented techniques are, in general, to prefer, since data-oriented techniques need to be performed periodically to obtain long-term benefits and thus the total cost will be higher than the initial investment of any process-oriented technique.

In the framework proposed in this paper, the providers should evaluate their convenience to improve the data quality level by also considering that low data quality levels raise poor quality costs, mainly due to service failures and consequent repair actions.

A fundamental hurdle is that costs and benefits of attaining a certain data quality level are difficult to estimate ex ante. We consider a distinction between non-quality and quality costs.

- **Non-quality costs:** they are costs associated with poor data quality and, consequently, with all the activities necessary to correct errors and re-execute tasks.
- **Quality costs:** they are associated to the activities and resources necessary in the improvement project.
Improvement interventions may be of variable complexity. They could regard the purchase and implementation of standard software tools (e.g., data cleaning tools), the design and the development of ad-hoc software modules or, in the most complex cases, the re-organization of the whole IT architecture (e.g. for improvement of information availability or security). Therefore, quality costs can include licence costs, hardware costs for the acquisition of new machines and human resources costs for analysis, development or implementation activities.

It is necessary, however, to consider that non-quality costs can be considered as a potential saving, and represent tangible benefits of quality improvement. The benefits of the improvement process are at least equal to the savings from non-quality costs. Additional tangible and intangible benefits can be achieved in higher-performance scenarios. It must be noted that the quality costs depend on the improvement techniques that are implemented and benefits are related to the type of services that are improved through data enhancement.

**Figure 1 - Isolated and interconnected services**

On the basis of the role played by information, it is possible to distinguish different types of IT services. In this paper, we consider a distinction between isolated and interconnected services (see Figure 1):

- **Isolated services**: these are services for which the output data are specially produced for the final user and they are not used in the information system of the organization, which supports the execution of the organization’s business processes.

- **Interconnected Services**: they are services which produce information that is also used in the organization’s daily operational activities.

Systems that provide isolated services can be compared to open loop systems in which the improvements in the quality of output data are totally dedicated to meet the user requirements. In fact, such improvements do not impact on the provider operational processes and benefits from data quality improvements will derive only by the increase of the customer satisfaction. Conversely, systems that provide interconnected services can be compared to closed loop systems in which improvements are likely to influence the organization’s internal business processes and will produce higher benefits for the provider. In fact, improvements of the output data will also impact on the correctness of operational data and thus, on the execution of all the business processes. In this case, improvements decrease the probability that services might fail as well as the poor quality costs.

Real-time data about stock quote rates, for instance, can be provided by either financial brokering institutions or merchant bankers. In the former case, we can label the service as isolated, since brokers simply collect data from different sources in order to satisfy the requirements of their customers. In the latter case, the stock quote provisioning service can be considered interconnected, since financial institutions, besides selling data to customers, are also likely to exploit the same data for their internal activities, e.g., managing customers’ investment portfolios.

Generally, we can introduce a coefficient $\alpha$ to express the degree of interconnection of a service. It defines the impact that a quality improvement intervention undertaken for a service has on the provider operational processes. If $\alpha = 0$, then the service provisioning process is not connected with the organizations business processes, whereas if $\alpha > 0$ the service provisioning process shows an increased degree of interconnection with internal business processes ($0 \leq \alpha \leq 1$).

Furthermore, it is also necessary to clarify that service providers are used to offer services along different quality configurations (i.e., service levels) in order to satisfy different user requirements. As
an example, we can consider the visualization of stock values in a trading activity, a classical financial service for which timeliness is a critical dimension. For the sake of simplicity, let us consider two classes of users: ordinary retail customers and traders. The two classes of users have different requirements on stock information. The ordinary retail users can tolerate a lower quality than the trader, as they usually access the service with a lower frequency. Moreover, errors on stock values have a considerably lower impact, since operations performed by ordinary retail users are usually less risky and involve lower amounts of money. On the other hand, the trader needs accurate and updated information and, therefore, requires high-quality information. The effects of an inaccurate or delayed value can be disastrous, since the trader is often involved in very risky operations involving stocks from a large portfolio of customers. Therefore, banks are likely to provide two different quality profiles for the stock quotes information service. The first profile is characterized by an acceptable value of timeliness while the other one specifies real-time information provisioning and is also associated with a higher cost.

In respect of this example, we consider an information service associated to several classes of users. Users belonging to a class have the same requirements on the quality of the data provided by the service S. In details, our model of service offerings considers a service S and assumes that a user (or customer) \( u \) is assigned to one of the \( K \) user classes \( UC_k \), where \( k = 1, ..., K \). Each class contains users with similar characteristics. The number of users in a given class \( UC_k \) is indicated as \( M_k \). Users belonging to the same class are associated with the same quality requirements for the service S. For each user class \( UC_k \), we define the data quality level \( q_{ck} \) defined in the service offerings \( QC(S) \) for service S. Note that each \( q_{ck} \) is calculated as a weighted average of the requirements specified for the different quality dimensions by using the formula shown in Eq. 1. Hence, the service offering \( QC(S) \) for service S is defined as a set of increasing data quality levels associated to \( K \) classes, that is:

\[
QC(S) = \{q_{c1}, ..., q_{cK}\}.
\]  

From the provider perspective, the aim is to define a service offering \( QC(S) \) that satisfies some optimization criteria. A first criterion can be of defining service offerings on the basis of the fulfillment of the user requirements. Usually, such criteria tend to minimize the specification of subjective quality levels, since service offerings are developed to best fit user requirements. In the next section we introduce a utility model for describing the provider and the customers’ interest, and define a criterion for defining service offerings which jointly considers the interests of both the provider and the customers.

### 4 A MODEL FOR SERVICE OFFERINGS EFFICIENCY ASSESSMENT

In order to define an efficient way for the provider to define service offerings and to decide the quality improvement actions to be performed on data, we first need to introduce a model which defines the provider and the customers’ utility functions in our informative service scenario. The model relies on the definition of utility functions for both the data provider and customers. In our model, we adopt quasi-linear utility functions (Jackson 2003). Quasi-linear utility functions represent an efficient and compact modeling tool for negotiations and bargaining problems in which it is easy to isolate, for every participant, value and payment terms. We argue that the case of data quality and, specifically, information service offerings falls within such category. Sources of benefits and costs related to data service offerings for providers and customers, in fact, have already been analyzed by a large body of academic literature (Batini et al. 2006, Eppler and Helfert 2004, English 1999, Loshin 2001).

Quasi-linear utility functions are such that the utility value for an agent on a given contract \( X \) is defined by two terms, i.e., a value and a payment term. The value term determines the value obtained by an agent from the contract, whereas the payment term refers to the amount of money that an agent is going to receive or pay for the contract. Value and payment terms can be either positive or negative.
For the provider, the payment term is positive and value term is negative, because the provider receives money from customers, but, at the same time, it sustains a cost for providing the negotiated contract, therefore losing utility. Conversely, the payment term is negative for customers, whereas the value term is positive, because the customers pay money for a contract and, at the same time, have a positive evaluation of the contract negotiated with the provider.

We first introduce the definition of quasi-linear utility functions for data providers and customers in the multi-class data service scenario introduced in the previous section. Then, we show how the utility model can be exploited to provide a criterion for the provider to define the optimal service offerings and, consequently, clarify which quality improvements need to be performed. The optimal service offering obtained through our model is then compared against the findings of the zero-defect approach for data quality management, which, generally, implies the complete fulfillment of the customers’ quality requirements.

Generally, a quasi-linear utility function defined for an agent $P$ behaving in a service provider’s perspective is defined as:

$$U_p = \text{Price}(X) - \text{Cost}(X)$$  \hspace{1cm} (3)

where $\text{Price}(X)$ is the price, that is, the amount of money obtained by $P$ for providing the generic contract $X$ (payment term), whereas $\text{Cost}(X)$ represents the cost sustained by $P$ to provide the contract $X$ (negative value term).

Similarly, for the generic agent $C$ behaving as a service customer, the utility of a contract $U_C(X)$ assumes the following form:

$$U_C = \text{Value}(X) - \text{Price}(X)$$  \hspace{1cm} (4)

where $\text{Value}(X)$ is the value generated by the contract $X$ to the customer, whereas $\text{Price}(X)$ is, as in $U_p(X)$, the price that the customer has to pay for receiving the contract $X$.

According to the model presented in Section 3, in our multi-class data service scenario, the contract $X$ assumes the form of the service offering $QC$:

$$X = QC = (qc_1, \ldots, qc_K)$$  \hspace{1cm} (5)

where $qc_k$ is the data quality level provided to customers in class $k$, with $k = 1, \ldots, K$.

In the following, we will consider two agents, i.e. the provider $P$, providing the service $S$, and the collection of customers $C$ of service $S$.

The total amount of money $\text{Price}(QC)$ received by the data provider $P$ for the provisioning of a given service offering $QC$ is given by the sum of the money received from customers in each service class defined in the service offering, that is:

$$P(QC) = \sum_{k=1}^{K} p(qc_k) \cdot M_k ,$$  \hspace{1cm} (6)

where $p(qc_k)$ is the price of data provided for users in class $k$, while $M_k$ is the number of users that belong to class $k$.

The term $\text{Cost}(QC)$ represents the cost sustained by the provider to provide a service offerings $QC$, and can be expressed as:

$$\text{Cost}(QC) = C_p(qc_K) - B_p(qc_K)$$  \hspace{1cm} (7)

where $C_p(qc_K)$ is the cost actually sustained by the provider to provide the maximum quality level $qc_K$ to its customers, whereas $B_p(qc_K)$ is a quantification of the benefits introduced in the provider’s internal business processes by attaining a maximum data quality level $qc_K$. $C_p(qc_K)$, is a function of only the maximum data quality level $qc_K$ in $QC(S)$ since we argue that, once the provider commits to
provide $q_{c_k}$ to its customers, the marginal cost of providing the data service with a lower quality level $q_{c_k}$, with $1 < k < K-1$, is negligible. Similarly, we also argue that it is rational for the provider to use, in its internal business processes, data at the maximum quality level $q_{c_K}$. Therefore, $B_p(q_{c_K})$ is a function of only the maximum data quality level $q_{c_k}$.

The value term $Value(QC)$ in $U_c(QC)$ can be expressed as the sum of values $v_i(q_{c_k})$ generated for each class of customers $k$. Therefore:

$$Value(X) = Value(QC) = \sum_{k=1}^{K} v_k(q_{c_k})$$  \hspace{1cm} (8)

Our objective is to study the optimal service offering $QC^*=(q_{c_1}^*,...,q_{c_K}^*)$ that maximises the sum of the utility for the provider and the service customers. Moreover, we demonstrate that such $QC^*$ differs from the optimal $QC_z$ imposed by the zero-defect approach to data quality management, which implies the service offering to fully satisfy the requirements of the customers. More specifically, in our model, we argue that the full satisfaction of customers’ requirements occurs when a service offering maximises the value $v_i(q_{c_k})$ for each class of customers. Therefore, in the zero-defect approach, the optimal service offering $QC_z$ can be defined as follows:

$$QC_z = (q_{c_1}^z,...,q_{c_K}^z)$$, where $q_{c_i}^z = \text{arg max}_{q_{c_i}} v_i(q_{c_i})$ for $i=1,...,K$.

The sum of the utility of customers and suppliers can be expressed:

$$U_p(QC) + U_c(QC) = Value(QC) - Cost(QC) = \sum_{k=1}^{K} v_k(q_{c_k}) - C_p(q_{c_k}) + B_p(q_{c_K})$$ \hspace{1cm} (9)

Since $U_p + U_c$, as a function of $QC$, is separable in the variables $q_{c_k}$, with $k=1,...,K$, the conditions under which $U_p(QC) + U_c(QC)$ is maximised can be expressed as:

$$\frac{\partial(U_p + U_c)}{\partial q_{c_k}} \bigg|_{k=1...K} = 0$$  \hspace{1cm} (10)

Since both $C_p$ and $B_p$ are a function of only $q_{c_K}$, for the first $K-1$ equations implied by Eq. 10, we can write the following:

$$\frac{\partial(U_p + U_c)}{\partial q_{c_k}} \bigg|_{k=1...K-1} = \frac{dv_k(q_{c_k})}{dq_{c_k}} = 0$$  \hspace{1cm} (11)

While the $K$th equation becomes:

$$\frac{\partial(U_p + U_c)}{\partial q_{c_k}} \bigg|_{k=K} = \frac{dv_k(q_{c_K})}{dq_{c_K}} - \frac{dC_p(q_{c_K})}{dq_{c_K}} + \frac{dB_p(q_{c_K})}{dq_{c_K}} = 0.$$  \hspace{1cm} (12)

In order to go into detail in the analysis of the optimal service offering $QC^*$, we need to characterise the functions $v_i(q_{c_k})$, $C_p(q_{c_K})$, and $B_p(q_{c_K})$ in our information service offering settings.

Considering past contributions (Batini et al. 2008, Eppler and Helfert 2004, English 1999, Loshin 2001) on data quality costs, it is possible to consider the following form of costs $C_p(q_{c_K})$ sustained by a provider:

$$C_p(q_{c_K}) = F + P \cdot q_{c_K} + I \cdot \exp(q_{c_K})$$  \hspace{1cm} (13)
where the $F$, $P$, and $I$ are coefficients that reflect the complexity of a generic data quality project. The coefficient $F$ is related to the fixed costs of the data quality projects required for achieving $qc_K$, such as licence costs or hardware costs for the software and IT infrastructure required by the project. The coefficient $P$ relates to the project development part, in which we have variable costs associated to the analysis and implementation activities that are evaluated by considering their duration and involved human resources. The coefficient $I$ is related to the improvement of some data quality dimensions (e.g., availability, accessibility, security). Such improvements usually require considerable changes in the whole IT architecture and therefore the costs associated to them grows exponentially with the level of data quality $qc_K$ that needs to be achieved.

We make the assumption that the benefits obtained by the service provider to attain a maximum data quality level $qc_K$ are a fraction $\alpha$, with $0 < \alpha < 1$ of the sustained costs. Such a fraction $\alpha$ is determined by the degree of interconnection of the provider’s internal business processes defined in Section 3. Specifically, the higher the degree of interconnection, the higher the benefits that the provider can obtain on its internal business processes. Therefore:

$$B_p(qc_K) = \alpha \cdot C_p(qc_K) = \alpha F + \alpha P \cdot qc_K + \alpha I \cdot \exp(qc_K)$$

We propose two different types of value functions $v_k = v_k(qc_k)$ for the set of customers in the generic $k$-th class.

**Type 1: Gaussian customers value functions.**

In this case (see Figure 2), the optimal data quality value $qc_k^z$ for customers in the $k$th class under the zero-defect principle is $qc_k^z = \mu_k$, that is, the one that maximises the customers’ value.

$$v_k(qc_k) = \frac{1}{\sqrt{2\pi} \sigma_k} e^{\frac{(qc_k - \mu_k)^2}{\sigma_k^2}}$$

**Figure 2 - Gaussian utility function for customers in class UC_k**

**Type 2: Monotonic increasing customers value functions.**

The second type of value functions considers monotonic increasing value that saturates at a certain value $qc^z$ (specifically, we use a sigmoid function to express this second type of value function, see Figure 3). Such level $qc$ is the one identified by the zero-defect approach as the optimal data quality level for customers in the $k$-th class, since it maximises the customers’ value.

$$v_k(qc_k) = \frac{K}{1 + e^{-qc_k}} - 0.5$$

**Figure 3 - Increasing Monotonic utility function for customers in class UC_k**
The Gaussian increasing value function is suitable to model cases in which customers cannot accept higher or lower quality values than the requested ones. Considering the example discussed in Section 3, normal customers can accept out-of-date stock values since they do not have to use these data in critical processes, but they cannot accept higher quality level, since this would require an additional cost that they should pay for information that they do not actually need. The monotonic increasing value function is suitable to model cases in which customer define their acceptable quality level as the minimum acceptable value. For example, traders obviously cannot accept out-of-date stock values and, therefore, they are likely to fix a minimum quality requirement. However, traders are also likely to be equally satisfied with a quality level that exceeds their minimum requirements, since they may need to deal with unpredictable and critical situations which could be benefit from higher quality of data.

In respect of Eq. 11, the optimal data quality level in our model \( q_{c_k}^* \), with \( k=1,\ldots,K-1 \), coincides with the optimal data quality model identified by the zero defect approach, that is, \( q_{c_k}^* = q_{c_k}^{\ast} \).

In fact, for both Gaussian and monotonic increasing value functions, the following condition holds:

\[
q_{c_k}^* = \left\{ q_{c_k} : \frac{d\nu_k(q_{c_k})}{dq_{c_k}} = 0 \right\} = q_{c_k}^{\ast} \text{ for } k=1,\ldots,K-1.
\]

In other words, both our model and the zero-defect approach to data quality management imply that customers who do not ask for the maximum level of data quality should be provided with a level of data quality that fully satisfy their requirements, that is, that maximises their value.

For the maximum level of quality provided to customers, the findings of our model differ from the corresponding findings obtained with the zero-defect approach, i.e. \( q_{c_K}^* \neq q_{c_K}^{\ast} \).

In our model, the data quality level \( q_{c_K} \) is determined by solving Eq. 12, which can be rewritten as:

\[
\frac{\partial\nu(q_{c_K})}{\partial q_{c_K}} - P(1-\alpha) - I \exp(q_{c_K}) + \alpha \cdot \exp(q_{c_K}) = 0;
\]

which then leads to the following equation:

\[
\frac{\partial\nu(q_{c_K})}{\partial q_{c_K}} = P(1-\alpha) + I \cdot (1-\alpha) \cdot \exp(q_{c_K}).
\]

A first consideration that must be made is that the maximum level of data quality \( q_{c_K} \) does not depend on the fixed costs \( F \) of the data quality project. This is consistent with the fact that, by definition, fixed costs must be sustained for any data quality project, the maximum level of attained quality \( q_{c_K} \) notwithstanding.

Eq. 16 can be solved graphically in two cases C1 and C2 that consider, respectively, Gaussian and monotonic increasing functions for modelling the customers’ value. A graphical representation of the solutions of Eq. 16 in case C1 and C2 is given in Figure 4 and Figure 5, respectively. Please note that in the graphical solution, the function \( f(x) \) represents the derivative of the customers’ utility function on \( v(q_{c_K}) \) (i.e. left argument in Eq. 16).

The graphical representation of the solution to Eq. 16 in case C1 is reported in Figure 4.
The first conclusion that can be drawn is that, generally, $q_{c_k}^* < q_{c_k}^\circ$, that is, our model implies a maximum data quality level that is lower than the optimal level predicted adopting the zero-defect approach. This is consistent with the fact that, while the zero-defect approach only considers the maximisation of customer’s requirements, our model considers a trade-off between the costs sustained by the provider to provide a certain maximum data quality level (and the benefits induced by these) and the value produced for the customers requiring maximum data quality.

Second, the maximum data quality level $q_{c_k}^*$ decreases as the costs (both $P$ and $I$) for providing a certain data quality level increase (see $q_{c_k}^*$ low costs and $q_{c_k}^*$ high costs in Figure 4). Moreover, $q_{c_k}^*$ decreases as $\alpha$ decreases, since both terms $P(1-\alpha)$ and $I(1-\alpha)$ increase. A lower value of $\alpha$ implies a lower degree of interconnection, as defined in Section 3, of the provider’s business processes. In our modelling of the informative service provisioning scenario, a lower degree of interconnection implies a decrease of the benefits induced on internal business processes by the attainment of a certain level of data quality. Therefore, our model can be used to identify which is the impact of the degree of interconnection on the decrease of the maximum data quality level $q_{c_k}^*$ that can be provided to customers.

Third, it has to be noticed that the more spike shaped the Gaussian function representing the value created for customers, the closer the quality level $q_{c_k}^*$ to the zero-defect approach level $q_{c_k}^\circ$ (see $q_{c_k}^*$ spike and $q_{c_k}^*$ low costs in Figure 4). This can be interpreted by stressing that when customers’ interested are clearly stated, i.e., the function representing the value created for customers in the Kth class is spiked around $\mu_K$, then it will be easier for the provider to identify the optimal trade-off between the costs sustained for providing quality of data and the value generated for customers (and this will be closer to the optimal satisfaction of customers’ requirements hypothesized by the zero defect approach to data quality management).

Finally, in case C1, it has to be noticed that when costs are too high, Eq. 16 cannot be solved, i.e., there is no intersection between the two functions (dotted and straight lines in Figure 4, respectively)
represented in the Figure 4. In other words, it is impossible for the provider to find the trade-off between the cost of quality of data and the value generated for customers.

\[
g(x) = P \cdot (1 - \alpha) + I \cdot (1 - \alpha) \exp(qc_K)
\]

Figure 5 - Determining the optimal data quality level (Case C2, Monotonic increasing customer utility)

The graphical representation of Eq. 16 in case C2 is shown in Figure 5. The major findings already discussed for case C1 hold also in this case. More in detail, the maximum data quality level \( qc_K^* \) predicted by our model will always be lower than the value \( qc_K^z \) implied by the zero-defect approach and \( qc_K^* \) decreases as (i) the costs sustained for providing data with a certain level of quality increases and (ii) the provider’s business process are less interconnected (i.e., \( \alpha \) decreases).

Similarly to what happens in C1, a solution to Eq. 16 may not be found if costs are very high also in C2. Moreover, it has also to be noticed that the value \( qc_K^* \) drastically decreases as the cost terms \( P(1-a) \) and \( I(1-a) \) increase.

5 CONCLUDING REMARKS AND FUTURE WORK

The paper has presented a novel approach for defining optimal service offerings for information services. In particular, our model defines the optimal service offering as the one that maximises the sum of the service provider and customers’ utility functions. The optimal service offering obtained with our model differs by the one defined by the zero-defect approach in the definition of the maximum quality level. In particular, our model argues for lower maximum quality levels, in order to keep into consideration the trade-off between the costs sustained by the provider for improving the quality of data, the value created by the service offering for customers, and the benefits obtained by the provider on its internal business processes from the improvement in the quality of data.

The limitations of our model imply the need for future work on the model development. First, the model relies on the ability of the service provider to estimate the utility functions of the classes of users for the provided service. Understanding preferences of users requires the development of user profiling and clustering techniques, which should be further investigated. Second, our model defines
optimality of service offerings in terms of the maximisation of the sum of the provider and customers utilities. Optimality may be defined according to other metrics involving utilities of the involved actors. In particular, we want to investigate the notion of equilibrium of service offerings, i.e., studying optimal service offerings that define an equilibrium among the service provider and the customer in the utility space.

Abstract

Most leading organizations, in all sectors of industry, commerce and government are dependent upon ERP for their organizational survival. Yet despite the importance of the decision to adopt ERP and its impact on the entire firm’s performance the IT literature has been in the large part silent on the nature of the ERP investment decision. This study is the first of its kind to determine the preference structure of senior managers around the organizational benefits and risks of adopting ERP. We present the results which provide interesting insights into how managers’ perceive the benefit and risk factors salient to the organization’s adoption decision. In line with prior research we found that improved productivity, and information and planning are important drivers of the ERP adoption decision. Moreover our findings reveal that the benefits of ERP are weighted almost twice as important as the risks when making an ERP investment decision. However when it comes to risk, interestingly managers consider issues such as top management commitment and vendor support as more important than financial risks.

Keywords: ERP, Adoption, Decision-making, Discrete Choice Analysis.
1 INTRODUCTION

Studies in the management and IT literatures that have focused on the ERP adoption decision are virtually silent on how managers make their ERP investment decisions, and the strategy making processes that support such decisions. This is despite the fact that ERP investments are generally considered to be a high cost and high risk investment for most firms. Over the past decade, companies have spent over US$300 billion dollars on ERP investments (Carlino and Nelson 2000; Shepherd and Klein 2006), and the failure rate outweighs the success rate (Hong and Kim 2002).

According to a review of published ERP research between 2001-2005, 47 percent of the existing research has focused on the implementation phase (Esteves and Bohorquez, 2007). The critical acquisition phase (or adoption phase) was the second lowest investigated—the lowest being the retirement phase of the ERP lifecycle. Esteves and Bohorquez logically argue that the limited number of studies attempting to investigate how adoption decisions are made in an ERP context is a real problem that needs to be addressed. They agree that the adoption stage is critical because as the stage preceding the implementation phase, it presents the opportunity for both researchers and practitioners to examine the dimensions and implications (benefits, risks, challenges, costs) of buying and implementing ERP software, prior to the commitment of formidable amounts of money, time and resources.

In terms of the strategic decision making process, scholarly effort to measure the process aspects of IT strategy frequently relates to the implementation of strategy or the deployment of resources and capabilities. This orientation tends to emphasize the “doing” rather than the “deciding” aspect of processes. But as Helfat et al. (2008) demonstrate, the processes for making decisions prior to taking action also matter, at least as much as deployment. This point is central to our research approach.

If strategies are made by patterns of decision making as Mintzberg (1973; 1985) suggests then studying the decisions made by senior managers would help to understanding the strategic processes of a firm. This is an idea supported by the strategic process literature which is focused on how firm capabilities can lead to improved organizational performance and competitive advantage. Strategic decisions are viewed as fundamental to firm performance because they can affect the future of the firm through actions taken, resources committed and precedents set (Mintzberg et al. 1976). Priem and Rosenstein (2000) add that “understanding the judgments of strategic leaders is essential to determining (1) how mental processes are manifest in the strategies they develop, and (2) how these processes and strategies affect firm performance” (p2).

Research in strategic management indicates that managers use intuition for key decisions, such as large capital investments (Dane and Pratt 2007), relying on what Hammond (Hammond 1974) describes as the cognitive process of last resort—human judgment. In complex real-world situations, the decision maker often has to rely on something other than facts and a full information when making decisions and resolving problems. Moreover, it is assumed that as the leader of the firm, it is the senior manager’s role to make the right judgment.

When it comes to ERP investments, the mixed results reported in industry research highlights the far reaching impact of poor strategic decision making processes (Shepherd and Klein 2006). For instance, in a survey of 232 managers conducted by Robbins-Gioia (2002), 51% of respondents viewed their ERP implementation as unsuccessful. One of the major problems identified was that organizations lacked a rigorous ERP evaluation and procurement process, which in turn, made it difficult to formulate effective investment decisions and avoid a failed ERP investment (Shang and Seddon 2002).

The purpose of this research is to open up the “black box” of managerial decision-making around ERP by measuring the relative importance of the factors that contribute to the decision to invest in an ERP system. To achieve this aim, we will utilize a novel method that will expose the organizational attributes considered to be most important and least important to the investment decision. We will use a utility based approach based on maximum difference scaling or best-worst experimentation. This
method has been successfully applied to many different contexts in order to identify the efficacy of managerial decision making (Buckley et al. 2007), and to provide insights into the preference structures for products and services (Coltman et al. 2007). To address the research issues and provide the focus for this paper we pose two questions:

1. What is the relative importance of the factors that influence the decision to adopt ERP?

2. How do key decision makers’ trade-off between the perceived benefits and risks when making an ERP investment decision?

This research draws on two streams of IT literature to determine the factors considered to be most relevant to the ERP adoption decision; (1) the research on the impact of IT, and (2) the specific literature on the organizational impact of ERP adoption and implementation. Whilst a review of the literature provides guidance as to those factors that are likely to drive an ERP adoption decision, there is little evidence regarding the relative importance of these factors to decision makers. This observation was also made by Keil and Tiwana (2006), who suggest that caution should be taken when attempting to hypothesize \textit{apriori} about the factors that have the greatest influence on the ERP investment decision, or the relative weighting that should be given to such factors by a manager charged with responsibility for making ERP adoption decisions.

The lack of past research in this area suggests that this issue may not be a theoretical problem, but rather, an empirical question that should be revealed through appropriate investigation. Furthermore, the IT and ERP impact literature acknowledges that ERP can both positively and negatively impact on organization performance. Yet, surprisingly, the literature has also not considered how both benefit and risk factors influence the decision to adopt ERP. In this study we examine how senior managers value the positive and negative aspects of an ERP investment decision.

2 THEORETICAL BACKGROUND

Studies in managerial cognition demonstrate that executives apply their own mental models to simplify the complex strategic problems they often need to solve (Porac et al. 1989). They use these models as templates to explain and interpret information relevant to decisions they need to make (March and Simon 1958; Walsh 1995). In other words, it is evident in the decision making process that decision outcomes are affected by the way a decision problem is framed. The presentation of a problem or how it is perceived will affect the choices made by the decision maker. This has a dramatic implication for executives, because how an issue is structured can directly impact the investment outcome. Whilst this highlights that managers may be biased in their decision making, using their own judgment to resolve a decision problem, it does not explain the process by which managers filter information in the decision-making process.

\textit{Cognitive categorization theory} argues that executives, during the awareness and comprehension (learning) stages of decision-making, will group information into categories in order to deal with the abundance of information available and to help them communicate with others about ambiguous strategic issues (Dutton and Jackson, 1987). Executives will then form utility preferences that ultimately form the basis of their strategic choices, in this case the choice to adopt an ERP system.

The filtering of information, which is part of the perceptual process, means that executives can have different perceptions about a problem and form different mental models around a particular decision. Starbuck and Milliken (1988) have identified two types of filtering that may occur: noticing and sense-making. As Tyler and Steensma (1998) suggest these perceptual differences occur because managers \textit{notice} different stimuli and attribute differing meanings to that information, in turn, this will lead to executive’s having different mental models around the decision to adopt enterprise systems.

The extant strategic management literature also suggests that threats and opportunities are relevant categories that are often used in strategic planning and environmental scanning activities (Christensen
et.al, 1982). Studies in the strategic decision making field have found that the categories of opportunity and threat are relevant and consequential for decision processes (Mintzberg et al. 1976). The literature on managerial decision making identifies opportunities as a “positive situation in which gain is likely” (Dutton and Jackson 1987). Alternatively, threats are seen as “a negative situation in which loss is likely” (Dutton and Jackson, 1987, p80). Following the work of Tyler and Steensma (1998) we can derive that the organizational benefits achievable through ERP adoption present as opportunities and the potential adoption risks are categorized as threats.

2.1 Benefits and Risks to ERP Adoption.

In an overview of the literature on the organizational benefits of IT, Mirani and Lederer (1998) begin to operationalize and capture the distinctions between benefits. They make an important point regarding the benefits of IT in organizations, which is that any instrument applied to capture organizational level benefits of IT must be tailored to the project being assessed. This fits with Pettigrew’s (2003) assertion that strategy research needs to address both the content and context of the phenomena under study.

The framework used for this study to assess the organizational benefits of ERP adoption is derived from the extant literature (Weill and Olson 1989; Sethi and Carraher 1993; Shang and Seddon 2002). The following dimensions, as presented in Table 1, are deemed as important antecedents to the ERP adoption decision.

Table 1. Key organizational benefit factors

In light of the problems organizations have had with ERP initiatives, it would seem reasonable to assume that risk factors would generate significant research attention. However, the risks around enterprise system investment are not well developed in the literature with most of the scholarly attention being directed towards the benefits. Esteves and Bohorquez (2007) concur and state that most of the studies that do focus on risk are case-based, exploratory studies and lack a strong theoretical basis.

The risk dimensions used in this study represent a synthesis of the major risk factors from the IT and ERP impact literature. This also includes work that has focused on critical success factors, because they are dimensions that if ignored can be detrimental to the success of the investment. These dimensions, along with the associated research are presented in Table 2.

Whilst prior research outlines the importance of both benefit and risks in terms of their impact on an organization there is a lack of research that considers exactly how these factors interact to influence the decision to adopt an ERP system. For example no research could be found to determine whether
cost is more important to a manager deciding to invest in ERP than vendor support or whether
productivity and operations is more important to a manager deciding to invest in ERP than
management commitment.

3 METHODOLOGY

An effective method for evaluating the issues impacting on the adoption of a new information system
(such as those related to an ERP investment decision) is to model preferences as a response to
experimentally designed decision profiles. This approach, commonly known as probabilistic discrete
choice analysis (DCA), has been used to model choice preferences of decision makers in a variety of
organizational areas spanning marketing, operations management, transportation and economics (e.g.,
Verma et al. 2006).

The statistical model underpinning DCA draws on Thurstone’s (1927) original propositions in
Random Utility Theory to provide a well-tested theory of human decision making that has been
generalized by McFadden (1974). This theory allows scholars to conceptualize individual choice as a
process of decision rules (Louviere et al. 2000). When selecting any product, service, or combination
of both, a customer will consciously or unconsciously compare alternatives and make a decision that
involves tradeoffs of the components of those choices. The result of this process is a choice outcome
that can be decomposed based on the options available within some underlying experimental design.

3.1 Best-worst Scaling

There are a number of different DCA methods that allow a researcher to elicit stated preferences that
can be used as a basis of understanding and predicting actual behavior in the marketplace. One
relatively simple method particularly useful in narrowing down and getting a quick snapshot of
preferences is best-worst scaling. The formal statistical proofs and the measurement properties for
best-worst scaling can be found in Marley and Louviere (2005). Fundamentally, best-worst scaling is
an ordering task that requires respondents to make a selection from a group of items and choose the
‘best’ (most preferred) and ‘worst’ (least preferred) items in a series of blocks of N>2 items. The items
could be attributes of a product, factors influencing a decision, or bundles of services and products.
The approach is particularly effective in creating a preference ordering for the items when the number
of items is large, as individuals are better able to determine which 2 of group of items are ‘best’ and
‘worst’ than they are the specific ordering of 1, 2, …, 12, 13. Best-worst scaling has the added benefit
that it is quick and simple to execute, provides results that are empirically consistent with more complex ordering tasks and theoretically in line with the precepts of random utility theory.

The cognitive process undertaken in the selection of the best-worst or least-most important items is statistically equivalent to:

- Identifying every possible pair of items available;
- Calculating the difference in utility between the two items in every pair; and
- Choosing the pair that maximizes the difference in utility between them.

Thus, the pair of items chosen maximizes the difference in the marginal utilities on offer between each of the various items in each block of items presented to the decision maker. Empirically, the distance between items is modeled as a difference where the relative ordering of the items is proportional to the number of times it is mentioned best less the number of times it is mentioned worst (Szeinbach et al. 1999).

In this study, we use best-worst scaling to determine the relative importance of the factors influencing the ERP adoption decision. This allows us to reduce a list of factors associated with the ERP adoption decision down to a manageable number of important components that can be scrutinized in more detail. In particular, we can use the resulting scale to make direct comparisons based on the preference for one factor versus any other factor in the original list.

### 3.2 Operational measures and survey construction

Preliminary research captured a wide range of factors that are important to the decision to adopt ERP. The factors selected in our study were based on an extensive review of the academic literature and two rounds of qualitative fieldwork. The literature review resulted in the identification of 10 factors that influence the ERP investment decision (see Tables 1 and 2). This list was then validated with a sample of IT managers using semi-structured interviews based on the laddered technique (see Reynolds and Gutman, 1988). This qualitative technique used means-end theory and probing to reveal a salient list of factors that either positively or negatively influence the ERP investment decision. The findings of these interviews helped us to recognize that business growth was an omitted driver of ERP investment, and that the cost factor needed to be separated to recognize the impact of actual versus opportunity costs, where the actual costs were further dissected to reflect differences between the initial investment and ongoing running costs. This increased our original list to 13 (see Appendix 1). While we acknowledge that this list is not exhaustive, we do believe the rigour of the above process does ensure that the list is representative.

As a final stage, and in line with the recommendations of Rossiter (2002), a second round of interviews was conducted with a sample of academic experts to validate the definitions and classifications of the 13 factors. The goal of this second qualitative phase was to ensure that each factor was concrete-singular. That is, we wanted to make sure that each factor had a common meaning across the respondent group. To do this, each expert provided qualitative feedback on the focus and purpose of the factor definitions. The construct definitions and labels were subsequently revised until all experts agreed on the definitions and the classification of the factor as either positively or negatively influencing the ERP investment decision.

Respondents were required to examine 13 sets of four factors. Within each set they were asked to indicate which factor they considered to be the most important, the next most important or the least important when investing in ERP (see Table 3). A balanced and incomplete block design was used to determine which factors appeared in which set, and to ensure that each factor appeared an equal number of times and at least once with all other factors (Street and Burgess 2004). The experimental designs that support this analysis also mean that we can obtain more data from each respondent. This increases the effective sample size, and allows us to obtain reliable estimates of demand preferences with smaller samples. This is a key advantage of DCA methods that is derived from assumptions regarding the independence of individual choices and the distribution and variance of measurement errors (for a more detailed explanation, see Louviere et al. 2000).
Which factor matters
MOST?

Set of factors for you to consider…

Which factor matters
LEAST?

- Low maintenance cost
- Improved IT infrastructure
- Adequate human resources
- Better compliance

Table 3. Example best-worst question.

4 ANALYSIS AND RESULTS

Fifty-seven middle-to-senior managers completed the best-worst experiment. The distribution of respondents by industry and occupation is shown in Table 4. In all cases the respondents were key decision makers that were involved in the evaluation of an ERP investment. Two industries dominated our sample, manufacturing and services, with the respondent roles including directors (CEO, GM) and IT executives (CIO, CTO and IS managers).

Table 5. Ranking of ERP decision factors

The best and worst frequency score were calculated for each of the 13 attributes according to the number of times the attribute was selected by respondents. The simple rank ordering process creates individual-level scales for each attribute that are easily comparable across the entire sample (see Table 5). The “best” column illustrates the frequency that the particular attribute was ranked “best” or matters “most” to respondents from the group of factors. For example, the top-scoring attribute was

Proceedings ECIS 2009
productivity and operations (selected 155 times), followed by information and planning quality (selected 106 times) through to opportunity cost (selected only 19 times).

The “worst” column shows the frequency with which respondents selected an attribute as the “least” important feature. To determine the rank ordering for the factors we created a best-worst ratio scale. This scale provides a relative rank for each factor compared to every other factor. To develop the ratio scale of “best” we calculated the square root (SQRT) of the weighted best/worst based on Luce and Suppes (1965) ranking theorem and the mathematical proofs provided by Marley and Louviere (2005).

The interpretation of Figure 1 requires some discussion because the scores are on a relative scale. This means that information and planning (2.23) is two times more important than competitive advantage (0.97) and four times more important than opportunity cost (0.57). Likewise, information and planning (1.95) is more than twice as important as human resources (0.80), compliance (0.79) and acquisition cost (0.74). In general, we see that ERP benefits outweighed the risks when it comes to making an ERP investment, with four of the top five ranked factors drawn from the list of potential investment benefits. Another effective way to evaluate how key decision makers trade-off between the perceived benefits and risks when making an ERP investment decision, is to compare the average B-W ratio score for the two groups of factors. Using the classifications shown in Appendix 1, we see that the benefit factors had an average B-W ratio score of 1.35 compared to just 0.80 for the risk factors. Stated simply, this finding reveals that benefits of ERP are weighted more than one and a half times more important as the risks when making an ERP investment decision.

Figure 1. Plot of B-W Ratio Scale

5 DISCUSSION

The results of this study highlight some interesting findings. Our study supports prior research on the impact of IT in the organization which suggests productivity and operational improvements remain important to organizations investing in ERP technologies. Numerous studies on IT impact and adoption report that operational and productivity improvements are a key driver of ERP adoption decisions (Mirani and Lederer 1998; Tallon et al. 2000; Shang and Seddon 2002; Gattiker and Goodhue 2004). Based on the theory of production, ERP adds value by increasing output whilst reducing costs, through the automation of production processes (Shang and Seddon 2002). For example, several previous studies have found that organisations that have invested in ERP lowered
inventories, shortened delivery cycles and had shorter financial closing cycles, which lead to an overall reduction in costs (Beard and Sumner 2004). In fact, productivity and operational improvements have long been considered as a central source of IT value.

We also report that improved information and planning has a positive influence on ERP adoption, given its ranking as the second most important factor. Access to accurate and timely information is a major source of value stemming from the adoption of ERP. The improvement of coordination amongst functional areas is central in supporting organisational processes and decision making (Sethi and Cárriher 1993; Tallon et al. 2000). The reporting functions of ERP enable faster retrieval of information formatted in a concise manner, thus allowing more control over organisational performance. This means that ERP is ideally positioned to provide decision and planning benefits through the use of centralised databases with built in analysis and business intelligence tools (Shang and Seddon, 2002).

Perhaps surprisingly, financial risks (acquisition cost, maintenance cost and opportunity cost), whilst being dominant factors in the literature around technology adoption and implementation, make up three of the four least important factors to the ERP adoption decision. When considered against the numerous other decision factors, cost based risks appear less important than prior research has led us to believe. For example, it has been observed that organisations cited such risks as a major deciding factor in their ERP purchase decision (Chau 1995; Gupta 2000; Keil and Tiwana 2006).

It is also interesting to note that the first risk factor deemed most important is management commitment, not financial risk. This finding could partly be attributed to the industry press around large ERP failures and past business experience. These reports have made managers increasingly aware of performance around ERP initiatives. We found that having the commitment of management was seen as almost two times more important than, gaining competitive advantage and was on par with creating business growth and information and planning improvements. Without commitment from managers to support strategic IT projects; in terms of resources, including buy-in from the business; the prospect of an ERP project is much less certain. In terms of the strategic management literature, the deterministic perspective suggests that managers are the key drivers of successful strategic initiatives.

Furthermore, the emphasis on benefits vis-à-vis risks in the ERP evaluation process could also provide valuable insight into why so many ERP investments fail. Drawing on the work of Kahneman and Tversky (1972), the findings of this study suggest that managers may be over optimistic about the performance and productivity rewards that may flow from an ERP investment, and subsequently marginalising or even ignoring the inherent risks. Interestingly, this would make ERP consistent with other past emergent technologies, where history has consistently demonstrated that even experts suffer from optimism bias when espousing the future benefits of new technologies (Avison and Nettler 1976).

5.1 Limitations and Future work

Much of our understanding of ERP has been shaped by interviews, case studies and industry surveys (Besson and Rowe 2001; Shang and Seddon 2002; Beard and Sumner 2004; Gargeya and Brady 2005). The few quantitative studies undertaken have essentially focused on single cases or limited sets of adoption antecedents (Hitt et al. 2002; Keil and Tiwana 2006). Whilst prior research and industry evidence has been able to tell us which factors are important, it has not determined the order of importance of these factors to the ERP adoption decision, or the relative importance of benefits vis-à-vis risks. This kind of information would surely be invaluable not only for academics studying enterprise system adoption, and for practitioners trying to make effective investment decisions, but also for ERP vendors trying to develop products that better match the preferences of their customers.

This research is the first to consider the relative importance of the organizational impact factors on the ERP adoption decision of senior managers. Moreover, the study has combined both benefit and risk factors to obtain a more realistic view of how senior managers evaluate the factors that influence an
ERP investment decision. By applying the best-worst method, we add to a growing body of research that suggests that such methods are less cognitively demanding and more accurate in their estimation of preference. Furthermore, the method applied in this study overcomes the inherent problems of scale bias and other scale issues (such as how to interpret individual ratings on a traditional scale). Future work can extend on this study by examining the impact of external factors on the preference structure and ERP adoption choice, or by replicating this research in different contexts and with different decision making factors.

TOWARDS UNFOLDING CRM IMPLEMENTATION CHALLENGES IN PAKISTAN: A CASE STUDY

Hamid, Huma, Brunel University, UK, currently working as Software Testing Engineer at Bentley Systems, Suite # 307, ETC, F-5\1, Islamabad, Pakistan, huma.hamid@bentley.com

Abstract

In the recent times, Customer Relationship Management (CRM) has become one of the most dynamic topics of Information and Communication Technologies (ICT), both in the academia and the market. This popularity is indeed a result of the promising features offered by CRM. All the studies to date have highlighted elements associated with CRM success by studying its adoption and implementation in the organizations, with a focus on developed countries. Despite the usefulness of these contributions, today, very limited information is available, where implementation of CRM systems has actually been evaluated in a developing country like Pakistan, employing an interpretive approach. Hence, this current research aims to address this gap in literature, not only by taking a non-traditional approach of success evaluation; using system’s stakeholders’ expectations as an evaluation criteria but also focusing a case study from Pakistan, where ICT industry and specifically CRM is in the initial stages of adoption. This research effort has not only revealed the social aspects of CRM implementation but also unfolded some cultural aspects associated with the CRM in Pakistan. In order to guide the research, theory of stakeholders’ expectation failures turned out to be the most suitable option.

Keywords: CRM, success evaluation, stakeholders’ expectations.
1. INTRODUCTION

The concept of maintaining effective relationship with customers has been there for the last two decades, but rapid advancements in ICT and data warehousing concepts, increased awareness of customers and the intense market competition has now given new dimensions to this domain. The reason for increased popularity of CRM is mostly due to the promising benefits it offers in the form of improved company’s performance and long term customer retention for obtaining healthier financial payoffs etc. (Chen and Popvich, 2003). In order to enjoy these promised benefits, several companies have made heavy investments in implementing this technology. However, unfortunately, reaping them does not appear to be an easy task and only 35% (Davids, 1999) to 45% (by Gartner Inc. mentioned in Yoon et. al, 2003 cited in Paulissen et. al, 2007) of the companies have been successful at harnessing them. As CRM implementation greatly affects a company’s external and internal operations, consequently, its successful implementation also becomes critical. Hence, CRM stands out in the pool of other ICT innovations because of its novelty, promising benefits and company wide scope which affects a major part of a company’s stakeholders e.g. employees, suppliers and customers etc.

This increased fame of CRM has also gained immense attention from the Information System (IS) research communities. Numbers of research studies are conducted in order to reveal different aspects of CRM implementation where a mainstream of studies (Bull, 2003; Kim and Pan, 2006; Corner and Hinton, 2002) revolves around identifying the Critical Success Factors (CSF), largely covering the socio-technical aspects. A, widely accepted view is that majority of the CRM related issues revolves around the human factor and particularly the stakeholders involved. Nevertheless, very few have actually identified the role and importance of stakeholders’ expectations associated with the successful implementation of this novel and fast growing technological innovation. Additionally, a strong need also exists in order to explain that how people behave in different social contexts with a particular focus on developing country, while implementing and operating CRM systems.

Therefore, keeping in view the above mentioned gap in literature, specialized role of the research presented here is to expose the practical world of CRM and gain a richer insight for a CRM project success evaluation, by taking an interpretive approach with a focus on the developing country of Pakistan. This has been done by using Theory of Expectation Failure (Lyytinen and Hirschheim, 1987) with a focus on its special instances (correspondence, process and interaction). Also, the study has considered two major types of stakeholders’ which were external (consultants) and internal (management and employees) to the organization. Additionally, an effort has been made to expose the interplay of these stakeholders’ expectations associated while CRM project implementation. The findings of this exploratory study will be able to help the relevant stakeholders to develop a better understanding of the potential problems associated with CRM systems implementation in accordance with the expectations developed at different levels. This, in return, will help them make informed decisions about implementing and managing CRM systems and improve their chances to get promised benefits with minimum losses. Also, the study has unfolded project implementation issues for the emerging IS industry of Pakistan.

Ensuing sections of this report covers different stages of this research study by giving a brief background of existing perspectives on both IS and CRM evaluation and a reflection on the selected theoretical perspective. This has finally aimed to evaluate a CRM implementation in the emerging ICT industry of Pakistan and along with exploring the role of expectations in successful CRM implementation. Finally, research findings and future research directions are highlighted along with some concluding remarks at the end.
2. BACKGROUND

This section presents a review of the state-of-the-art literature in the areas of CRM and IS success/failure studies with a focus on Theory of Expectation Failure done so far. The chapter also presents a reflective illustration of the theory chosen to carry out this research.

2.1. Customer relationship management

Despite the popularity of CRM, still no single agreed definition exists and varying perspectives are found in literature to define CRM. Some researchers view it as a management approach to maintain relationships with customers using technology (Schellong 2005) for others it stands as an IS which enables an organisation to realise a customer focus (Bull, 2003). Another view in the research considers CRM as an essential strategy that integrates knowledge management, data mining, and data warehousing concepts to support an organisation’s decision-making process of maintaining long-term relationship with its customers (Cunningham et al, 2004). In simple words, CRM has established itself as an integrated synergy of people, processes and technology to maintain long-term customer relationship (Chen and Popovich, 2003). The current research study has also revealed that even within a single organization, different stakeholders associated different meaning to this concept depending on their vision, knowledge, role and scope of work. Majority of the client organizations in Pakistan, view CRM as an automation of call centre operations rather a company wide solution.

2.2. Existing perspectives on CRM success evaluation

The surveyed literature has exposed varying perspectives related to CRM evaluation. One view is that, CRM is an integration of technologies, business processes and people; therefore, the perceived success of CRM is subjected to the successful integration of these three entities. Whereas, a dominant stream of research has been devoted to discover the CSF where majority of the CRM practitioners believed that success of any CRM project is dependent on the successful management of these CSFs. Few of such CSFs identified and emphasized in CRM projects evaluation case studies include: need for a strategic vision of CRM (Chen and Popovich, 2003), top management support (Chen and Popovich, 2003), effective leadership (Bull, 2003), interdepartmental communication and coordination (Parvatiyar and Sheth, 2001), employees engagement and motivation (Chen and Popovich, 2003), integration with existing applications (Pan and Lee, 2003) and alignment with existing business processes (Chen and Popovich, 2003). In a similar study, Bull (2003) has investigated the issues ELMS Ltd. faced while CRM adoption and discovered that CRM project turned out to be a failed project due to lack of management commitment, customer driven culture, in-house expertise and resources and a bad outsourcing experience, thus emphasizing on the fact that successful implementation of CRM is subjected to the successful adoption of the mentioned CSFs.

Yet, another view over the matter holds the position that majority of the issues related to CRM implementation are not technical in nature but they revolve around the human factors. It is believed that CRM won’t be successful without managing its impact upon the people who will interact with this system. Although, this factor is predominantly viewed as the most critical factor which decides the fate of any CRM project, however a gap in the available literature and implementation practices has been also highlighted which fails to explain that how people and specifically different stakeholders behave in different social contexts while implementing and operating CRM systems. Even though, the above mentioned range of studies have successfully identified the areas which can cause problems during a CRM project implementation, but further information available on the root cause analysis of such
problems is very limited. Therefore, a strong need has been raised in order to find out the reasons of ignoring such CSF’s by analyzing the CRM project’s implementation in different social contexts.

2.3. Existing perspectives on IS evaluation

Now coming towards the pool of literature which covers IS evaluation studies over the last few years. Numerous studies have been conducted to evaluate and analyze the success/failure of IS from varying perspectives which gave rise to a hot debate between different schools of thoughts. Adding towards the debate around evaluation studies, DeLone and McLean (1992) have fairly argued that out of hundreds of studies conducted for evaluating success/failure of IS, there are as many measures as there are individuals who presented these studies. Largely accepted IS project evaluation includes the measures for success as e.g. use of system by its intended users, user satisfaction, improved decision making, better job performance and financial payoff etc.

Thus, there are various ways in which a system can be analyzed for success in different phases of its implementation and use. But again, like CRM literature, IS success evaluation literature is concentrated around factor-based studies and lacks in the identifying role of organisation in influencing the whole range of activities that can affect project outcomes (Sauer et al, 1997).

A number of researchers have taken into account the renowned perspective of project management factors (resources, time, team and cost) and technology factors (hardware, software, system crashes etc) for IS evaluation. Glass (1999) has criticized the traditional project management constructs which has failed to give a complete picture and reasons for project failures. Third category consists of organisational factor (efficiency and effectiveness) and fourth one has covered the environmental factors (social/economic/political) of IS success/failure (Drummond, 1996). Recent studies have also reported that most of the issues related to IS implementation are either social or political in nature. Therefore, IS evaluation studies ignoring these critical dimensions, present a very limited aspect of any IS failure, hence suffering from conceptual weaknesses.

To address the gap of limited evaluation aspects, a new notion of expectation failure of stakeholders has gained attention of different researchers in the recent years. This theory strongly holds the view that for different people (known as stakeholders), success holds different meaning. It also challenges the fact of measuring success on generalized basis and strongly argues that success is a rather subjective measure. In the next section, theory of Expectation Failure will be discussed in more detail.

2.4. Theory of stakeholders expectations failure

According to the Theory of Expectation Failure, a system is perceived as a failed system when it fails to meet the expectations and satisfaction levels of the stakeholders involved with it (Lyytinen and Hirschheim, 1987). Though this theory has been presented in late eighty’s by Lyytinen and Hirschheim, still it has formulated the basis of the studies conducted for evaluation of stakeholders’ expectations for the IS projects at different stages primarily because of its inherent understanding of strong relationship between IS and its stakeholders’ perception of success.

Lyytinen and Hirschheim (1987) argued that evaluation of success presented in different literature studies for IS projects, lacked in defining IS failures and success. Most of the studies identify only one or limited aspects of the IS failures. Therefore, according to Lyytinen (1988) problems with IS systems and projects are too many and just few features are not sufficient to describe this rich phenomenon. To answer the limitations and gaps in the literature available for IS failures, Theory of Expectation Failure
has been presented. Theory of Expectation Failure not only takes into account the multidimensional view of project failure but also represents the pluralistic and political account. Moreover, it doesn’t neglect the human factor and give immense importance to the stakeholder’s associated with any IS project. It also covers three other notions of failure (correspondence, process, interaction) which are special instances of this bigger theme as shown in Figure 1.

![Figure 1: Special Instances of Expectation Failure](image1)

Considering Davies et al’s (2004) view that failure is not an objective concept and it depends on the position and perspective of the definer, Lyytinen and Hirschheim's (1987) concept of the expectation failure holds a special position in the IS evaluation literature as it refers to the inability of an IS to meet a specific stakeholder group’s expectations having varying perceptions of IS success. These people, which are known as system stakeholders, possess some distinct characteristics and they affect and are affected by IS implementation and its usage, which purely depends on their role, relationship and level of impact with respect to the system. Failure for one group or an individual might be success for another group(s) or individual(s). Therefore, no generic or absolute definition of success/failure exists and it is relative to different stakeholders.

2.5. Expectation failure and CRM systems

Current literature has revealed a strong relationship between stakeholders’ expectations and an IS by using expectation failure notion. But it is also found that, CRM being a novel and most popular IS innovation of the recent years has remained deprived of such a rich evaluation phenomenon and CRM based studies suffered from the similar conceptual weaknesses as identified by the supporters of expectation failure theory for other IS projects. It is evident from the earlier discussion, that CRM holds a very special place in the IS domain due to its globally wide scope where CRM may affect much larger number of stakeholders (internal or external) on national/ international level which have already implemented it or looking at its worldwide trends to make decision for its adoption. Therefore, this attractive, popular, global and specialized system itself raises the need to explore it using rich phenomenon of success evaluation in order to understand its failure reasons in a better way. Based on the above discussion, a strong need has been raised to evaluate a CRM project implementation in a developing country like Pakistan by using the above mentioned rich phenomena of success assessment. Moreover, system implementation challenges and role of different CRM stakeholders in the particular social and cultural context of Pakistani ICT market can also be explored and analyzed.

In order to answer the above research queries, a case study of Pakistani bank has been used to evaluate the success/failure of a CRM implementation project. As Theory of Expectation Failure was used to guide the research therefore, certain aspects are taken into account for the analysis of a CRM system being implemented i.e. i) what are stakeholders’ expectations or common pool of values associated with CRM at different levels? ii) How far these expectations are translated to meet the final objectives of CRM project? iii) How CRM project survived the correspondence, process and interaction
evaluation (this includes the relevant measurement criteria against all these special instances e.g. time, cost and resources overrun, number of change requests and level of acceptance of design objectives, employees training and response to system etc)? It is also worth mentioning here, that in Theory of Expectation Failure, the nature of assessment procedure is informal (no well defined technique is applied), dynamic and against a continuous measurement scale. Other than that, study also revealed aspects of expectation development and affect on final outcome.

3. RESEARCH METHODOLOGY

To achieve the guiding principles of interpretive research, a combination of different research methods were selected. For data collection, a specialized form of interviews (i.e. telephonic interview), open ended email communication and media reports were used. Interviews are generally considered as one of the most strong and popular methodological approaches, whereas telephonic interview is also a well supported practise which can be considered due to limitations of resources (distance, time, cost and participants availability (Saunders et. al, 2003). All the interviews were conducted using telephone from UK to the participants in Pakistan and to ensure that maximum advantage, all the interviews were tape-recorded with the permission of the participants. Moreover, open ended email communication during interaction with the participants also greatly helped to seek richer insight about the research questions by engaging research participants into open-ended discussions about their personal experiences. Some press releases available on the vendor and client companies’ websites have also been used as research data. In these press releases, both the client and consultants have shared their expectations they have associated with that particular CRM implementation project. Total 9 participants were invited to take part in the research study and data was collected over a time period of almost 6 months.

The researcher aimed at analysing the data collected from the study by identifying relevant themes from the data relating to the research question by using thematic analysis approach (Boyatzis, 1998). Boyatzis (1998) has defined thematic analysis as a process which assists in the encoding of qualitative data by identification of specific themes. The data was analyzed using combination of both deductive and inductive approach for research. The reason for adopting these two approaches for data analysis further supports the idea of using initial combination of hybrid methods (semi-structured and in-depth interviews, open-ended communication and media reports) used for data collection mentioned in the above section.

4. CASE STUDY: IMPLEMENTATION OF CRM IN BANK A

This section unfolds the current practices of Pakistani CRM by using case study of a bank. Before going into the details of the selected case study, the rationale behind choosing this particular case study from the banking sector is also worth mentioning here. Currently there are two sectors in Pakistan which are highly influenced by the latest advancements in ICT to stay abreast in the competition i.e. banking and telecom sectors. One possible reason of this could be that, even internationally these two sectors are found to be the most adaptable ones in embracing the technological changes. Secondly, in the recent years major foreign investments have been made in Pakistan, particularly in these two sectors. A number of telecom companies and banks have started their operations locally, where they not only brought their business setups to the local market but, also carried along the latest technological systems already popular and proven successful in these companies in their respective (developed) countries. This shift has given a new challenge to the local players, but also opened new horizons of technological advancements for them to level the competition brought by the foreign
companies. Hence, out of the limited CRM implementations in the local industry, majority CRM case studies can be found in these sectors. Now selecting bank’s case study out of that was a limitation, because the data provided by the resources from telecom companies was not sufficient enough to build a case. The researcher strongly felt that due to immense competition, major players of telecom industry were also reluctant to share their true insight experience of CRM implementation.

4.1. Rationale behind CRM adoption

Bank A refers to a newly established bank which aimed to rapidly expand its network of branches both locally and internationally. It planned to capture the consumer market by offering a wide range of financial products and services along with the adoption of state-of-the-art technology to stand out in the market. The top management of Bank A took a major decision on CRM adoption and this motive was considerably seemed to be inspired by the popularity of CRM’s success in the international financial sector. Therefore, a strong commitment and support to exploit the existing opportunity in the form of CRM technology was witnessed within the top management of Bank A. This fits in what Corner and Roger (2005, page. 268) highlighted as “It is reasonable to assume that the software systems used as the technology basis for CRM are reasonably competent because many are sold, and in similar environments will have been successful”.

4.2. CRM system selection and requirement gathering phase

Just like majority of the companies in the market, Banks A had no option but to render services of a CRM vendor/solution providing companies (referred as consultants) due to insufficient in-house expertise (even if it was a primary choice or not). After a detailed market research, the Bank A’s management finalized the solution which not only suited their existing needs but also offered much more than they actually required, it was rather 100 years ahead of the Bank A’s capabilities and expectations (as claimed by the consultants). The world wide popularity of that particular product played a major role in its selection. It would be interesting to mention here that, the product was selected on the basis of popularity, rather than the actual need, therefore critical phase of requirement gathering started after the system’s selection. But this order is also justified as at project selection level, only abstract level requirements are shared and detailed business process re-engineering normally starts after system selection. In the requirement gathering phase of Bank A, business professionals, executive level management and managerial heads within their own respective domains coordinated with the consultants. Till that point, the middle management and lower level staff was not even aware of any such initiative. Though rumours were circulating about an upcoming system, but no official information was provided to take employees into confidence. This greatly challenges the need raised by Corner and Rogers (2005) that, employees needs to be informed and engaged beforehand.

This lack of communication brought what numerous studies have indicated i.e. employees’ resistance due to lack of information. Therefore, an interesting situation was raised when a middle manager was introduced to explain his core business operation and the consultant tried to impress him with an efficient technical functionality for opening a new bank account by reducing time from one hour to two minutes. It was expected by the consultants, that the manager will be agreed at once. However, the manager insisted on doing it the way it was previously done, where a new customer had to fill-in a lengthy paper application form of up to 15 pages. Upon enquiring about the reason for this resistance, two different view points were found at both the ends. The consultant responded that it was just lack of awareness at their client’s end who didn’t know what they were missing. While on the other hand, the manager explained that his resistance was merely because of data validity and security concerns which are more important than a remarkable technical functionality. However, at the end of the day the
manger had to convince himself and his resistance was over shadowed by the functionality being offered. Upon agreeing on the system’s requirements product development phase started.

4.3. First demonstration phase

Upon completion of the product development, first demonstration phase was held after few months. During first demonstration of the application, normally termed as the testing phase, the Bank A’s management was highly impressed with what the system could perform. Different responses were observed at this particular stage:

- The top management’s initial response exhibited that the system lived up to their initial expectations and they were glad that new systems will help them to monitor staff level activities.
- Call centre agents were particularly excited as in they view CRM is to handle call centre operations.
- IT support department team was puzzled and was in a dilemma whether they actually needed this system? Because once the new system would be in place, they would need to adapt to it, otherwise their jobs would be at an obvious stake.
- Sales and marketing managers were particularly excited and looking forward to see that how their reporting and analysis will become easier and better.

At this stage, a major concern identified by the consultants was lack of awareness at employees’ level which caused job insecurity and low motivation among them. Whereas, the management didn’t find these concerns of much importance, therefore did no effort to eliminate them.

4.4. Final rollout phase

After the satisfactory results of the initial testing phase, a staged implementation was adopted where CRM application was implemented in one department after another. This implementation went smoothly with no delays, concern or systems integration issues as previous application was replaced by new one. After completion a follow-up visit was conducted by the consultants in order to analyze the system’s performance. Some interesting observations were made by them, which are not new to CRM literature.

- The call centre staff particularly complained about the complexity of user interface having too many screens. According to them, it has actually increased the response time to customers instead of making the tasks easier (as they were told).
- Most of the staff particularly avoided talking to the consultants about the system as they feared that speaking negatively about the newly deployed solution early in its stages will pose threat to their jobs. The consultants observed scarce use of the system. The obvious reason for this was inadequate training and also less knowledge sharing culture between employees which also affected the expected outcomes and also the possible systems benefits.
- Some unrealistic assumptions on the part of higher management regarding the response of employees also contributed to the situation. They had the assumption that the employees will get used to the new system with the passage of time especially when they will realize that it is an ultimate solution to their day to day problems. It was also assumed that since the employees have been briefed positively about the functions of the system, therefore, they would definitely be happy to use it and explore it themselves rather than providing formal training sessions.
- The management was also reluctant to provide access to critical data to the lower-level staff. On the other hand, the consultants held the view that to get better results from the system it was an important working practice.
Throughout the implementation, consultants kept on reviewing the status and recapturing different responses to revisit their implementation strategies. With that, CRM implementation phase ended without any significant time, cost and resources overrun issues (as mentioned by research participants, no research data/project reports have been shared with the researcher in support of this argument). Later on, during another follow-up visit, some better response from employees was observed. Also, within 2 months of system deployment, no major change requests were made by the client and system use was also improving gradually.

5. **KEY FINDINGS AND ANALYSIS**

In this section, the researcher has discussed the research findings, where different instances of expectation failure and varying expectations of different stakeholders during the multiple phases of the CRM project are revealed. Study has also exposed the dynamism of expectations which affected the perspectives about project success. Some traits associated with the Pakistani working culture were also unfolded. In order to find the answers, theory has been mapped against practices, where close similarities between theory and practise are found and some already known issues are witnessed.

5.1. **Project failure modes in light of expectation failure**

In order to use the Theory of Expectation Failure, special instances were used for assessment, where measurements were taken during different phases of implementation. A summary of different project phases and special failure instances of expectation theory are presented in the Table 1.

<table>
<thead>
<tr>
<th>Project Phase</th>
<th>Analysis</th>
<th>Evaluation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Failure Mode : Correspondence</strong></td>
<td>• Successful achievement of design objectives is correspondence success. In case of Bank A, design objectives translated in terms of requirement specification were seemed to meet. Possible reason was not competency of consultants or managers; rather system was selected on the basis of its already renowned worldwide features. Therefore, Bank A tried to adapt itself according to already available functionality and process redesigned by the consultants. Also, no major change requests were made within 3 month of project launch, which strongly reinforce the above mentioned point.</td>
<td>Quite Successful</td>
</tr>
<tr>
<td>System Selection &amp; Requirements Gathering</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Process</strong></td>
<td>• Exact cost and time was not shared with the researcher even on enquiring but both the parties claimed that there were no significant delays cost or time overruns. Therefore the project was assumed to be finished within the planned time and resources. • No major technical, system or process integration issues were reported.</td>
<td>Quite Successful</td>
</tr>
<tr>
<td>Over all Project Implementation</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Interaction</strong></td>
<td>• Negative attitude towards system, scarce use of it and complaints about the complex user interface were reported and also used as assessment for interaction failure mode. Possible reasons of this could be inadequate training and management’s resistance to allow access to critical data to lower level staff. • System use was increased with time but it is really hard to say if that improvement came due to increase in satisfaction level or system use was enforced.</td>
<td>It was overall together a win-win situation. Though, data was not sufficient to support complete success of complete failure</td>
</tr>
<tr>
<td>Project Launch Phase</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
If we analyze the CRM implementation of Bank A within pre and post-implementation phases, it is found to be fairly successful against correspondence and process instances. Design objectives which management expressed in the form of system’s scalability, automation of major operations (especially call centres) and monitoring of staff activities were fairly met by the system. Due to less rigidity in the business process being a young bank, also played a major role in having flexible design objectives. But, it was strongly felt that measuring design objectives is a hard task, also mentioned by Theory of Expectation Failure. These objectives are not always expressed and requirement specification is just a too little aspect which can cover the overall design objectives. Also, validation of mentioned objectives is challenging. Therefore, this dimension of project evaluation provided very limited information to decide a project’s success. The project performed well against “process instance” which was basically due to the fact that top management being major project’s sponsor, provided sufficient resources and priority to the project as needed. On the other hand, if user attitude and system use is considered as assessment criteria, the system significantly failed from user interaction point of view. Yet again, these two measurement criteria were not sufficient for a fair assessment as in case of Bank A, where system use was finally enforced by the higher management and employees had no option but to use the system.

Not many studies have highlighted the silent but significant role of consultants for the overall project’s success during implementation phases. In this case, consultants being a major stakeholder contributed towards the overall project success. They remained optimistic throughout the project and guided their client on certain occasions. Oppositely, consultants were also fortunate that Bank A was a committed and flexible client. It was also found that “expert power” has great role in developing and managing expectations. The consultants equipped with power of expert technical knowledge, throughout lead the whole project and their hold on the project planning and layout seemed very strong. With that, they were able to mould their client as per their project planning and project outcomes. This depicts that consultants and their client shares a very strong and dynamic relationship. This relationship affects the overall expectations about the project and by shaping them and achieving them at later stages.

5.2. Additional themes

Apart from analyzing the project implementation in a particular social context for a particular case study, few additional themes were also identified during the research study. One prominent theme was cultural difference of Pakistani working practices from the western world from where majority of the CRM solutions are being “imported”. Few observations which were made during the research study particularly for Bank A and generally for Pakistani CRM industry are as follow:

- Even though number of companies within Pakistan have already adopted, in process of adoption or making up their mind for adopting CRM, still there are certain cases where this decision is merely influenced by the international market trends rather than companies’ actual needs as it is also witnessed in this particular case study. Though, this trend can be good or bad, both ways.
- The research participants shared the view that majority of the CRM client organizations’ vision lack clarity. Particularly in the banking sector, CRM is no more than an automation of call center operations. Such clients either turn out to a blessing for the vendors as they know less and get easily convinced or totally get the other way around and increasing the project failure risk.
- Higher managements mostly work in an autocratic way, where middle management and non-managerial level employees are less empowered. They mostly had the view that it’s not important to tell their subordinates about an upcoming system. A call centre agent neither has the time, nor interest in knowing what system his company would be launching. He would do whatever he was being told. In this particular research study it was found that neither the staff was officially
informed about the system nor sufficient training sessions were conducted. That resulted in job
insecurity, lack of confidence and resistance to use the new system. Although, this factor was
later eliminated by enforcing system use by the managers.

- The renowned theme of CRM being integration of people, process and technology which is
  emphasized by the research participants, mostly found as a lip praying service and not as a
  working practice. Technology is mostly considered as the ultimate solution to achieve potential
  benefits and end users of technology are mostly ignored. But, the extent of this trend tends to vary
  from company to company as well. Firms’ employees having a history of frequent changeovers of
  systems and technology are found to be more adaptable and vice versa.

- Two very interesting comments were made by the CRM implementation consultants with regards
to CRM practices in Pakistan. One view was “CRM will blend and merge itself with the local
colours and flavours just like the international fast food chain McDonalds did, not only bringing
new recipes from foreign countries but also adding and maintaining the taste of local culture”
and the other view was “The concept of democracy which is so popular in the Western world can
not be applied with its full strengths in Pakistan due to less education, knowledge and awareness
to select the right leader, same goes for CRM. The solution is indeed international but it will take
immense learning experience to get it matured in the Pakistani corporate environment”

- It is also believed that problems with CRM implementation in Pakistan are same as they are
internationally. Rather, they can become worse due to less technical culture and rigid working
environment especially in the public sector.

6. FUTURE RESEARCH AND CONCLUSION

In this particular research study, an effort has been made to understand and analyze the implementation
of one of the most popular and novel IS innovations i.e. CRM in a particular social context by using a
Pakistani bank’s case study. The research has its limitations in certain areas which include i.e.
unavailability of official data about the current size and capabilities of Pakistan’s CRM industry, CRM
industry is in still early stages of adoption in Pakistan, research study has limited to only one detailed
case study due to limited participation from industry and also the time and resource constraints has
restricted the effective generalization of findings. It is therefore suggested that, future research can take
larger research samples to identify and verify the established relationships and also the researchers
need to identify the organizational level changes in Pakistani working culture which has a promising
future in IT growth.

The research study has revealed that certain social and environmental factors affect any IS project’s
success and its possible outcomes. Also, the project success or failure has various dimensions
therefore, analysing a project from multiple dimension has provided a better and clear view of the
overall picture. People factor has play a very critical role in project’s success therefore; they are needed
to be managed wisely. Technology alone can not perform miracles if people do not use it properly. In
this regard, relationship shared by different stakeholders is also critical to any CRM project success.

There are certain culture differences within Pakistani CRM market which can adversely affect CRM
success therefore, instead of merely following the international trends, an effort should be made by the
companies to increase awareness at all levels within a company so that better results can be achieved.
The future of Pakistani CRM market is getting better and better and there is a great potential for
getting the promised benefits from the CRM systems. Only suggestion I would like to make is that
instead of reinventing the wheel, stakeholders should learn from the mistakes of the western
companies. If they have imported the solution from these developed countries, then those failure lessons should also be imported and applied in order to avoid damage and financial losses.

PREDOMINANTLY ELECTRONIC OR PERSONAL SERVICE DELIVERY? A CASE IN THE WEALTH MANAGEMENT CONTEXT

Sunikka, Anne, Helsinki School of Economics, Department of Business Technology, Runeberginkatu 22-24, 00100 Helsinki, Finland, firstname.surname@hse.fi

Abstract

Financial services have been a recurrent subject of a multichannel inquiry but investigation into the wealth management area is scarce. This paper intends to fill the gap and presents the results of a questionnaire directed at customers of a financial conglomerate. The objective of this research is to examine which variables influence consumers’ channel preferences in the wealth management context, and to find out possible differences between the customers who prefer predominantly electronic service or personal service delivery. Logistic regression and t-tests are used in the analysis. The perceived channel attributes of personalization, convenience and safety, relationship strength, and the internet and wealth management knowledge influence the channel preferences. Typical wealth management customers prefer multichannel service delivery; only 4% of customers prefer pure electronic service, and 14% of customers prefer pure personal service. There are several aspects that differentiate those customers who prefer predominantly electronic or personal service. The preference for the electronic channel indicated investments in shares, independent decision making style in wealth management tasks and reliance on electronic information channels. In addition, the customers who perceive relationship strength with the service provider as weaker prefer predominantly e-services, which should give impetus for action among the management in the financial service companies.

Keywords: Multichannel, Wealth Management, Electronic Service, Personal Service, Relationship Strength
1 INTRODUCTION

Multichannel customer management is the design, deployment, coordination, and evaluation of channels through which firms and customers interact, with the goal of enhancing customer value through effective customer acquisition, retention and development (Neslin et al. 2006). Multichannel retailing is assumed to offer synergies, as it can result in an increased customer base, added revenue, and higher market share (Berman and Thelen 2004). A well-integrated multichannel strategy includes product, service and quality consistency across channels, highly-integrated promotions and integrated information systems that share customer and offering information. Much of the multichannel research has taken place in the financial industry for several reasons. Financial services have been in the forefront of the new technology deployment, since the financial industry is essentially an information-based industry (Dewan and Seidmann 2001). In addition, financial service providers control both their online and offline channels and can decide fairly freely how to develop the channels, and where the focus of the development should be. In the financial sector, multichannel service delivery is thus commonplace. The average adoption rate of online banking is high in the Nordic countries making the need for multichannel strategy essential. According to the statistics from spring 2008, 83% of Finns use the internet, and 72% of the population are online banking users (Statistics Finland, 2008).

This study is based on the results of both qualitative and quantitative data that were collected under a larger research project. The main aim of the project was to develop a comprehensive wealth management service concept for individual customers. The qualitative methods included financial expert interviews and consumer focus group discussions. The main focus of this paper is, however, on reporting the results of a questionnaire sent to customers of a Nordic financial conglomerate (N = 291). The sample customers have some property and savings, representing thus a customer segment that financial service providers will find increasingly interesting in the future. They are, however, not entitled to private banking services. In our case financial conglomerate only customers who have 100 000 € of assets for investment purposes can use private banking services. The sample customers thus manage their assets either independently or after infrequent consultations with a financial advisor.

This paper broadens the research focus from transactional services (mainly payment of bills and checking account balances) to wealth management services. For the purposes of this study, we understand wealth management broadly as those activities focusing on financial issues in the households; real and financial assets and liabilities, including insurances for protection of possessions and persons. We emphasize a comprehensive view to wealth management services, and recognize that wealth management requires knowledge and experience that are not necessary in day-to-day running of financial affairs. For example, in the preliminary testing phase of the wealth management service concept, a financial security check” – the opportunity for consumers to map their own financial situation – and compare it with others belonging to the same demographic group, was appreciated.

The objective of this research is to examine which variables influence consumers’ channel preferences in the wealth management context. Consequently, a model of variables influencing the consumers’ channel preferences is developed. We examined the channel attributes; convenience, security and personalization, and whether customers’ perceptions of the relationship strength with the service provider are associated with channel preferences. In addition, internet and wealth management knowledge and experience were hypothesized to have an impact on the channel preferences. Our paper thus concentrates on finding an answer to the question: What variables influence consumers’ channel preferences in the wealth management context? In addition, we carry out an exploratory analysis on how predominantly electronic service (PES) and predominantly personal service (PPS) customer groups diverge from each other.

This paper is structured as follows. We first discuss the literature investigating the multichannel usage, and then develop the hypotheses for the model. In section three we describe the data and methodology used in the empirical study. After that, the results based on the binary logistic regression and t-test analysis are presented. Finally, the results and theoretical and managerial implications are discussed.
2 THEORETICAL BACKGROUND AND HYPOTHESES

Sousa and Voss (2006) define multichannel service as a service composed of components that are delivered through two or more channels. According to Neslin et al. (2006), practitioners have five challenges to address in the effective management of the multichannel environment: i) data integration, ii) understanding consumer behaviour, iii) channel evaluation, iv) allocation of resources across channels, and v) coordination of channel strategies. Academic research has mostly addressed the question of consumer behaviour, and has concentrated on three main channels: catalogs, bricks-and-mortar stores, and the internet.

Previous research has given evidence for reasons for channel choice and concluded that multichannel consumers, in general, buy more (Kumar and Venkatesan 2005). According to Neslin et al. (2006), the main determinants of customer channel choice can be divided into five groups: *marketing efforts* (Ansari and Mela 2003), *channel attributes* (Devaraj et al. 2006), *channel integration* (Montoya-Weiss et al. 2003), *social influence and situational factors* (Burke 2002, Dabholkar and Bagozzi 2002) and *individual differences* (Durkin 2004). In addition, the *task characteristics* of goal-directed or experiential tasks (Hoffman and Novak 1996) and the *type of products purchased* (Chiang et al. 2006) influence the channel choice. Less research has been conducted in the area of data integration even though it is important for financial companies (see however, Cappiello et al., 2003).

It is likely that the characteristics of wealth management services influence the channel choice and the need for channel interaction. Long-term wealth instruments and services consist mainly of credence attributes (Darby and Karni 1973), and are marketed and sold with promises of future revenue streams and credibility of the service provider (Harrison 2000). The channel – service framework (Apte and Vepsäläinen 1993) concludes that complex and infrequently used services would typically require personal interaction whereas simple and frequent transactions can be carried out as a self-service. In addition, the media richness theory (Daft and Lengel 1986) emphasizes the richness of personal contact, and its superiority in dealing with complicated issues in comparison to, for example, phone calls or e-services.

Most of the multichannel studies in the financial services context have examined the association between channel choice and loyalty, and the findings have been contradictory. On one hand, multichannel environment can be seen eroding loyalty because it encourages extensive search and enables easy switching to another service provider. In addition, electronic channels entail little human contact, which itself can erode loyalty. Wright (2002) claims that new channel technologies have loosened the relationship between the banker and the customer. On the other hand, multichannel usage might also enhance loyalty (Shankar et al. 2003). According to Wallace et al. (2004), multichannel usage is associated with higher perceptions of the provider’s service offering, which in turn leads to higher customer satisfaction and loyalty. Coelho et al. (2003) investigated 62 UK financial service companies and found that multichannel companies enjoyed higher sales levels but lower profits. It seemed that multichannel companies suffered especially in terms of customer service and customer retention. Thus, providing good, coordinated service is a challenge for multichannel companies. In general, however, several research results indicate that channel choice has no association with loyalty in the banking context (e.g. Colgate and Smith 2005; Herington and Weaven 2007).

Only few studies have examined services related to maintaining and accumulating wealth. Falk et al. (2008) found that in Germany, the status quo bias is a powerful hindrance for consumers to turn to electronic services in the investment context, and especially older, male consumers and inexperienced internet users preferred continuing to use purely personal service. Ding et al. (2007) examined what combination of features financial institutions should offer to satisfy the needs of the high involvement customers who preferred using the e-service, multichannel or personal service for investment needs. Within these different customer segments the customer needs regarding online features differed, indicating a need to personalize the multichannel offering for each customer segment. The electronic service segment included 52 %, multichannel 37 %, and personal service 11 % of the sample’s customers in the study (Ding et al. 2007).
Channel preferences (dependent variable in the model)

Channel choice can range from pure electronic channel (self-service) to pure personal service. The dominant view of the experts we interviewed was that in wealth management tasks, personal encounter with a financial advisor is the best way to influence customers, especially when the customers are inexperienced. More experienced customers might be able and willing to turn to electronic services. Thus, the multichannel view emerged very strongly in the interviews. However, a linkage between the relationship strength and channel preferences could not be made. In the consumers’ focus group discussions, the internet was mentioned as an information source but e-services of banks were not discussed. Topics like security or privacy did not emerge directly in the discussions. Instead, consumers talked spontaneously about the need for trust in the wealth management relationship and their partial distrust in financial advisors (Sunikka and Peura-Kapanen 2008a, 2008b).

The channel preferences are measured with one item “I prefer taking care of my wealth” with anchors at 1, signifying electronic channel delivery and 7, signifying interaction with a financial advisor. The midpoint 4 denotes customers that prefer electronic and personal service delivery to the same extent. For the purposes of the binary logistic regression analysis, customers were divided into two groups; those who prefer predominantly electronic service, PES-group (choices form 1 to 3, n = 72) and those who prefer predominantly personal service, PPS-group (choices from 5 to 7, n = 160). We decided to omit those customers who chose the mid-point 4 from further analysis (n = 59).

Channel attributes

Previous research has identified several reasons why consumers adopt new technology. Especially in the financial service sector, research has concentrated on examining the antecedents of electronic banking adoption (e.g. Durkin, 2004). The technology acceptance model, TAM, (Davis 1989) has identified usefulness and ease of use as the main variables for explaining why consumers adopt new technology. In addition, the consumer readiness (Meuter et al. 2005) and the technology readiness (Parasuraman 2000) constructs explain why some consumers feel more comfortable with new technology than others.

Convenience, security and personalization represent channel attributes in this study. For example, Szymanski and Hise (2000) found convenience to be an important factor in e-satisfaction. Convenience is understood in terms of consumers’ time and effort perceptions related to using a service. Fun of interaction was not included as an attribute since electronic banking (also for wealth management tasks) is considered as a utilitarian electronic service (van den Heijden 2004). In an online context, security, and the perception of trust have been identified as important determinants of customer willingness to use electronic services (Casaló et al. 2007, Yousafzai et al., 2003). According to a recent Eurobarometer (2008) study, consumers in the Nordic countries trust banks and financial institutions to use their personal data in an appropriate way. Personalization has been taken into new levels in the electronic environment, and research interest has continuously increased (for a review, see Fan and Poole, 2006). The chosen attributes were combined with two tasks: information search about wealth-related issues, and buying or selling of assets. Hence, we combined three channel attributes with two wealth management tasks.

We hypothesize that all relationships between the channel attributes and the channel preference are positive. In other words, if a respondent thinks that information search is convenient with the help of a personal financial advisor, the customer is expected to choose options from 5 to 7 and thus indicate her/his preference for the personal service delivery channel. If, on the other hand, a customer regards electronic service as a convenient channel in information search, s/he is expected to choose options from 1 to 3 and thus show preference for the predominantly electronic service delivery. Descriptive statistics of the items and constructs are presented in Appendix 1.

**H1:** Customer’s perception of the channel convenience will be associated with the customer’s channel preferences.
**H2:** Customer’s perception of the channel security will be associated with the customer’s channel preferences.

**H3:** Customer’s perception of the channel personalization will be associated with the customer’s channel preferences.

### Relationship strength

Incorporating the relationship strength as one of the variables in the model was motivated by the question whether financial service relationships are perceived as strong or weak by the consumers. Financial service relationships are often used as examples of the relationship management approach, which is defined as activities directed towards establishing, developing and maintaining successful relational exchanges (Morgan and Hunt 1994). However, there are doubts about the strength of ties that consumers feel towards their financial service providers in the current era where “the competitor is only a click away”.

In contrast to the research on service quality, satisfaction and loyalty (e.g. Beerli et al., 2004), there are only few studies on relationship strength. Donaldson and O’Toole (2000) and Hausman (2001) have examined relationship structure and strength and its impact on performance in a non-finance B2B context. Wong and Sohal (2006) have developed a model of relationship strength in the retail sector, and claim that their results could be generalized to banking and insurance industries. Other researchers have concentrated on the salesperson’s role (Bove and Johnson 2001), or on comparing varying levels of relationship strength in different service industries (Ward and Dagger 2007). Ward and Dagger (2007) found out that of the five service contexts they studied, customers in general perceive that the relationship with a bank represents medium level strength; the strongest relationship is usually with the hairdresser, and the weakest with a cinema.

In this study, relationship strength is defined as the extent, degree, or magnitude of relationship which is governed by the amount of trust and the level of commitment the customer feels towards the service provider (Bove and Johnson 2001). The relationship strength is particularly applicable in situations where the service involves a high component of interpersonal delivery, and when the service is varying and high in experience or credence qualities, making quality difficult to predict or evaluate and therefore increasing the customer perceived risk (Sheth and Parvatiyar 1995).

Ball et al. (2004) grouped the antecedents of loyalty as follows: characteristics of the environment (perceived switching costs or technological changes), characteristics of the dyadic relationship (shared norms or relationship duration), characteristics of the consumer (relationship tendency or involvement in the category), and consumer perceptions of the relationship with the company (service satisfaction, trust and service quality). Consumers’ perception of the relationship strength with the service provider is thus perceived as an antecedent of loyalty. In this paper, the perceived relationship is understood purely from the consumer’s point of view. Originally, we had three items to measure the relationship strength; however, the transactional item had to be excluded from further analysis since it did not fit with the other two items of the construct.

**H4:** Customer’s perception of the relationship strength with the service provider will be associated with the customer’s channel preferences.

### The internet variables: knowledge and experience

In line with previous studies (e.g. Montoya-Weiss et al. 2003), increased familiarity (knowledge and frequency) of the internet usage is likely to result in increased use of electronic services. According to Alba and Hutchinson (1987), knowledge can be divided into subjective and objective knowledge. Subjective knowledge is the own perceived level of knowledge, in this study the self estimated ability to use the internet. Objective knowledge was not measured in this study.

Experience with the internet, both the length of time the consumer has used the internet and the frequency of the internet usage, as well as the versatility of the tasks, are expected to influence channel preferences. In this study, frequency of usage (in hours per week) represents the internet experience.
**H5:** The internet knowledge will be associated with the customer’s channel preferences.

**H6:** The internet experience will be associated with the customer’s channel preferences.

### Wealth management variables

Knowledge on different instruments is assumed to increase the confidence of customers in their own ability to conduct wealth-related tasks independently, without turning to customer representatives for assistance. The frequency of wealth management transactions is also assumed to increase the likelihood of electronic channel usage. Associated with this is the nature of the financial assets owned since, for example, ownership of liquid assets (e.g. shares) can require frequent transactions and might thus result in preference for multichannel and electronic channel service delivery.

**H7:** Wealth knowledge will be associated with the customer’s channel preferences.

**H8:** Wealth experience will be associated with the customer’s channel preferences.

---

**3 METHODOLOGY**

Our qualitative data examined wealth management behaviour both from the point of view of consumers and service providers. At first, focus group discussions were carried out with 33 consumers in six sessions and 11 individual interviews with financial experts. Based on the results of this qualitative phase and an earlier literature, a questionnaire was constructed. The questionnaire included several themes ranging from motivations for financial behaviour to customer views of total wealth management services. Most of the items used in the questionnaire were adapted from previous studies. In addition, practitioners and academics participating in our research project commented extensively on the questions resulting in several changes to the final questionnaire form. 1500 questionnaires were sent out to customers of a financial conglomerate. Two mailings were used. The customers were chosen from the database of the financial services company, and are representative of relatively wealthy customers. The response rate was 20.6 % (309 returned questionnaires), which can be considered satisfactory considering the length of the questionnaire, the sensitivity of the topic, and the fact that this was a mailed survey. After having removed incomplete responses, 291 usable responses were available for our analysis.

---

**4 RESULTS**

The demographics of the 291 respondents were the following: 57 percent were female, the average age was 49 (range from 25 to 75), and 49 percent had a polytechnic or a university degree. Nearly 70 percent earned less than 40 000 € per year and the group owning between 100 001 and 250 000 in assets was the biggest group (35 %). 83 percent of the respondents lived in smaller towns and rural municipalities.

---

**Figure 1. Model for channel preference in the wealth management context**

---

Proceedings ECIS 2009
Confirmatory factor analysis (CFA) was conducted using principal component analysis and orthogonal varimax rotation. Appendix 1 depicts the constructs that were used in the logistic regression model. The security attribute on buying and selling loaded on the convenience attribute, leaving only one item, the security of information search, to represent the security construct. The reliabilities of the constructs (Cronbach’s alpha values) ranged from 0.76 for convenience to 0.84 for relationship strength. Nearly all tasks were considered more convenient, more personalized and more secure when conducted as PPS. Only the information search item was considered slightly more convenient as PES. Correlations among variables ranged from -0.35 (personalization and frequency of wealth management decision making) to 0.64 (channel attributes personalization and convenience).

We conducted a stepwise binary logistic regression with SAS 3.0 to test the hypotheses. The explanatory variables were derived from the factor analysis and the significant variables are presented in Table 1 below. The dependent variable is channel preference, 1 for PES and 0 for PPS. We used the question “I prefer taking care of my wealth” with anchors at 1 for purely electronic channel and 7 for purely personal channel to distinguish those who prefer PES (from 1 to 3, 25% of the respondents) from those who prefer PPS (from 5 to 7, 55% of the respondents). We decided to omit those customers who chose the mid-point 4 to denote their channel preference (20% of the respondents). However, multichannel service delivery was clearly the dominant service delivery model since the pure electronic channel was preferred only by 4 percent and pure personal service by 14 percent of the respondents.

Table 1: Influential variables for channel preferences

The -2Log likelihood of the final model was 83.651, R-Square 0.556 and Max-rescaled R-Square 0.874. In the likelihood ratio test for the global null hypothesis (beta = 0), chi-square was 160.901 with 6 DF (<.0001). No additional effects met the 0.05 significance level after Step 6. Somers’ D denotes the strength and direction of the relation between pairs of variables. It is the difference between the percent concordant and the percent discordant divided by 100, in our model (96.6 - 3.4)/100 = 0.933. The C measure (equivalent to a well-known measure of ROC) is 0.966, which corresponds to the model discriminating the responses well.

The channel attributes of personalization, convenience and safety are all positively related with the channel preference (H1 – H3); those who rate these attributes high for personal service also prefer PPS delivery. Relationship strength is also positively related with the channel preference; those who perceive a stronger relationship with the service provider prefer PPS delivery in the wealth management context (H4). The relationships with the internet knowledge (H5) and wealth management knowledge (H7) with channel preference are reverse; that is, the increase in these variables indicates a move from personal service preference to multichannel and electronic service preference. The relationships between the internet experience and wealth management experience with channel preference were not statistically significant; we thus reject H6 and H8.

In order to develop a deeper understanding of the differences and similarities between the customer groups that preferred PES or PPS delivery we carried out t-tests with variables that were not included in the logistic regression model (see Appendix 2 for details). We used the same binary variable as in the logistic regression to group the data. Even though we did not think that demographic variables
would have an impact on the channel preferences, there was a statistically significant difference between the groups. PPS was preferred by older customers; the average age of PPS customers was 50 years in comparison with 46 years in PES group (p = 0.0308). PPS group consisted of 63% of females whereas PES group included only 36% of female. In addition, members of the PPS group owned less shares. We asked about the sources of information that customers considered as the most important in the financial decision making context. PPS group turned to financial advisors for information whereas PES group used a variety of information sources to support them in the financial decision making: especially electronic channels but also printed articles and own previous experience. When decision making style in financial matters was specifically inquired, PES group acted independently, relying on their own expertise whereas PPS group needed more advice and reassurance from others. PPS group had a more favourable view of the marketing activities of the financial institutions; seeing marketing as aiming at the good of the customer rather than pushing products to customers. Customers in PPS group intended to increase the use of services of the current service provider indicating behavioural loyalty even though there was no statistically significant difference with the intentions to use services of other companies between the PPS and PES groups. The PPS group also felt that they had invested more effort in finding a suitable service provider creating thus higher switching barriers. In general, PES group had a more critical attitude towards financial service providers than PPS group.

5 DISCUSSION AND CONCLUSIONS

This paper focused on understanding customers’ multichannel usage in the wealth management context, and especially the linkage between the relationship strength and the channel preferences. Multichannel service delivery is clearly preferred to pure electronic service delivery (4%) or pure personal service delivery (14%) in wealth related tasks. Only the information search task was considered slightly more convenient as predominantly electronic service (PES) than personal service, whereas convenience, personalization and safety constructs were all seen as predominately personal service (PPS) attributes. Channel preferences in wealth management are also influenced by the relationship strength; those who perceive a stronger relationship prefer using PPS. Increasing internet and wealth management knowledge, on the other hand, makes customer prefer switching to the multichannel and electronic service delivery.

The t-tests between the PPS and PES groups revealed quite distinguished profiles of the two customer groups. Those who preferred PES were demographically more likely to be younger males and they had more investments in shares than the PPS group. The preference for increased electronic channel usage might be partly explained by their willingness to use e-services for share trade transactions. The PES group used more versatile information sources than the PPS group who mainly relied on the information provided by their primary financial service provider. In addition, customers in the PES group preferred making independent decisions instead of turning to financial advisors for advice. Perceptions about the advice that the financial service companies offered differed too; the PES group thought that the advice of the financial service companies mostly promoted the products or services of the particular company, and not the good of the customer. Furthermore, the behavioral loyalty and perceived switching costs diverged confirming the stronger perceived relationship between the PPS customers than the PES customers with their financial service provider.

Traditional wealth services require expertise and are thus labor intensive. As the number of consumers willing and able to invest is expected to increase in the future, the challenge of suitable service channel combinations will intensify. When electronic and personal services are combined the wealth management service providers are not only able to offer services to a larger number of customers but can also provide more comprehensive and more integrated services to cover consumers’ wealth management needs as a whole. The findings of our study show that those who prefer PES are more knowledgeable and willing to make independent decisions in wealth management issues than the PPS customers. However, there are only 25% of PES customers in this sample compared with 55% of PPS customers. Thus, even though customers are active users of online banking in everyday monetary affairs, the majority of customers seem to need personal interaction with the financial advisor in a
more complex context at the moment. Also, since the multichannel strategy emerged as the most preferred channel choice both electronic and personal channels have to be developed in an integrated manner.

As it seems that the PES customers perceive a weaker relationship with their service provider, the financial service providers should emphasize the added value that their electronic channel provides for the customers. Nowadays, information technology offers several possibilities for automated and personalized service delivery. However, e-services are not necessarily perceived as personalized even though customers find their own account and transaction information in the online applications. The information provided by the financial service provider is not personalized, and not necessarily relevant for the customers’ situation, or their financial objectives in life. A more personalized experience could be offered with a tool that aggregates the customers’ financial transactions in order to show their financial status and the allocation of wealth automatically, without manual calculations. A more hedonic application is a widget that is provided by an e-service of one bank: the customer can choose a certain objective for savings, for example, a vacation trip, and the widget records all the savings by depicting a piggy bank that is becoming rounder when the savings amount accumulates. In addition, chat and VoIP could be harnessed for customer service purposes since one of the recurrent sources of complaints is that it is difficult to get in contact with financial advisors. However, the linkage to personal service should always be kept in mind, and the PES customers should be served efficiently when they need personal service. For example, Colgate and Smith (2005) studied multichannel financial services, and concluded that a good relationship with a financial advisor can build trust among the e-service customers.

Our research has the following limitations. Only customers of one service provider were surveyed, limiting the external validity of the study. Because the questionnaire was long (11 pages), and there were several themes, the number of items for the channel and relationship questions was restricted. According to Drolet and Morrison (2001), one-item constructs are not necessary harmful in service research. For example, Shankar et al. (2003) only used one-item constructs in their multichannel study. The main reason for this was to avoid the excessive length of the questionnaire, as in our case.

It should be noted that we do not know if customers who perceive weaker relationship prefer PES, or if the usage of PES leads to weaker relationship due to the decreasing amount of personal contact. More studies should concentrate on finding out how the financial service offering should be combined in various channels, and what kind of services are regarded as attractive in the electronic channel. Further studies should also examine other industries and companies to confirm the relationship between the electronic service usage and relatively weaker relationship with the service provider.

RECONCEPTUALISING THE INFORMATION SYSTEM AS A SERVICE
(RESEARCH IN PROGRESS)

Gable, Guy, Queensland University of Technology, Brisbane, Australia  g.gable@qut.edu.au
Rai, Arun, Georgia State University, Atlanta, USA  arun.rai@ceprin.org

Abstract

The study will cross-fertilise Information Systems (IS) and Services Marketing ideas through reconceptualising the information system as a service (ISaaS). The study addresses known limitations of arguably the two most significant dependent variables in these disciplines - Information System Success or IS-Impact, and Service Quality. Planned efforts to synthesise analogous conceptions across these disciplines, are expected to force a deeper theoretical understanding of the broad notions of success, quality, value and satisfaction and their interrelations. The aims of this research are to: (1) yield a conceptually superior and more extensively validated IS success measurement model, and (2) develop and operationalise a more rigorously validated Service Quality measurement model, while extending the ‘service’ notion to ‘operational computer-based information systems in organisations’. In the development of the new models the study will address contemporary validation issues.

Keywords: ISaaS, IS as a Service, IS-Impact, IS success, Information system success, Service quality, IS service quality, Formative construct validation.
1 INTRODUCTION

The study aims to make parallel contributions to the two fields of Information Systems and Services Marketing. The study proceeds from a central interest in the importance of evaluating information systems (IS) in organisations, and adopts the IS-Impact model of (Gable et al. 2008) as the primary commencing theory-base. Akin to analytic theory1 (Gregor, 2006), IS-Impact is conceptualised as a formative, multidimensional index, wherein the dimensions have a causal relationship with the overarching measure – IS-Impact.

IS have evolved to be intertwined with organisational processes, users increasingly interacting with the IS to co-produce the service and the IS accommodating heterogeneity in process and information needs (Rai, Lang, & Welker, 2002). Yet, research to date measuring IS success (including IS-Impact) has, typically, implicitly regarded the IS as a ‘product’, thereby possibly underestimating its service value to stakeholders. In parallel with continuing validation and generalisation of the ‘IS-Impact’ model (Gable et al., 2008), there is value in reconceptualising the IS ‘as a service’ (ISaaS) and ultimately triangulating measures of ‘ISaaS’ with IS-Impact. Important research questions are: ‘Does conceptualising the IS as a service yield a more complete and accurate estimate of its impact?’ and ‘Is the Service Quality of the IS already accounted for wholly or partially by existing IS-Impact dimensions and measures?’

From an Information Systems perspective, main intended outcomes are to: (1) explore implications for evaluating IS from conceptualising the IS as a service; (2) bring conceptual clarity to the Information Systems discipline regarding the alternative notion of Service Quality as a ‘dimension’ of Information Systems Success (SVQD) as suggested by DeLone and McLean (2003); and (3) further validate the IS-Impact model of Gable et al. (2008). From a Services Marketing perspective, main intended outcomes of the study are to: (1) develop, and operationalise a more rigorously, empirically validated Service Quality measurement model; and (2) extend the ‘service’ notion to ‘operational information systems in organisations’ (IS).

1.1 Significance for practitioners

The Information and Communications Technology (ICT) market in Australia alone is worth $38B, 3rd largest in Asia-Pacific (10th in the world). This spend is by both private and public sector, and by both large and small organisations (SME spend in Australia in 2003 was $12B). Complex and expensive IT innovations (e.g. Enterprise Systems) are transforming organisations and industries, but not always for the better. Yet, IT investments are seldom systematically evaluated post-implementation, and where assessed, the process and measures are typically idiosyncratic and lacking credibility. Reliable, valid and comparable indicators of the impact of IS are required for organisations to know how their IT investment is performing, to maximise benefits, and to better plan future IT investments.

1.2 Significance for research

The study addresses known limitations of what may be the two most important dependent variables in

---

1 The first of Gregor’s (2006) five types of theory in IS, analytic theories, “analyse ‘what is’ as opposed to explaining causality or attempting predictive generalizations … they describe or classify specific dimensions or characteristics of individuals, groups, situations or events by summarizing the commonalities found in discrete observations” (2006, p.612).

2 The concept of IS-as-a-service (ISaaS), coined here for the first time, should not to be confused with the notion of ‘Software as a Service’ (SaaS), which refers to a means of software deployment whereby payment is typically on a usage basis. Neither should ISaaS be confused with the ‘Service Quality of the IS function’ (sometimes ambiguously referred to as ‘IS Service Quality’), most notably introduced in 2003 by DeLone & McLean (2003) to their IS success model.
Information Systems and Services Marketing research, namely Information System Success or IS-Impact, and Service Quality. The study is novel in aiming to cross-fertilise learnings of these two disciplines; efforts to harmonise conceptions of IS-Impact and Service Quality being expected to force a deeper understanding of the broad notions of success, quality and satisfaction and their interrelations.

2 LITERATURE REVIEW

2.1 IS success measurement

While the assessment of IS Success is consistently reported by organizational executives throughout the world as a key issue (e.g., Irani and Love, 2000, Thatcher and Oliver, 2001), there is little consensus among practitioners or researchers on how best to measure the impact of IS in organizations. (Sabherwal et al. 2006:1849) observe, “Despite considerable empirical research, results on the relationships among constructs related to information systems (IS) success, as well as the determinants of IS Success, are often inconsistent.”

The (DeLone and McLean, 1992) IS Success model is most widely cited, and includes six constructs: System Quality, Information Quality, Satisfaction, Use, Individual Impact, and Organisational Impact. Nonetheless, a range of concerns have been suggested with past attempts to validate that model, including: poor measurement (e.g., incomplete or inappropriate measures) (DeLone and McLean, 1992, DeLone and McLean, 2002, DeLone and McLean, 2003, Gable, 1996, Melone, 1990), lack of theoretical grounding and, hence; lack of agreement on appropriate measures (Bonner, 1995, Myers et al., 1998); myopic focus on financial performance indicators (Ballantine et al., 1996, Kaplan and Norton, 1996); weaknesses in survey instruments employed (e.g., constructs lacking in validity); or inappropriate data collection approach (e.g., asking the wrong people, unrepresentative sample) (Seddon et al., 1999). Moreover, the lack of consensus on such a central dependent variable, compromises the comparability of study results and hinders the cumulative research tradition.

Gable et al. (2008) introduce the IS-Impact model (see also Gable et al. 2003, Sedera & Gable 2004), which, based in DeLone and McLean’s work, overcomes many concerns with past IS Success models (see Figure 1). In attention to proliferation of overlapping measures, (Gable et al. 2008) comprehensively evaluated existing items, resolving redundancy and identifying new measures for contemporary IS. Their model reconciles persistent confusion regarding the role of the DeLone and McLean constructs as measures versus explanandum, conceptually demonstrating their value as both. Their analysis represents the first test of the sufficiency and necessity (or not) of the six DeLone and McLean constructs; they ultimately evidence the sufficiency and necessity of the four IS-Impact dimensions. They argue the redundancy of Use, and consistent with contemporary views in Information Systems and other disciplines, they present a strong rationale for conceiving Satisfaction as a consequence of success (and antecedent) rather than a dimension (Figure 1).

User satisfaction has been possibly the most extensively employed single measure for IS evaluation [DeLone and McLean, 1992, Doll and Torkzadeh, 1988, Etezadi-Amoli and Farhoomand, 1991, Gatian, 1994, Igbaria and Tan, 1997, Lucas, 1975]. Several widely cited studies developed standard instruments that measure satisfaction [Bailey and Pearson, 1983, Baroudi and Orlikowski, 1988, Doll and Torkzadeh, 1988]. Early satisfaction constructs in IS success evaluation (e.g., user information satisfaction—Bailey and Pearson 1983) have been found to mix measures of multiple success constructs (e.g. quality and impact) rather than measuring a distinct satisfaction construct [Gable 1996]. Rai et al (2002), state that user satisfaction has been measured indirectly through Information-Quality, System-Quality and other variables in prior studies. Additionally, [Sedera and Tan, 2005] demonstrated – through content analysis of 192 satisfaction-related items from 16 Satisfaction instruments – that 98% (189) of the measures readily map into existing measures pertaining to: System-Quality, Information-Quality, Individual-Impact and Organizational-Impact; with only 2% of the items (3 items) appearing to measure Satisfaction explicitly.

The conception of Satisfaction as immediate consequence of IS-Impact too has support in the Marketing discipline. Services marketing researchers e.g. [Brady et al 2005; Anderson and Sullivan 1993; Spreng and MacKoy 1996] employ a nomological
Gable et al. (2008) define the IS-impact of an Information System (IS) as “a measure at a point in time, of the stream of net benefits from the IS, to date and anticipated, as perceived by all key-user-groups”. The four-dimensional IS-Impact measurement model consists of two halves; the “impact” half includes Organizational-Impact and Individual-Impact dimensions; the quality half includes System-Quality and Information-Quality dimensions. The IS-Impact model, by design, is intended to be robust, simple and generalizable, to yield results that are comparable across time, stakeholders, different systems and system contexts. The model and measurement approach employ perceptual measures and offer an instrument that is relevant to all key stakeholder groups, thereby enabling the combination or comparison of stakeholder perceptions. Such a validated and widely accepted IS-Impact measurement model has both academic and practical value.

![IS-Impact Model](image)

*Figure 1 – The IS-Impact Model as mapped into IS-Net* (from Gable et al. 2008:395)

### 2.2 Service quality measurement

Practitioners and academics have sought since the 1980s to better understand the quality of services (Brogowicz, Delene and Lyth 1990). The measurement of Service Quality has been of central interest to the Services Marketing discipline for several decades. Online services today are pervasive and service quality is recognised as a key contributor to national economies and an increasingly important competitive differentiator.

SERVQUAL (Parasuraman, Berry & Zeithaml 1988) a multi-item scale that decomposes the notion of service quality into five constructs: tangibles, reliability, responsiveness, assurance and empathy, has been the most widely employed and cited measurement model. (Parasuraman, Berry and Zeithaml 1988) define ‘service quality’ broadly as “a global overarching judgment or attitude relating to the overall excellence or superiority of a service;” nonetheless, the term has many interpretations. Though there has been considerable progress on how to measure service quality perceptions, little consensus has been achieved on what should be measured. There is agreement that service quality is multi-dimensional, but little agreement as to the nature or content of these dimensions (Brady and Cronin 2001). In example, within the banking sector, there exist multiple service quality models, each

---

net that positions Satisfaction as immediate consequence of Service Quality; Satisfaction being antecedent of Behavioural Intention.

5 The IS-Impact model is shown here as mapped into the (Benbasat and Zmud (2003) nomological net IS-Net. (Gable et al. 2008) reconcile DeLone and McLean, IS-Net and IS-Impact.
consisting of varying numbers and nature/content of dimensions. More recent work by Brady and Cronin (2001) has provided a new and integrated conceptualisation of service quality. Brady and Cronin argue convincingly that customers form service quality perceptions on the basis of their evaluations of three primary dimensions: outcome quality, interaction quality, and environmental quality; these three primary dimensions are composed of multiple sub-dimensions.

In the 1990s, in recognition of the expanding service role of the IS function, Information Systems researchers such as Pitt et al. (1995) proposed that SERVQUAL be adapted to provide information about user satisfaction with the IS function. Despite some criticism (e.g. van Dyke, Prybutok, & Kappelman, 1999) the IS-adapted SERVQUAL has been praised for its practical relevance (Jiang, Klein, & Carr, 2002) and continues to be used to evaluate technical support service interactions (e.g. Carr (2002)). More recently IS researchers have also adapted SERVQUAL for use in the evaluation of electronic service environments such as e-commerce web sites (e.g. van Iwaarden, van der Wiele, Ball, & Millen, 2003) and Internet banking sites (e.g. Jayawardhena, 2004).

Conceiving a product as a set of service characteristics is not entirely new. It was first suggested by Lancaster (1966) four decades ago, and several researchers have since applied Lancaster's ideas. Saviotti and Metcalf (1984) used the idea of a product as a set of service characteristics to develop a framework for the evaluation of technological phenomena such as cars, and Gallouj and Weinstein (1997) used it to interpret innovation processes.

2.3 Contemporary Construct Validation

Construct validation issues and concerns have generally been under-addressed in many fields of research endeavour, with the Information Systems and Marketing disciplines responding relatively recently. Burton-Jones and Straub (2006) focus on the importance of operationalisation in light of the specific research context, theory and hypotheses, highlighting concerns with over-reliance and inappropriate reliance on ‘omnibus’ constructs.

Recent work by Jarvis et al. (2003) and Petter et al. (2007) suggests extensive misspecification and validation of constructs as ‘reflective’ that are on closer scrutiny in fact ‘formative’. Reflective constructs have observed measures that are affected by an underlying latent, unobservable construct (MacCallum & Browne 1993), while formative constructs are a composite of multiple measures. A change in the reflective construct affects the underlying measures, while changes in the formative measures cause changes in the underlying formative construct. Because measurement error impacts the structural model, misspecification of constructs as formative or reflective increases the potential for both type I and type II errors. Though not explicitly acknowledged nor addressed in the Services Marketing literature, the SERVQUAL and B&C models are ‘formative’ (as is IS-Impact). Thus, while the B&C Model (Brady & Cronin 2001) represents the most rigorously validated existing Service Quality measurement model, validation of the B&C model has to date not accounted for its formative nature.

Petter et al. (2007) have cast doubt on the validity of many mainstream constructs employed in IS research over the past 3 decades. They critique the almost universal conceptualisation and validation of these constructs as reflective. They are politic in not citing specific infractions but, rather, they list a range of studies and example constructs that have been ‘properly’ specified as reflective or formative. It is noteworthy that no examples of the proper specification of either the Individual-Impact or Organisational-Impact dimensions are cited (recognising that their list is not intended to be comprehensive). Cited examples of the proper specification of other of the DeLone and McLean dimensions are few, particularly in light of their extensive employment in IS research (e.g. only 1 example each of System-Quality and Information-Quality, both from the same study (Wixom & Todd 2005)). The IS-Impact model (Gable et al. 2008), however, is formative and is validated as such.

Each of IS-Impact, SERVQUAL and B&C and whatever ‘new’ model that derives from the Identification-Phase, employs survey instruments and multi-item scales that aim to measure real world
phenomena or latent constructs. Allport and Kerler (2003, p.356) suggest that ‘measurement is perhaps the most difficult aspect of behavioural research’. Validation of such latent constructs typically employs the so-called classical test theory (CTT), however, other approaches are gaining traction. In example, Item Response Theory (IRT) Rasch (1993) employs statistical models to achieve the ‘objective’ measurement of latent traits. And though relatively few papers in leading IS journals report the use of the Rasch IRT model [exceptions include Dekleva and Drehmer (1997) and Alvarez et al. (2007)], several recent marketing papers have suggested advantages of this approach (e.g. Salzberger and Sinkovics 2006).

3 THE CONCEPTUAL STUDY MODEL

The initial study model, developed in the first phase of the study, is depicted in Figure 2. This conceptual model incorporates three sub-models, and evaluates the relative power of IS-Impact, IS-Impact+ (IS-Impact plus SvQD) and ISaaS to predict Satisfaction.

The 1st sub-model: IS-Impact (as reproduced top Figure 2), with a strong basis in work by DeLone and McLean (1992, 2003), includes 4 dimensions in two halves, representing ‘the stream of net benefits from an Information System to date and anticipated as perceived by all key-user-groups’ (Gable et al. 2008). The ‘impact’ half measures benefits to date, or Individual-Impact and Organizational-Impact. The ‘quality’ half, uses System-Quality and Information-Quality as proxy measures of probable future impacts.

The 2nd sub-model: IS-Impact+, is a variant on IS-Impact which includes SvQD as a 5th dimension. There is potential for confusion here between our broader notion of ISaaS and the DeLone and McLean (2003) notion of Service Quality as a ‘dimension’ of Information System Success (SvQD). DeLone and McLean (1992), the most widely cited IS success model, extended their model in 2003 by including Service Quality (SvQD) as additional to their original dimensions of system success. Citing Pitt et al. (1995) they emphasise the dual role of contemporary organisations as both information provider (producing an information product) and service provider (providing support for end user developers) and argued for the inclusion of ‘service quality of the IS function’ as a dimension when evaluating IS success. Various researchers have employed ‘service quality of the IS function’ as a dimension in evaluating system success (Pitt et al. 1995; Jiang et al. 2002; Laurn & Lin 2003; DeLone & McLean 2004). (Watson, Pitt and Kavan 1998) argue the need to identify actions at the strategic, tactical and operational levels that will yield maximum improvement in IS service quality.

The 3rd sub-model: ISaaS, derives from more recent work by Brady and Cronin (2001). Consistent with ideas espoused by (Dabholkar et al. 1996, 2000), it represents service quality perceptions as multilevel and multidimensional, the rationale being that customers tend to cognitively decompose service quality dimensions into various sub-dimensions (Carman 1990), and a hierarchical structure accounts for the complexity of human perceptions (Dabholkar et al. 1996). Brady and Cronin (2001) bring substantial clarity and harmony to the measurement of service quality, their model in some sense subsuming SERVQUAL. Their third order model (ISaaS in Figure 2) relates service quality perceptions to the three dimensions – Interaction quality, Environment quality, and Outcome quality; each of which has three sub-dimensions that define the basis of service quality perceptions. They further suggest that for each of these sub-dimensions to contribute to improved service quality perceptions, the quality must be perceived to be reliable, responsive and empathetic.

The study aims to exploit perceived potential from cross-fertilisation of ideas between the IS and Marketing fields, the hierarchical structures of the IS-Impact and B&C models being analogous in several ways. In example, (Gronroos 1982), as cited in (Brady & Cronin 2001, p.35), suggests two main service quality dimensions where ‘Functional quality represents how the service is delivered; that is, it defines customers’ perceptions of the interactions that take place during service delivery. Technical quality reflects the outcome of the service act, or what the customer receives in the service
encounter.’ With the ‘operational’ IS (the focus of IS-Impact – and the unit-of-analysis in this study), where the system itself is conceived as a stream of services or a systematised (automated) service, the system (and its quality) are the ‘functional’ and its impacts are the ‘technical’ (or outputs). Note that the key distinction made in the IS-Impact model, between its Quality and Impact halves, is also similar to Alter’s distinction (in Seddon et al. 1999) between ‘internal performance’ and ‘external performance’ which respectively refer to ‘how well the system operates internally’ versus ‘how well the system achieves it purpose’ (1999, p.48).

The IS-Impact Model

IS-Impact+

Details of the ISaaS sub-model in Figure 2, tentatively (thus the cloud) reflect the B&C model. The B&C model may ultimately be supplanted by a partially or substantively different model deriving from the exploratory Identification-Phase of the proposed study (see Figure 3). In the simplest scenario, the B&C model is adapted to the purpose of ISaaS. This may involve some variation of its dimensions or sub-dimensions (potentially the only variation being with the adaptation of its items). In example, an open issue is whether all nine B&C dimensions are relevant when conceptualising the IS as a service. Dependent on the operational definition of the IS, the B&C ‘Environment’ dimension – a) may not vary with different IS (‘I use different systems, but all from the same PC and desk’); b) may be optional (‘with my WiFi laptop I work from wherever I am’); or c) may more appropriately refer to the web environment (the look-and-feel of the virtual environment). In a more extreme scenario, inductive attention to quality-citations gathered in the exploratory Identification-Phase may suggest a radically different ISaaS model structure from that of the B&C model.

Finally, note that in the study model, the Satisfaction construct is: a) the immediate consequence of each of IS-Impact, IS-Impact+ and ISaaS; b) the only reflective construct in the study model (all others expected to be formative), this being a requirement for full identification of the formative IS-Impact, IS-Impact+ and ISaaS models (see Jarvis et al. 2003; Petter et al. 2007); and c) to be operationalised in full light of the model and study intent, as per Burton-Jones and Straub (2006).
4 APPROACH AND METHODOLOGY

4.1 The Study Design

To operationalise and validate the ISaaS model, the study employs a longitudinal, multi-method research design, extending the research cycle proposed by MacKenzie and House (1979) and McGrath (1979) for developing and validating a measurement model. The research design (Figure 3) entails two main phases and three surveys: (1) an exploratory-phase, to develop the hypothesised measurement model, and (2) a confirmatory-phase, to test the hypothesised measurement model against new data gathered. The exploratory phase adheres with the two-step approach of Burton-Jones and Straub (2006) for operationalising constructs and identifying measures, the related aim being to adequately account for the context of contemporary IS, and to ensure model completeness and an appropriate and complete choice of measures and dimensions.

The exploratory phase consists of two surveys, an identification-survey followed by a specification-survey. The identification-survey, akin to the ‘function’ phase of the Burton-Jones et al. (2006) approach, is intended to identify the salient dimensions and measures of the study ISaaS conceptual model (bottom sub-model in Figure 2); these dimensions and measures will later become the basis of an a-priori model to be operationalised in the specification-survey.

The study model will be tested empirically, primarily employing 1-7 point Likert survey data gathered longitudinally in relation to Enterprise Systems – Financials (the financial module of large enterprise Systems packaged software suites. E.g. SAP, ORACLE, Peoplesoft, …). The study will be restricted to Financials, they being ‘relatively’ simple and homogenous (across organisations); and, as intra-organisational systems, only internal stakeholders need be canvassed. In order to gain a holistic view, all key-user-groups (Gable et al. 2008) will be surveyed, namely, Strategic, Management, Operational and Technical. Target sources of data include organisations with which the team has a track-record; e.g. Queensland Government agencies (mainly SAP Financials) and Universities (various).

In response to concerns expressed by Salzberger and Sinkovics (2004) and others, with classical test theory (CTT), an extension of the proposed study will entail the operationalisation and validation of all study constructs, employing both CTT and Item Response Theory (IRT) approaches, and corresponding comparison and triangulation of results.

The Identification-survey aims to generate a comprehensive inventory of ‘qualities’ of services experienced. Respondents are prompted to describe (both closed and open questions), and anchor their responses in, the target Financial system. Part B of the instrument seeks brief, qualitative, textual statements on perceived ‘qualities’ of that system as a service. These statements are decomposed into their component quality-citations (content analysis), then mapped into candidate frameworks (target: minimum inter-coder reliability of 80%). To the extent that any one of the frameworks (e.g. SERVQUAL, IS-Impact, B&C …) is fully instantiated and fully accommodates the quality-citations, it may be considered complete (manifests content validity) and appropriate. Should none of the candidate frameworks adequately accommodate the quality-citations, a bottom-up and more grounded approach will be attempted, seeking to identify salient dimensions and sub-dimensions from the data. The main outcome of this stage is the ISaaS a-priori model.

The Specification-survey (the 2nd survey) aims to further specify and test the a-priori ISaaS model employing data gathered (primarily 7-point Likert scales) with an instrument that operationalises the dimensions, sub-dimensions and measures deriving from the identification-survey (possibly a variant of the B&C model; possibly something quite different). In order to establish internal validity for a formative index, we follow guidelines by Bagozzi (1994), Diamantopoulos and Winklofer (2001) and Spector (1992). We also follow Jarvis et al.’s (2003) procedures for achieving identification of formative indicators, aiming for construct identification through both measurement (employing reflective criterion measures) and structural relations (the path with Satisfaction).
The Confirmation-survey aims to further validate the study model and instrument deriving from the exploratory-phase, and to further illustrate the mutual exclusivity and additivity of the measures and dimensions in the Model using confirmatory data analysis techniques and new data. In this phase of the study, we have the further objective of parallel testing of CTT and IRT data measurement approaches. Thus, four main bodies of data are required: (1) ISaaS CTT data, (2) ISaaS IRT data, (3) IS-Impact+ (subsumes IS-Impact) CTT data, and (4) IS-Impact+ IRT data. The effort and complexity of operationalisation is not underestimated. And though the team has comparatively advantageous access to large organisations for evidence, careful consideration in detailed design of data collection will need to address potential respondent fatigue and CMV (e.g. through random sub-sampling, longitudinal sampling). To complete the research cycle proposed by Mackenzie et al. (1979), construct validation tests similar to the Specification-Survey are conducted on the Confirmation-Survey data.

5 PROGRESS TO DATE AND NEXT STEPS

A literature survey has been completed, examining relevant issues relating to IS Success and to Service Quality measurement in the Services Marketing discipline. An evaluation has been made of current challenges in relation to construct measurement and validation in research. This has incorporated a literature review supported by a conceptual analysis. A basis for synthesising concepts from IS Impact measurement and from contemporary Service Quality measurement has been established. An initial conceptual Service Quality model has been developed as the basis for creating the a-priori model to be tested and refined into a validated ISaaS model.

The study has been proposed to the Australian Research Council, and acknowledges the generous support of that effort from a panel of two experts who offer alternative perspectives on the study design and developments. (1) Professor Teck Hua Ho, William Halford Jr. Family Professor of Marketing, Berkeley, brings a strong quantitative marketing perspective and a track record of research into consumer satisfaction (e.g. Ho 2006). (2) Associate Professor Judy Drennan, Faculty of Business, Queensland University of Technology, has specialist expertise in Services Marketing and Service Quality measurement (e.g. Drennan et al. 2003). The authors are optimistic the study will continue with ARC support. The study is regardless in 2009 proceeding with the Identification-survey.

Abstract: Information communication technologies (ICTs) have significantly revolutionized travel industry in the last decade. With an increasing number of travel companies participating in the Internet market, low price has become a minimum qualification to compete in the Internet market. As a result, e-service quality is becoming even more critical for companies to retain and attract customers in the digital age. This study focuses on e-service quality dimensions in the Internet market with an empirical study on online travel service. The purpose of this study is to develop a scale to evaluate e-service quality from the perspectives of both online companies and customers, which provides fresh insight into the dimensions of e-service quality. The results in this study indicate that trust from the perspective of customer and ease of use from the perspective of online company are the most critical and important facets in customers’ perception of online travel service quality, while reliability, system availability and responsiveness have influence on customer’s perception of online travel service quality as well, but the influence is not so strong as that of trust and ease of use. Online travel service companies should pay attention to the facets of reliability, system availability and responsiveness while focusing on the facets of ease of use and trust in order to improve their online travel service quality to customers.

Key words: E-service, Quality, SERQUAL, Online Travel Service.
1 INTRODUCTION

With the rapid development of information and communication technology, Internet and World Wide Web (WWW) have become important tools in business, which has a major impact on business world. Internet has significantly revolutionized travel industry in the last decade. In the early stage of Internet market, online travel service companies had competed with traditional travel service companies by providing travel service at lower prices. With an increasing number of travel companies participating in the Internet market, the initial price advantages in online travel service has nullified, and low price has become a minimum qualification to compete in the Internet market (Sohn and Tadisina 2008). Therefore, travel companies operating in the Internet market need to find something else to attract customers to their online travel service. Oliveria et al. (2002) state that electronic service (e-service) might be the key to long-term advantages in the digital times, and e-service quality is becoming even more critical for companies to retain and attract customers in the digital age (Oliveria et al. 2002).

Though e-service is very important in the Internet market, most online travel companies seem not to focus on their online service to customers. They do not recognize that the competition among online travel companies relies mainly on their online service, and they do not have the motivation to adopt some strategies to develop or improve their online travel service to customers. Even though some companies have realized the importance of online travel service to customers, they seem not to understand customer’s perception of online travel service and how customers assess their online travel service quality.

Currently, despite many studies concerning traditional service quality, relatively few studies have been conducted in the Internet market, and even less on online travel service quality. This study focuses on e-service quality dimensions in the Internet market with an empirical study on online travel service. The purpose of this study is to develop a scale to evaluate e-service quality, which provides fresh insight into the dimensions of e-service quality. Internet-based travel companies mainly provide intangible service to customers. Thus, in this study the meaning of e-service indicates any intangible product-related services over the Internet provided by Internet-based travel companies.

The remainder of this paper is organized as follows. Following the introduction, the second section provides a relative literature review on both service quality and e-service quality construct. The third section presents the research hypotheses and research model. The fourth section is on empirical data analysis, and the fifth section discusses the results and the findings of this study. Finally, the study concludes with a discussion of the limitation of the study, and the future research in this field is presented as well.

2 LITERATURE REVIEW

2.1 Service Quality

Traditional service quality refers to the quality of all non-Internet based customer interactions and experiences with companies (Parasuraman et al. 1988). Service quality is determined by the difference between expected service and perceived service from companies (Zeithaml 1998). Parasuraman et al. conduct empirical studies in different service industries to develop and refine the service quality instrument (SERQUAL) to assess companies’ service quality (Parasuraman et al. 1988, 1991, 2005). They aim at providing a generic instrument for measuring service quality across a broad range of service categories. The widely used SERQUAL instrument is composed of five dimensions (Parasuraman et al. 1988), which is based on the original ten dimensions of service quality put forward by Parasuraman et al. (Parasuraman et al. 1985). The five dimensions of SERQUAL are:

- **Tangibles:** The appearance of physical facilities, equipment, personnel and communication materials;
- **Reliability:** The ability to perform the promised service dependably and accurately;
Responsiveness: The willingness to help customer and provide prompt services;
Assurance: The knowledge and courtesy of employees and their ability to convey trust and confidence;
Empathy: Care and individualized attention provided to customers.

The five dimensions of SERVQUAL was initially used to measure service quality in various service companies, including banks, credit card companies, telephone companies and travel companies, and was found to be valid in the traditional service market. Some academic researchers applied the SERVQUAL scale to measure service quality in the context of e-service. However, SERVQUAL has been considered problematic and may not be quite appropriate for e-service quality evaluation. The reason is that e-service is different from traditional service with three aspects standing out: the absence of sales staff, the absence of traditional tangible element, and self-service of customers. In this light it is clear that the SERVQUAL is not suitable for measuring e-service quality, and it is meaningful to develop an instrument for measuring e-service quality.

2.2 Development of E-service Quality Measures

With the increase of e-service adoption in business field, the importance of measuring and monitoring e-service quality in the virtual world has been recognized, and e-service quality posits to be a hot topic in research field. Some academic researches have already been conducted to develop e-service quality measurement. From the existing literature, it is evident that these studies have been conducted mainly in the domains of online retailing service, online shopping website quality, and e-service quality. There has been limited attention on online service sector.

Much of the studies in e-service quality take a combination of traditional service quality dimensions and web interface quality dimensions as the starting point. Dabholkar (1996) conducts a research work on the dimensions of e-service quality focusing on website design, and he argues that 7 dimensions of e-service quality can be illustrated as the basic parameters in the judgement of e-service quality, including website design, reliability, delivery, ease of use, enjoyment and control (Dabholkar 1996). Yoo and Donthu (2001) develop a 4-dimension scale called SITEQUAL to measure online service quality of website, and the four dimensions are ease of use, aesthetic design, processing speed, and interactive responsiveness (Yoo and Donthu 2001). Cox and Dale (2001) set up 6 dimensions of online retailing service quality with the comparison of the traditional dimensions of service quality, and the six dimensions are website appearance, communication, accessibility, credibility, understanding and availability (Cox and Dale 2001). Wolfinbarger and Gilly (2002) develop an e-service quality scale which was initially titled COMQ and later was progressed to eTailQ with the following four dimensions: website design, reliability, security and customer service (Wolfinbarger and Gilly 2002, 2003). Lociacono et al. (2002) develop an e-service quality scale called WEBQUAL, which is composed of 12 dimensions (Lociacono et al. 2002).

There is growing recognition of different variability in the outcome of e-service quality studies in terms of the quality dimensions (Waite 2006; Kim et al. 2006). Recently research on e-service quality shows more different dimensions in e-service quality (Madu and Madu 2002, Surjada et al. 2003; Santos 2003; Yang et al. 2003, 2004; Field et al. 2004; Kim and Stoel 2004; Yang and Fang 2004; Long and McMellon 2004; Gounaris et al. 2005; Lee and Lin 2005; Kim et al. 2006; Fassnacht and Koese 2006; Cristobal et al. 2007). Madu and Madu (2002) develop a 15 dimensions scale of e-service quality based on better understanding of customer and providing services to meet the needs and expectations of customers (Madu and Madu 2002). Santos (2003) argues that both active and incubative dimensions are important in e-service quality, and both of the dimensions should be taken into account in e-service quality assessment. An 11 sub-dimensions scale is put forward based on the two dimensions of e-service quality (Santos 2003). Field et al. (2004) develop a process model for assessing and improving service quality by identifying e-service system entities and transactions between those entities and mapping key quality dimensions onto them (Field et al. 2004). Gounaris et al. (2005) argue that the dimensions of perceived e-service quality are influenced by different
antecedents (Gounaris et al. 2005). Yang (2002) identifies the differentiation among dimensions between online-purchaser and non-purchaser (Yang 2002). Yang and Fang (2004) further examine the differentiation of dimensions to online service satisfaction and dissatisfaction. They suggest that there are four salient quality dimensions leading to both satisfaction and dissatisfaction: responsiveness, reliability, ease of use and competence (Yang and Fang 2004). Zeithaml et al. (2000, 2002) and Parasuraman et al. (2005) carry out a study on Internet service quality based on their earlier research on service quality in the traditional distribution channels, and develop an E-S-QUAL scale based on the 7 dimensions proposed by Zeithaml (Zeithaml 2000, 2002; Parasuraman et al. 2005). The E-S-QUAL scale comprises 11 dimensions in e-service quality, and later Parasuraman et al. (2005) develop the E-S-QUAL into a seven dimensions scale (Parasuraman et al. 2005). Kim et al. (2006) extend the dimensions developed by Parasuraman et al. (2005) into a 9 dimensions scale in e-service quality in order to use them for content analysis and evaluation of websites in the apparel retailing sector (Kim et al. 2006). Sohn and Tadisina (2008) put forward a 6-dimension model for e-service quality assessment based on their empirical study in Internet-based financial institutions (Sohn and Tadisina 2008).

There are some other significant discussions related to e-service quality as well, for example, in the contexts of technology readiness, service experience, customer satisfaction and web site loyalty. Yen (2005) articulates that the importance of attributes of online customer’s satisfaction is dependent on technology readiness (Yen 2005). Research on the antecedents to e-service adoption also suggests that e-service experience has impact on customers’ perception and evaluation of e-service quality (Yang and Jun 2002; Rowley 2006). Cristbal et al. (2007) suggest that the perceived quality of a web site or the degree of customer’s satisfaction to a web site is especially relevant to customer’s loyalty to a web site, and propose a four dimensions scale of e-service quality based on customer’s satisfaction and web site loyalty (Cristbal et al. 2007).

3 RESEARCH MODEL AND HYPOTHESIS

Though studies on service quality and e-service quality have been conducted, and different scales have already been developed for measuring e-service quality, the existing research on e-service quality has been described as fragmented (Wolfinbarger and Gilly 2003). A comprehensive framework is needed to identify the dimensions of e-service quality. After combining and synthesising the existing construct of both service quality and e-service quality, a perceived e-service quality construct is proposed, which consists of the dimensions from both online companies’ and customers’ perspectives. The proposed e-service quality model comprises 9 dimensions: ease of use, website design, reliability, system availability, privacy, responsiveness and empathy from the perspective of online companies, and experience and trust from the perspective of customers (See Figure 1).

Ease of use

Ease of use is defined how easy it is for customers to use website. Website should be designed for customer’s ease of use, including searching, navigating and use. Ease of use is an important determinant in the incubative dimension of e-service quality. Ease of use has been highly rated in customer’s e-service quality measurement, and it has been noted by some researchers (Dobhokar 1996, Zeithaml et al. 2002, Yang 2001, Fassnacht and Koese 2006).

Website design

In the virtual environment of e-service, for customers website is the main access to online organizations and to a successful purchase process. The deficiency of website design can result in a negative impression of the website quality to the customers, and customers may exit the purchase process. Website is the starting point for customers to gain confidence. Website design can influences customers’ perceived image of company, and attract customers to conduct purchasing online easily with good navigation and useful information on the website. Website should provide appropriate information and multiple functions for customers.
Reliability
Reliability refers to the consistency of performance and dependability of companies (Parasuraman et al. 1985, 1988). According to some empirical studies, reliability is the most important dimension of e-service quality. In the virtual environment, it is vital to make customers to trust that the company is going to perform what it promises to do. Reliability can make customers recognize the consistency and credibility of the company as well.

System availability
System availability refers to the correct technical function of the website. In e-service, the system availability makes customers always accessible to the online service offered by online companies, which can help customers to have a good image of online companies. If customers can not use the online system when they need online service, they will switch to some other online companies.

Privacy
Privacy refers to the degree to which the website is safe and customer information is protected. This dimension holds an important position in e-service. Customers perceive significant risks in the virtual environment of e-service stemming from the possibility of improper use of their financial data and personal data.

Responsiveness
Responsiveness refers to effective handling of problems and returns via the Internet. In e-service, company’s prompt service to customers via the Internet can make customers feel more comfortable during purchasing and continue purchasing without interruption.

Empathy
Even though there is no direct human interaction in the virtual e-service process, some human contacts are involved in e-service, for example e-mail communication. Providing customer individual attention
shows empathy to customers. Response to customers should always be cognizant of customer’s needs and show understanding of customer’s needs. In the virtual environment of e-service, empathy is important in customer’s perception of the e-service quality without face-to-face encounter. Accordingly, it is hypothesized that:

\[ H1: \text{Ease of use positively relates to customer’s perception of e-service quality.} \]
\[ H2: \text{Website design positively relates to customer’s perception of e-service quality.} \]
\[ H3: \text{Reliability positively relates to customer’s perception of e-service quality.} \]
\[ H4: \text{System availability positively relates to customer’s perception of e-service quality.} \]
\[ H5: \text{Privacy positively relates to customer’s perception of e-service quality.} \]
\[ H6: \text{Responsiveness positively relates to customer’s perception of e-service quality.} \]
\[ H7: \text{Empathy positively relates to customer’s perception of e-service quality.} \]

**Experience**

Experience is related to customers’ previous e-service usage behaviour. Online experience is customers’ total impression about the online company resulting from customers’ exposure to a combination of virtual marketing tools. Customers’ online experience embraces elements like searching, browsing, finding, selecting, comparing and evaluating information as well as interacting and transacting with the online company (Constantinides 2004). Customers’ online experience can influence their future purchasing intentions, their attitude toward e-service and their satisfaction.

**Trust**

In the context of the Internet, trust toward online companies is often regarded as a key factor of e-commerce growth, online success and competitiveness (Gounaris et al. 2005). Trust in e-service is related to the buying and payment process, the reliability of the website, privacy and securities issues, order fulfilment, service delivery, after sales service and the reputation of the company. Customers’ trust to online companies is critical for online companies’ success. Accordingly, it is hypothesized that:

\[ H8: \text{Experience positively relates to customer’s perception of e-service quality.} \]
\[ H9: \text{Trust positively relates to customer’s perception of e-service quality.} \]

The definitions of the nine dimensions are illustrated in Table 1.

4 RESEARCH METHODOLOGY

4.1 Data Sample

The empirical sample of this study was the customers of some online travel companies in China. The customers were asked to indicate the dimensions which influence their evaluation of online travel service quality. It is based on their previous experience of online travel service booking. The questionnaire was developed mainly based on the scales from previous researches. A five-point Likert-scale ranging from strongly disagree (1) to strongly agree (5) was used to measure each item. The items for measuring the nine dimensions of e-service quality are built based on the instruments developed in previous researches as discussed in the literature review. Some modification and reword in the scale has been conducted to meet the requirements of this study.

The questionnaire was distributed to the customers by mail. Totally 1500 questionnaires were mailed to potential respondents, and 503 of the 1500 individuals replied. Among the 503 responses, 50 of them indicated that they have little or no experience of online travel service booking from online travel companies. The remaining 453 responses are the basis of this study. The 30% response rate can be considered acceptable since generally the response rate for questionnaires in information systems domains is between 8 and 15%. The age profile of the respondents represents most age groups with the majority (58%) being in the 18 to 35 age range and 62.7% of the respondents are male. The sample is considered to represent the Internet users in China. The demographic information of the respondents is shown in Table 2.

Table 2. Demographic Information of Participants

4.2 Measurement Validity

The data analysis was performed using Partial Least Squares (PLS), PLS-Graph Version 3.0, to obtain estimates for the measurement and structural parameters in our structural equation model (Chin et al. 2003). PLS has enjoyed the increasing popularity in recent years because of its ability to model latent construct under the conditions of non-normality and that the theoretical framework is not fully crystallized (Chin 1998).

Convergent validity indicates the extent to which the measures of a construct that are theoretical related are also related in reality. Convergent validity can be evaluated by inspecting the factor loadings of the measures on their respective constructs (Chin 1998; Hulland 1999; Tenenhaus et al. 2005), and the reliability of the measures can be assessed using composite reliability (CR) and average variance extracted (AVE). In this study most of the factor loading are satisfactory with the cut-off value above 0.7, except that the factor loading of three items are acceptable with the cut-off value
between 0.5 and 0.7 (Hair et al. 2006). In this study the values of composite reliability (CR) and average extracted variance (AVE) satisfy the threshold value of 0.7 and 0.5 respectively (See Table 3), which demonstrates good internal consistency and suggests good convergent validity and reliability of the measures in this study (Fornell and Larcker, 1981).

Table 3. Psychometric properties of measures

Discriminant validity can be verified with the square root of the average variance extracted for each construct higher than any correlation between this construct and any other construct (Fornell and Larcker 1981). As shown in Table 4, each construct shares a greater variance with its own measures than with any other construct. This reveals that each construct is more closely related to its own measures than to those of other constructs, and discriminant validity is supported in this study (Fornell and Larcker 1981).

### 4.3 Hypothesis Testing

In this study we use a bootstrapping procedure to test the effects and the statistical significance of the parameters in the structural model. The findings in this study provide significant support for some of the hypotheses proposed in this study. Ease of use, reliability, system availability, responsiveness and trust are supported to be positively related to customer’s perception of e-service quality, while website design, privacy, empathy and experience are not supported to be related to it. Ease of use is the most important factor in e-service quality evaluation ($\beta=0.345$, p<0.001). Trust is the second important variable ($\beta=0.342$, p<0.001). In addition, reliability, system availability and responsiveness significantly affect customer’s perception of e-service quality while website design, privacy, empathy and experience have no significant impacts on customer’s perception of e-service quality. The proposed research model explains 45.7% of e-service quality. The results are shown in Figure 2.

![Figure 2. Structural analysis of the e-service quality model](image-url)

*Note: ***: p-value<0.001, **: P-value<0.01, and *: p-value<0.05*
5 DISCUSSION

Customer perceived e-service quality is one of the critical determinants of the success of online business (Yang et al. 2004). Accordingly, there is a rise of research on the construct of e-service quality. Currently, most of the research is conceptual in nature or based on a few case studies. Though there are survey-based empirical studies examining the construct of e-service, most of them focus on the dimensions from the perspective of online companies, and few studies have been conducted to investigate the dimensions from the perspective of customers, for example customers’ attribute.

In order to fill the research gap, this study empirically examines the construct of e-service quality from the perspectives of both the online companies and customers in the context of online travel service. This study develops a comprehensive instrument to evaluate e-service quality. The results in this study indicate that there are five key dimensions of e-service quality, including ease of use, reliability, system availability and responsiveness from the perspective of online companies, and trust from the perspective of customers. The results of reliability and validity test of the scale demonstrate good psychometric properties of the scale.

The five dimensions have different influence on customers’ perception of e-service quality. Ease of use and trust are ranked as the most critical and important facets of e-service quality, and have the strongest influence on customer’s perception of e-service quality. In this regard, it is noteworthy that ease of use attribute relates to how easy it is for customers to use the website and trust is involved in the confidence among customers by providing prompt and information rich service. Thus, the results of the study suggest that there is a need for online travel companies to place extra emphasis on their website attribute and their service process pertaining to these two dimensions of ease of use and trust.

For online travel companies, providing e-service with good quality involves much more than creating an excellent website for customers. Online travel companies should design its websites to be as easy as possible for customers to use. Online travel companies still need to pay attention on the building of trust in customers, which can help to improve their e-service quality, which prompts the managers to develop right strategies to build trust in customers. Of course, offering true and accurate information on the website might be the first strategy to help online travel companies to build up good image in customers’ mind, and the accurate service delivery might help to improve the confidence of customers. The two strategies can be the most basic strategies to build trust in customers, and some other strategies are needed as well.

Though reliability, system availability and responsiveness have significant influence on customers’ perception of e-service quality, the influence is not so strong compared to the influence of ease of use and trust. The reason might lie in the fact that the service on the three dimensions in online travel industry in China has been developed into a mature period.

Surprisingly, the study results indicate that privacy does not have significant influence on customer’s perception of e-service quality. However, for online companies it is still necessary to assure customers through website design cues and communications to signal customers the privacy of their websites.

In summary, the results in this study support the following conclusions. First, in general comparing the influence to customer’s perception of e-service quality, the dimensions from perspective of the online companies is stronger than that from the perspective of customers. Secondly, trust and ease of use are the most critical and important facets in customers perception of e-service quality. Third, though reliability, system availability and responsiveness are not as important as ease of use and trust, they are still important facets of e-service quality, and online companies should pay attention to them as well while focusing on the facets of ease of use and trust in order to improve online travel service quality. Forth, though privacy has not found to be a significant facet in customer’s perception of online travel service quality, it is still necessary to for online travel companies to assure customers the privacy of their websites.
6 LIMITATIONS AND FUTURE RESEARCH

This study has offered some valuable insight into studies on e-service quality, which involves a number of limitations that need to be acknowledged. First, the empirical study was conducted only in China. It is recommended to replicate the study in different nations to get international sample. Second, the study tests how the experience and trust of customers influence customers’ perception of e-service quality, other aspects of customers, such as attitude to e-service, education, social presence, have not been considered. Thus, there is scope for further work on the other measurement of e-service quality from the perspective of customer.

Abstract

In today’s economy, firms are affected by various government regulations that have implications for their information systems (IS). Regulatory pressure has become a major driver behind IS adoption. Nevertheless, it is currently unknown how regulatory pressure affects adoption success. Using an institutional theory lens, this research proposes that regulatory pressure affects some well established success factors of IS adoption. In particular, we hypothesise that regulatory pressure has a positive effect on top management support, project champion and formal project management; but a negative effect on project team competence. Hypotheses will be tested using a survey approach.

Keywords: Regulatory Pressure, Compliance, Adoption, Success.
1 INTRODUCTION

Experience from practice shows that the success rate of information system (IS) adoption is generally low, with estimations ranging from 16% (Lee, 2003) to 40% (Liang et al., 2007). Motivated by the need to increase the success rate, much research has been conducted into IS adoption (Wixom & Watson, 2001; Premkumar et al., 1997; Lam, 2005). Prior studies suggest that adoption success is influenced by a range of success factors such as top management support (Akkermans & van Helden, 2002; Wixom & Watson, 2001) and formal project management (Aladwani, 2002). Nevertheless, because success factors appear mainly as independent variables in prior studies, there is a lack of knowledge about parameters that influence these success factors. For example, it is not clear why top management support varies across projects (Akkermans & van Helden, 2002). Understanding what affects the success factors can provide a much-needed new perspective on adoption success.

This paper proposes regulatory pressure as one of the parameters that influence success factors of IS adoption. Regulatory pressure occurs when governmental agencies directly or indirectly force firms to change their IS. In today’s economy, firms are affected by various government regulations that have implications for their IS (Krell & Matook, 2007; Braganza & Franken, 2007). For example, many firms in Europe and the US have recently been affected by new auditing regulations based on the Sarbanes-Oxley Act (SOX) (Marnet, 2007). Numerous firms found that their current IS were insufficient to achieve SOX compliance, for instance because of low security standards or a lack of financial monitoring systems. Thus, firms needed to alter their IS to ensure compliance (Sipior & Ward, 2007). Indeed, compliance affects varies IS projects in firms – examples reach from changes to spreadsheet software to the adoption of ERP systems (Gartner, 2008a). Many firms have started to appoint information technology (IT) compliance managers (Gartner, 2008b), and it is estimated that firms spend up to 15% of their IS budgets on regulatory compliance (Gartner, 2006).

IS adoption projects that are affected by regulatory pressure are different from other adoption projects because they are influenced by requirements defined in government regulations. For example, government regulations influence the schedule of adoption projects. Most government regulations define compulsory due dates by which compliance must be achieved (Haworth & Pietron, 2006). As a result, firms are forced to bring forward adoption projects that were actually planned for a later time, or even initiate unplanned adoption projects (Garcia, 2004). Consequently, it is reasonable to assume that regulatory pressure should affect adoption success factors. For example, if a government regulation influences the adoption schedule, and imposes penalties if the adoption is not completed on time, a firm might apply formal project management to ensure that the schedule is adhered to. Understanding how regulatory pressure affects success factors is important, particularly in a time like now when many industry sectors face increasing levels of governmental regulation. Nevertheless, there are currently no studies investigating how regulatory influences affect success factors.

Our paper applies an institutional theory perspective to address this gap. Using DiMaggio’s and Powell’s (1983) work on institutional pressures, we propose that regulatory pressure affects adoption success factors established in prior research. In particular, we hypothesise that regulatory pressure has a positive effect on top management support, project champion and formal project management; but a negative effect on project team competence. The mostly positive effects of regulatory pressure might surprise practitioners, but can be explained through our lens of institutional theory.

This research is expected to contribute to the IS literature in two ways. First, it is an initial attempt to investigate the effects of regulatory pressure on adoption success and provides a new perspective on success. This new perspective is important because in the information age, more and more regulations require firms to make changes to IS. Further, the recent economic and political development in many countries suggests that in the near future, some industries like banking or stock trading will face higher levels of government regulation. Against this backdrop, understanding the effects of regulatory pressure on IS adoption success is useful to increase the currently low success rate of IS adoption. Second, this paper contributes to IS research because it identifies regulatory pressure as a parameter influencing success factors of IS adoption. Future research can use our study as a starting point to identify other parameters, analyse how and why success factors of IS adoption occur in firms, and

Proceedings ECIS 2009
examine interactions between parameters. This work will help firms to deliberately model the success factors and increase IS adoption success. The remainder of this paper is organised as follows. Next, we outline how we use institutional theory as a theoretical lens to study regulatory pressure. Then, the hypotheses are developed, and the methodology is described. Finally, we discuss the current stage of the research.

2 AN INSTITUTIONAL THEORY PERSPECTIVE ON REGULATORY PRESSURE

In contrast to other theories on macro organisational behaviour like the resource-based view (Teece et al., 1997; Barney, 2002) and transaction cost economics (Williamson, 1981), institutional theory assumes that changes in structures and behaviours of firms are less driven by the desire to increase efficiency or create competitive advantage, but rather by a need of legitimacy (Meyer & Rowan, 1977). According to institutional theory, firms constantly aim to maintain and increase legitimacy through complying with pressures that arise from their institutional environment (Mizruchi & Fein, 1999). Three types of pressure exist: mimetic pressure, normative pressure, and coercive pressure (Dimaggio & Powell, 1983). Mimetic pressure arises from uncertainty. In situations when firms possess insufficient knowledge to evaluate alternative behaviours, the mere fact that another institution pursues a particular behaviour increases the legitimacy of this behaviour and hence, the firm mimics this behaviour (Haveman, 1993). Normative pressure, by contrast, results from norms defined by institutions such as professional or industrial associations. Once a firm has internalised a norm and decision makers identify with the norm, behaviours that comply with the norm legitimate the firm (Palmer et al., 1993). Coercive pressure, finally, stems from institutions in a firm’s environment that are powerful enough to reward or sanction a firm’s behaviour, for example large customers, suppliers of scarce resources, or governmental agencies (Guler et al., 2002). Complying with requests from these institutions enables the firm to benefit from rewards and avoid negative sanctions (Dimaggio & Powell, 1983). The focus on legitimacy makes institutional theory an ideal theoretical lens to study regulatory pressure because the main motive behind regulatory compliance is legal legitimacy (Liang et al., 2007).

Regulatory pressure is a special form of coercive pressure (Hu et al., 2007). It arises exclusively from the requirements forced upon a firm by governmental agencies (Braganza & Franken, 2007). There are two reasons why regulatory pressure tends to affect firms stronger than other institutional pressures. First, the regulatory environment in most countries is constantly changing due to ongoing changes in the national and international political development (Damianides, 2005). In contrast to other pressures, one particular change in government regulations affects a tremendous number of firms in a market or country at the same time (Haworth & Pietron, 2006). As a result, regulatory pressure affects firms more frequently than other pressures. Second, it lies in the nature of governmental agencies that they are powerful and impose strong negative sanctions on non-complying firms. For example, the retail multinational TJX failed to comply with US data security regulations and was convicted by a US court to pay compensations of several million US dollars after customer’s credit card details were stolen from the TJX customer relationship management system (DataBreaches, 2008). Firms are highly motivated to comply with regulatory pressures because they aim to avoid the negative sanctions which are associated with non-compliance (Abrahami, 2005).

In the information age, regulatory compliance often requires changes to IS. In most cases, firms do not initiate adoption projects solely for the purpose of compliance. Rather, firms review previously planned adoption projects and make changes to these projects to ensure that compliance is achieved (Hu et al., 2007). Think, for example, of a firm that needs to adopt a financial monitoring system to comply with a regulation. If this firm had planned to adopt a new accounting system in the next time anyway, managers might decide to modify the accounting systems to ensure that the system can be used for financial monitoring as required for compliance. Only if this is not possible the firm will consider initiating a completely new adoption project (Ghandforoush et al., 1999). Regulatory pressure is mostly not the sole driver behind adoption projects, but one of many drivers; and the strength of regulatory pressure as an adoption driver varies across adoption projects.
3 EFFECTS OF REGULATORY PRESSURE ON ADOPTION SUCCESS

For the purpose of this research, IS adoption is defined as the process during which a firm becomes capable of using an IS (Iacovou et al., 1995). Adoption includes, for example, the installation of technical system components, and the revision of firm processes. Adoption is completed when all technical components have been implemented, processes have been revised, and the firm possesses the necessary knowledge to use the IS. The actual usage of the IS is not part of the adoption, rather, it happens directly after the adoption (Iacovou et al., 1995). Iacovou’s definition was selected for this research because it enables the identification of a point of time when the adoption process is completed, and adoption success can be measured.

Commonly, adoption is considered to be successful if the new IS is implemented within budget, if all critical deadlines are met, and if all pre-defined technical requirements are implemented (Wixom & Watson, 2001). Success according to these criteria has been labelled differently in the literature and is referred to as “project implementation success” in this paper. Although prior research agrees that project implementation success is vital for adoption success as a whole, it is possible that an adoption is unsuccessful even if budget, schedule, and technical specifications are completely adhered to (Debrabander & Edstroem, 1977). This can happen, for example, if the pre-defined technical requirements are insufficient to support the firm’s business processes. In this case, managers might consider the adoption unsuccessful because they feel that the usability of the adopted system is low.

To account for this possibility, we build on Hong and Kim’s work on organisational fit (Hong & Kim, 2002) to expand on our definition of adoption success. Organisational fit is defined as the congruence between the IS and the business context in which it is adopted. The business context includes the business processes that an IS facilitates or supports. Many practitioners argue that IS adoption can only be successful if the IS is adequate for a firm’s processes (Gattiker & Goodhue, 2004) and hence, organisational fit is an important component of adoption success. For the purpose of this paper, it is therefore defined that adoption success is comprised of two components: project implementation success and organisational fit success, i.e. the level of organisational fit achieved during the adoption project.

Adoption projects that are initiated because of regulatory pressure differ from other adoption projects. The timing of the project and the technical characteristics of the adopted system are determined externally because they are strongly affected by a government regulation (Braganza & Franken, 2007; Haworth & Pietron, 2006). The stronger regulatory pressure becomes as a driver, the stronger will the adoption project be determined by these externally defined characteristics. By nature, government regulations are composed without special attention to the situation of a particular firm. Hence, timing and technical characteristics are affected by decisions made without consideration of a firm’s strategy, technical infrastructure, or usual IS adoption procedures. For example, a firm might normally go live with new ISs at a time of the year when key IT staff can be expected to be present. However, because of a particular law, the firm could be forced to go live on January 1st, which might conflict with the vacation roster. If the firm has other reasons than compliance to go live with this system on January 1, and compliance is a weak driver behind a particular adoption project, it can be expected that measures will be taken long in advance to ensure that key staff is available. Hence, the government regulation does not require much additional effort. However, if regulatory pressure is a strong driver behind the adoption, and there are no other reasons why the firm would go live on January 1, the additional effort due to the government regulation is tremendous, and ensuring that all key staff are available is a challenge. In this paper, we argue that challenges like this affect some of the adoption success factors identified in prior research. Next, we hypothesise which success factors we propose will be affected.
3.1 The Effect of Regulatory Pressure on Top Management Support

Many studies have demonstrated that adoption success is affected by top management support for an adoption project (Caldeira & Ward, 2003; Wixom & Watson, 2001; Akkermans & van Helden, 2002). Institutional theory suggests that top management support is affected by regulatory pressure. According to institutional theory, institutional pressures affect a firm if powerful agents within the firm recognize the pressure, and perceive that compliance is important and will increase legitimacy (Dimaggio & Powell, 1983). Hence, regulatory pressure will only affect macro organisational behaviour if top executives are aware of a change in government regulations, and of rewards and sanctions associated with compliance and non-compliance (Haworth & Pietron, 2006). Because non-compliance is associated with strong negative sanctions, compliance is considered a top management issue (Garcia, 2004). Even though related decisions can be delegated to a lower management level, top management supervises compliance-related actions and has a strong interest in the successful completion of these activities (Braganza & Franken, 2007). Thus, if regulatory pressure is a strong driver behind an IS adoption project, and the completion of the project is important for compliance, top management will be strongly interested in the adoption project. Hence, top management will strongly support the project. The stronger the regulatory pressure behind an IS adoption, the more will top managers be interested in the project and support the project. Hence, it is hypothesised:

**H1:** The strength of regulatory pressure has a positive effect on top management support.

3.2 The Effect of Regulatory Pressure on Project Champion Commitment

A project champion is a person who actively promotes his vision of an adoption project in a firm with the goal to ensure project success. The level of champion commitment varies across adoption projects. While in some cases project champions are formally appointed but do not engage in any particular activities to promote the project, other project champions frequently and vigorously communicate the benefits of the project (Orlikowski et al., 1995; Lai, 1997). Prior studies have shown that adoption is more likely if a project champion strongly commits to an adoption project (Orlikowski et al., 1995; Akkermans & van Helden, 2002; Lai, 1997; Wixom & Watson, 2001; Premkumar & Ramamurthy, 1995).

The project champion is either a senior manager himself, or he is appointed and supervised by a senior manager (Teo et al., 2003). As discussed before, institutional theory suggests that if regulatory pressure is a strong driver behind an adoption project, senior managers will be highly aware of sanctions associated with compliance, and will commit to avoiding sanctions. Therefore, it can be expected that the project champion will also be committed to avoiding sanctions, either because of his position in the firm, or through the supervision of the manager who appoints him. Consequently, the champion will be highly motivated to engage in actions to promote the project and hence ensure adoption success. Therefore, it is hypothesised

**H2:** The strength of regulatory pressure has a positive affect on project champion commitment.

3.3 The Effects of Regulatory Pressure on Formal Project Management

Formal project management is defined as the degree to which formal methods are used to plan, organise, and monitor an adoption project (PMI, 2004). Varies studies showed a positive relation between formal project management and adoption success (Akkermans & van Helden, 2002; Umble et al., 2003; Aladwani, 2002). In the context of regulatory compliance, formal project management is important because as discussed before, adoption projects are affected by externally determined requirements defined through government regulations, for example requirements that refer to the adoption schedule or to technical specifications. The stronger regulatory pressure becomes as an adoption driver, the more is the adoption project defined by externally determined requirements. Typically, such requirements occur within short periods of time and cannot be planned in advance (Garcia, 2004). Nevertheless, according to institutional theory, firms will attempt to comply with all governmental requirements even if the time frame is unusually short to ensure legal legitimacy.
Thus, firms are challenged to complete adoption projects within a short period of time even if these projects conflict with their usual practices. We argue that firms will opt for highly formal project management to meet such challenges. For example, in case the adoption schedule forced upon a firm through a regulation conflicts with the firm’s usual adoption practices, the firm might use a formal project staff plan to ensure that all required staff are available for the adoption. The more dominating regulatory pressure becomes as an adoption driver, the more challenges will arise, and the more will firms attempt to ensure adoption success through formal project management. Hence, it is hypothesised:

**H3:** *The strength of regulatory pressure has a positive effect on formal project management.*

### 3.4 The Effects of Regulatory Pressure on Project Team Competence

IT competence is defined as “the set of IT-related knowledge and experience” of a person (Basselier et al., 2003). Consequently, project team competence is the set of knowledge and experience of the project team related to a particular adoption project. The required set of knowledge and experience is different for each adoption project (Aladwani, 2002). In times of rapid technology changes, team members need to learn and redevelop their skills for each project (Stratman & Roth, 2002). Hence, firms often regroup project teams, form new teams for particular adoption projects, and retrain team members formally or on-the-job.

In cases when regulatory pressure is a strong driver behind IS adoption and technical requirements are largely determined by government regulations, it is particularly important to retrain team members to ensure that the team possesses the necessary competences to implement the technical requirements. Hence, it is necessary to define formal training measures, expose team members to similar adoption projects where they can get informal training “on the job”, or even hire new team members who possess the necessary qualifications (Walz et al., 1993; Newell et al., 2004). However, most measures to increase team competence require a certain period of time, at least several months, before they yield results (Biros et al., 2002). This is problematic because of the low predictability of changes in the regulatory environment (Garcia, 2004) and the externally defined due-date for compliance (Haworth & Pietron, 2006). According to institutional theory, achieving compliance at the required time will be more important for the firm than completing all competence-increasing measures because of the immense importance of legitimacy (Hu et al., 2007). Hence, it can be expected that in situations when regulatory pressure is a strong driver of IS adoption, the firm will have insufficient time to develop project team competence, and hence it is hypothesised

**H4:** *The strength of regulatory pressure has a negative effect on project team competence.*

### 3.5 The Effects of the Success Factors in the Context of Regulatory Compliance

As discussed before, top management support, project champion, formal project management, and team competence are well established success factors in the literature. An overview over prior research on these success factors is provided in Table 1.

<table>
<thead>
<tr>
<th>Success Factor</th>
<th>Supporting Studies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top management support</td>
<td>(Caldeira &amp; Ward, 2003; Wixom &amp; Watson, 2001; Akkermans &amp; van Helden, 2002)</td>
</tr>
<tr>
<td>Project champion</td>
<td>(Orlikowski et al., 1995; Akkermans &amp; van Helden, 2002; Lai, 1997; Wixom &amp; Watson, 2001; Premkumar &amp; Ramamurthy, 1995)</td>
</tr>

</tr>
</tbody>
</table>

*Table 1. Success factors of IS adoption.*
Due to the lack of prior studies on IS adoption success in the context of regulatory pressure we need to re-confirm that these factors are positively associated with adoption success in our special case. There are no hints in institutional theory why any of the success factors would be negatively associated with success, or not associated with success at all, when regulatory pressure is an adoption driver. Hence, in accordance with prior literature, it is hypothesised:

**H5a:** Top management support has a positive effect on adoption success.

**H5b:** Project champion commitment has a positive effect on adoption success.

**H5c:** Formal project management has a positive effect on adoption success.

**H5d:** Project team competence has a positive effect on adoption success.

### 3.6 Control Variables

While we believe we developed sound hypotheses and use a valid approach to test them, we still acknowledge that adoption success is affected by a range other variables that are not accounted for in our research model. We therefore introduced control variables in our research design which are summarised in Table 2. The research model with all hypotheses and controls is presented in Figure 1.

<table>
<thead>
<tr>
<th>Control Variable</th>
<th>Definition</th>
<th>Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firm size</td>
<td>Size of a firm in terms of number of employees and sales in the last financial year</td>
<td>Firms of different sizes might be affected by different government regulations. Further, firms might struggle to successfully adopt IS due to a lack of resources.</td>
</tr>
<tr>
<td>Industry</td>
<td>Industry in which the firm primarily operates</td>
<td>Firms of different industries might be affected by different government regulations. Further, firms might use industry-specific systems that are easier or more difficult to adopt than systems used in other industries, hence success might vary across industries.</td>
</tr>
<tr>
<td>System complexity</td>
<td>Complexity of the adopted system in terms of technology and required integration with other systems</td>
<td>Complex systems might be more difficult to adopt successfully than less complex systems.</td>
</tr>
<tr>
<td>Project size</td>
<td>Size of the adoption project in terms of number of team members, duration of the project, and project budget</td>
<td>Large projects might exceed budgets and schedules more often than smaller projects because they are more difficult to plan.</td>
</tr>
<tr>
<td>Time elapsed since adoption</td>
<td>Time elapsed since users started to use the adopted system for their regular work tasks</td>
<td>The respondent’s recall of the adoption project might fade or change in the time after the adoption.</td>
</tr>
</tbody>
</table>

4  METHODOLOGY AND CURRENT STAGE OF THE RESEARCH

This research applies a survey approach because it provides statistical power and is an appropriate basis for generalisation (Hair, 2006).

4.1  Research Instrument Development

The survey instrument was developed in a four-step procedure as follows. First, we conducted a literature review to find previous survey instruments for our constructs (Singleton & Straits, 2005). For each construct, several instruments existed in prior research.

Second, we built on prior survey instruments to design the first version of the survey instrument for this research. Because none of the selected instruments had been used in a regulatory pressure context before, we slightly adjusted the wording of some items to make them adequate for the purpose of this research. With the exemption of adoption success, all constructs were identified as reflective. Adoption success was modelled as a formative second-order construct because prior research showed that the two dimensions, project implementation success and organisational fit success, do not necessarily correlate (Hong & Kim, 2002).

In a third step, we evaluated the survey instrument using an academics panel and a practitioner panel. The academics panel comprised five experienced IS academics who were presented with a list of items for each construct. Using a 7-point scale, the academics were asked to evaluate how well each list of items represented the related construct. Further, the academics were also asked to provide comments on the items and constructs. The practitioner panel comprised four IT managers who represented our target participants. Again, participants were shown a list of items for each construct in our questionnaire. On a scale from 1 to 7, the participants indicated how easily answerable the items were. Further, the managers were also asked to provide comments. The average score of the constructs awarded by the academic panel was 5.8, and the average score awarded by the practitioner panel was 5.7. Given the mostly positive feedback from the academic panel, these scores were deemed acceptable. Some changes to the item wordings were made based on comments provided by the panels.

The fourth and final step was the pilot study. The research instrument was electronically distributed to IT managers in Australian firms. 30 usable responses were received. Construct reliability was evaluated using Cronbach’s Alpha. Generally, values above 0.7 are acceptable (Hwang, 2008). All calculated Alphas were above this threshold (see Table 3). Thus, no further changes were made to the research instrument. The final survey instrument is summarised in Table 3. All items are measured on a 7-point Likert scale.

</tbody>
</table>

Table 3.  Survey instrument (control variables omitted).
4.2 Data Collection and Analysis

Data will be collected through a survey amongst IT managers, IT directors and CIOs. This target group was chosen because prior research has shown that IT managers and IT executives are able to evaluate the success factors investigated in this research and the level of adoption success (Cragg et al., 2002; Harland et al., 2007; Wixom & Watson, 2001). Further, they are also aware of compliance-related IS decisions (Garcia, 2004) and thus, they are able to evaluate the strengths of regulatory pressure as a driver behind IS adoption.

Originally, we aimed to apply an online survey approach. However, an analysis of comments from companies that had been invited to participate in the pilot study and had replied that they felt unable to do so showed that in response to recent social engineering attacks, when IT managers were deceived in fraudulent surveys to reveal confidential IT information that would later be used for hacking attacks, many companies have implemented policies that restrained IT managers from participating in online surveys. Therefore, we will apply a mixed electronic and paper survey approach in the main study to increase the response rate. We aim at 200 usable responses.

Data will be analysed using structural equation modelling (SEM)/Partial Least Squares (PLS). PLS is a latent SEM technique that utilises a principal-component based approach to estimation. It can handle formative constructs (Chin & Newsted, 1999) and is robust to small sample sizes (Majchrzak et al., 2005).

5 CURRENT STAGE OF THE RESEARCH

Data was collected in March 2009. A total of 210 responses from eligible respondents were received. At the time of writing the camera-ready version of this paper, the SEM analysis is in progress.

Abstract

Regulatory compliance has become a critical concern for many industries around the globe and investment to achieve compliance has increased drastically inline with that concern. While Information Systems (IS) are considered a part of the support architecture, anecdotal evidence suggests that organisations struggle with finding the right tools and guidance on approaches for compliance management. For this reason, we undertake a review of the current research on compliance management topics in the Information Systems domain, with the ultimate goal to carry out a gap-analysis between research-based solutions and the current needs of compliance management professionals. In this paper, we consider thirteen Information Systems journals and perform an exhaustive analysis of the type of compliance management research published at these venues in the last five years. The analysis found forty-five relevant articles, which were then further classified depending on the type of their contribution. The results of the analysis suggest that IS research in managing compliance has received increasing attention in the recent years. The study also suggests that research has predominantly focussed on exploratory studies, rather than proposition of solutions that can assist organizations in their compliance management regimens.

Keywords: IS Journals, Regulation / Deregulation, Literature Review, Business Process Management
1 INTRODUCTION

Today, regulatory compliance has attracted much investment by organisations across the globe (Braganza & Franken 2007). The boost in compliance related investment is primarily a consequence of regulatory mandates that emerged as a result of events that led to some of the largest scandals in corporate history, such as Enron, WorldCom (USA), HIH (Australia) and Societe Generale (France). Compliance essentially means ensuring that business processes, operations and practice are in accordance with a prescribed and/or agreed set of norms. Introduction of regulations such as Sarbanes-Oxley Act of 2002 (SOX), Health Insurance Portability and Accountability Act of 1996 (HIPAA), Gramm-Leach-Bliley Act of 1999 (GLB) has made regulatory compliance a focal point of many organisations. Organisational units or department such as finance, administrative and information systems are affected by these changes. The investment is necessary for organisations to remain in business (Perskow 2003, Anon et al. 2007), since non-compliance to some government and legal requirements can have dire consequences.

Each new introduced regulation carries with it a potentially significant cost of implementation for those organizations that fall under its control. SOX spending has reached US$6B in 2007 in USA alone, which represents only a fraction of the total compliance effort (Reilly 2007). Meanwhile, analysts predict that overall USA spending on governance, risk and compliance (GRC) will exceed US$32B in 2008 (McGreevy 2008). Hence, increasing compliance expectations are a significant financial drain on organizations and are often considered as a burden rather than a business opportunity. The burden is magnified by the apparent lack of guidance from the research community on the best ways to approach compliance management. In this study, we define compliance management as mechanisms to keep enterprise’s businesses safe from possible violation of regulatory compliance. In his work, Kharbili (2008) stated that compliance management also refers to standards, frameworks, and software used to ensure the company’s observance of legal texts.

There is ongoing discussion on the roles of Information Systems (IS) as enabling technology that facilitates achieving and demonstrating compliance. Although some of the discussion focuses more on the use of IT as a supporting technology to achieve compliance, research also exists on management related issues, for example, how compliance affects CIO responsibilities in the organisation (Berghel 2005) and (Braganza & Franken 2007). While compliance management does not appear to have become a main stream of IS research at this point in time, the apparent lack of guidance for compliance management professionals motivates us to develop a comprehensive understanding of the focus, extent and shortcomings of compliance management research in the Information Systems community. The final goal is the derivation of an industry-relevant research agenda for compliance management. In order to develop such an agenda, two aspects are required, viz. an understanding of the current state of research, and an understanding of current problems exhibited in practice. In this paper we address the first aspect.

We proceed as follows. The next section presents a discussion of the methodology employed to assure a rigorous and relevant analysis of compliance management research. Section 3 presents an in-depth analysis of the relevant research. In section 4 we present a discussion of the results and conclude the paper in Section 5 with a discussion of limitations and future work in this area.

We expected that the majority of the research would be published since 2006, however we considered all papers published at these outlets in 2001-2008 so as to identify any changes in trends and also a change in foci of compliance management research (e.g. a shift of focus to SOX). In total, the data set consisted of 5633 articles. Each paper was prepared and included in a full text search for the purposes of identifying contributions relevant to the compliance management domain. Full text searches were conducted on the data set, using a keyword of “compliance” and “compliant”. Following a stage of eliminating paper duplicates in the search results (i.e. ensuring that a paper that matched both search criteria is only counted once). This analysis provided us with a set of 510 articles. As a further step to assess paper relevance to the domain of compliance management, we inspected the occurrence of the search terms in the paper text, and included only those that had three or more hits. This step reduced and focused the data set on 178 papers.

With the reduced set of papers, a review of each paper and its contribution was carried out. This review included reading the abstract, introduction, and scanning through the main contributions of the remainder of the paper as well as its conclusions. This stage was the most critical part of the study, since it provided an understanding of the contribution of the paper and what aspects of regulatory compliance were addressed (and in what way). This stage of the analysis was helped through a framework that was developed to analyse the contributions of compliance management research. The framework is presented in Figure 1. Within this framework, we differentiate between case study and exploratory papers, versus papers that provide a solution to a compliance management related problem. These identify the two main classes of research approaches. The solution papers were further classified in terms of their focus on preventative, detective or corrective measures. The papers were also classified by geographic region of application of the paper (North America, South America, Africa, Asia-Pacific, Europe), domain of application or industry sector (Financial, Healthcare, E-Commerce, etc) and type of compliance considered (to (1) Regulations or Legislation, (2) Standards and Code of Practice, (3) Business Contracts, Service Agreements etc. and (4) Corporate Policy). The latter classification is intended to provide research context.

This last stage of the analysis and the careful reading of each paper resulted in a further reduction of the data set. Despite the papers having more than three references to “compliance” or being “compliant”, many were determined not to present a main contribution to the domain of compliance management. Instead, they mentioned compliance in various parts of the discussion and future work, however did not focus on the topic, or the notion of compliance was significantly different, e.g.
compliance to a network protocol, or XML format, etc. Accordingly, the analysis reduced the set of papers from 178 to 45.

3 ANALYSIS

Table 1 shows the breakdown of papers relevant to compliance management and their source of publication. Out of 5633 articles, only 45 articles match the regulatory compliance context as explained above. This represents 1.3% of BPMJ articles, 2.4% of CAIS articles, 0.8% each for CACM and JI&M, 0.6% EJIS, 0.7% of JISR, 1.4% of JAIS, and 0.4% for MISQ. Five other journals (JIS, ISF, ISJ, IS and JMIS) did not contain any articles that match the compliance context. We expect that the significantly higher number of matches in the CAIS and CACM journals, may be influenced by the nature of the journal itself, which caters to exploratory type articles. At the early stage of the compliance management research in Information Systems, one would expect that there would be an increased focus on exploratory papers first, so as to understand the problems at hand, before a surge in papers presenting Information Systems solutions. Although the relatively low number of publications may be seen as not encouraging, the IS research community should not take it as an indicator of insignificance. Indeed, the roles of IS or IT as enablers of regulatory compliance have increased year by year (Smith & McKeen 2006).

Table 1. Sources and Frequency of Publication

The next step in the analysis carried out the classification with respect to the type of publication, viz. case study/exploratory and solution. As expected in an emerging research domain, the majority of the publications were found to be in the case study or exploratory paper category - 35 (76.1%) of the articles are case study/exploratory articles and nine (19.6%) are solution articles. However, there are two (4.3%) articles that matched both types of articles. The results suggest that research on regulatory
compliance solution has being initiated but remains still in the early exploratory stages, not yet progressing to a stage where many Information Systems solutions are proposed or discussed. This finding is inline with the need to identify the problems at hand first, before proposing solutions. Figure 2 presents the breakdown of the papers by type of contribution.

**Figure 2. Distribution of Articles by Type**

Furthermore, we were interested to determine the emergence of compliance management research in Information Systems publication outlets. The breakdown of compliance management per year of publication is shown in Figure 3. The figure clearly shows that a spike in publications was recorded in 2006. We posit that this finding is in line with the increased focus on SOX Act of 2002 and also an early focus on HIPAA. A characteristic of publishing in the Information Systems discipline is a lag of generally one to two years from time of writing to time of actual publication. Accordingly, this situation would imply that increasing focus began around 2002, when HIPAA was being seriously considered and the SOX Act was introduced. Prior to this event, little literature on compliance management exists, despite some other regulations having already been proposed (e.g. HIPAA). We expect the increasing trend to continue in 2008, despite the perceived drop in compliance management publications. One of the limitations of the study pertaining to the specific year of 2008 is that while some of the newly published contributions have already been indexed, many have not. Due to this restriction, Figure 3 only includes some of the early 2008 research.

**Figure 3. Distribution of Article per Type per Year**
Further analysis was done to identify the type of domain application that was the focus of the paper. Figure 4 shows the results of that analysis, which found that the application of regulatory compliance discussed in the articles was dominated by three domains, viz. auditing, finance and healthcare, which made up 76% of the articles. On the other hand, domains such as e-commerce and the environment were only discussed in 13% of the articles proportion. The remaining articles, which represent 11% of the focused data set, did not have a specific domain of application with regard to regulatory compliance.

![Figure 4. Articles by Domain of Applications](image)

In looking at the distribution of articles per region, we have been able to identify the main geographical areas of application as reported in the papers. The analysis was performed by inspecting not the country of publishing authors but rather the locality of case studies or exploration on regulatory compliance discussed in the articles. The analysis found that 22 out of 37 case study/exploratory articles represent the North America region. This proportion of almost 60% of the articles that focus on the North America region might be due to most of the regulatory compliance requirements being introduced earlier in the North America region than others. The finding indicates that there is a need to explore compliance management in different regions, in particular focusing on whether differences exist between practices in the various regions. The focus on other regions is not, however, nonexistent, with two and three articles representing Asia-Pacific and Europe regions respectively. The other 10 articles were categorised as non-specified because they applied to either all regions or did not explicitly state the region of the case study.

![Figure 5. Articles Population by Region](image)

The careful classification of the papers also resulted in the elucidation of details in terms of the regulations that are the focus of the Information Systems research community. The analysis found that 42 out of 46 articles had specified the regulations that the research was relevant to. While eight articles discussed the details on regulatory compliance type only in general without focusing to specific
regulation name (e.g. contract compliance in general), the 34 remaining articles specifically named a
single regulation in the discussion. Detail for the distribution of articles by their regulatory focus is
presented in Table 2.

Table 2. Distribution of Regulatory Compliance Type by Name

Most prominently, HIPAA (Health Insurance Portability and Accountability Act of 1996) had the
highest perceived focus, being the focus of eight publications. SOX (Sarbanes-Oxley Act of 2002) and
ISO (ISO17799, ISO14000, ISO9000, and ISO9001:2000) followed with six articles each. Lesser
focus was placed on SLA (Service Level Agreement) and CFIP (Code of Fair Information Practice).
Nine papers mentioned a variety of regulations. These include Controlling the Assault of Non-
Solicited Pornography and Marketing Act of 2003 (CAN-SPAM), New Zealand Privacy Act,
Electronic Record Management Policy, European 1995 Personal Data Protection Directive,
Accreditation Board for Engineering and Technology / Computing Accreditation Commission
Standard (ABET/CAC), American Election Committee Voting System Standards (AEC), Eco-
Management Audit Scheme (EMAS), Capability Maturity Model Integration - Software
Engineering(CMMI-SW), and Fair Credit Reporting Act 1970.

We were further motivated to investigate whether clear specific foci exist with the main geographic
regions of interest. In the North America region, the focus is led by Auditing applications (with seven
articles). This focus was followed by Healthcare and Finance applications with six and seven articles
respectively. While Auditing remains as focus of the application in Asia-Pacific and Europe with one
article for each region, Healthcare applications did not attract any discussion from Asia-Pacific and
Europe regions.

Furthermore, we reviewed the same articles by discovering the type of regulatory compliance being
discussed in those articles with consideration of the region of application. The review shows that most
of North America region articles (17 articles) focus on regulatory compliance. This focus is followed
by a focus on compliance with standards as second popular type in North America (with 3 articles).
The foci for Asia-Pacific region include regulatory compliance and contract compliance, with one
article for each type. The Europe region also appears to focus on standard and regulation compliance,
with two and one articles respectively. Our analysis did not identify any contributions that specifically
address compliance with policies.

Further to the detailed investigation carried out on the case study/exploratory articles, the articles that
were classified as solution providing articles were also reviewed in terms of the type of solution
presented. This process involved identification of articles that referred to solution approaches. These
articles were classified as either preventive, detective, or corrective in nature. The study reveals that 7
out of 11 articles offer a preventive solution, while the remaining (four) articles offer a detective
solution. No corrective solutions we identified in the data set. The situation might be explained be a
preference in compliance management for preventive solutions, given the high penalties for non-
compliance with some regulations (not only in terms of costs but also in terms of reputational damage,
etc). The actual solutions presented in the papers vary from contribution to contribution. Some of the solutions, for example, (Agrawal et al. 2007) and (Weitzner et al. 2008) addressed the detective type of solution. In particular, (Agrawal et al. 2007) introduced the Hippocratic Database Compliance Auditing component, which facilitates the privacy officer to conduct a series of audits, in a matter of minutes, to reliably isolate potential sources of information leaks in electronic health records. (Banker et al. 2007), have discussed a simple model in which contract monitoring cost in addition to search and coordination cost is introduced to capture the complexity in buyer-supplier relationships. Another work, (Volonino 2003) presented an overview of e-evidence and computer forensics and their implication to IS. Thus there is significant diversity in the various solution papers.

4 DISCUSSION

The findings from the analysis have provided us with a number of interesting facts with regard to the current focus of IS journal articles associated with regulatory compliance. We summarize these as follows:

- Research Trends and Focus
  The trends of regulatory compliance IS research articles show significant growth starting in year 2003. The majority of these contributions feature exploratory research as compared to research that provides specific solutions. Our findings also reveal that the articles are dominated by work that discusses regulatory compliance associated with North America cases. This research is also linked to a number of regulations that have been introduced in the region i.e. HIPAA, GLB, COPPA, SOX, and CAN-SPAM Act.

- Domain of Application
  Auditing, Healthcare and Finance are the domains that attracted most concern in the articles. This implies the critical applications of compliance. However, since these domains are predominant in North America region the necessity of other domain of applications might emerge differently in other region.

- Type of Regulatory Compliance
  Perhaps because articles were dominated by North America region, regulation is the anticipated type of compliance and is shown to have attracted most discussion. In contrast, other types such as policy, contract and even standard did not get as much attention. This further show that most of the solutions discussed also focus on achieving compliance with regulations.

- Focus of the Solutions
  All solution associated with regulatory compliance discussed in the articles focus either on preventive or detective type of solutions. It may be hard in general for IS community to contribute to this aspect as corrective measures are an outcome of business/legal advice and strategy. However, it needs to note that it is not always possible to mitigate the risk even when a compliance product is involved and hence corrective measures become inevitable (Mercuri 2004).

- Regional
  As mentioned earlier, North America cases feature prominently in the discussion of regulatory compliance in IS research. Future work is clearly needed to study the impact of regulatory compliance in other regions.
This paper presents a first comprehensive snapshot of the development and focus of compliance management related research in the Information Systems discipline. The analysis is motivated by the recent changes that drastically change the IS/IT functions within organisations so as to achieve compliance. The articles were gathered from 13 IS Journals, which consist of articles from 2001 until early 2008. The sources for the analysis, which constitute of 5633 articles, were filtered through three stages of filtration that finally narrow it down to 45 articles. The filtered articles were then subjected to classification and analysis based on a proposed framework. The study reveals that the majority of the related IS publications are exploratory in nature. We posit this to be an indication of the relative immaturity of the research in this domain, where problems are still being identified rather than solutions being provided. While we concede that many solutions might perhaps be published in more technical venues (Sadiq et al. 2006), the role of Information Systems in supporting and demonstrating compliance should be exhibited with solutions papers in the IS domain also.

The work has a number of limitations. While all care was taken to download the full set of journal papers that represents the selected journals and years, this selection was limited to soft copy papers only. Papers available in print version (and not already digitised) were excluded from this analysis. Given the focus on recent years, we do not expect this limitation to have a significant impact on the data set. Additional limitations stem from the currently incomplete set of journals for the year 2008. Only a small number of papers published this year have been indexed, these papers will be included in the analysis as soon as they become available so as to present an up to date snapshot of compliance management research.

Future work in this area involves two major steps. The first is an extension of the IS journals to also IS conference venues, which have a shorter time to publication and would provide more detail on the development of maturity in the compliance management research area. Second, a series of interviews and focus groups has been initiated in order to collect the compliance management problems, as experienced by compliance management professionals, and as observed by compliance management consultants and auditors. The ultimate goal is to perform a gap-analysis between industry needs and the focus of the research community, resulting in an industry-relevant research agenda for the coming years.

Abstract

Information quality (IQ) has become a critical concern in today’s organisations. Although recent studies of information systems indicate an increasing importance of IQ, foremost research is still limited. Indeed, little is known about the impact of various design decisions on IQ. Recent research shows that security measures are increasingly important for any information system; however security measures are often introduced without considering the effect on IQ. At the same time, literature provides us with indications that trade-offs between various IQ dimensions exist. In this article we aim to investigate how security measures impact on different IQ dimensions. We carried out an experiment, which indicates that security measures have a significant effect on timeliness, whereas other dimensions are not particularly influenced. This observation led us to the proposal of cost-benefit considerations, an important aspect for IQ management. The study is valuable for both research and practitioners. Further research studies can build on our observations and extend the research. Practitioners are provided with arguments for considering IQ trade-offs in relation to security measures.

Keywords: Information Quality, Trade-offs, Security, Cost-Benefit model
1 INTRODUCTION

Over the last two decades researchers have addressed data quality (DQ) and information quality (IQ) from various view points. Researchers have developed many frameworks, criteria lists and approaches for assessing and measuring IQ. Also, literature provides us with numerous case studies, investigating IQ in practice. However, despite the increasing interest in this topic, little is known about the effects and relations between different criteria of IQ. Knight and Burn (2005) point out that despite the sizeable body of literature available relatively few researchers have tackled quantifying some of the conceptual definitions such as security and accessibility. We aim to address this limitation of foremost research and intend to provide insight into associations of different IQ criteria.

Due to the increasing importance of security and accessibility we focus on these aspects and their implications on other IQ dimensions. In our previous research (Fehrenbacher and Helfert, 2008) we show that the importance of security and accessibility as IQ criteria has increased. This is accompanied with an increase in security requirements and complexity of information systems. Due to the increasing complexity and variety of access methods, question about its impact arises. What are implications of security measures on other IQ criteria? Does architecture have a significant (moderating) effect on the relationship between IQ criteria? What is the difference in the impact of accessibility from a workstation compared to a mobile device?

In order to address current limitations, this research focuses on the security and accessibility dimension of IQ. Review of related research shows that most IQ frameworks consider accessibility and security; however researchers classify or consider these IQ dimensions diversely among various IQ frameworks. Furthermore, our research indicates an impact of security and accessibility on other IQ dimensions. An experiment is conducted to evaluate the effect on IQ dimensions of varying levels of security to an Information System (IS). It allows for a thorough analysis of accessibility as a dimension of IQ. We propose a research model and illustrate results of an experiment, which support our research hypothesizes.

The paper is structured as follows. Section 2 reviews related work and provides indications for IQ assessments and trade-offs. Section 3 centers on selected IQ dimensions and proposes a research model and the underlying assumptions. Section 4 presents an experimental research and illustrates the key results. Section 5 discusses the implications of our research and proposes some considerations concerning cost-benefit considerations. We conclude our paper in section 6, in which we discuss some limitations of our research and summarize further research directions.

2 RELATED WORK

Many studies have confirmed that IQ is a multi-dimensional concept (Ballou and Pazer 1985, Redman 1996, Wand and Wang 1996, Wang and Strong 1996, Huang et al. 1999). Over the last two decades, different sets of IQ dimensions have been identified from both the database and management perspectives. Often IQ and DQ alike has been defined as "fitness for use", in that way that data or information of high quality “meets or exceeds users’ requirements.” (Wang and Strong, 1996). Most researchers consider IQ by a set of dimensions that are able to describe different characteristics of data or information. Following many other research, we do not distinguish explicitly between DQ and IQ since our findings are general and suitable for both concepts. Therefore, both terms are used in this article interchangeable.

The literature provides numerous definitions and classifications of IQ dimensions analyzing the problem in different contexts and from different perspectives. Common examples of IQ dimensions are accuracy, completeness, consistency, timeliness, interpretability, and availability. Many researchers have proposed several measures and approaches for each IQ dimension. Some suggestions
include aggregation functions (e.g. weighted sum, ratio, max, and min) in order to provide a unique IQ index. Considering different measurement values of the same dimensions or different measures associated with heterogeneous dimensions is challenging and the subject of current research in IQ.

A variety of IQ assessment methodologies have been proposed over the last decade. We select five popular methodologies (Redman 1996, Huang et al. 1999, Lee et al. 2002, Pipino et al. 2002, and Stvilia et al. 2007) and evaluate these by following criteria: definition of IQ dimensions, classification of IQ dimensions, model, tool, and case study. Definition of IQ dimensions describes which IQ dimensions and perspectives are defined. Classifications of IQ dimensions are used to compare the classification of dimensions in each methodology. The theoretical basis of the methodology is described in the category model. Tool expresses how the methodology is implemented. Case study concentrates on the empirical feasibility of these methodologies.

If the methodology is only applied to a specific domain, it is considered as a specific methodology. If the methodology can be applied to multiple domains, it is regarded as a generic methodology. If the case study is provided in the literature, we classify the methodology as a practical study otherwise it is theoretical. We summarize our evaluation of the five methodologies and their characteristics in table 1.

Table 1. Comparison of IQ assessment methodologies

Pipino et al. (2002) categorizes IQ assessment into objective and subjective assessment. Objective IQ assessments reveal IQ problems in databases while subjective IQ assessments reflect the needs and experiences of data consumers. In order to discuss IQ assessments from objective and subjective perspectives, we follow this general classification.

Objective IQ assessment measures the extent to which information conforms to quality specifications and references. We distinguish objective IQ assessments into two categories: intrinsic and real-world IQ assessment. Intrinsic IQ assessment follows a data perspective and uses data specifications to assess the quality of the data in the database. For example, Savchenko (2003) develops item frequency
rules and regular expression patterns to facilitate an automated intrinsic IQ assessment. Real-world assessment follows the ontological perspective and compares real-world facts to discover IQ deficiencies. For example, Wand and Wang (1996) identify data mapping deficiencies between real world states and its representation in information systems. Overall, objective IQ assessment can be considered as the procedure of comparing current data value with an ideal data value of high quality.

Subjective IQ assessment measures the extent to which information is fitness for use by information consumers. Information consumers assess IQ according to their demands and expectations. Subjective IQ assessment follows the user perspective and focuses on discrepancy between the current quality of information and the user’s expectation. In order to indicate the differences between objective and subjective IQ assessment, we provide a comparison in table 2.

| Table 2. Comparison of objective and subjective IQ assessment |

Objective IQ assessment uses mostly software applications to evaluate the data in a database by a set of quality rules. This can often been carried out automatically. Subjective IQ assessment uses typically a survey or interview approach to measure the contextual information by data consumers. The advantage of objective IQ assessment is that it allows one to automatically process large data sets. Subsequently to the assessment, the objective approach obtains a single or aggregated assessment result. Subjective IQ assessment normally involves data users’ opinion or evaluations on data samples. Although subjective assessment may contain different assessment results due to the different opinions and roles of information consumers (Strong et al. 1997), the advantage of subjective IQ assessment is the measurement of a comprehensive set of IQ dimensions. Furthermore, certain IQ dimensions such as believability and reputation are only suitable for subjective IQ assessment. Recognizing the advantages of both objective and subjective assessment, researchers (Pipino et al. 2002, Kahn et al. 2002) have combined objective and subjective IQ assessment.

A number of literatures have analyzed dependencies of IQ dimensions. Ballou and Pazer (1995) propose a framework to investigate tradeoffs between accuracy and timeliness in the context of decision making. Redman (1996) points out that timeliness has an impact on accuracy. Ballou and Pazer (2003) model the utility and tradeoffs between completeness and consistency. Olson (2003) implies the relationship between accuracy and completeness and states that consistency is a part of accuracy. Cappiello et al. (2004) analyze the time-related accuracy and time-related completeness in multi-channel information systems. Amicis et al. (2006) propose a data-driven approach to analyze the dependency between syntactic accuracy and timeliness as well as the dependency of completeness and timeliness.

Observing the literatures above, we divide relationships of IQ dimensions into two categories: negative correlated and positive correlated dependencies. Negative correlation refers to the improvement of one IQ dimension that may lead to a decreasing value in another dimension (often also referred as IQ tradeoffs). For example, by introducing new information to improve completeness, the new introduced information may be inconsistent with the existing information. In this manner, completeness and consistency are negatively correlated. Positive correlation means two IQ dimensions are mutually contributing to a shared set of IQ problems. For example, when timeliness and accuracy are sharing outdated data as their mutual IQ problem, the improvement of timeliness may lead to an increasing value in accuracy. In this way, timeliness and accuracy are positively correlated. According to the discussion above, we summarize correlations of IQ dimensions in table 3.
Improvement of certain information quality dimensions, may lead to a decreasing value in other dimensions: tradeoffs between completeness and other dimensions, accessibility and other dimensions, security and other dimensions, relevancy and other dimensions.

When we improve IQ dimension 1, IQ dimension 2 may be improved or remain at the same quality value. The quality values depend on the mutual IQ problem.

Table 3. Dependency of IQ dimensions

Many researchers have indicated various relations between IQ criteria, such as timeliness and availability. In table 4 we combined a list of common IQ criteria and relations described in literature (Fehrenbacher and Helfert, 2008). We indicate a potential negative (N) or positive correlation (P). As the list indicates, various trade-offs of IQ dimensions can be assumed. However, most researchers merely propose some form of relations but do not further investigate the strength or direction of the relation.

Table 4. Selected relationships of IQ criteria

Based on a framework proposed by Wang and Strong in 1996, we evaluated in a recent empirical research the importance of IQ dimensions (Fehrenbacher and Helfert, 2008). Comparing the item rankings our research showed a similar ranking pattern, however accessibility and security among...
others received increasing importance. Due to its increased importance but limited attention in foremost literature, we decided to focus our research on security and accessibility. To illustrate the effects and implications of trade-offs among IQ dimensions, we analyse particular effects of security and accessibility on timeliness.

3 INFORMATION QUALITY DIMENSIONS AND RESEARCH MODEL

3.1 Security and Accessibility as IQ dimensions

The literature has put forward a number of frameworks and classified the dimensions associated with each of these frameworks. In addition to the variety of IQ frameworks, most provide their own definitions for security and accessibility associated with particular IQ frameworks. Generally it can be assumed, that an increased level of security impacts on the accessibility to an information system. The relationship between security and accessibility allows for examination of the attributes of accessibility. Thus, accessibility in essence is a function of security. An examination of the accessibility dimension directly relates to the accessibility dimension. Loshin (2001) describes it as the degree of ease of access to information as well as the breadth of access. Wang and Strong (1996) consider that access security is also an important concept that must be taken into account when considering the dimension. Batini and Scannapieco (2006) describe accessibility in terms of the ability of the user to access the data from his / her own culture, physical status / functions and technologies available. In summary, the definition of accessibility is framework dependent. Nonetheless, there is also an ongoing debate about the relation of accessibility to IQ and some frameworks do not even consider it as a dimension of IQ.

With a view to analyzing in more detail the frameworks that are of specific interest to the accessibility dimension, we examined selected IQ frameworks. Table 2 summarizes these frameworks outlining the dimensions associated with each framework. We selected most prominent frameworks in the field of IS and IQ research. The examination allows this research to focus in more detail on the frameworks that pertain to accessibility as noted in column three of table 2.

<table>

</tr>
</thead>
<tbody>
<tr>
<td>Zeist and Hendricks (1996) (Extended ISO Model)</td>
<td>Functionality, Reliability, Efficiency, Usability, Maintainability, Portability</td>
<td></td>
</tr>
</tbody>
</table>
The examination of the IQ frameworks in table 5 demonstrates that accessibility does feature as a dimension to varying degrees across many frameworks. Reviewing these selected frameworks resulted in a list of drawbacks, which current frameworks do not address. We identified the following five key research challenges related to the accessibility and security dimensions of IQ:

- What are the impacts of accessibility / security on the overall IQ?
- How do accessibility / security impact on other dimensions in an IQ framework?
- Do current IQ frameworks provide valid and reliable measures?
- Is the impact of accessibility / security consistent across IQ frameworks?
- What impact do multiple access / security methods have upon IQ?

Answering these questions would allow for providing an insight or even quantifying the impact of accessibility and security on other IQ dimensions and thus on IQ.

3.2 Hypothesis and Assumptions

As discussed above, research has indicated many relationships between IQ dimensions. Several studies aimed to investigate the relationship between selected dimensions, however regarding its importance
accessibility and security related trade-offs are often not considered. We centre our research on these important dimensions, and investigate their effect on other IQ dimensions. From the related literature above, we can hypothesis a general relation between the dimensions. However, little is know of which dimensions are affected or their significance.

In our article we centre on process oriented IQ dimensions such as timeliness and availability. Other intrinsic IQ dimensions, such as consistency, completeness and accuracy are less affected. Considering Security measures, we assume following indicative relationship. As security measures are increased, **timeliness and availability decrease. Other dimensions are not affected**. Security measures act as independent variable, whereas other IQ dimensions act as dependent variables. We assume that this effect can be perceived by information users, and thus result in a lower perceived IQ. There are many suggestions for discrete measures for IQ values, and thus we can assume such measure. For security we assume a categorical measure, consisting of advanced, intermediate and basic security measures.

## 4 AN EXPERIMENT TO SUPPORT THE RESEARCH MODEL

In order to support our research model, we conducted an experiment. In contrast to other research methods, experimental research is particularly suitable for the identification and study of relationships between a small number of variables. Experimental research is found to be effective in addressing the cause and effect relationship (Campbell and Stanley 1963, Jarvenpaa et al. 1985). Although our experiment represents a simplified real world scenario, it assists us to understand fundamental relationships between IQ criteria. However, one of the challenges is the isolation of and control of exogenous factors, such as decision complexity and experience.

Data can be collected in a number of ways in order to answer research questions. It can be gathered by direct observation or reported by the individual. Fisher et al. (2001) indicate that systematically collecting data to measure and analyze the variation of one or more processes forms the foundation of statistical process control. In the case of an experiment a variable is manipulated and the corresponding effect on the other variables is noted. Fisher et al. (2001) also point out that a statistical experiment is a planned activity where variables that have the potential to affect response variables are under the control of the researcher.

In order to examine the impact of accessibility dimension as an IQ dimension, we examine four IQ dimensions across three architectures and two IS domains. The aim of this experiment is to demonstrate what trade offs if any are associated with varying levels of security.

- **IQ Dimensions:** As IQ is a multidimensional concept the impact on individual dimensions is examined in the experiment. For our research, we selected four dimensions that are common across IQ frameworks free-of-error, completeness, consistency and timeliness. In order to measure IQ, a subset of the questions from the AIMQ (Lee et al. 2002) methodology are employed. The specific survey questions with respect to free-of-error, completeness, consistency and timeliness were used.

- **Architectures:** Web, Client Server, Work Station

- **Domains:** The two IS domains are a library system and a student exam result system. The major areas of functionality of both systems were employed during the experiment. Three different access methods were used namely workstation, client server and web. These are used on day to day operation of both systems. All users were also day to day operators of the systems.

The experiment sets different levels of security and measures the corresponding effects on the four dimensions. Three levels of security are manipulated in the experiment basic, intermediate and advanced. Basic security has no restrictions set while the advanced level is stringent. There were twenty seven participants for the library system and eighteen for the student exam result system. The results recorded are the average scores for the twenty seven participants of the Library IS and eighteen participants of the student exam system IS. The experiment was conducted over a two day period in March 2008. The results of our experiment are illustrated descriptively and set out in a number of tables below (tables 6 – 11). Subsequently we describe and interpret the results.

Table 11. Student Exam IS Domain – Security Level Basic
The results are based on a subset of the AIMQ survey instrument (Lee et al. 2002). This questionnaire has been used in many studies. Appendix one lists the questions that were employed in the survey. The key findings of the experiment indicate that as security levels are manipulated the other IQ dimensions are affected. Fisher et al. (2001) point out that if data is not accessible then quality will decrease because information can not be accessed in a timely fashion. There is a trade-off between security and timeliness. Our result show timeliness is significantly affected. As the level of security became more advanced the users survey results with respect to the timeliness dimension were less and less satisfactory. This research indicates that security as a dimension of IQ can have different levels and the more access is restricted the greater the dissatisfaction with the timeliness dimension. It is not merely two states of accessible and inaccessible.

A closer examination of the timeliness dimension is warranted. For example in table 6, table 7, table 8 which reflect results with respect to the library IS there is an increase in satisfaction in the survey results with respect to timeliness as the level of security is lessened. At a high level of security the satisfaction with timeliness is 46% for web access, 48% for client server and 56% for work-station. This is an average satisfaction of 50% with the timeliness dimension. As can be seen from the results the average increases to 61.6% for intermediate and 85.6% for a basic level of security. The results for the student exam system IS domain display a similar pattern with an average of 55% satisfaction with the timeliness dimension when there is an advanced level of security where as at a basic level of security the satisfaction was at 83%.

The other dimensions surveyed; free-of-error, completeness and consistency did not radically change across IS domain. Another interesting finding was the users’ satisfaction with the IQ dimensions when web architecture was employed. It compared less favourably with client server or workstation architectures. This was the case for both domains examined.

5 IMPLICATIONS – TOWARDS A COST/BENEFIT MODEL

As our research above indicates, there is an interesting relationship between timeliness and security. In the following section we analyse the implications of these observations, and examine the impact of IQ level from a cost and benefit perspective.

The trade-off between security and timeliness is often analyzed in real-time applications. In fact, these applications have clear timeliness constraints but sometimes they can also have security issues in addition to timing constraints. The timing constraints of real-time applications are typically specified in the form of rules that require that an operation has to be completed in a specified time. Failures of such rules can cause critical situations since the provided results may be useless if not timely. Real-time systems are often adopted in particular environments such as defence systems, air traffic control or stock trading where data security is a fundamental aspect. These scenarios require access restrictions in order to differentiate the data accessibility on the basis of the users that require some information. Security and timeliness requirements conflict with each other since the implementation of methods to guarantee data security may introduce some delays in the application execution. Whether to maintain timeliness or security is dependent upon the system.

Let us consider a system A in which security is preferred to timeliness and a system B in which timeliness is preferred to security. Considering the level of security (SL), we can assume that timeliness is inversely proportional to the security level along a general exponential decay trend. On the contrary, increasing the security level the quality costs increase exponentially. In fact, large investments are needed for a secure system and thus for the adoption of complex protocols. We make the assumption that the economical benefits deriving from IQ are proportional to the value assessed for the IQ dimensions. Along these considerations, it is possible to compare costs and benefits related to the different security levels and evaluate the total profit in the two considered scenarios. Cost and benefit analysis show (see Figure 1) that it is possible to define the most suitable security level by
calculating, the maximum value of profit, resulting from the subtraction of the security costs from the IQ benefits.

![Diagram showing cost/benefit analysis]

Figure 1. Cost/benefit analysis – (a) Security is considered more important than timelines, (b) timeliness is considered more important than security

## 6 CONCLUSIONS

In literature as well as in practice, it is often assumed that in order to reach the maximum IQ and the best satisfaction of user requirements maximum IQ is required. However, this disregards the existence of trade-offs among IQ dimensions. Our research indicated that there are significant effects between information system decisions, such as security measures, and IQ. Applying three distinct security levels, advanced, intermediate and basic, we found that timeliness is significantly affected. Other dimensions are not significantly affected in our experiment. The research led us to the proposal of some cost-benefit considerations. As discussed, the perception of IQ is important in order to evaluate an optimal security level.

Although we provided an experimental research design, which provided some insights into the relationship between security and IQ as well as IQ trade-offs, our research is still rather conceptual. Due to the relatively low number of participants, the analysis is descriptive. In future research we intend to extend the number of participants and apply suitable quantitative analyses techniques. We also plan to investigate further IQ trade-offs, which subsequently assist us to understand cost-benefit considerations. However, although our research has some limitations, we believe that the results are beneficial for researchers and practitioners. Further research studies can build on our observations and extent the research with experimental or empirical research approaches. A number of the IQ frameworks examined in table two do not consider security. As a result of the initial findings of this research especially with respect to the key finding of security levels and the timeliness dimension it is suggested IQ frameworks need to take the levels of security into account. This it is argued will lead to a more comprehensive view of IQ. Practitioners are provided with arguments for considering IQ trade-offs in relation to security measures. This research suggests that the factors with respect to the architecture employed need consideration when IQ policies are being designed and implemented. Furthermore, in contrast to many empirical researches, this article applies an experimental research approach. The authors believe that this more rigorous approach can complement and enhance the IQ research area, in which case studies are dominating. The authors strongly believe that more experimental research is needed in order to complement the important but often practical oriented research in this particular domain.

Abstract

Recently, several disasters have affected the tourism industry. In order to mitigate the effects of disasters, increasing the level of preparedness is essential. However, despite the devastating effect disasters can have on tourism, few tourism organizations have properly developed disaster strategies as an integral part of their business plans. Emergency management systems that utilize mobile communication infrastructures can provide prompt information delivery to save human lives. Several supra-national initiatives and research projects are working on possibilities to facilitate mobile communication networks for emergency management systems. However, the success of such systems depends on users being familiar with the service, which is difficult to achieve, if the system is solely used for emergency management. Therefore, we propose a system design that allows the integration of mobile value-adding services. We also present exemplary services, which offer value to tourists and create business opportunities for the tourism industry. The central component of our proposed system design is a service platform, which communicates with mobile network operators and provides basic services for service providers from the tourism industry and the emergency manager via service interfaces.

Keywords: Emergency Management, Tourism, Mobile Communications, Design Science.
1 INTRODUCTION

Disasters can have negative and lasting effects on the tourism industry (Faulkner 2001). In recent years, several crises and disasters have affected the global tourism industry (Ritchie 2004). Examples comprise terrorist attacks (Paraskevas and Arendell 2007), political instability (Fuller and Fugal 2008), economic recession (Kreimer et al. 2003), bio-security threats and natural disasters (Hystad and Keller 2007). Since tourism is also an important economic factor for many countries and many destinations depend on tourism for their growth and survival, there is an increasing pressure on managers and policy makers concerned with tourism to consider the impact of crises and disasters on the industry and to develop strategies to deal with their impacts (Ritchie 2004). In order to mitigate disaster effects and to accelerate the healing process, it is essential to undertake steps to increase the level of disaster preparedness, including infrastructure investments for warning systems and training activities (Johnston et al. 2007). However, despite the devastating effect disasters can have on tourism, few tourism organizations have properly developed disaster strategies as an integral part of their business plans (Faulkner 2001). Emergency management systems (EMS) provide the capability to address this dilemma and to enable disaster forces to manage disaster events, including detection and analysis of incidents (Carver and Turoff 2007). Persons in charge should be supported to prepare evacuations, control and support disaster forces and to locate victims (Carver and Turoff 2007). Since mobile communication infrastructures offer standardized wireless communication services in almost all countries (GSMworld 2008) and allow a fast diffusion of information, they provide a promising technological basis for saving human lives in emergencies. If a disaster event occurs, they can for example allow emergency managers to distribute warnings to the effected areas by cell broadcast to ensure warnings of potential victims in time (Fritsch and Scherner 2005). One of the most promising initiatives is described in the recently published report on the Commercial Mobile Alert System (Federal Communications Commission 2008) which is supposed to be in operation in 2010.

One of the most crucial requirements for preparedness is that ordinary people are used to the system in order to react on warning signals without any delay (Gruntfest and Huber 1989). Meeting this requirement is extremely difficult if the system design is solely used for early warnings. The success of emergency management systems clearly depends on well-trained users being familiar with the service functionalities provided (Turoff et al. 2004a). For an infrequently used emergency management system, limited practical experience of users can be expected (Manoj and Hubenko Baker 2007). Technically, many services used for emergency management systems do not differ from services used in day by day use cases. For example the upload of a picture could be used to inform emergency managers but also for online community services. The challenge is that both functionalities have to be integrated in a design, which allows both perspectives and supports the user to become familiar with the functionalities itself. We will therefore argue that offering mobile value-adding and emergency management services via the same infrastructure could create new business opportunities for the tourism industry. Services can be used to improve the holiday experience for tourists and to help tourist guides to manage the customers. For example, (Zipf and Malaka 2001) argue that location-based services in tourism settings can provide the basis for a range of novel tourism-related applications and open up new business opportunities to service providers. Integrating value adding mobile services into an emergency management system thus improves users’ familiarity with the system while at the same time offering a perceived value to customers. Furthermore, revenue created by value-adding services could provide the necessary funds to finance the investments in the mobile emergency management system. Besides sharing the costs for operating the infrastructure, the idea of providing both commercial and disaster warning services based on a technically integrated platform positively affects users’ experience due to a common client base.

This paper is structured as follows. We first present the methodological approach of our work in section 2. In section 3, we derive requirements for emergency management systems from the literature, discuss how current systems rate against these requirements and propose a system design to
address them. In section 4, we introduce exemplary value-adding mobile service in the tourism sector and discuss possibilities for integrating them into an infrastructure that can be used for emergency management systems as well as possible business implications. The limitations of our work are stated in section 5 and section 6 provides a conclusion.

2 METHODOLOGICAL APPROACH

We address the introduced problem with a conceptual system design providing a technological basis for emergency management and value-adding services being offered to different parties. This system design represents an IT artefact instantiation that aims at contributing to the problem’s solution, i.e. at (1) minimizing the impact of crises or disasters and at (2) offering novel services to customers. As system architectures, system designs or prototypical software applications, IT artefact instantiations demonstrate the feasibility of an approach developed. Due to its utility-centric focus, design science research contributions present novel IT artefacts and suitable evaluation approaches that address the artefact’s appropriateness to contribute to the problems’ solution (Nunamaker et al. 1991). These two facets of rigorous design science-oriented research contribute to the foundations and the methodologies pool of Information Systems research, i.e. they contribute to its knowledge base (Hevner et al. 2004). In the following, we present a design of an emergency management system, which utilizes communication facilities of mobile communication networks such as GSM. In contrast to existing approaches such as the Global Disaster Alert and Coordination System (GDACS) (European Communities 2008), our system design provides facilities for integrating EMS functionalities and commercial value-adding services on the basis of a common platform. In order to evaluate our proposed system design, we then present exemplary value-adding services that demonstrate its feasibility. Further evaluation is provided by a qualitative analysis of potential benefits being provided to the different parties including the public sector, the industry and customers. We therefore follow the classic approach of design science-oriented research (March and Smith 1995) as we first present a developed IT artefact and we second evaluate the artefact’s benefits for potential users. Therefore, and e.g. in contrast to behavioural science oriented research, the goal of this contribution is utility, namely the benefits our system design can provide (Simon 1969).

3 EMERGENCY MANAGEMENT SYSTEMS

Having outlined our methodological approach, we will now derive system requirements from the literature and review how they are addressed by existing emergency management systems. We then use these requirements as the basis for a proposed system design.

3.1 System Requirements

From the literature we derived the following high-level requirements that need to be addressed by an emergency management system, which could also be used for secondary purposes. They comprise (1) system effectiveness (Johnston et al. 2007), (2) reliability (Zeckhauser 1996), (3) cost efficiency (Zeckhauser 1996), (4) smooth service integration (Ritchie 2004), (5) multilateral user interaction (Turoff et al. 2004b), (6) availability (Faulkner 2001) and (7) security (Valtonen et al. 2004). In the following, we further explore these identified requirements:

**Effectiveness:** Effective early warning systems have to be based on regularly used communication infrastructures and people have to know how to react on visual and acoustic warning signals (Johnston et al. 2007). This requirement holds for commercially successful infrastructures (Buhalis 1998) as well as early warning systems. This requirement suggests that commonly used infrastructures, like those operating on the GSM specification provide a suitable basis for mobile services. GSM represents a standardized communication link between disaster management forces and victims being already used by a large installed base of more than 2 billion customers worldwide (GSM-Association 2008).
Reliability: Despite effectiveness, reliability of underlying networks is an important success criterion, as up-to-date systems have to be regularly maintained to ensure reliability. Therefore, this requirement is tied to regular usage (Kron and Thumerer 2002) of the system by parties involved into emergency management. Furthermore, potentially affected people have to be involved in preparedness measures. Otherwise, alerting systems that are not regularly used for other purposes often become outdated, unmaintained and do not get adapted to changing requirements (Gruntfest and Huber 1989).

Cost efficiency: The system shall offer interfaces to existing legacy systems providing the opportunity to include available information from sources of the public sector and third parties. Furthermore, it should provide functionalities to direct messages in a cost-efficient manner (Zeckhauser 1996; Zhao et al. 2005). Major revisions on mobile communication infrastructures and on mobile devices of customers will thus violate this requirement. Secondary use of early warning systems in terms of offering value-adding services shall be supported. The European Telecommunications Standards Institute (ETSI) is developing a worldwide interoperable architecture for emergency management services, in which commercial use is explicitly mentioned (European Telecommunications Standards Institute 2007).

Smooth service integration and device interoperability: End-users should be able to use their already existing equipment without being forced to invest in additional technology. High prices for new equipment tend to result in reduced acceptance by end-users (Chen et al. 2002) and therefore the interoperability with already existing mobile devices must be considered. In the E911 project, end-user technology is regulated and mobile operators have to ensure that certain technologies are available at the end-users side (Federal Communications Commission 2001). In a report for the Federal Communications Commission (FCC) (Hatfield 2002) argues that the lack of integrated commercial services is one of the major obstacles E911 is facing. We therefore conclude that the lacking integration of emergency management and commercial location based services needs to be addressed in holistic manner.

Multilateral user interaction: For supporting front-line responders in forming dynamic teams, the underlying system design shall support multilateral point-to-point communication and provide availability of locally available human and technical resources. This requirement implies that the system design is able to assign access control right on the spot in emergency cases (Turoff et al. 2004b).

Availability: Availability of emergency management systems has been investigated in depth by many authors and is a common problem for systems dealing with disasters and other events with similar impacts on human life (Faulkner 2001). Taking into account that the convergence of data services in terms of using common communication infrastructures, such as internet protocol-based networks, affects all levels of preparedness, the problem of limited availability is not unique to our suggested design infrastructure. Looking at the category of predictable events within an expectable timeframe, such as storms, heavy rain and to certain degree earthquakes, the problem of limited availability during events is clearly dominated by the benefit that warnings communicated in textual and acoustical form can be brought out to potential victims.

Security: Besides availability, other security-related requirements have to be fulfilled by emergency management systems. End-users should be able to verify integrity and authenticity of emergency messages at any time (Valtonen et al. 2004). Furthermore, the system has to ensure that no party could deny its responsibility having sent notifications to potential victims. (Fritsch and Scherner 2005) proposed a system in which early warning functionalities, enhanced by privacy-preserving mechanisms, are described. Based on this work, a detailed analysis how authenticity, integrity and non-repudiation can be provided by using electronic signatures has been provided in (Roßnagel and Scherner 2006).
3.2 Existing Emergency Management Systems

Several supra-national initiatives and research projects are working on possibilities to facilitate mobile communication networks for emergency management systems. Most initiatives, as those described below, are mainly concentrating on certain phases of disasters (McEntire et al. 2002), such as detecting events and forecasting the impact. Other approaches concentrate on early warnings by providing mechanism for delivery of warnings and instructions to potential victims. The GDACS (European Communities 2008), an initiative initially launched by the European Commission, focuses on gathering information about earthquakes and tsunamis. The system automatically evaluates their impact and disseminates the information to prior registered persons around the world. Messages are delivered by SMS or E-mail, depending on the customers preferences. We conclude that the approach addresses the requirements of cost efficiency by using commonly available communication channels. However, effectiveness is only partially addressed since it can not be ensured that the addressee realizes the warning and could act accordingly.

The SMS-alert initiative in the Netherlands allows local residents to subscribe, and receive SMS text alerts from the local police regarding activity in their geographic area (Korteland and Bekkers 2007).

3.3 Proposed System Design

The proposed system design is based on Fritsch and Scherner (2005), in which early warning functionalities of a mobile emergency management system are described. To open up the system design to commercial service providers, we have defined roles of the public sector and the tourism industry. Both entities are operating on a subset of responsibilities and features that the whole system provides. Therefore, their roles are introduced as sub-roles. They have access to the underlying communication infrastructures and thereby, each provides specific services the stakeholder is specialized in. Figure 1 illustrates how the different parties interact within our system design and which services are provided by and to whom.

The central component in our design is the service platform, which is maintained by the platform operator. The platform communicates with mobile network operators and provides basic services for service providers from the tourism industry and the emergency manager via standardized service interfaces. The basic services include localization of mobile subscribers, message delivery via SMS and CBS, multilateral data transfer, access to information databases, support for mobile communities and billing services for mobile payment and mobile ticketing.

The platform operator can be a public or private entity. Its main task is to operate the information system infrastructure and to provide basic services via service interfaces to the involved parties.
Several different entities could take on this role. The platform could for example be operated by the tourist office of the destination. The tourism experience could be improved by new tourism services offered using this platform and by establishing a powerful emergency management system signalling preparedness to potential tourists. Naturally, commercial service providers could operate this infrastructure on behalf of the tourism office. Also, companies with a strong commitment to the destinations community, such as public transport providers, could take on the role of platform providers. For example the German research project VeRSiert (Projekt VeRSiert 2008) has proposed a similar infrastructure (Roßnagel et al. 2008a), which is operated by a public transport provider for coordinating major events in Cologne (Roßnagel et al. 2008b). The role of platform operator could also be fulfilled by commercial service providers, who charge for the basic services that are offered over the service platform.

Figure 1: Proposed system design

The emergency manager provides all emergency management related services to ordinary people and ensures efficient notifications, which is henceforth classified as service category 1. Furthermore, this role makes services available to the tourism sector and its employees (service category 2) in order to help them to prepare for emergencies and to offer guidance in emergency situations. For the implementation of these emergency services, the emergency manager utilizes the basic services provided by the service platform. The tourism industry offers commercial services to tourists (service category 3), which we elaborate in section 4. These services are built upon the basic services provided by the service platform, which allows a rapid development of services due to the already existing building blocks. The service aggregation on behalf of the tourism industry is done by the platform operator who takes on the role as an information intermediary (Bhargava and Choudhary 2004) providing n to m links between different entities of tourists and the tourism industry. Offering commercial services via the same infrastructure is one of the major challenges. The contribution of this approach is therefore that a) people get involved in mobile services as they are offered by mobile emergency services and b) commercial players have a vital interest in keeping the used infrastructure up-to-date. The presented system design allows sub-roles for providing different services via the same infrastructure. Thus, the integrated communication infrastructure (service platform) provides the public sector (emergency manager) and the tourism sector (tourism service providers) with access to their customers and clearly separated duties and responsibilities, solely for their use cases. Thereby the
emergency management system can meet the requirements effectiveness, reliability and cost efficiency by using the same infrastructure for several different use cases. It is not a stand-alone system, which has to be maintained separately and necessary adaptations to changing requirements are becoming more likely. The system now serves a regular secondary use. Furthermore, the stakeholders get used to the system in day-by-day use cases and gain experiences how to react to different messages.

4 MOBILE VALUE-ADDING SERVICES

We will now focus on exemplary mobile value-adding services and their integration with the emergency management system. After a description of potential exemplary services we will discuss service integration and economic feasibility. A broader discussion of tourist services that are suitable for integration into an emergency management system can be found in (Scherner and Muntermann 2008).

4.1 Exemplary Services

Buhalis (1998) and Buhalis and Licarta (2002) analyzed that information intermediaries are a suitable infrastructure component for offering services to an installed base of travellers by providing information from various sources in a concise manner. In Lee and Mills (2007) it is suggested that the key factors for travelling customers’ satisfaction regarding the support through mobile devices are determined by a) the degree of perception and b) by the perceived value of services provided. Satisfaction of customers is, following this argumentation, determined by using attractive (e.g. location- and profile-based) services compliant with privacy settings. In a tourism context, there are several such services imaginable. In many cases, a service may be offered free of charge to enhance the tourism experience. Examples are mobile hotel reservation services (Hotel Reservation Service 2008), services provided by local authorities for promoting points-of-interest as well as events and services (State Capital Stuttgart 2008). The same services could also be offered as commercially by charging for the added value they provide. We will now present two use cases in more detail to illustrate the potentials of mobile support in tourist destinations.

4.1.1 Mobile Destination Management

The Aladdin research project funded by the European Union aimed at developing a prototype of a mobile destination management system for tour guides, travelers and local small and medium enterprises (SME) (Aladdin Project 2008). The system provides incoming tour operators with an improved and cost-efficient mobile workspace to support their business processes, allowing small companies to compete with larger incoming tour operators. Furthermore, it allows SMEs located at the tourism destination to offer their services and content in an easy accessible way to potential customers. In addition, tourists can enhance their experience by using the offered services and by obtaining additional information about the tourist destination (Altenhofen et al. 2008). The Aladdin project had a focus on the business processes and on use cases that take place at the destination. Based on this research, different prototypes that support tour guides and travelers have been developed. An evaluation of the Aladdin prototype including field tests in three different destinations showed that users are particularly interested in information on points of interest, routing services, access to information services such as weather and traffic reports, as well as an emergency support (Aladdin Project 2007).

4.1.2 Mobile Community Services

There exists a large variety of mobile communities, which focus on satisfying needs of different types of mobile users, such as mobile gaming or mobile dating. Common to all of them is their reliance on mobile communication technologies for providing value-added services to community members. One
such community that represents an economically powerful sector within the tourism industry is the sports fishing community. Sport fishing enjoys a huge popularity in many industrialized countries and the economic impact of sport fishing itself has been well recognized in recent years (Arlinghaus 2004). The study reports that the total economic impact in Germany alone amounts to more than six billion Euros per year including direct and indirect impacts on the domestic economy\(^1\). Similar estimations have also been reported in the literature for other economies with only small variances for many highly industrialized countries (US Fish and Wildlife Service 2001; Moon and Souter 1995; Schwärzel-Klingenstein et al. 1999). In Arlinghaus (2004) the behavioural pattern of German sport fishers was analyzed and it was revealed that 60 percent of the sample population spend more than half of their total fishing time in foreign countries. Each fishing trip is characterized by different subsequent phases, which are the planning phase, the event itself, and a recollection phase (Arlinghaus et al. 2002). The first and the last phase can easily be conducted without any mobile support. However, the users’ demand for mobile services increases shortly before and during the event, because fishing is a location and event-driven activity. Sport fishers and other stakeholders of the sport fishing industry could benefit from multilateral mobile interactions: Sport fishers share secrets on fishing hotspots and favourite baits only with well selected buddies and many of them communicate their catches immediately to their community members. While looking for new and promising fishing places, sport fishers need to know where to obtain fishing permits and what the terms of usage (catch and release, allowance of living bait, etc.) of certain water courses are. Location-based services could support them in obtaining permits and help targeting advertisements for equipment, hotels and further services. The Norwegian fishing administration of Oslomarka\(^2\) already offers some of these services on their website (Oslomarkas Fiskeadministrasjon 2008), including delivery of fishing permits via SMS. Another use case for mobile support is the determination of the genus and species of the fish caught. The phenotype of fish is heavily related to environmental conditions, like water and food and therefore the same species might look entirely different in varied watercourses (Militz et al. 1984). Thus, sport fishers often see themselves confronted with a fish they cannot easily identify and might violate closing seasons or allowed minimum length by keeping the fish. Traditionally, consulting and gossiping is done between community members who need to be reachable in a reasonable timeframe and need sufficient information for valid decisions. The FishBase initiative (Froese and Pauly 2008) has set up a database which can help to figure out what kind of fish has been caught. The success of this database is due to the broad audience that contributes and enhances the data entries and provides knowledge to the on-site audience.

### 4.2 Service Integration and Benefits

The service platform provides a centralized access point to the mobile communication infrastructure, which can be utilized for emergency management and commercial mobile value-adding service as described in the previous section. It offers basic services on which tourism and emergency service can be build upon. Since the same underlying technology is used for both services, economies of scale have a significant impact on the cost structure of these services. By utilizing the basic services provided by the service platform, a quick development of value adding mobile tourism services can be achieved. Furthermore, the central platform offers service providers from the tourism industry, which is largely driven by small and medium enterprises (Werthner and Ricci 2004), a possibility to offer mobile services without the necessity to maintain the underlying infrastructure. By including tour guides and other employees of the tourism industry into preparedness activities, tourists have a contact point they are familiar with. Furthermore, these persons normally have an increased foreign language competence which is an advantage during crisis (Manoj and Hubenko Baker 2007). Combining emergency activities and mobile community services, e.g. by forming spontaneous first aid teams or

\(^2\) Recreational Areas around Oslo
providing up-to-date information (Palen et al. 2007), shows on the other hand that preparedness can benefit from commercial services provided on the proposed infrastructure. Integrating these services into an emergency management system could improve users’ familiarity with the system while at the same time offering a perceived value to the customers. Figure 2 illustrates an infrastructural concept for such an integration.

![Figure 2: Service integration](image)

The public sector at the destination can also profit from the service integration. Signalling preparedness to prospective customers (i.e. tourists) has a positive impact on the destination’s image and can therefore positively influence the productivity of the domestic economy (Paraskevas and Arendell 2007). A positive image can contribute to a positive reputation in the long-term and therefore increase the popularity of the destination (Paraskevas and Arendell 2007). Via the sub-role of emergency managers, the public sector has an instrument at hand for optimizing the training and preparedness of emergency forces as well as the overall coordination of safety services. One contribution of the proposed system is that the pool of emergency forces has been enlarged to members of the tourism industry. Due to the vital interest of the tourism industry and community service providers to offer attractive services to their customers, tourists and community members could benefit from a wide range of potential services. Using the same infrastructure for emergency services and commercial services increases the familiarity of users with the system, its messages and provided functionalities. In touristic settings, the system design can be used to form dynamic travel teams for enhancing everyone’s safety and convenience in an unfamiliar environment. The same holds for mobile communities in which single members can benefit from the experiences and willingness to communicate of other community members. Furthermore, having a reliable link to a trusted group of entities may result in many use cases in an increased perceived usefulness of location-based services.

5 LIMITATIONS

First steps on how to combine emergency and commercial services via the same infrastructure have been sketched out. However, a detailed analysis and estimation of the impacts and interdependencies of a jointly used infrastructure on the development and the acceptance of mobile emergency services is still missing. The discussed advantages of this approach are limited by the degree of cooperation which decision makers of emergency services might be willing to allow. Also, usability aspects of such systems, like possible steps to ensure that the users pay attention to incoming messages, need to be further researched. A first step in that direction is to use different acoustic and visual signals for
emergency and commercial services to raise the awareness of the users. Furthermore, the availability of different infrastructural components is a major issue and precautions against breakdowns have to be incorporated into networks. Evaluating the readiness of infrastructures for mobile emergency services remains a challenging subject for further studies.

6 CONCLUSION

In this contribution, we proposed an emergency management system design based on mobile communication infrastructure, which allows the integration of mobile value-adding services to improve users’ familiarity with the emergency system. Following the design science research approach we first derived system requirements from the literature. They comprise (1) system effectiveness, (2) reliability, (3) cost efficiency, (4) smooth service integration, (5) multilateral user interaction, (6) availability and (7) security. Based on these requirements we addressed the introduced problem with a conceptual system design. In addition, we presented exemplary mobile value-adding services that could be integrated into the emergency management system and discussed the benefits to the users of such a system. We conclude that the proposed system design could help to increase users’ familiarity with the system, offer a perceived value to the tourists and create new business opportunities for the tourism industry.

Abstract
The complexity of the information systems field often lends itself to classification schemes, or taxonomies, which provide ways to understand the similarities and differences among objects under study. Developing a taxonomy, however, is a complex process that is often done in an ad hoc way. This research-in-progress paper uses the design science paradigm to develop a systematic method for taxonomy development in information systems. The method we propose uses an indicator or operational level model that combines both empirical to deductive and deductive to empirical approaches. We evaluate this method by using it to develop a taxonomy of mobile applications, which we have chosen because of their ever-increasing number and variety. The resulting taxonomy contains seven dimensions with fifteen characteristics. We demonstrate the usefulness of this taxonomy by analyzing a range of current and proposed mobile applications. From the results of this analysis we identify combinations of characteristics where applications are missing and thus are candidates for new and potentially useful applications.

Keywords: Taxonomy, Taxonomy Development, Mobile Application, M-Commerce, Mobile Business.

1 INTRODUCTION

A fundamental problem in many disciplines is classifying objects of interest into taxonomies. Biology has studied this problem extensively and developed a number of classification schemes that order the complexity in the living world and provide a foundation for biological research. In the management science and information systems fields, the importance of taxonomies is well recognized. Several taxonomies exist in various domains, including manufacturing services (e.g., Miller and Roth 1994) and decision support systems (e.g., Alter 1977). These taxonomies provide fundamental research foundations in the form of a common domain language in which problems and their solutions can be defined and explored.

Although the process of developing a taxonomy has been studied in a number of disciplines (e.g., Sokal and Sneath 1963 and Eldredge and Cracraft 1980 in biology; Bailey 1994 in the social sciences), little has been written about this process in the field of information systems. A well-conceived method for developing taxonomies in information systems would serve as a basis for developing new taxonomies that could bring order to complex areas and potentially lead to new research directions. The purpose of this research-in-progress paper is to present such a method and to demonstrate its applicability by developing an exemplary taxonomy.

We apply our taxonomy-development method to mobile applications. We have chosen this domain because of its increasing complexity with many mobile applications existing today and new
applications appearing regularly. Users, researchers, and developers need to be able to determine where a new mobile application fits with existing applications in order to determine if it is something entirely new and unique, a significant variation of an existing application, or just a retread of what we already have. A taxonomy of mobile applications would provide a basis for making this determination and could point out voids where new applications might be developed.

This paper is organized as follows. First, we discuss our research approach (section 2). Then we review the literature related to taxonomy development (section 3) before presenting our method for developing taxonomies in information systems (section 4). Next we review existing mobile application taxonomies (section 5) and demonstrate the use of our taxonomy development method to develop a new taxonomy of mobile applications (section 6), which we present in detail (section 7). Finally we show how our mobile application taxonomy can be used to analyze current and future applications (section 8) before summarizing our results and providing suggestions for future research (section 9).

2 RESEARCH APPROACH

This paper is based on the design science research paradigm that aims to address new knowledge about artificial (i.e., man made) objects that are designed to meet certain goals and provide utility to their users (Simon 1969). March and Smith (1995) present four kinds of contributions (artifacts) and two characteristic processes (research activities) that characterize design science research in IS.

The four central research outputs are constructs, models, methods, and instantiations. As a most fundamental artifact type, constructs define a conceptual vocabulary that provides the basis for representations of problem domains or for the construction of models. Models describe the relationship among developed constructs, that is, they describe how things are. Methods describe a set of defined steps to provide a solution to a given task. Finally, instantiations are implementations that operationalize other artifacts. As system architectures or system designs, they demonstrate the feasibility and applicability of the models and methods developed.

The two processes that characterize design science research are artifact building and artifact evaluation. Since utility is of vital importance, design science research aims at developing novel artifacts and suitable evaluations that assess the artifact’s appropriateness to contribute to the problem’s solution (Nunamaker et al. 1991).

We present a method that provides guidance for researchers developing a taxonomy for a specific domain. This method is an artifact that serves as a basis for future design science research, the purpose of which is to develop new taxonomies. Such new taxonomies are artifacts (models) in themselves.

We use the two processes of design science in our research. First we build an artifact (method) for developing new taxonomies. The process of taxonomy development is a complex task because the explanatory power of a taxonomy that constitutes its usefulness to users depends on a well-defined set of dimensions. The method we present guides users on how to define these dimensions.

Second we evaluate the artifact (method) we have built by using it to develop a taxonomy that describes and classifies existing or future objects in a specific domain in a sensible way. The domain we have chosen is that of mobile applications, an important research area in IS (March et al. 2000).

The result of the second step is an artifact (the taxonomy) that is subject to evaluation. Therefore, we evaluate the taxonomy by assessing its efficiency to classify objects in the problem domain of interest (i.e., existing and proposed future mobile applications). Evaluation results then provide evidence if it is necessary to redefine the underlying dimensions of the taxonomy.

3 TAXONOMY DEVELOPMENT

Suitable taxonomies play an important role in research and management because the classification of objects helps researchers and practitioners understand and analyze complex domains. The reduction of
complexity and the identification of similarities and differences among objects are major advantages provided by taxonomies (Bailey 1994). Furthermore, taxonomies enable researchers to study the relationships among objects and, therefore, to hypothesize about these relationships. As a vocabulary of a domain and as a set of defined constructs, taxonomies can add to the IS knowledge base and therefore lay the basis for future research approaches (Hevner et al. 2004; March and Smith 1995).

Developing a taxonomy is a complex process. Biology, with its well-known taxonomy of living organisms, provides some guidance. The traditional Linnaean taxonomy, commonly found in biology textbooks, classifies organisms based on a predefined hierarchy of categories from kingdom to species. Determining where a new organism falls in the taxonomy involves identifying into which classification the organism fits at each level of the hierarchy. Biological taxonomy development also includes phenetics and cladistics. Phenetics, also called numerical taxonomy, involves classifying organisms solely on the basis of their similarity. Characteristics are identified and organisms with similar characteristics are clustered using statistical methods to distinguish them from other organisms (Sokal and Sneath 1963). Cladistics, on the other hand, looks at the evolutionary relationships among organisms, not just their common features (Eldredge and Cracraft 1980). Thus two organisms may be closely related in a cladistic taxonomy because they have a common ancestor even though they do not share certain characteristics, thus putting them in different groups in a phenetic analysis.

Bailey (1994) provides a thorough review of taxonomy development in the social sciences. Bailey makes a distinction between a typology and a taxonomy, saying that the former is derived conceptually or deductively and the later is derived empirically. In the conceptual typology approach, the researcher may propose a typology of categories or types based on a theoretical ideal or model. In the process the researcher could define an ideal type, which Bailey (citing Weber 1949) explains is the “extreme” or “nirvana” of types. The ideal type is used to examine empirical cases in terms of how much they deviate from the ideal. Alternatively, the researcher could define a constructed type, which, as Bailey (citing McKinney 1966) explains, is not the ideal but based on reference to empirical cases. The constructed type is used to examine “exceptions” to the type. The ideal type can be compared to the highest value in a set of data (assuming highest is best) whereas the constructed type can be compared to the mean of the data (Bailey 1994, 23).

In the conceptual taxonomy approach the proposed classification is not based on empirical data, although such data could be brought in toward the end of the process. The empirical approach, on the other hand, starts with data and derives the classification from this data using cluster analysis or other statistical methods (Bailey 1994, 34). The goal is to find similarities among the data and to classify similar objects into the same category. Each category in the resulting taxonomy is called a taxon (plural taxa). Using the concepts from biology, this approach is phenetic.

Bailey (1984) describes the approaches just examined as different levels – conceptual and empirical – of a two-level model. Although researchers can approach classification through either level, he suggests that a common and often more useful approach is to use a three-level model that includes conceptual, empirical, and indicator or operational levels. In this method the researcher has two choices. One is to start with the deductive approach and then to examine empirical cases (deductive to empirical) to see how they fit with the conceptualization. The other choice is to start with empirical data clusters and then to deductively conceptualize the nature of each cluster (empirical to deductive).

4 AN APPROACH TO TAXONOMY DEVELOPMENT IN INFORMATION SYSTEMS

We now present our approach to taxonomy development for objects in the information systems field. Following the design science paradigm, we are building an artifact that is a method.

We choose to use the term taxonomy for our classification because it is more common and recognizable than the term typology, although we recognize that the later may be more correct in some situations. We define a taxonomy $T$ as a set of $n$ dimensions $D_i$ ($i=1, \ldots, n$) each consisting of $k_i$
mutually exclusive and collectively exhaustive characteristics $C_{ij}$ ($j=1, \ldots, k_i$) such that each object under consideration has one and only one $C_{ij}$ for each $D_i$. The goal is to develop a taxonomy with a set of dimension each consisting of a set of characteristics that sufficiently describes the objects in a specific domain of the information systems field.

Our purpose is to develop a useful taxonomy, but not necessarily a best or optimal one, as the later may be a moving target that could change over time as information systems evolve. A review of the literature found little help identifying metrics for evaluating taxonomies. Indeed, Bailey (1994, p. 2) makes this clear when he repeatedly asks which of his example classifications is “best” without giving guidance for finding the answer other than saying that “a classification is no better than the dimensions or variables on which it is based.” Thus we are left on our own to define a useful taxonomy. We proposed that a useful taxonomy has the following desirable attributes:

- It should be concise. It should contain a limited number of dimensions or a limited number of characteristics in each dimension, because an extensive classification scheme with many dimensions and many characteristics would be difficult to comprehend and difficult to apply.
- It should be sufficiently inclusive. It should contain enough dimensions and characteristics to be of interest. For example, a taxonomy with only one dimension and two characteristics within that dimension would not be very interesting. This attribute can conflict with the conciseness attribute.
- It should be comprehensive. It should provide for classification of all current objects within the domain under consideration.
- It should be extendible. It should allow for additional dimensions and new characteristics within a dimension when new types of objects appear.

Our approach to developing a taxonomy is phenetic, looking at the characteristics of the objects being examined. We do not look at the evolutionary development of the objects, and thus our approach is not cladistic. Our approach uses Bailey's three-level indicator model in which we combine both the empirical to deductive approach and the deductive to empirical approach.

Before starting to develop a taxonomy, the researcher must decide on the most comprehensive or meta-characteristic that will serve as a basis for the classification. The choice of the meta-characteristic should be based on the purpose of the taxonomy. For example, assume that the researcher is trying to classify computer platforms (hardware and operating system) into a taxonomy. If the researcher's purpose is to distinguish platforms based on processing power, then the meta-characteristic is the hardware and software characteristics, such as CPU power, memory, and operating system efficiency, that impact measures of power such as speed and capacity. On the other hand if the researcher's purpose is to distinguish among computer platforms based on how users use them, then the meta-characteristic is the capability of the platform to interact with users, such as the number of simultaneous users and user interface. The choice of the meta-characteristic must be done carefully as it impacts critically the resulting taxonomy. Further investigation of the selection process is needed.

We see meta-characteristics appearing research that develops taxonomies for various purposes, although they are not identified as such. For example, Nickerson (1997) develops a taxonomy of collaborative applications based on the meta-characteristic of communication among group members. Williams, Chatterjee, and Rossi (2008) choose two meta-characteristics – design and objectives – in developing their taxonomy of digital services. Leem, Suh, and Kim (2004) develop a classification scheme for mobile business models based starting with the meta-characteristic of “business players.”

We find Bailey's (1984) three-level indicator model to be most appealing for the development of taxonomies in the information systems field. It does not take a single approach but relies on both deduction and empiricism. We do not propose that our approach is the best or only taxonomy development method in the information systems field, only that it follows from the taxonomy development literature and is practical.
Figure 1 shows the approach that we propose based on Bailey’s model. The researcher begins by examining a subset of objects that he/she wishes to classify. These objects are likely to be the ones with which the researcher is most familiar or that are most easily accessible, possibly through a review of the literature. Next the researcher identifies general characteristics of these objects. In what ways are objects similar? What distinguishes objects from each other? Identification of these characteristics leads to the first effort at a taxonomy. The characteristics are grouped into dimensions that form the initial taxonomy. Each dimension contains characteristics that are mutually exclusive and collectively exhaustive. For example, dimension D₁ may group characteristics C₁₁, C₁₂, and C₁₃ and dimension D₂ may group characteristics C₂₁ and C₂₂. All objects have one and only one of the characteristics C₁j in dimension D₁ and one and only of the characteristics C₂j in dimension D₂. Some dimensions may be dichotomous (e.g., D₂) and some may not be (e.g., D₁). This process is based on the (limited) empirical data that has been gathered about objects and the deductive conceptualization of the researcher. Thus, up to this point the process follows Bailey's empirical to deductive approach.

Now the researcher reviews the first taxonomy to look for additional conceptualizations that might not have been identified or even present in the original empirical data. In the process new characteristics may be deduced that fit into existing dimensions or new dimensions may be conceptualized each with their own set of characteristics. It may even be the case that some dimension or characteristics are combined so that fewer dimension and/or characteristics result. The researcher examines empirical cases using the new characteristics and dimensions to determine their usefulness in classifying objects. Out of this step comes a revised taxonomy. This process follows Bailey's deductive to empirical approach. The researcher then repeats the empirical to deductive and deductive to empirical approaches, as appropriate, until the researcher is sufficiently satisfied that the taxonomy has the attributes of conciseness, sufficient inclusiveness, comprehensiveness, and extendibility. Such closure is subjective and difficult to define; further investigation is needed to clarify it.

Figure 1. The taxonomy development method
Figure 1 also shows how the taxonomy could be used after it is completed. One use could be to identify missing objects in the taxonomy. For example, there may be no objects that have certain characteristics, such as C_{12} in dimension D_1 and C_{21} in dimension D_2. There are several reasons for such a situation. The characteristic or combination of characteristics might be undesirable for the objects under consideration or it might be difficult or infeasible to create an object with the characteristic(s). Alternatively, no one may have thought of creating an object with the specific characteristic(s). In this situation, researchers or practitioners may try to create objects with the missing characteristics, thus expanding the set of objects in the domain. If this process continues long enough new objects may start to appear that do not fit in the taxonomy resulting in the need to start the taxonomy development process over again from the beginning.

5 MOBILE APPLICATION TAXONOMIES

Before using our method to develop a taxonomy of mobile applications we review the literature on the subject. Unfortunately, in mobile commerce and mobile business there exist little research on taxonomies. Only a few taxonomies have been proposed (e.g. Lehmann and Lehner 2002, Okazaki 2005), and there is a lack of a general taxonomy of mobile applications.

Kemper and Wolf (2002) propose a taxonomy based on a three-dimensional classification scheme. The chosen dimensions are degree of innovation, speed of development, and risk, and a set of characteristics focused on mobile application development. The taxonomy is narrowed down to the development process and does not feature the specific characteristics of mobile applications.

Leem et al. (2004) develop a hierarchical classification scheme based on mobile business models. In a first step, they partition into the two dimensions of B2C and B2B/B2E business models. They subdivide each of these dimensions into further dimensions. Their approach enables practitioners and researchers to classify mobile applications from a business model perspective. Thus it can support managerial decision-making and be a basis for mobile business model research. Their approach, however, focuses on a specific perspective and does present general mobile application classifications.

A basic two-dimensional classification scheme of mobile services is suggested by Nysveen and Thorbjørnsen (2005). They group services by type of interactivity and process characteristics. Both dimensions feature binary categories (person- vs. machine-interactive and goal-directed vs. experimental) only. The resulting fourfold scheme provides limited descriptive power. Williams, Chatterjee, and Rossi (2008) also discuss a taxonomy of digital services, but not just mobile services.

Heinonen and Pura (2006) developed a classification scheme for mobile services from a customer-centric perspective that is based on the four dimensions of type of consumption, context, social setting and relationship. Identifying industry specific classification as a limitation of their taxonomy, they suggest further research towards a more general taxonomy of mobile applications.

Dombrovskia and Ramnath (2007) present a taxonomy that focuses on applications they call "mobile, pervasive," which they characterize as "an application integrated with its physical environment and/or aware of its location." Their taxonomy consists of six general dimension – transitionality, time constraints, goal, collaboration, lifetime, and centricity – and seven location and location-related awareness dimensions – absolute location, space, proximity, transition, event, object, and operational.

Finally, Dobson (2004) does not classify applications per se, but instead provides a detailed classification of location in pervasive computing. He gives seventeen types of answers to the question of where someone or something is, ranging from absolute position to unknown, and organizes these answers into hierarchical taxonomy of location.
6 DEVELOPMENT OF A TAXONOMY OF MOBILE APPLICATIONS

With this background we now apply the approach described previously to develop a taxonomy of mobile applications. Again, using the design science paradigm we are validating the artifact (method) built previously by using it to develop another artifact, specifically a model.

We define a mobile application as a use of a mobile technology by an end-user for a particular purpose, e.g., purchase a ring tone, check a weather forecast, transfer funds at a bank, make an airline reservation. Mobile applications are provided by mobile services that have the infrastructure necessary to deliver the application. A mobile service, however, may provide several different applications under the umbrella of one service. For example, a mobile service may provide information about popular music and sell MP3 music files. For this paper we view these as two different applications – one, an informational application, and the other, a transactional application – both provided by one service.

We are interested in the use of applications, not in their hardware/software characteristics such as type of mobile device used or speed of network connection. We want to be able to use our taxonomy to identify how users use applications currently or may use applications in the future. Specifically, the purpose of our taxonomy is to distinguish among mobile applications based on how the user interacts with the application. Such a taxonomy will be able to help us identify whether new applications are truly unique from the user's perspective and where applications do not exist in the taxonomy suggesting opportunities for new applications. Thus the meta-characteristic for our taxonomy development process is the interaction between the user and the application. We start by listing a number generic mobile applications derived from the literature (Varshney and Vetter 2002, Varshney 2007). We note that this list is not exhaustive.

- Mobile communications
- Mobile messaging
- Mobile navigation
- Mobile TV
- Purchasing location-based contents
- Mobile inventory management for a company
- Product location and tracking for individuals
- Mobile auctions & financial services
- Mobile games – individual
- Mobile games – group
- Mobile advertisement user – specific
- Mobile advertising – location-specific
- Mobile entertainment services (contents-on-demand, live events)
- Mobile personal services (mobile dating)
- Mobile distance education – offline
- Mobile distance education – online
- Mobile product recommendation
- Mobile telemedicine and patient monitoring
- Mobile ticketing
- Mobile communities
- Mobile emergency/safety management
- Mobile habitat/environmental monitoring
- Mobile social networking

We begin by noting certain user interaction characteristics of these applications. With some applications users interact synchronously (in real time) with information flowing from the application to the user and with the user engaging in financial transactions. An example of this type of application is purchasing location-based contents such as weather information. With other applications users interact asynchronously (not in real time), they only report information to the application, and they do not engage in a financial transaction. An example is mobile inventory management. We continue by finding other applications with these characteristics. Once we gain confidence that we have identified some distinguishing characteristics, we group these characteristics into dimensions as follows:

- Temporal dimension: synchronous and asynchronous characteristics
- Communication dimension: informational and reporting characteristics
- Transaction dimension: transactional and non-transactional characteristics

At this point we have our first taxonomy, which we have derived using an empirical to deductive approach. Reviewing the taxonomy we deduce that the communication dimension may also have a bi-directional characteristic in which information flows from the application to the user and from the user...
to the application. We find that some applications (e.g., mobile auctions) have this communication characteristic. We call this characteristic interactional and add it to the communication dimension:

- Communication dimension: informational, reporting, and interactional characteristics

We have modified our taxonomy using a deductive to empirical approach. We continue in this way to develop newer versions of the taxonomy, going either from empirical cases to deduction or deduction to empirical cases. For example, we speculate that some applications can interact with anyone, that is, they are public, and some applications can only be used by individuals who have certain privileges such as those who work for a company, that is, they are private. We identify instances of these types of application. For example, purchasing location-based contents is a public application and mobile inventory management is a private application. Thus we add another dimension to the taxonomy:

- Public dimension: public and private characteristics

This new dimension creates the next version of our taxonomy. We continue in this way until we are satisfied that we have identified dimensions with characteristics for a taxonomy with the attributes of conciseness, sufficient inclusiveness, comprehensiveness, and extendibility. Deciding when to end the taxonomy development process is highly subjective.

Rather than continuing with a detailed description of the development process we present in the next section our final taxonomy of mobile applications that we derived by following this iterative process.

7 A PROPOSED TAXONOMY OF MOBILE APPLICATIONS

Our taxonomy of mobile applications is based on the meta-characteristic of the interaction between the user and the application. It consists of seven dimensions, some of which have already been described. We summarize all the dimensions and their characteristics here. For another discussion of these dimensions see Nickerson, Varshney, Muntermann, and Isaac (2007).

Temporal dimension. The user can interact with some mobile applications in real time, meaning that the application services the user’s request almost immediately, whereas the interaction between the user and the application may be deferred in other applications. The temporal dimension identifies when the user and the application interact. It has the following characteristics:

- Synchronous: user and application interact in real time
- Asynchronous: user and application interact in non-real time

Communication dimension. Information may flow uni-directionally between the user and the application or bi-directionally. The communication dimension relates to which way information flows as the user interacts with the application. Its characteristics are as follows:

- Informational: information flows only from the mobile application to the user; uni-directional information flow to the user; information push from the application to the user
- Reporting: information flows only from the user to the mobile application; uni-directional flow from the user; information pull by the application from the user
- Interactional: information flows in both directions between the user and the mobile application; bi-directional flow between user and application; information push and pull

Transaction dimension: Some mobile applications all users to purchase goods or services, normally through a financial transaction, while others do not. The transaction dimension captures this characteristic of the user interaction. This dimension has the following characteristics:

- Transactional: user can purchase goods or services through the application
- Non-transactional: user cannot purchase goods and services through the application

Public dimension: Mobile applications may be available to the general public, or their use may be limited to members of specific groups, such as certain employees of a business. The public dimension relates to whether the application is generally available. Its characteristics are the following:
• Public: application can be used by any user; may be limited to a group but any user may self-select to be part of the group that uses the application
• Private: application can only be used by a pre-selected (by a third party) group of users

Multiplicity (or participation) dimension: Although mobile applications can be used by many users simultaneously, users are often not aware of this characteristic and view their use of the application as singular. With some applications, such as multiple user mobile games, the user knows that he or she is part of a multiple-user community using the application. The multiplicity dimension captures this concept of individual or multiple user interaction with the following characteristics:
• Individual: one user; user experiences the application as if he/she were the sole user
• Group: multiple users; users view use of the application as part of a group

Location dimension: Some mobile applications provided customized information or functionality based on the user’s location, whereas other applications do not depend on where the user is located. The location dimension deals with whether the location of the user is used to modify the interaction of the application with the user. It has the following characteristics:
• Location-based: mobile application uses the user’s location
• Non-location-based: mobile application does not use the user’s location; the mobile application may know the user’s location but it does not use this knowledge to modify the user interaction

Identity dimension: Like the location dimension, some mobile applications adjust their information or functionality based on an awareness of who the user is, whereas other applications do not depend on the user’s identity. The identity dimension relates to whether the identity of the user is used to modify the way the application interacts with the user application based on the user’s identity. This dimension has the following characteristics:
• Identity-based: mobile application uses the user’s identity
• Non-identity-based: mobile application does not use the user’s identity; the mobile application may know the user’s identity but it does not use this knowledge to modify the user interaction

8 USE OF MOBILE APPLICATION TAXONOMY

The final steps in our taxonomy development process are to use the taxonomy to analyze objects of interest. Table 1 lists the generic mobile applications identified earlier (not an exhaustive list) and the characteristics of each application using the dimensions we have identified in our taxonomy. The decisions to identify characteristics for an application in this table are based on our understanding of each application. It is possible that variations of the applications may exist or become available in the future with different characteristics. Such variations can be easily added along with new applications.

We observe several things from this table:
1. There are a large number of generic mobile applications and some applications exist in more than one variation to suit different requirements.
2. The use of seven dimensions and fifteen characteristics appears to be sufficient to describe an application. These dimensions and characteristics also are helpful in differentiating among or classifying diverse applications.
3. There are an approximately equal number of synchronous and asynchronous applications in this list. In the future, new applications could emerge that will be “preferred” to run in synchronous mode, but if network infrastructure is experiencing high traffic load, these applications could adjust to run in asynchronous mode.
4. Only two applications in this list are reporting. Although the current needs of the user for reporting may be met via PC or laptop, it is expected that such requirements will move to handheld devices as many other applications have moved in the past. Thus more research could be done in designing mobile applications that have the reporting characteristic. Many of the reporting applications may be followed by user actions supported by one or more other mobile applications.
5. There is a good balance of transactional and non-transactional applications in this list.
Table 1. Characteristics of selected generic mobile applications

6. There are only four private applications in this list, although several applications can be modified to limit them to private users, including mobile distance education. The overwhelming number of public applications could be because most mobile applications are B2C at this time. As more mobile B2B or B2E applications are developed, there are likely to be an increase in applications with the private characteristic.

7. There are six group applications in this list. There may be an opportunity, however, for more new mobile group applications. It should be noted that most of the wireless infrastructure is not designed to support group-oriented applications due to resource and bandwidth limitations and the difficulty in supporting group mobility. Also, the resource and networking requirements may grow non-linearly with an increase in the group size. These factors may hinder the design and development of group-oriented mobile applications.

8. There is a good balance of location and non-location based applications in this list. In practice, the range of location capability varies among wireless networks, from no location management to
some location management in some places to highly accurate location management. With increased use of location technologies such as GPS, RFID, and sensor networks, there will be more infrastructure support for location-based applications.

9. There are fewer non-identity based, or anonymous, applications than identity based applications in this list. More work should be done in designing non-identity based applications. More specifically, some people might be more comfortable conducting transactions and interactions for services/contents if their identity is not known or kept secret.

These observations are based only on the listed applications, which is not exhaustive. As more applications are analyzed using the taxonomy, additional observations may be made. Also work can be done in studying the demographics of the users of these applications and designing applications to suit different age groups with varying requirements. Most of the mobile applications are designed for working adults, but there are opportunities to design new applications for young adults, older adults, and geriatric populations. For example, an application could be developed to fill a void identified in the taxonomy that is a reporting, non-transactional, private, group application for older adults. This application would allow users to report wellness and interesting tidbits from their daily life to a group of geriatric friends who may not be able to meet face-to-face often.

9 SUMMARY AND CONCLUSION

This paper describes a method of taxonomy development that can be used in the information systems field. The method, developed by following the design science paradigm and based on the taxonomy development literature, uses an indicator model that combines both empirical to deductive and deductive to empirical approaches. The process is iterative and terminates when the researcher is satisfied that the taxonomy has the attributes of conciseness, sufficient inclusiveness, comprehensiveness, and extendibility.

We evaluate the method by developing a taxonomy of mobile applications with seven dimensions – temporal, communication, transaction, public, multiplicity, location, and identity – and fifteen characteristics. We show that the dimensions and characteristics in this taxonomy are useful by analyzing some current and proposed mobile applications. Using this taxonomy, we identify that there are fewer applications among those considered that have the characteristics of reporting, private, group, and non-identity based, and we suggest that new applications can be designed.

The application of our method to the development of a mobile application taxonomy demonstrates that the method can be a useful approach to taxonomy development. We note, however, that one test of a method is not sufficient to show its ultimate usefulness and that further tests are needed. Our analysis of mobile applications using the mobile application taxonomy shows that the taxonomy resulting from our method is a useful tool for analyzing current and future mobile applications.

Further research in this area can follow several paths. One is to continue to explore the effectiveness of the proposed taxonomy development method by applying it to other domains, possibly resulting in improvements in the method. The second path is to refine the mobile application taxonomy by adding, deleting, changing, or combining dimensions, and to continue to test the taxonomy's efficacy by categorizing more mobile applications. A final research path is to use the results of the analysis in Table 1 or similar tables derived by applying the taxonomy to identify voids that could lead to the design and development of potentially more suitable mobile applications or the redesign of existing applications to better support user needs. The work can be extended in the future by elaborating more on user needs and the current context. We continue to explore all these avenues of research.

Abstract

As Mobile Network Operators are turning their attention to value added services, the need for innovative technology platforms designed for mobile digital contents management becomes evident. Such phenomenon is enhancing the strategic relevance of the “Mobile Middleware Technology Providers” (MMTPs) within the Mobile Content Value Network. The purpose of this paper is to explore which are the most critical choices to be made at a business model design level for a MMTP, to understand how these parameters are interrelated and can be combined to give rise to differential business models, and finally to delineate what are the most significant underlying “strategic patterns” driving the first steps of MMTPs activity within the Mobile Content competitive arena. The research relies on the adoption of a multiple case studies methodology: through 72 semi-structured interviews, 24 MMTPs were analyzed. The research findings show that some key business model parameters identified by the existing literature can be applied to MMTPs’ business model design process, while others were missing or not made explicit. Moreover, three noteworthy business models currently adopted by MMTPs – “Pure Play”, “Full Asset” and “Platform & Content Management” business models – were identified, associated respectively to three underlying strategic patterns – “stay on core”, “grow, wait and see” and “aggressive downstream”.

Keywords: Mobile Communications, Business Model, Strategy, Multiple Case Studies.
INTRODUCTION

Forced to face the gradual leveling off of voice revenues (Nomura, 2005; Arthur D. Little/BNP Paribas, 2005) that lead to a subsequent decrease of Average Revenue per User (Muller-Veerse, 1999; MacKenzie, O’Loughlin, 2000), Mobile Network Operators (MNOs) are to cope with a new dilemma: how to generate revenues for sustaining their future growth. The answer seems to come from the development of a wide and appealing offer of value added, non-voice services, pertaining to the so-called Mobile Content segment (Peppard, Rylander, 2006; Kuo, Yu, 2006; Maitland et al., 2002; Li, Whalley, 2002; Noordman, 2006).

However, the strategic reorientation of MNOs will not be straightforward, and won’t take place overnight. Specifically, on the technology architecture level, MNOs will need to introduce new solutions capable of overcoming the constraints and limitations of legacy systems and of the oversimplified Short Message Service Centers, not suitable for providing carrier-grade performances when dealing with “rich media” digital contents. Such solutions are here named “Mobile Content and Service Delivery Platforms” (MCSDPs), and can be defined as middleware platforms combining a wide set of functionalities – consistently aggregated into different modules, and equipped with network-side and device-side interfaces, thus creating an integrated suite with the purpose of supporting some or each phase of the mobile digital content creation, management & delivery process.

The diffusion of second generation delivery platforms will enhance the strategic relevance of a new player typology: the platform supplier, from now on referred to as “Mobile Middleware Technology Provider” (MMTP). Such players are converging in the Mobile Content market from several neighboring business areas, and their moves can reshape Mobile Content’s Value Network, potentially determining unexpected competitive attritions between these new players and incumbents.

These new competitive dynamics deserve attention from both researchers and practitioners. In particular, questions arise concerning the strategies Mobile Middleware Technology Providers will elaborate to compete in the market, and the business models they will hence design and adopt.

The purpose of this paper is to explore which are the most critical choices – i.e. parameters or “building blocks” – to be made at a business model design level for a MMTP, to understand how such parameters are interrelated and can be combined to give rise to differential business models, and finally to delineate what are the most significant underlying strategies or “strategic patterns” that seem to be driving the first steps of MMTPs activity within the Mobile Content competitive arena.

As a result, a reference model will be created, whose main objective is to provide a description of the key parameters characterizing MMTPs’ business models, to identify the extreme values such variables can assume, and to evaluate and assess the strategic implications of each building block choice. Moreover, the main existing combinations of parameters, which create the business models currently employed by this typology of companies, will be analyzed and interpreted, so to make some inferences regarding the relative overall strategies.

LITERATURE REVIEW

2.1 Mobile Middleware Technology Providers Definition

The literature dealing with technology enablers for Mobile Value Network is quite fragmented, and fails to provide a clear and unified definition of Mobile Middleware Technology Providers. Moreover, such players are also associated with several different sets of roles – i.e. set of distinct value added activities covered within a value system.
This lack of homogeneity in definitions is mainly due to the current complexity characterizing the Mobile Content Value Network itself, which results from the juxtaposition of different major value chains and systems, classifiable as follows: Network transport; Applications operation; Content provisioning; Payment processing; Providing device solutions; Network equipment provisioning; Middleware/platform provisioning (Yankee Group, 2000). As a consequence of the different points of view taken, different definitions and roles arise for Mobile Middleware Technology Providers.

Focusing on the activities strictly related to creation, management & delivery of mobile digital contents, the Value Network here proposed is composed by two parallel but interconnected layers – consistently with the “layered architecture” concept introduced by Huemer (2006):

1. **Content & Service Layer**, covering the activities related to the lifecycle management of mobile digital contents and services;

2. **Platform Layer**, undercurrent to the previous layer, which comprises the activities of designing, producing and operating the middleware platforms destined for mobile contents management and delivery.

![Mobile Digital Content & Service Value Network](image)

**Figure 1. Mobile Digital Content & Service Value Network**

The interconnection between the layers becomes evident with the activity of Content Publishing on the MCSDP. The Content & Service Layer can be divided into an “upstream chain”, encompassing the activities from content creation to its preparation for delivery, and a “downstream chain” considering the stages following the content commercialization.

The main focus of MMTPs resides within the Platform Layer: the middleware technology enablers are active in MCSDP design, manufacturing, provisioning – i.e. supplying the platform to the customers, mainly MNOs and/or Mobile Content & Service Providers (MCSPs), operation – i.e. platform technical maintenance and upgrading, and management – i.e. overall handling of the platform’s functionalities, from content publishing to physical distribution, exclusively from a technological point of view; marketing and selling activities are therefore excluded from this area, and belong to the “Content Delivery & Market Making” activity. Nevertheless, an extension of the MMTPs domain to include one or many overcurrent activities may be plausible: such alternative positioning, deriving
from specific choices made at a strategy definition level, would however potentially determine a competition between MMTPs and MCSPs. The strategic implications of this scenario will be discussed later.

As a result of the Value Network model presented above, and given the range of activities topped by this typology of players, a unified and unambiguous definition of the player typology under scrutiny can be offered, thus filling the existing literature gap: Mobile Middleware Technology Providers players are traditionally positioned on the Platform Layer – the technology enabling Value Chain for Mobile Content market, and their core role encompasses some or each activities related to the development of middleware Mobile Content and Service Delivery Platforms.

2.2 Business modelling design parameters

The concept of business model generally refers to the “architecture of a business” or the way firms structure their activities in order to create and capture value (Timmers, 1998; Rappa, 2000; Weil, Vitale, 2001; Hawkins, 2001). As a literature stream, Business model design has evolved from a piecemeal approach that looked for the single identification of typologies or taxonomies of models, to one searching for the development of a clear and unambiguous ontology – that is, the definition of the basic concepts of a theory – (Osterwalder, 2004), that could be employed as a generalized tool for supporting strategy analysis on firms. In parallel, business model has become an extensive and dynamic concept, as its focus shifted from the single firm to the network of firms, and from the sole firm’s positioning within the network to its entire interrelations and hierarchies (Ballon, 2007).

What is widely accepted by the literature is that a business model shall be analyzed through a multi-category approach, being a combination of multiple design dimension, elements or building blocks. However, the proposed dimensions are quite diverse, and the existing body of knowledge shows a lack of homogeneity.

Noteworthy attempts of providing a unified and consistent framework can be found in Rappa (2001), Weil and Vitale (2001), Osterwalder (2004), Haaker et al. (2004) and Ballon (2007) – this last study showing specific focus on Mobile Telecommunication Industry. The recurrent parameters of their models can be brought back to the general concepts of “Value”, i.e. the way a firm creates actual benefits to its customers and to itself through its value proposition and financial configuration, and “Control”, i.e. the inter-firms or Value Network relationships the firm is involved in and controls over.

The literature review on business model design allowed to individuate a further literature gap: as the Mobile Content segment is a relatively young market, and as the “advent” of MMTPs within such market’s boundaries is an extremely recent phenomenon, only few consolidated theories on strategy creation and business model design in the market context and with reference to the specific player typology under consideration are present.

Therefore, starting from the existing literature on business model design, and taking into account the building blocks so far pinned down, this research attempts to identify the key business model parameters for MMTPs, and to assess the strategic implications of the “parameters mix” actually employed by these players operating in the Mobile Content market.

3 RESEARCH METHODOLOGY

The present research is based on case studies, defined by Yin (2003) as “empirical inquiries that investigates a contemporary phenomenon within its real-life context, especially when the boundaries between phenomenon and context are not clearly evident; and in which multiple sources of evidence are used”. Qualitative research methodology was chosen as particularly suitable for reaching the research objectives, which aim at understanding the complex phenomenon of business model design
development within a given industry – i.e. Mobile Content – and with reference to a specific typology of players – MMTPs –, and thus at building new theory – or extending existing theories – on it.

To accomplish the previously identified research propositions, 24 in-depth exploratory case studies on MMTPs were performed. Coherently to the research methodology employed (Pettigrew, 1988), the firm sample was not randomly selected, but firms were picked as they conformed to the main requirement of the study, while representing both similarities and differences considered relevant for the data analysis. The main predetermined filters used to discriminate among firms were: the international reach of the firm – assumed if at least two national markets were served –; the presence of a well-defined line of business – if not the core business – dedicated to the commercialization of Content and Service Delivery Platforms or MCSDP modules; and the presence of an offer directed to the Mobile Telecommunications market. The following table provides the full list of analyzed companies.

| Table 1. Theoretical sample of companies interviewed |

A multiple case study approach reinforced the generalizability of results (Meredith, 1998), and allowed to perform a cross analysis on parameters, to pinpoint differentials in terms of parameters combination – to see which variables changed and which remained constant going from one business model to another –, due to the presence of extreme cases, polar types or niche situations within the theoretical sample (Meredith, 1998). The unit of analysis for each case study were the set of decision made at a business model design level.

As the validity and reliability of case studies rest heavily on the correctness of the information provided by the interviewees and can be assured by using multiple sources or “looking at data in multiple ways” (Eisenhardt, 1989; Yin, 2003), multiple sources of evidences or research methods were employed: interviews – to be considered the primary data source –, analysis of internal documents, study of secondary sources – research reports, websites, newsletters, white papers, databases, international conferences proceedings –. This combination of sources allowed to obtain “data triangulation”, essential for assuring rigorous results in qualitative research (Bonoma, 1985).

From January to July, 2008, 72 semi-structured interviews – both face-to-face and phone interviews – were held with 65 persons identified as key participants in the firms’ strategy definition and business model design processes at different levels. The population of informants included top and middle managers – e.g. Presidents Chief Executive Officers, Chief Information Officers, Chief Financial Officers, Marketing & Sales Managers, Project Manager, Software Engineers and Developers –. The semi-structured nature of the questionnaire made possible to start from some key issues identified through the literature, but also to let innovative issues emerge.

Given the explorative nature of the study, the business model variables identified through the literature analysis only constituted a starting point to guide the interviews: the identification of core business models parameters and the disentanglement of their combinations to create a thorough business model will represent a key finding of the present research.
4 MMTP BUSINESS MODEL CORE PARAMETERS

The research carried out through the multiple case studies allowed to shed light on the core business model design parameters for Mobile Middleware Technology Providers. The findings are synthesized in the “MMTP Business Model Parameter Reference Framework” below provided, which identifies three macro-dimensions, in turn divided into 9 parameters.

1. **Value Proposition parameters.** Platform characteristics; Offer positioning; Platform provisioning; Additional services; Resources & competencies.

2. **Value Network parameters.** Vertical integration; Customer ownership.

3. **Financial Configuration parameters.** Revenue model; Cost model.

As it will become clear by analyzing the framework, some building blocks were borrowed by previous models – in particular, Ballon (2007), while others, as not present in the existing literature or not made explicit, were modified or originally created through the empirical research to better express some aspects strictly linked to MMTPs.

For each and every parameter, the “value range” is identified, i.e. the extremes values the variables can assume, which also represent the major trade-off between opposite choices; the main strategic implications deriving from the parameters adoption are also discussed.

- **Platform characteristics.**

  As the MCSDP is the core element of MMTPs’ value proposition, its characteristics are a key parameter to be modeled, for they strongly affect the firm positioning. The main alternatives here are developing a modular and interoperable solution versus an integrated and stand-alone system. Should the platform be modular and interoperable, it would allow an easier and faster market diffusion – such choice being advisable for new entrants, searching for quick consolidation within the market (Blind 2005), thanks to the access to a wider customer base; however, to modularity and interoperability is often associated the risk of easy substitutability. In addition to this, a higher modularity and interoperability of MCSDPs can also give rise to interesting “co-opetition” – coexistence of “cooperation” and “competition” – phenomena among MMTPs, where competitors on a project/product can be partners for the modular development of a different project/product. On the other hand, providing an integrated and scarcely interoperable platform slows down the market penetration process, but if the solution is adopted by MNOs or MCSPs, it strengthens the ties between the customers and the technology supplier, potentially generating lock-in effects.

- **Offer positioning**

  Offer positioning is related to the choice of developing a MCSDP devoted to the management & delivery of “mature” contents – Sms, Mms, logos, wallpapers, ringtones and so on (Bertelè et al., 2008), or meant to deal with more innovative and cutting edge services – like video services or Mobile Tv. While operating in traditional segments grants faster platform diffusion, but forces the MMTP to face a higher level of competition – with a risk of seeing a gradual “commoditization” of its products, the coverage of forefront areas could position the firm in attractive niches, but may even imply higher demand risks, as the uptake of such services is hardly predictable.

- **Platform provisioning**

  The MCSDP provision modality is an emergent parameter, particularly interesting in the case of MMTPs, as it influences the kind of relation the technology supplier creates with its business customers. Installation in MNOs’ or MCSPs’ house is a typical choice for standard, out-of-the-box solutions which only need parametrization, and implies both an increased technical independence on MNO/MCSP side, and a clear separation between customer-supplier businesses. A particular case of housing is represented by the choice of full outsourcing – coming from a cross-fertilization of the MCSDP market from the IT platform and System Integration markets, where this practice is
widespread; in this alternative, the MMTP physically installs the platform within the customer’s structure, and thoroughly takes on its technical management. On the contrary, the hosting or Application Service Provisioning (ASP) option sees the MMTP maintaining the core platform within its perimeter, and supplying it to its customer following the “software as a service” model: this allows the technology provider to keep a greater presidium on the platform, and to exploit both scale and scope economies on the platform provisioning infrastructure.

- **Additional services**
  Another original parameter for MMTP business model design, additional services refers to the complementary offer accompanying the MCSDP selling, which can range from a simple technological management of the platform’s operation – e.g. maintenance, upgrading etc. – to, in some rare case, as discussed in the next paragraph, a commercial management of the contents and services published on the MCSDP itself. While the first choice is a natural consequence of the platform provider’s traditional role, the second implies an atypical evolution of MMTP positioning and market scope, and gives rise to the insurgence of a value network “structural equivalence” (Gulati et al., 2000) between MCSPs and MMTPs, thus determining competitive attrition among the two player typologies.

- **Resources & Competencies**
  As the “research based view” and the “dynamic capabilities approach” state, a firm’s collection of path-dependent core resources and competencies strongly influence its ways of seeking competitive advantage (Hamel, Prahalad, 1990; Teece et al., 1997). As a consequence, if the prevalence of technology oriented R&C makes a firm better disposed towards a mere technological partnership with its potential customers, the unbalance towards content oriented resources and capabilities enhance the MMTP tendency to propose itself as an “editorial partner” to MNOs, that is, a player capable of covering the activities of content creation, management and market making.

- **Vertical integration**
  The level of vertical integration refers to the MMTP coverage of activities in the Mobile Content Value Network. A positioning on the Platform Layer activities denotes a clear choice of self-relegation to a peripheral place in the network, covering a technology enabler role which does not go beyond the MCSDP provisioning and management processes, and stays out the downstream chain that allows direct contact with the end user. Contrariwise, selecting a positioning embracing an integrated technological and commercial management of both the platform and the contents published on it, puts the MMTP in a more central role in the system, closer to the “network focal” – the MNO – and to the primary source of revenues – the end customer – (Gulati et al., 2000; Peppard, Rylander, 2006). Of course, such strategic choice implies a more direct competition with MCSPs.

- **Customer ownership**
  Strongly related to the choices concerning vertical integration, customer ownership deals with the nature of the relationship established between the MMTP and the end customer. An intermediated customer ownership on the Technology Provider’s part implies a higher reliance on MNOs and MCSPs; the MCSDP vendor only receives indirect revenues streams from its business counterparts. Instead, a direct relationship with the end customer enhances the MMTP position in the Value Network, causing competitive attritions with MCSPs.

- **Revenue model**
  The revenue model parameter refers to the kind of revenue streams flowing from the MNO/MCSP to the MMTP, that can vary from mere selling of the platform, to a full revenue sharing agreement on the contents/services delivered through the MCSDP. The choices related to this element, are strictly linked to the platform provisioning parameter, and shall be considered extremely critical,
because of their many implications on the firm’s overall positioning and strategy. While system selling is based on a spot and fixed revenue for the MMTP, and presupposes a clear distinction between its business and the ones of its customers, the full revenue sharing solution rests on a division of potential revenues coming from contents/service selling to end customers. As such, the latter solution is strongly affected by the uptake and the consequent success of the service provided by MNOs and MCSPs; therefore, the MMTP revenues are spread on the whole service lifecycle, and are subject to a higher variance, for the technology provider is sharing not only opportunities, but also risks related to the service commercialization, finding itself in a “business sharing” condition.

The case studies showed that system selling and revenue sharing agreements only represent the extremes of the _continuum_ of solutions available: in between, players can go for hybrid alternatives, like the combination of a “start-up fee” – also known as “set-up fee” or “minimum granted” – covering MCSDP development and installation costs, and a “monthly rent” for the platform provisioning; a “monthly rent” integrated with a “consumption fee” after exceeding predetermined thresholds of usage; or else, a “start-up fee” plus a “revenue sharing” agreement.

- **Cost model**

The cost model refers to the nature of investment undergone for MCSDP development. If the investment are concentrated on the MMTP side, the risks associated to the project are not shared, but the player can benefit from a greater strategic independence after the solution is created. In the case of joint investment between the MMTP and the MNO/MCSP, the risks related to the project are spread on several actors; still, the MMTP enjoys less freedom, as its choices will have to be aligned with the strategic priorities of its partners.

Vertical Integration

- Platform Layer coverage
- Relegation to technology enabler role.

Customer Ownership

- Intermediated
- Direct
- Increased dependence on MNO/MCSP
- More central role in the VN. Competition with MCSP.

Revenue Model

- System selling
- Full Revenue sharing
- Clear separation between MMTP and MNO/MCSP business
- Business sharing (opportunities/risks) between MMTP and MNO/MCSP.

Cost Model

- Concentrated investment
- Joint investment
- Increased independence.
- Risk sharing.
- Increased dependence on MNO/MCSP.

Table 2. MMTP Business Model Parameters reference framework

In the next section, the noteworthy combinations of business models parameters, as emerged from the case studies, will be disclosed, and the related strategies will be described.

5 EMERGING BUSINESS MODELS AND CORE PARAMETERS

After identifying the strategic implication of single business model parameters, the further step of the study focuses on discovering and interpreting MMTPs’ emerging business models and strategies.

The in-depth analysis on the theoretical sample of 24 firms allowed to identify three main emerging business models currently developed and adopted by these players, corresponding to noteworthy specific combinations of parameters: such business models were then associated to three underlying “strategic patterns” that appear to be driving the players activity in the Value Network.

1. “Pure play” Business Model, determined by a “Stay on core” strategic pattern;
2. “Full asset” Business Model, determined by a “Grow, wait and see” strategic pattern;

![Figure 2. MMTPs emerging business models and strategic patterns](image-url)
The “Pure Play” Business Model is adopted by 14 firms out of 24, and is characterized by: a value proposition strongly focused on technology, in terms of platform provisioning – in-house installation is preferred to ASP or outsourcing, additional services – restricted to platform management, and resources & capabilities mainly technology oriented; a clear positioning on the Platform layer of the Value Network – distant from the end customer, bringing about a sharp distinction between the MMTP and MNO/MCSP businesses; and a financial configuration resting on fixed revenues and concentrated investments. The model is therefore defined “pure play” as the MMTPs employing it have pursued a consistent alignment between internal structure and external positioning, totally focused on the role of technology enablement.

The strategy determining this architecture is called “stay on core”, as all the informants of the firms comprised in the cluster declared that the business model design process was guided by the strategic choices of focusing on the traditional core business, oriented to the simple offer of technology. Other motivations leading to such conservative strategic positioning were the decision to restrain from representing a threat – real competition or even potential overlapping of activities – to their current customers, MNO/MCSP, and the unwillingness to internally develop \textit{ex novo} the structure and know-how necessary for creating and commercializing digital contents.

The adoption of “dirty” business models characterized by a non-transparent positioning towards the customers is explicitly criticized. In particular, the establishment of a full revenue sharing agreement is considered not advisable by the large majority of “pure play” firms – the informants belonging to 12 companies out of 14 labeled it as “way too risky” or “unfeasible”, for the following reasons: the revenue models structure grants extremely low margins to the technology provider – ranging from 1% to 5% of the total revenue; revenue sharing relies too strongly on the delivered services’ performance, and usually turns into a “loose-loose” game for the MMTP – if the service is unsuccessful, a full coverage of MCSDP development and installation costs is not assure; but even if the service proves itself appealing to the market, the MMTP is often forced to renegotiate the contract and reduce its share of margins, due to the higher bargaining power its customers possess.

The “Full Asset” Business Model is adopted by 8 firms. It differs from the “pure play” model in the tendency shown by these MMTPs to acquire and/or develop a wide portfolio of assets, resources and capabilities, not only related to the Platform Layer, but also to the Content & Service Layer. Nevertheless, for the moment these players are not leveraging on their “full asset” portfolio, as their actual coverage is still concentrated on technology activities, not being far from the positioning chosen by “pure play” MMTPs.

Analyzing the interviews, it is possible to argue that these firms are following a “grow, wait and see” strategy, as they recognize the value of creating a know-how on content creation and commercialization, and keep on investing on their pool of assets, but are still reluctant to abandon their traditional business. They would rather wait that the market takes a more defined shape, where they hold a consolidated position as a technology enabler; as soon as “time is right”, they may decide to exploit their high competitive potential, expanding their scope to the market making of contents and services.

The “Platform & Content Management” Business Model is only adopted by 2 firms: still, it deserves attention as its implications for the future development of the whole Value Network can be extremely significant. The MMTPs employing this model have extended their reach to the Content & Service Layer, embracing an integrated technical-commercial management of mobile digital contents. Their value proposition lists to hosting solutions of platform provisioning, to additional services related to content market making, and to content-oriented resources & capabilities; their vertical integration is high, covering activities which grant higher customer ownership; their financial configuration sees the possibility of establishing revenue sharing agreements, as well as joint investments.

Taking advantage of the evolved relationships cultivated with their partners – the MNO Vodafone in one case, and the Media Company Mediaset in the other, these players made innovative and explorative strategic choices, particularly aggressive in the downstream activities close to the end
customer. Their aim is to contribute in creating the commercial ecosystem that represents the main outlet for their technology solutions, and at the same time to place themselves in a more central position in the network, closer to the network focal and to the end user.

The drawback of this new role is related to the competitive dynamics that it could generate. MCSPs could see their business threatened, and start perceiving MMTPs as competitors: to retaliate, they could try to strengthen the ties linking them to Content Providers and Operators, thus isolating the platform providers; the biggest MCSPs could also undertake a process of upstream integration, acquiring the skills to internally develop their MCSDP. However, as the phenomenon of overlapping between MMTPs and MCSPs is extremely recent and not yet generalized, its competitive evolutions are still hardly foreseeable, and shall be subject to future research.

6 CONCLUSIONS

The research allowed to identify the core business model design parameters for Mobile Middleware Technology Providers; moreover, it shed light on how these building blocks are currently combined by MMTPs to give rise to complete business models architectures, and what strategies seem to drive such design choices.

Concerning the first major research objective – the business model parameters identification, the findings shows that some key business model parameters identified by the existing literature can be applied to MMTPs’ business model design activity, while others were missing or not made explicit. With reference to the second research objective – the individuation of the analyzed players’ design choices, three noteworthy business model currently adopted by MMTPs – “Pure Play”, “Full Asset” and “Platform & Content Management” business models – were identified, associated respectively to three underlying strategic patterns – “stay on core”, “grow, wait and see” and “aggressive downstream”. Thanks to the rigor of the methodology employed, and to the width and significance of the theoretical sample analyzed, these research can be replicated, and its findings can be generalized.

The paper’s value for researchers can be brought back to its contribution to Value Network, Business model design and Strategy definition theories. Existing literature on Value Network – with specific reference to the Mobile Content Network – was extended, through the provisioning of a unified definition for the player typology under scrutiny and its role in terms of activities covered. Business model design literature was applied to the study of a new player typology, and original design parameters, as well as their combinations to create a first “taxonomy” of MMTPs business models, have emerged. Moreover, the relation between strategy creation and business model design was made explicit, through the identification of business model design choices’ strategic implications.

The value for practitioners lies in the creation and provisioning of a “reference framework” capable of supporting the decision making process of business model design for a MMTP, as it presents strong ties between business model parameters and strategic implications.

The research represent a significant step towards the development of business model design theory with reference to Mobile Middleware Technology Providers. However, it does not analyze the potential different performances coming from alternative parameters selection. Future works will have to concentrate on the identification of newly emerged strategic patterns, resulting in alternative combinations of business model parameters, and to develop comparative or “benchmarking” analysis among them, in order to explain any differential in firms performances, pinpointing which single parameter or parameters mix may be seen as the origin of such deltas.

Abstract

This research builds on the literature on information technology and organizations to suggest an alternative to the current understanding of the production of computer-generated representations of work. This literature sees computer-generated representations of work as automatic outcomes of information technology that managers use to scrutinize employees. We present an ethnography of a desk-based sales unit which suggests that first-line managers can address the tension between the need to enforce prescribed goals and procedures and the need to adapt to and protect employees’ improvisation by forfeiting surveillance and instead use information technology to build a façade of compliance with prescribed goals and procedures. Our results to shed light on the hidden labours behind representations of compliance and place agency in the centre stage of the process of producing computer-generated formal representations of work.

Keywords: Information system use, control systems, managerial work, improvisation.
1 INFORMATION TECHNOLOGY AND THE MANAGER’S DILEMMA

How do first line managers use information technology to address the tension between the pressure to enforce prescribed procedures and goals and the pressure to adapt to local contingencies dictated by customers and employees?

One the one hand first-line managers have a stake in enforcing compliance with prescribed procedures and with prescribed goals. First-line managers’ rewards and their careers depend on their ability to enforce compliance with the organization’s goals and procedures (Drucker, 1993; Ivancevich, 1974; Kamoche, 2000). Compliance with prescribed goals and procedures makes first-line managers more visible to upper-level managers, opening up access to informal networks of power and influence (Jackall, 1989). We refer to the pressure and incentives to enforce compliance as the ‘bureaucratic pull’. On the other hand, first-line managers are the only level of management that is close enough to employees to be able to face directly the ‘improvisational pull’: our label for the inadequacy of prescribed procedures to which employees need to adapt to (Lipsky, 1980; Prottas, 1976; Orr, 1990) to face everyday’s contingencies. This unavoidable inadequacy requires employees to improvise their own procedures for their organization’s sake. A case to the point is the phenomenon of “zeal strike” where employees fully apply prescribed procedures to block work completely.

The management literature has documented three tactics to deal with the first-line manager’s dilemma – the tension between the bureaucratic pull and the improvisational pull: adapting, imposing and compromising (Adler & Borys, 1996; Dutton, Ashford, O’Neill, & Lawrence, 2001). When adapting (e.g. Blau, 1955), first line managers allow employees to adapt prescribed procedures to the contingencies of their everyday work. When imposing (see Gouldner, 1954, chapter 11) first-line managers enforce compliance with prescribed procedures and goals, irrespectively of these contingencies. When compromising, first-line managers attempt to strike a balance by enforcing some prescribed procedures while adapting others to local contingencies (Bartunek, Krim, Necoechea, & Humphries, 1999).

Research treats these three alternatives as equally viable independently of the material aspects of the experience of the first-line manager’s dilemma. However, as Yates (1989) has shown, the use of information technology in organizations, shapes the material experience of the first-line manager’s dilemma. Upper level managers’ assessment of employees’ compliance with prescribed goals and procedures is, in modern organizations, mediated by computer-based formal representations of work. Strictly speaking, in this condition the bureaucratic pull is a pull to produce a representation of compliance with prescribed roles, rules, procedures and goals with the use of information technology. This gives first-line managers another alternative to address the first-line manager’s dilemma: a tactic that focuses on using information technology to create a representation of compliance without enforcing the compliance with goals and procedures that underlies that representation.

This paper explains how this façade-creation tactic can be enacted by drawing on the computer based practices that first-line managers use to address the tension between a strong bureaucratic pull and a strong improvisational pull. To achieve this result we conducted an ethnographic study of a sales unit during the 3 months preceding and the 12 months succeeding the implementation of a CRM system (Siebel & House). We draw on these data to explore first-line manager practices in dealing with the tension and unpack their consequences for theory of technology in the workplace and managerial practices.
2 METHOD

2.1 Research setting

DeskSales, the unit where we did this study, is a business-to-business desk sales unit at E-Tel, a large European telecommunications firm. Its employees (desk salespeople) had two sets of tasks: to sell and to do saleswork. Selling consisted of persuading customers to buy the products and services offered by E-Tel. Saleswork included all the ancillary activities to selling, such as creating sales plans and contacting customers regularly to detect sales opportunities. DeskSales deals with large corporate customers (retail, finance, and tech sectors) working in cooperation with the field sales teams to achieve prescribed sales targets. In practice, each customer has one account team headed by a field sales manager who supervises two to five field salespeople. To each account is allocated a Desk Salesperson who can be tied to max four accounts. Desk Salespeople work in teams of seven to thirteen under a Desk Sales Manager. They report to one of three Senior Desk Sales Managers in the unit who in turn report to the unit’s General Manager. The structure is shown in figure 1.

Figure 1  The structure of DeskSales (example shows Retail and Tech accounts)

E-Tel implemented Siebel to assist Desk salespeople do their work and at the same time, used to assess their performance. Siebel is a sales automation system that is designed to help salespeople throughout the sales process. It allows salespeople to store and access information about their customer contacts; keep track of their present and past saleswork and store and access information about their open sales. Siebel is also a management tool and it was used as such by E-Tel’s managers to supervise desk salespeople’s sales and saleswork. Siebel data were also the basis to calculate the bonuses of salespeople and their managers. Finally the data collected in Siebel were used to justify promotions and account assignments. Siebel was thus at the core of the experience of managers and employees in their everyday work in E-Tel sales units.

2.2 Research procedures

This research focused on documenting Desk salespeople’s and desk sales managers’ work practices. For this purpose one of the authors conducted an ethnography during the first 15 months of DeskSales’ existence. The core dataset for this paper is a set of observations of the managers practices during 51 phone-based desk sales team meetings which we used to infer the practices that desk sales managers enacted in these meetings to address the challenges of prescribed vs. improvised work. These data were complemented with observations (including desk salespeople’s initial and ongoing training), 55 interviews with desk salespeople, sales managers, the unit’s general manager, field salespeople, and the unit’s training staff.
Analysis began by coding full transcriptions of phone-based team meetings, fieldnotes and interviews to articulate the challenges that desk salespeople and their managers faced when attempting to shape the formal representations of their work and by documenting the practices they enacted to do so (Barley, 1990). These challenges and tactics were arranged into narratives (Carlile, 2002) to articulate the processes by which desk sales managers and desk salespeople were able to participate in the production of the formal representation of their work. In what follows, we document the bureaucratic pull and the improvisational pull over desk sales managers and explain the practices that they enacted to address the tension created by these two forces.

3 THE DESK SALES MANAGER DILEMMA

Desk sales managers faced an especially straining experience of the first-line manager’s dilemma. Mariah, who was DeskSales’ General Manager during the period of this study, enforced demanding sales targets creating a strong bureaucratic pull. Desk salespeople’s inability to sell and their unwillingness to report sales and saleswork in Siebel fed a sizeable improvisational pull over desk sales managers.

3.1 Bureaucratic pull

Mariah saw her role as that of promoting DeskSales to the rest of the company. In her own words, she was “the one who sells their [desk salespeople’s] effort. I am the salesperson for the desk role.” Mariah used the unit’s sales target to showcase DeskSales’ value to the rest of the company. In the fiscal year of 2002/2003 Mariah committed to a stretch target of 350 million dollars of sales in 8 months, far exceeding the unit’s initial sales target of 330 million dollars in 12 and thus raising the bureaucratic pull over desk sales managers who were responsible for this target. Mariah also imposed three saleswork targets: desk salespeople had to report making seven calls to customers each day; all of the sales reported in Siebel had to have a complete salesplan; and no desk salesperson could have errors in their sales records in Siebel. Mariah supervised, rewarded and enforced Desk salespeople’s progress towards reaching their sales and saleswork targets. Desk salespeople called her the “Demonic Mistress of Siebel” because of her focus on enforcing reported sales and reported saleswork in Siebel. Mariah claimed that Siebel made her job “much easier,” not only because she could use it to supervise Desk salespeople’s but also because it made DeskSales performance “transparent” to upper-level management: “if you don’t have a shared system, people will just think that you’re making up the numbers – with a shared system it’s totally transparent.”

Mariah did not use Siebel to report automatically the sales and saleswork that desk salespeople logged in the system. Instead she had her desk sales managers prepare these reports. Reporting became an opportunity for compliance. Desk salespeople rarely reported enough calls to customers to meet their saleswork targets for each week. When Desk Sales Managers were creating their team’s weekly report, they had the opportunity to ask their Desk salespeople to report enough calls to customers to hit those saleswork targets. Additionally, this practice allowed desk sales managers to have their Desk salespeople change sales records in Siebel so that, for example, if a Desk Saleswoman had hit her sales target for any given week, she could report sales in excess of that target in the next week so as to also meet her targets then. This effort to use Siebel’s weekly reports to create a representation of compliance for every Desk Salesperson in their team occupied the majority of desk sales managers’ time at work. When asked to reflect on the negative elements of her job as a Desk Sales Manager, Linda complained:

One of the major problems we have had at DeskSales is that we need to keep proving ourselves [...W]e have to keep producing statistics and spreadsheets and things like that and for me personally as a Desk Sales Manager, having to produce these things to feed them up so that [our General Manager] can justify what we’re doing [...] so that [top managemers] are happy. So it
takes a lot of time and it’s unproductive work as well because it doesn’t help you make more sales, it’s just looking back, so that justification process is quite frustrating.

This was but one of many comments of the kind by desk sales managers. Creating reports from Siebel data was thus not only a time consuming activity, but one which desk sales managers interpreted as being of little if any value.

Mariah’s use of reporting shaped desk sales managers’ experience of the first-line manager’s Dilemma in three ways. First it added a set of reporting tasks to desk sales managers’ everyday work, reducing the amount of time they had available to manage and supervise their Desk salespeople. Second it added to the bureaucratic pull: desk sales managers not only had to make sure that their Desk salespeople engaged in the sales and saleswork need to meet their targets, but also that their Desk salespeople reported those sales and that saleswork on Siebel. Finally, it sharpened the challenge created by the bureaucratic pull: strictly speaking, desk sales managers had to enforce the representation of sales and saleswork on Siebel, rather than the actual execution of sales and saleswork.

To summarize, the bureaucratic pull under Mariah was driven by a “stretch” sales target that had Desk salespeople achieve more revenue than E-Tel upper-level managers required, and in less time. This push was strengthened by the increased amount of reporting work that desk sales managers and Desk salespeople had to do but it was partially alleviated because Mariah’s targets were focused on the act of reporting sales and saleswork, not on that of carrying these out.

3.2 Improvisational pull

Desk sales managers had to rely on their Desk salespeople to hit the sales and saleswork targets set by Mariah. Desk salespeople, however, had to hit their sales and saleswork targets under challenging conditions. They did not have sales skills and they were not trained to sell. Desk salespeople were hired from temporary staffing agencies or from E-Tel residential call centres, possessing little work experience and no experience in business sales.

The training that Desk salespeople received upon joining the unit was meant to address Desk salespeople’s inexperience with sales. Mariah’s efforts to enforce sales and saleswork targets, however, deteriorated the quality of incoming Desk salespeople’s training, thus strengthening the improvisational pull over desk sales managers. Mariah enforced saleswork targets based on the number of people allocated to the team, independently of whether they were on training, on sickness leave or on holidays. This led desk sales managers to forbid incoming Desk salespeople to attend most the training sessions. Desk sales managers had desk salespeople spend as much time as possible at their desk, reporting sales and saleswork in Siebel. This reduced desk salespeople’s confidence in their ability to sell because they felt they could not address even the simplest of requests. The week after the training ended, Ted, a newly hired Desk Salesperson, complained to the other Desk salespeople in his cohort that he got an email from his field salesperson asking Ted to price a product. Ted confessed, “I couldn’t understand a word of what was written in it”. This lack of sales skills and sales training was amplified by difficult relationships with field salespeople. Donald, a Desk Salesman in one of the two Finance Desk Sales Teams, voiced a common complaint:

[My job] is quite frustrating, at the moment. I find it quite difficult to get into the account. Quite difficult to sell. Because [...] it’s quite a large account team, they’re involved in sort of building the networks and the relationship with the customer; [...] it’s quite hard for me to get into the account and find a specific role in it. So I find myself just getting on, getting on with [service issues such as] backup for the systems engineers and that sort of stuff so it’s quite frustrating.

Mariah’s tenure coincided with an increased enforcement of Siebel use throughout E-Tel. Desk salespeople took on the increased Siebel work that field salespeople had to complete in exchange for being
able to claim some credit for part of field salespeople’s sales. Desk salespeople also attempted to take over field salespeople service work for their customers. The goal was to increase their interaction with customers to get some of the orders that customers would place with E-Tel’s service units. To this end, Desk salespeople introduced themselves to customers as their “single point of contact at E-Tel.” Desk salespeople’s goal was to have a service relationship with their customers unmediated by field salespeople. This gave Desk salespeople visibility of their customers’ orders – orders that they could report in Siebel as the outcome of their own effort. These two tactics helped Desk salespeople contribute towards their team’s sales targets, partially alleviating the improvisational pull over desk sales managers.

3.3 Addressing the first-line manager dilemma through an electronic façade

Mariah’s demands on desk sales managers’ reporting work left them with very little time to spend actively managing their desk salespeople. Nonetheless, desk sales managers needed to have a high level of visibility and control over desk salespeople’s sales and saleswork because their bonus was only paid if every single desk salesperson on their team met their targets. To address this challenge, desk sales managers focused their interaction with their desk salespeople on a phone meeting with their team (labelled the “team audio-call” at DeskSales), which took place about once every week or once every two weeks – depending on how well the team was doing against its sales and saleswork targets. Although these meetings were conducted over the phone, they were also face-to-face in the sense that the team’s Desk Sales Manager and its Desk salespeople were sitting at their Desk in DeskSales’ open space. Desk sales managers chose to conduct these meetings over the phone to keep them private and to avoid disturbing the other Desk Sales Teams. These calls could range from a five-minute announcement to an hour-long scrutiny of each Desk Salesperson sales targets, but on average they lasted for about 30 minutes. An analysis of all the audio-calls observed during Mariah’s tenure as DeskSales General Manager shows that desk sales managers used these calls to enact four practices to ensure that their Desk salespeople met their targets for reported sales and reported saleswork in Siebel.

The four practices were: monitor Desk salespeople’s representation work (reporting sales and saleswork in Siebel); enforce representation work on Desk salespeople; reward Desk salespeople for their representation work; and advise Desk salespeople in how to hit their targets through representation work. These practices are explained below.

Monitor

Desk sales managers could observe very little of desk salespeople’s everyday work. The amount of reporting work that desk sales managers had to do prevented them from observing their desk salespeople’s work directly. Desk sales managers could only see the sales and saleswork that desk salespeople reported in Siebel. Desk sales managers could not see two aspects of Desk salespeople’s work that were crucial to assess their desk sales teams’ ability to reach its sales targets: their progress towards closing their open sales in Siebel and the sales that they could report as their own in Siebel but had yet to do so. The analysis of the audio-calls observed during Mariah’s tenure reveals that desk sales managers used these calls to monitor these two aspects of their Desk salespeople’s work. Anthony’s team audio-call of February, 24th shows how desk sales managers used these calls to monitor what their Desk salespeople were doing to close the open sales they reported in Siebel. Here we present a fieldnote of a typical sort audio-call:

Anthony’s call started by calling Gregory: "what's the scores on the doors for you today?" Gregory said that his open sales were still far from closing. Anthony then called Kevin, who replied: "I'm just catching up on stuff." Anthony retorted: "that's very specific Kevin" and laughed. Anthony then called Alexander who said that he had spoken with one of his field salespeople and that he had gotten permission to report a sale worth 100 000 dollars under his
own name in Siebel. He said that his 15 million-dollar open sale was now only due to close in March ("sorry Anthony"). Then it was Mark's turn, who said that he was “just following up stuff.” The audio-call ended here.

As Anthony’s audio-call highlights, desk sales managers used these calls to see what they could not see in Siebel – the full process of their Desk salespeople’s representation work. Siebel only showed part of this process: the value of the each Desk salespeople’s open sales. It did not show the progress sales that Desk salespeople had made towards reporting these sales as closed in Siebel. Without their audio-calls, desk sales managers were not able to assess which of their Desk salespeople’s open sales were going to be reported as closed and which would be reported as lost or cancelled.

Desk sales managers also used their audio-calls to monitor Desk salespeople’s use of Siebel to report sales. Once Desk salespeople reached their targets for the quarter, they stopped logging sales in Siebel. They waited for the next quarter to log the sales they were allowed to report as their own in excess of what they needed to meet the current quarter’s target. This allowed Desk salespeople to hit their targets every quarter. If their Desk Sales Team as a whole was lagging behind its sales targets, however, it was in desk sales managers’ interest to have these hidden or latent sales logged in Siebel. This would not help letting Desk salespeople hit their targets but it would allow the team as a whole to do so. In the second quarter of 2003, Roy’s team was lagging behind their sales target, although Karl, one of his Desk salespeople, had already reached his own sales target. In one of his team’s audio-calls towards the end of the quarter, Roy attempted to have his Desk salespeople report all the sales they could in Siebel. During the audio-call, he said, "knowing that we have a gap of 1 million, we need to have a pipeline of 3 million to make sure that we hit that.” With that in mind, he asked if they had "any sales squirreled away under the blankets.” “Do you have anything that you decided, "let's chuck it away for next month or let's keep this one off the radar,” “do we have any sales records below 30% [probability of closing] that we could progress over the value chain in the next month?” He asked everyone individually, by calling their name. Adolph and Barry said that they didn't. Stewart shook his head with a smile, "that was a very shady no" Roy said "do you have one?" Stewart said that he did. Roy said "let's not move everything to 90% percent and expose ourselves, [but] if we're 100% sure put it up to 40%, [Mariah] is going to be looking at where we add value and if she only sees Stewart’s [sales numbers] she may wonder what the hell we're doing here."

Desk sales managers focused their supervisory role on a very specific part of Desk salespeople’s work: reporting sales and saleswork in Siebel. More broadly, what is striking about desk sales managers’ use of their audio-calls to monitor their Desk salespeople was their choice of target. Desk sales managers did not observe, nor did they seek to observe the work that allowed Desk salespeople to report sales and saleswork in Siebel. Desk sales managers only sought to observe the reporting work.

Enforce.

Siebel reports and team audio-calls often revealed a sombre picture of Desk salespeople’s ability to reach their monthly reported sales and reported saleswork targets. The gap between the amount of sales and saleswork that Desk salespeople had actually reported and the amount of sales and saleswork they needed to report for their team to hit its targets was often too wide. Desk sales managers addressed this gap by enforcing representation work – ordering their Desk salespeople to report sales and saleswork in Siebel.

Desk sales managers used their audio-calls to enforce representation work in two ways. One was by exposing desk salespeople’s lack of achievement hoping that they would be shamed into compliance. Desk sales managers announced each Desk Salesperson’s sales and saleswork numbers in audio-calls. In his audio-call of January, 15th, Ferdinand announced the closed sales reported in Siebel in an effort to get his Desk salespeople to report more closed sales. Ferdinand started by announcing the total revenue
figures for each Desk Salesperson. Laura has 5 million, "well done." Oscar "hot on your heels," Ferdinand added to Laura. Kyle got 67,000, "well done." Nancy, has "lots of quotes" but she needs to "translate them into [closed sales] in Siebel.” Nancy replied that quotes would take 2 to 3 months to be in Siebel because she needs to track them down with Service. Christine had 1.5 million: "Christine is really storming up now, well done Christine." Ferdinand said that the team as a whole had brought in 10 million of revenue. "When people from management come down you should know this so that you can tell management so that we'll look good,” Ferdinand added. Desk sales managers made Desk salespeople’s numbers visible to each other was by using their team’s whiteboard. Whiteboards were designed in table format. Desk sales managers used these tables to record their Desk salespeople’s achievement towards their targets. Linda, a Desk Sales Manager in one of the Finance teams explained her rationale for having a whiteboard by stating that, “those who feel embarrassed because they’re not at the top […] quite often come up [to talk to me] and say ‘I’m not doing well here’ and then we’ll have a discussion about that.”

The other way in which desk sales managers enforced representation work was by directly instructing Desk salespeople to report sales and saleswork in Siebel. In his audio-call of May 2nd, Andrew instructed his Desk salespeople to report sales following Siebel’s sales cycle. Siebel had a model of the stages that a sale had to go through. After going through his Desk salespeople’s open sales, Andrew then asked if there were any large sales to be closed that week. Stella said that she would probably have something next week. Michael said that he had his “80K one,” but he was still unsure when he was going to put it on Siebel. Andrew replied, "don't keep too much off Siebel, our team doesn't loose any open sales and that's not good.” Larry added, "if you look on Siebel, we have a very high conversion rate, that's not a true picture.” Andrew said that "we don't want open sales to be logged in Siebel at 100% probability, that looks very reactive.” Larry retorted, "yes, but we get a lot of orders" and Michael replied, "well, we can hold them and log them at a lower probability and close them a few days later.” Andrew said that "we need to follow all steps [stages in the sales cycle] because it puts them [open sales] on the radar early.” Andrew instructed his Desk salespeople to follow Siebel’s sales cycle to create the representation of selling when in fact they only reported sales that field salespeople had already closed.

Thus, when feelings of shame did not ensure that Desk salespeople met their targets for sales and saleswork, desk sales managers ordered them to report more of both. The analysis of audio-calls observed during Mariah’s tenure shows that desk sales managers enforced reporting work, not sales or saleswork. Desk sales managers did not make their Desk salespeople’s sales or saleswork visible to others, only the representation of those sales and that saleswork. Similarly, desk sales managers did not order their Desk salespeople to sell more or to make more calls to customers. Instead, they ordered them to log more sales or report more calls to customers in Siebel. Desk sales managers enforced Desk salespeople’s representation work, not their work itself.

Reward.

Desk sales managers also used their team’s audio-calls to reward their Desk salespeople. Desk sales managers offered good quality and high-priced alcoholic beverages to their Desk salespeople as an incentive to achieve specific, short-term reporting goals. In his audio-call of July 7th, Josh, A Desk Sales Manager in one of the Technology and Media teams, announced an incentive to reward the Desk Salesperson that reported the largest number of open sales in Siebel during the upcoming month. Josh announced pompously that he will give a bottle of champagne to the person that reported the most open sales on Siebel, "I want proper [open sales records] going on there, not a load of bollocks. I want to see them actually converted into [closed sales]." Scott, one of the Desk salespeople on the team, asked "what make of champagne?" Jason replied “Bollinger.” Josh added that "this incentive is just a launch pad. I want this to go along, it's part and parcel of the role, really."
Desk sales managers also used symbolic rewards – plastic Oscar figurines, paper ribbons and tin cups – to reward reporting sales and saleswork. These rewards were not aimed at fostering an increase in sales and saleswork. Instead, these rewards aimed at recognizing Desk salespeople’s achievement towards their reported sales and reported saleswork targets. Andrew had his “Golden Salesman” award for the Desk Salesperson whose sales totalled the highest revenue each week. At the start of his audio-call on August 15th, Ferdinand, a Desk Sales Manager for Retail teams announced that it was time to award "the trophy,” "Oscar is not the best performer anymore, although he might be,” Ferdinand proclaimed. He said that "this week the trophy is going to someone that has been exhibiting the right behaviors, it's Casey!” Casey raised his arms in sign of victory and the team applauded. Ferdinand handed him the trophy while saying, "we got some feedback on your sales plans that you actually took them seriously, while a lot of the others were taking the piss. Also you had a great turnaround in your [reported sales] in the past two weeks." Mild applause followed. Ferdinand said that it was time to take the picture and Casey moved next to the window and Ferdinand used a Polaroid instant-camera to take a picture of him with the trophy. Casey then put the picture and the tin trophy on top of his desk.

Desk sales managers also used formal E-Tel incentives to reward their own team. In his audio-call of July 24th, Daniel, a Desk Sales Manager in one of the Technology and Media team used a bottle of champagne he earned at a sector event the previous day to reward Andy, one of his team’s top Desk salespeople. He said that "Christian [the Technology and Media Top Manager] loves us,” and that "Christian has completely bought into this model [of using Desk salespeople]" because he was “very pleased” with the work they were doing. Daniel pulled out a bottle of champagne and said that "I was dragged on stage and Christian gave me this bottle of champagne and there was a lot of applause.” He added, "you're the ones doing the hard work, so I want to give this bottle of champagne to you.” He said that he realized that he couldn't share the bottle of champagne with everyone, so he was going to give it to the person with whom senior management was most impressed, Kevin. Everyone applauded and Daniel handed the bottle of champagne to Kevin.

Desk sales managers’ rewards thus followed their monitoring and enforcing practices. They focused on Desk salespeople’s representation work, no their actual sales or saleswork. Material and symbolic rewards recognized the use of Siebel to report sales and saleswork, not sales and saleswork themselves.

Advise.

Desk sales managers could enforce and reward their Desk salespeople’s representation work but still see their team lagging behind its reported sales and reported saleswork targets. Desk salespeople could have the motivation to report sales and saleswork but not the skills to sell, the permission to log as their own the sales made by their field salespeople, or the opportunity to call their customers. To address this, desk sales managers advised their desk salespeople to on how to reach their sales and saleswork targets. The analysis of audio-calls shows that desk sales managers advised their Desk salespeople in three ways. First, desk sales managers helped Desk salespeople reach their revenue targets by telling them how to use E-Tel’s information systems to find revenue. In her audio-call on March, 4th, Nina, a Desk Sales Manager in one of the Retail teams, explained how to use one of E-Tel’s information systems to find revenue that Desk salespeople could claim as their own. She explained to her Desk salespeople that "in E-Tel you'll soon find that things aren't like they should be: sometimes [some of the product revenue from your accounts] is not visible on ARTS [E-Tel’s automatic revenue tracking system].” Nina added that "If I spend the whole day [selling] to [one of my accounts] and they're not in the system, I would be wasting all my time because I wouldn't see the revenue.” She continued: "sometimes you get products allocated to your account on ARTS that the [customer hasn’t bought] and they [bring revenue]: those ones you want to keep, so keep quiet.” Nina explained: “basically, the more you look, the more you'll find and it's a way to get revenue...
without having to sell anything. Of course, you will eventually have to sell something, but it's a good way to hit numbers."

Second, desk sales managers also helped their Desk salespeople meet their targets for reported sales by giving them specific advice on how to establish relationships with their field sales teams. In her audio-call of February, 19th, Nina used a question made by Dennis, a Desk Salesperson on her team, to explain to her Desk salespeople how to get field sales people to allow them to log sales in Siebel. Towards the end of the team’s audio-call Dennis raised his hand and Nina gave him leave to speak. Dennis said that there were a lot of large open sales for his accounts in Siebel and asked Nina how he could get some of the credit for those sales. Nina told the story of how Robert, another Desk Salesman on her team, got involved in an 8.6 million dollar opportunity that was about putting E-Tel Broadband access CDs in a retailer’s stores. Nina explained how Robert's involvement was limited to calling the stores to make sure that they got the disks. Nina said that "even making a quote [giving the price of a product] is involvement.” She concluded: "what I would do is ask the account team if there's something I can do to help.”

Thirdly, desk sales managers advised their Desk salespeople on how to log sales and saleswork in a way that helped Desk salespeople reach their targets consistently. Andrew told his Desk salespeople to refrain from reporting sales in Siebel after they had reached their quarterly targets. He advised his Desk salespeople to report those sales in the following quarter to make their targets easier to reach. In his January 15th audio-call, Ferdinand advised his Desk salespeople on how to go about reporting customer calls in Siebel. Ferdinand told them to report "any contact with customer” in Siebel. Laura, one of the Desk salespeople on his team, asked if the "emails that you get" count. Ferdinand said that they did, but "try to keep it relevant,” "I don't want Siebel clogged” with irrelevant information. "You would want to add on a call from a customer clarifying what that quote was.” He was quick to add: "Don't make your numbers plummet because of that." Don concluded "it's the [target] thing" and Ferdinand nodded in agreement. Don said that the point is to "hit 10 and then worry about relevance after [they hit 10].” Ferdinand said that to reach targets the boundaries can be "stretched" but then they should "retract.”

Desk sales managers’ actual advice sharpens the case that they were focusing on reporting work. Desk sales managers might need to monitor, enforce and reward representation work because Desk salespeople were engaging in sales and saleswork without reporting it in Siebel. Desk Sales Manager’s advice, however, focuses on how to scavenge unclaimed sales and how to persuade field salespeople to allow Desk salespeople to take credit for field salespeople’s sales. The tactics that desk sales managers taught to their Desk salespeople in their team’s audio-calls helped Desk salespeople hit their reporting targets without actually engaging in any of the work they reported.

4 DISCUSSION

The way desk sales managers addressed their experience of the first-line manager’s dilemma shows how information technology can be used to address these opposing forces by creating a façade of compliance with the bureaucratic pull, reducing the improvisational pull to employees’ ability and willingness to participate in the production and reproduction of that façade. This suggests an alternative view of the production of computer-generated formal representations of work that complements the dominant view of this process (cf. Ball, 2003; Findlay & McKinlay, 2003; Sewell & Wilkinson, 1992; Townsend, 2005). This dominant view hinges on the assumption that work and its formal representation of information systems are tightly coupled. This assumption has two corollaries. One is that managers use computer-generated formal representations of work to supervise work down the organization. The other is that employees have agency over these representations because these are generated by information technology as employees use it in the course of their everyday work. This view places deviance squarely with workers and establishes access to information as the core element of the struggle for power in organizations.
However, studies of the production of computer-generated formal representations of work that follow a structurational approach to IT suggest that the tight coupling between work and its formal representation is dependent on the everyday practices of managers and employees. This tight coupling is thus not a feature of technology but a consequence of people’s actions (cf. Orlikowski, 1991).

Our analysis suggests that Desk salespeople’s experience explains how a different pattern of production of computer-generated formal representations of work can emerge and be sustained. At DeskSales, desk sales managers and Desk salespeople’s use of information technology kept Desk salespeople’s work and its representation in Siebel were, at best, loosely coupled. Desk salespeople could produce a representation of compliance with sales and saleswork targets without any sales and without engaging in any saleswork (and yet staying legit). Desk sales managers used those Siebel-generated formal representations of work to show compliance upward, forfeiting scrutiny except when Desk salespeople were not representing compliance. When enacting such a set of practices, desk sales managers produced condensed, closed summaries of Desk salespeople’s work. The goal was to make scrutiny more difficult and less likely.

Under such conditions, desk sales managers could focus exclusively on enforcing representation work—the work of producing a representation of compliance with prescribed roles, rules, procedures and goals, without actually complying with any of these. Desk sales managers used their own improvised information system to enforce representation work by supervising down based on informal representations of work. This pattern of production of computer-generated formal representations of work widened the gap between Desk salespeople’s work and its representation.

This view of the production of computer-generated formal representations of work that we inferred from Desk salespeople’s experience at work is not a replacement, but a complement to the dominant view on this phenomenon. Desk salespeople’s experience and that of the research settings featured in the current literature on IT and organizations are two patterns that are produced by the same process, a process that hinges on the tightness of coupling between work and its representation in computer-generated formal representations of work, as determined by managers’ and employees’ practices.

5 CONCLUSION

The first-line manager’s dilemma is a common theme in both empirical and theoretical accounts of bureaucracy. These accounts show that first-line managers can address this dilemma by enacting tactics that can range from an imposition pattern—thus yielding to the bureaucratic pull—to an adaptation pattern, yielding to the improvisational pull. The literature on IT and organizations has argued that in context of computer-mediated supervision only an imposition pattern is sustainable. Desk sales managers’ experience shows that in contexts of computer-mediated supervision there is another alternative—creating an electronic façade of compliance. The way E-Tel’s upper-level managers used Siebel to supervise Desk salespeople’s work suggests that the assumption of tight coupling between employees’ action and its representation in formal information systems is not empirically universal. The disconnect between Desk salespeople’s work and its representation in Siebel allowed desk sales managers to interpret the bureaucratic pull as a push to create a representation of compliance. Desk sales managers limited their imposition of prescribed roles, rules, procedures and goal on their Desk salespeople to the creation of a representation of compliance with DeskSales prescribed goals. Desk sales managers interpreted the first-line manager’s dilemma at DeskSales as a problem of managing their employees’ representation work, instead of their sales and saleswork. To this end, desk sales managers created a parallel set of prescribed rules, roles and processes to manage their Desk salespeople’s representation work. To use desk sales managers’ favorite metaphor for Siebel, IT is indeed a window into everyday work, but instead of being a passive representation such as that allowed by the windows in Foucault’s panopticon, it is an active representation, such as that allowed by a “shop window” … dressed up to impress observers.

Abstract

In a previous paper, we have found empirical evidence supporting a positive relationship between network centrality and success. However, we have also found that more successful projects have a lower technical quality. A first, straightforward argument explaining previous findings is that more central contributors are also highly skilled developers who are well known for their ability to manage the complexity of code with a lower attention to the software structure. The consolidated metrics of software quality used by the authors in their previous research represent measures of code structure. This paper provides empirical evidence supporting the idea that the negative impact of success on quality is caused by the careless behaviour of skilled developers, who are also hubs within the social network. Research hypotheses are tested on a sample of 56 OS applications from the SourceForge.net repository, with a total of 378 developers. The sample includes some of the most successful and large OS projects, as well as a cross-section of less famous active projects evenly distributed among SourceForge.net’s project categories.

Keywords: social networks, software quality, software design skills.
1 INTRODUCTION

Social networks represent social systems characterized by very large numbers of individuals and relationships among individuals. By empirically analyzing the evolution of OS networks modeled as sets of cooperation relationships among project contributors, previous research has tested the following principles:

- The probability with which a new relationship connects to a contributor is exponentially proportional to the number of existing relationships involving the contributor (Xu et al. 2006; Gao and Madey 2007). This law applies to a variety of social networks and is often referred to as the rich-get-richer evolution principle (Albert and Barabási 1999).

- As a consequence of the rich-get-richer principle, OS networks have a few nodes with a number of relationships significantly higher than the network’s average, called hubs. The alternative random evolution principle has been found not to apply to OS networks, i.e. relationships are not uniformly distributed across nodes (Xu et al 2006).

- Hubs have been found to follow a life cycle. Hubs appear, grow, and ultimately stop growing and quickly disappear (Gao et al. 2005).

- The creation of hubs is enabled by the ability of some nodes to evolve considerably faster than the average evolution rate of the network (Gao et al. 2005).

In the OS context, Grewal et al. (2006) have hypothesized that hub contributors have a positive impact on the success of the projects they are involved in. Their claim is that the rich-get-richer principle suggests that hub contributors have the ability to attract further contributions and, thus, positively influence the evolution of their projects. The literature provides numerous metrics that help verify whether a node is a hub, called centrality metrics (see Section 2). Grewal et al. (2006) have tested whether higher values of centrality metrics are positively correlated with the ranking measure of project success. By testing correlation for 12 projects from SourceForge.net written in Perl, Grewal et al. (2006) have found mixed results that only partially support their hypotheses. A possible problem with their approach to testing is the size of the social network that they have considered, which is limited to the contributors of a few projects and their direct connections to other contributors in the SourceForge.net community, while the literature clearly indicates that the laws governing a social network can be observed only if the network is analyzed in the large (cf. Newman et al. 2006).

In a previous paper (Barbagallo et al. 2008), we have tested Grewal et al.’s relationship on a significantly larger sample and actually found empirical evidence supporting the relationship between centrality and success. The relationship between centrality and project success has clear implications for managers. A company that is interested in making business through OS could aim at having its developers become hubs as a way to enhance success. However, in our previous research, we have also found that more successful projects have a lower technical quality. This paper aims at understanding the reasons behind the negative relationship between success and quality. Is success in and of itself detrimental to quality or are there drivers of quality other than success that help explain quality degradation? If so, are these drivers related to centrality?

Answering these questions can help managers understand the implications of gaining a more central position in the network as a way to reach success. The software engineering literature explains that there exists a trade off between quality and costs. Since quality represents an investment in the long term, managers are often willing to accept a lower level of quality if it represents a way to have a marketable output more quickly (Tan and Mookerjee 2005). Explaining the relationship between success and quality can help managers understand whether an OS social network represents a governance structure that allows deliberate quality to cost decisions or it creates new and negative quality degradation effects.

The presentation is organized as follows. Section 2 reviews the literature on social networking centrality metrics and software design quality metrics. Section 3 discusses our research hypotheses, while Section 4 describes the operationalization of variables, the data sample used to verify our hypotheses, our statistical

approach and reports the results of empirical testing. Finally, Section 5 provides a discussion of empirical findings and outlines possible directions for future research.

2 RELATED WORK

This section reviews the literature focusing on the concepts of centrality in social networks and software design quality.

2.1 Centrality in Social Networks

The concept of centrality has been defined as the importance of an individual within a network (Freeman 1979). Centrality has attracted a considerable attention as it clearly recalls notions like social power, influence, and prestige. Over time, several metrics have been introduced to formalize and then measure centrality from different points of view.

The first metric of centrality, called degree centrality, discussed by Freeman (1979), is defined as the number of links of a node normalized to the total number of links in the network. Degree centrality still represents the simplest and most widely used indicator of centrality, as it is intuitive and easy to calculate (Choi et al. 2006). A node that is directly connected to a high number of other nodes is obviously central to the network and likely to play an important role (Sparrowe et al. 2001). A node with a high degree centrality has been found to be more actively involved in the network’s activities (Hossain et al. 2006).

Freeman has also introduced the metric of betweenness centrality (Freeman 1979). This metric is defined as the average frequency with which a node is crossed by the shortest path connecting two generic nodes of the network. This metric is widely used in the literature, as it represents the simplest way to measure the ability of a node to reach other nodes in the network and act as an intermediary of the interactions between them. Over time, several refinements of the original Freeman’s metric have been proposed. For example, Newman (2003) has posited that a random walk among all possible paths should be considered as opposed to the shortest path. Although the opposite claim could be put forward too, Newman’s metric has the advantage of lowering the complexity of the algorithm to calculate betweenness centrality.

Freeman has also proposed the metric of closeness centrality, which is meant to extend the concept of betweenness centrality by measuring how far an actor is from all other actors in the network along the overall shortest path (Freeman 1979). This metric is less intuitive and more difficult to calculate than the previous two and has obtained a more limited success. Freeman notes that closeness centrality can be associated with the idea of independence of a node, since high values of closeness involve a lower need to depend on other nodes in order to communicate with other parts of the network. However, the metric becomes meaningless if applied to disconnected networks, as it cannot be calculated for non-reachable nodes. A more recent metric proposed by Stephenson and Zelen (Stephenson and Zelen 1989), named harmonic centrality, represents a measure of closeness centrality that considers harmonic distance in place of shortest path distance.

Previous to Freeman, Bonacich (1972) introduced the metric of eigenvector centrality, which measures centrality as the principal eigenvector of the whole network’s adjacency matrix. The disadvantage of this approach is that the eigenvector of the adjacency matrix must be calculated iteratively and convergence can be very slow. This metric has had limited success, especially due to its mathematical and computational complexity. Furthermore, Borgatti (1995) has noted that eigenvector centrality is conceptually similar to degree centrality. However, it should be acknowledged that the PageRank metric proposed by Brin and Page (1998) is based on the notion of eigenvector centrality. Even earlier than Bonacich, Katz (1953) and Hubbell (1965) introduced two centrality metrics, which, similar to eigenvector centrality, consider a node important if it is connected to other important nodes. However, both indices have series convergence issues that have limited their use in practice.

This paper focuses on degree and betweenness centrality, according to their original definition provided by (Freeman 1979). Degree and betweenness centrality represent the most intuitive and widely used metrics of centrality. We acknowledge that closeness and eigenvector centrality are also theoretically important metrics of centrality in the field of social networks, as discussed in (Borgatti et al. 2006). However, their greater conceptual and computational complexity makes them more difficult to use in empirical research on large social networks.

Proceedings ECIS 2009
Software Design Quality

This paper focuses on the quality of software design, i.e. on the internal quality of software. Previous literature suggests that higher values of software design quality metrics represent drivers of a number of external quality variables, such as testability, correctness, and reliability (Boehm 1976, Brito e Abreu and Melo 1996, Marinescu 2005). In turn, these external quality variables affect user satisfaction and can influence software adoption and actual usage (Bevan 1995). However, the direct analysis of external quality variables, i.e. of software effectiveness variables, is outside of the scope of the present paper.

Software design quality can be measured by analyzing the design properties of source code. There exists a consolidated body of literature focusing on code-based design quality metrics. Traditionally, the measurement of code design quality is based upon i) complexity and ii) design quality metrics. The first research contributions were aimed at providing operating definitions and metrics of software complexity, focusing on the analysis of the code’s information flow. Cyclomatic Complexity (McCabe 1976), Software Science (Halstead 1977), and Information Flow Complexity (Henry and Kafura 1981) represent the most widely used metrics from this early research.

Over time, design quality has become of increasing importance to cope with the continuously growing size of software systems. Research has started to distinguish between the complexity due to poor design quality and the inherent complexity of software due to requirements (Troy and Zweben 1993). The main contribution of these studies has been to show that design quality is necessary to handle the complexity caused by challenging requirements.

With the advent of the object-oriented programming paradigm, coupling, cohesion, inheritance, and information hiding have been identified as the basic properties of software design quality (Emerson 1984, Symons 1988, Chen and Lu 1993, Sharble and Cohen 1993). Based on these four basic properties, a number of metrics have been proposed to evaluate the design quality of object-oriented software. The most widely known metrics have been first proposed by Chidamber and Kemerer (1994) (WMC, NOC, DIT, RFC, LCOM, and CBO) and by Brito e Abreu (1995) (COF, PF, AIF, MIF, AHF, and MHF). These milestone contributions have started a lively debate within the software engineering community on the consistency and generality of such metrics (Harrison et al. 1998). As a matter of fact, metrics such as CBO, NOC, MIF, and DIT represent a standard and are included in most development environments, such as Eclipse and Visual Studio.NET. This paper focuses on these standard metrics.

CBO, NOC, and DIT have been found to impact on software maintainability and, hence, on maintenance effort and costs (Li and Henry 1993). Increasing software design quality is viewed as a costly activity that pays back in the long term by reducing the cost of subsequent maintenance interventions (Slaughter et al. 1998). With proprietary software, companies usually take a short-term perspective and tend to develop code faster at the expense of quality, which, in turn, tends to decrease over time (Tan and Mookerjee 2005). As observed by Tan and Mookerjee (2005), the deterioration of quality over time leads to a break-even time when a short-term perspective becomes economically inefficient and companies should invest in quality. This can be obtained either by replacing old software with new code of higher quality or by launching a maintenance initiative aimed at increasing quality without necessarily developing new functionalities, commonly referred to as refactoring (Fowler et al. 2001).

In OS applications these phenomena are difficult to observe. Some projects become inactive when they reach the end of their lifecycle and, until then, they are continuously maintained. However, projects reach their end for a number of reasons that may not be related to quality deterioration. For example, solo projects, i.e. projects launched and maintained by individual programmers, are often active for a very short period of time and come to an end due to lack of interest from the OS community.

The most successful projects, such as Linux and PostgreSQL, are still active although they are considered mature. Koch (2004) has noted that in OS projects refactoring tends to be a continuous process and developers allocate time and effort to quality improvements when needed. A previous work by Capra et al. (2007) has studied the refactoring process of a sample of 95 OS applications (1251 versions) from SourceForge.net. Empirical analyses have showed that the number of versions between two subsequent refactorings is highly variable. On average, a significant quality improvement can be observed in 40% of the total number of versions, while Tan and Mookerjee (2005) have found that in a sample of closed source applications refactorings occur in about 10% of an application’s versions.
Previous literature indicates that the cost benefits of quality improvements are reaped over time. However, it provides only partial evidence to demonstrate that quality investments have a positive balance (Slaughter et al. 1998). From a theoretical standpoint, Tan and Mookerjee (2005) suggest that quality investments typically represent a zero-sum game. However, the only clear empirical result is that quality involves an investment and, in the short term, it represents a cost. OS projects challenge also this result, since continuous refactoring practices should release similarly continuous cost benefits. A previous work by Capra et al. (2008) has empirically verified that quality and development effort are not correlated in OS projects, supporting the theoretical observations of Tan and Mookerjee (2005). In this paper, we consider software design quality and development effort as independent variables.

3 HYPOTHESES

In a previous paper (Barbagallo et al. 2008), we have found empirical evidence supporting the following hypotheses:

- Projects involving contributors with a higher level of centrality are more successful.
- Projects involving contributors with a higher level of centrality are able to attract a greater development and maintenance effort.
- More successful projects have a lower software design quality.

Overall, these hypotheses indicate that involving contributors that play a more central role in the social network helps projects to attract investments and eventually reach success. However, it does not seem to help the quality of the software artifact. These findings are counterintuitive, since they show that more successful projects (in terms of SourceForge.com ranking) have lower technical quality. In the paper, we discuss the possible reasons behind this inverse relationship between success and quality. A first, straightforward argument explaining previous findings is that more central contributors are also highly skilled developers who are well known for their ability to manage the complexity of code with a lower attention to the software structure (Lakhani and Wolf 2003). The consolidated metrics of software quality used by the authors in their previous research represent measures of code structure. Structure is generally considered a proxy of quality, as it represents the main driver of software maintenance costs (Li and Henry 1996).

This paper aims at providing empirical evidence supporting the idea that the negative impact of success on quality is caused by the careless behaviour of skilled developers, who are also hubs within the social network. Our first research hypothesis addresses the relationship between centrality and developers’ skills. In contexts different from OSS, the literature acknowledges that social networks are a significant enabler of knowledge transfer processes and related effectiveness (Reagans and McEvily 2003, Tsai 2005). In particular, higher levels of betweenness centrality in the network have been found to be correlated to a greater timeliness in reaching new information, while higher levels of degree centrality have been found to influence the ability to gain access to a broader information base (Mehra et al. 2001). In the OSS context, a more central position in the social network surrounding a project can foster the growth of the community by means of the rich-get-richer effect (Gao and Madey 2007). In turn, a more central position can help improve the communication with other network members, increase the number of cooperation opportunities within a variety of projects, help gain new skills, and ultimately develop a broader expertise. (Kidane and Gloor 2005) have found a correlation between group density and its performance and creativity in the case of Eclipse community. These benefits create a virtuous circle, contributing to the growth of developers as hubs of the network. This leads us to our first research hypothesis:

H1: More skilled contributors are involved in projects with a higher level of centrality.

Our second research hypothesis addresses the relationship between skills and quality. As noted before, skilled developers have the ability to solve problems quickly and efficiently, but are less willing to design code according to the software engineering principles ruling structured development (Lakhani and Wolf 2003). It has been demonstrated that organizations tend to apply their most skilled developers in complex tasks, where devising an efficient algorithm is more important than obtaining a well-structured and maintainable software (Faraj and Sproull 2000). These results are interesting in a OS context, since we know from Capra et al (2008) that the governance model of an OS project can resemble that of a closed source project, with a single sponsor company developing the bulk of code. Furthermore, hub nodes tend to experience an exponential growth, as the probability to gain new relationships has been found to be exponentially proportional to the number of existing relationships (Xu et al. 2006, Gao and Madey 2007).
The rate of new change requests (new features, bug reports, etc.) grows accordingly. Hypothesis H1 posits that more skilled developers are involved in more central projects and, therefore, can benefit from all the advantages of their central position in terms of knowledge transfer. However, they are also burdened by a greater information load related to communicating and coordinating with other contributors in development activities and also in a number of non-development activities, including debugging, translation, advisory, and documentation. Hinds and McGrath (2006) have empirically found that highly connected social networks (that is, networks with a high average value of degree centrality) cannot be considered as an effective support to distributed project development. Findings prove that the coordination overhead caused by the extension of the network increases the effort required for software development and maintenance. Therefore, more central developers can be supposed to spend more time in coordination and less time in quality, which, in the short term, represents a time investment that they may not be able to afford given their information overhead. This leads to our second research hypothesis:

H2: Projects involving more skilled contributors have a lower software design quality.

4 METHODOLOGY AND RESULTS

This section presents the operationalization of the variables involved in our testing and the data sample used for empirical verifications.

4.1 Variable Definition and Operationalization

Network model. We model OS social networks as two-mode undirected affiliation networks (Wasserman and Faust 1994) with two types of nodes: developers and projects. A node representing a developer, say d, is associated with another node representing a project, say p, when d is a member of p’s team of contributors. Two distinct one-mode networks can be derived from a two-mode network by considering either developers or projects only:

- Developers network. All nodes represent developers. Two nodes are linked when both developers are members of the same project team.
- Projects network. All nodes represent projects. Two nodes are linked when corresponding projects have at least one developer in common.

Metrics of centrality. The degree centrality (Freeman 1979) \( c_d(n_i) \) of node \( n_i \) is defined as the ratio of the number of edges involving node \( n_i \), \( \rho(n_i) \), to the total number of nodes in the network excluding node \( n_i \):

\[
c_d(n_i) = \frac{\rho(n_i)}{(N-1)}.
\]

The betweenness centrality (Freeman 1979) \( c_b(n_i) \) of node \( n_i \) is defined as the average frequency with which a generic node \( n_i \) crosses node \( n_p \) to reach a different node \( n_k \) trough a shortest path:

\[
c_b(n_i) = \frac{2}{(N-1)(N-2)} \sum_{j\neq i} g_{jk}(n_i) g_{jk}^{-1},
\]

where \( g_{jk} \) represents the total number of shortest paths from \( n_j \) to \( n_k \) and \( g_{jk}(n_i) \) represents the number of shortest paths between nodes \( n_j \) and \( n_k \) crossing \( n_i \). The metric is normalized to the maximum number of shortest paths crossing \( n_i \) in an undirected network with \( N \) nodes. Betweenness centrality is a measure of the ability of a node to control the information flows in the network. A node with a high betweenness centrality can be considered as an important information broker for the network, as it is likely to receive and convey many information flows (Hossain et al 2006).

Degree and betweenness centrality for developers’ and projects’ networks are indicated with apex \( d \) and \( p \), respectively. For the sake of simplicity, we refer to the degree and betweenness centrality of nodes in the developers’ networks as developer degree centrality (\( c_d^d \)) and developer betweenness centrality (\( c_b^d \)), respectively. Similarly, we refer to the degree and betweenness centrality of nodes in the projects’ networks as project degree centrality (\( c_d^p \)) and project betweenness centrality (\( c_b^p \)), respectively.

Metrics of software design quality. Two of the most referenced suites of object-oriented design metrics have been included in our metrics’ set, as suggested by Harrison et al. (1998): the MOOD metrics’ set for the evaluation of quality at the software system level (Brito e Abreu 1995), and the Chidamber and Kemerer (1994) metrics’ suite for the evaluation of quality at the class level. The four chosen metrics (MIF, NOC, MOOD, and MOOM).
CBO, DIT) are the most preferable to provide measures of inheritance and coupling, which are two of the three sets of fundamental quality metrics, and also the most studied in literature (Capra et al. 2008).

**Metrics of skills.** Two metrics deal with skills in our model, skill level and skill range. The skill level metric $SL_k$ of project $k$ is defined as the mean value of the average per-skill level of the developers involved in the project:

$$SL_k = \sum_{i \in k} \frac{SK(i, s)}{MAX\_VAL \cdot ns(i)}$$

where $SK(i, s)$ is the level of skill $s$ of developer $i$, $S(k)$ is developer $i$’s set of skills, $MAX\_VAL$ is a constant representing the maximum skill level (5 in SourceForge.net), $ns(i)$ is the total number of skills of developer $i$, and $nd(k)$ is the total number of developers working at project $k$.

The skill range metric $SR_k$ of project $k$ is defined as the ratio between the number of distinct skills owned by at least one developer in the project and the total number of skills in the project:

$$SR_k = \frac{NDS_k}{NS_k}$$

where $NDS_k$ and $NS_k$ are the total number of distinct skills and the total number of skills in project $k$, respectively. The skill range measures the diversification of skills within a project. For example, if a project has two developers with the same skill set the metric will evaluate to 0.5, while if the skill sets of the two developers are disjoint the metric will be equal to 1.

### 4.2 Data Sample

The data set used for this study has been gathered by analyzing a sample of OS community applications from the SourceForge.net repository. Data on skills have been extracted by analyzing each developer’s profile on SourceForge.net. Since mining on line repositories (such as SourceForge.net) can lead to controversial results because of the varying quality of available data (Howison and Crowston 2004), a first sample of applications (AS1) has been selected according to the following criteria:

- **Project maturity:** active and beta status or higher (inactive and less mature applications have been excluded because of their instability and low significance).
- **Version history:** at least 5 versions released.
- **Programming language:** Java.
- **Domain:** selected applications are uniformly distributed across the SourceForge.net domain hierarchy.

A second sample of applications (AS2) has been considered to allow the correct evaluation of the social networking metrics described in the previous section. Applications belonging to sample AS2 have been selected by relaxing some of the criteria used to select applications of sample AS1. AS2 includes all the active projects of SourceForge.net written in Java. This sample has been used to build a SourceForge.net social network as wide as possible, with the aim of overcoming network size limitations of previous research (Newman et al. 2006). As suggested by Marcoulides and Sounders (2006), confidence intervals at level $\alpha = 0.05$ have been computed for the variables involved in hypotheses testing in order to assess the adequacy of our sample size. Although the sample is not extremely wide, the confidence intervals are relatively narrow for all the considered variables. Data on all the applications of samples AS1 and AS2 refer to June, 30th 2007 to guarantee the temporal consistency of the data sets. Table 1 presents cardinalities of application samples AS1 and AS2.

</table>

*Table 1. Cardinity of datasets AS1 and AS2*

Social networking metrics have been derived from the analysis of the social network of the applications included in sample AS2. Social network data has been derived from the SourceForge.net data warehouse.
(Gao et al. 2007) for all the applications in sample AS2, and processed by a tool developed ah-hoc. The computation of social networking metrics has been performed by analyzing the SourceForge.net social network with Pajek (Batagelj and Mrvar 1997), one of the most used and referenced tools for large networks analysis.

Software quality metrics have been evaluated by analyzing the source code of all available versions of each project in our dataset AS1, and considering average values for each metric. Source code has been analyzed with a tool developed ad-hoc. The tool provides data on all the software quality metrics described in Section 4.1, performing static analyses of Java source code. The static analysis engine is based on the Spoon compiler (Pawlak 2005), which provides the user a representation of the Java abstract syntax tree in a meta-model that can be used for program processing.

Statistical analyses and structural equation model testing have been performed with SPSS and AMOS.

4.3 Measurement Model

The measurement model has been defined to verify the assumption that social networking and software design quality metrics actually measure different aspects of the same phenomena. A principal component analysis (PCA) has been performed on both sets of metrics to verify the assumption. Results of such analysis are shown in Table 2.

Figure 1. Measurement model of design quality

Figure 1 presents the measurement model related to the design quality set of metrics. In this case only one factor has been extracted, and has been labelled as Design Quality.

Figure 2. Measurement model of centrality

Figure 2 shows the measurement model related to the social networking set of metrics. As it can be noted, two different factorization variables have been identified, related to the centrality of developers and of projects, respectively. In turn, these two latent variables have been found to be different aspects of the same concept, that has been named Centrality.

</table>
Table 2. PCA results and estimates of regression weights for the measurement models of Figure 1 and Figure 2

Table 2 shows the results of the PCA performed on the different parts of the measurement model, along with the standardized regression weights of the relationships between latent and observed variables. Results show that all the factorizations should be considered acceptable, since all the composite factor reliability values are greater or very close to the threshold value of 0.700 as suggested by Bagozzi and Yi (1988). All the relationships considered between the set of observed variables (either referred to centrality or software design entropy) and the latent variables are significant with $p < 0.001$: this confirms that the factorizations in the measurement model were performed correctly.

4.4 Structural Model Testing

The estimation results of the research model in Figure 3 used to test the research hypotheses are shown in Table 3. Please note that, for sake of simplicity, the model in Figure 3 is a simplified version in which the factorizations related to the latent variables Design Quality and Centrality discussed in the previous section are not shown. Variables Design Quality, and Centrality have been controlled by project age Age, as suggested by Banker and Slaughter (2000), although the controlling variable Age is not shown to reduce the complexity of the model in Figure 3.

![Figure 3. Structural model for the verification of research hypotheses](image)

![Table 3. Estimates of regression weights for the research model of Figure 3](table)

All the relationships hypothesized between model variables are significant with $p < 0.05$, that is, can be accepted at a significance level $\alpha = 95\%$. Table 4 shows that the overall model fit is satisfactory.

![Table 4. Goodness of fit indices for the research model in Figure 3.](table)

Research hypothesis H1 (more skilled contributors are involved in projects with a higher level of centrality) is represented within our model by the regression relationship between Centrality (independent variable) and Skill Level (dependent variable). Our analysis shows that the regression weight is positive and statistically significant ($b = 0.329$, $p = 0.045$). Consequently, research hypothesis H1 is verified.
Hypothesis H2 (projects involving more skilled contributors have a lower software design quality) is tested by the relationship between Design Quality and Skill Level, where the former is the dependent variable. Since the regression weight is negative (b = -0.556) and the estimation of this relation is significant (p = 0.050), hypothesis H2 is verified. Please note that Skill Level is controlled by Skill Range in order to consider not only the depth of skills but also the heterogeneity.

5 DISCUSSION AND CONCLUSIONS

Empirical results support hypothesis H1, thus confirming centrality as a significant driver of the expertise of developers. Therefore, knowledge seems to represent a first, fundamental benefit of being a hub node in an OS network. Previous to our work, the literature has described the role of social networking as enabler of knowledge transfer processes and related effectiveness. As noted in Section 1, our work is the first empirical contribution providing empirical evidence to support the relationship between network centrality and expertise. In particular, we have made an effort to overcome some of the limitations of previous research by measuring our centrality metrics on the largest network of Java projects that can be built from SourceForge.net, which includes all the relationships among contributors, both direct and indirect. It should be noted that the metrics of centrality have been originally defined to account for both types of relationships (Freeman 1979).

Results also support hypothesis H2, suggesting that more skilled developers will tend to produce a software with a lower design quality. Even if this seems counterintuitive, it should be noticed that hubs in OS communities are involved in several projects and incur a coordination overhead that reduces the share of time that they can devote to quality. The literature indicates that quality represents an investment that requires time and provides its pay-offs over time in terms of lower maintenance costs (Slaughter et al. 1998). The coordination overhead caused by a more central role may reduce the willingness of developers to invest in quality.

It should be noticed that in our model the relation between success and design quality remains significant, thus indicating that development skills are only one of the factors impacting on quality. Future research will investigate the possible influence of other factors that, overall, may have a mediation effect on success.

Our results show that centrality metrics are significant proxies of developers’ skills that should be monitored from the perspective of a project administrator or team manager. However, they also prove that projects with more skilled team members tend to have a lower design quality of software. This has a number of potential consequences that might be visible to users and could cause negative effects over time. From previous case studies such as Mozilla and Eclipse, it is clear that in order for a social network of a project to become a global success, a refactoring intervention is needed, with a consequent infusion of large investments. The natural behaviour of the social network does not seem to be able to cope with these levels of growth. While it can help a project to start growing and reach a significant level of success, above a certain level it may represent a weak management lever. This is consistent with previous literature positing that excessively large social networks have a lower effectiveness (Herbsleb and Mockus 2003) and represents an interesting subject for future research.

Abstract

Most management models that support software development, information technology (IT) service management, or other IT related tasks have been developed based on extensive experience with these tasks. Their recommendations are, therefore, often named base, good, or best practice. We examine in this paper whether these models are also suitable to support use and adaptation of open source software (OSS) within adopting organizations. OSS is widely used as it exhibits some very appealing features. However, if companies take full advantage of the flexibility OSS affords, especially the possibility to customize it, relating processes get quite complex. Careful control of these processes becomes crucial and use of proper management processes almost mandatory.

In the paper, we first determine the special needs of OSS customization and then examine three popular models as to how well they can support this activity. The examined models are ITIL Version 3, SPICE (ISO/IEC 15504), and V-Modell XT.

Our research shows that none of the models sufficiently covers the needs of OSS customization. While some aspects of OSS customization can be dealt with in the models or require only minimal modifications of the models, none of the models includes best practices for the management of intertwined and concurrent internal and external development.

Keywords: Open Source Software, best practice, customization, adaptation, software development.
1 INTRODUCTION

OSS is developed by many individuals and many organizations. An organization that uses and customizes OSS must carefully manage the development process in order to achieve high quality software (SW) and avoid errors. Frameworks or models for management of SW development were mainly designed for development under single control. Therefore, our research question is: Can models for SW development and use directly be employed by an organization that customizes OSS for its own purposes? In the first subsection, we briefly describe some aspects of OSS that are important in our case. Then, we briefly recall the rationale for software development models and we name three models that we want to examine in detail.

1.1 Open Source Software

The term OSS denotes SW which source code is available under a copyright license in compliance with the Open Source Definition (Open Source Initiative 2008). It has to be distinguished from the term Free Software which is defined by the Free Software Foundation (Free Software Foundation 2008) founded by Richard Stallman. It originated the popular OSS Licence GNU GPL. The Free Software Foundation places an emphasis on the freedom of the SW; for this paper we chose the term Open Source Software (OSS) to place an emphasis on the availability of the source code.

OSS has gained popularity mostly through Linux, an operating system project started by Linus Torvalds, but joined by many developers distributed all over the world (Raymond 2001). Linux was first popular with technically versatile persons but is now available in distribution packages that do not require extensive computer skills. Its use increased with the diffusion of Internet. One example of an OSS commonly used with Linux is the Apache web server [http://httpd.apache.org]. While both Linux and Apache offer general core functions, increasingly OSS for specific applications is gaining popularity, e.g., in the area of business intelligence The Eclipse BIRT (Business Intelligence and Reporting Tool) Project, [http://www.eclipse.org/birt/phoenix/]). Even Enterprise Resource Planning Systems are meanwhile available as OSS (e.g., SQL Ledger [http://www.sql-ledger.org/].

While OSS needs not necessarily to be available at no cost, it often is. Therefore, it is highly relevant for companies trying to lower licence fees. In fact, costs seem to be the main reason for OSS adoption (e.g., Dedrick and West 2004).

The development of OSS by many distributed developers is referred to as an OSS project. The core developers provide an “official” release. Adaptations between releases may be published by the core developers or anyone else. However, there may be also adaptations executed within an organization that are not made available to the public. Adaptations by firms outside of the SW industry seem to be rare. There are different reasons for the reluctance of organizations to modify OSS. First, they may not have a need to do so. Second, they may not possess the skills or capacity to do so (Madanmohan and De’ 2004). There is also a difference in attitude towards OSS adaptation depending on the type of OSS. Organizations are more willing to adapt application-oriented non-infrastructure SW than infrastructural SW (Wichmann 2002, Dedrick and West 2004). Both, adoption and adaptation of OSS may be hindered by licensing intricacies. Some OSS licenses require that all modifications are provided to the public. This is just the opposite of why companies customize standard SW: because they do things differently than others. They usually do not want to reveal their processes to others.

According to a recent citation of a study by Gartner (Morgan 2008), OSS is used in 85 percent of all companies, the other 15 percent planned to do so within the next 12 months. Given this state, whether organizations customize OSS or “just” use it without own adaptations, the question arises whether the models considered below support OSS use. In fact, a possible lack of adequate support may lead to problems or create an obstacle to a wider adoption and use of OSS.
Even if companies do not adapt OSS after adoption, the quick release of new versions of OSS, modifications that are not part of an official release, and possible forking in OSS projects require an active management of OSS use. Therefore, it is worthwhile examining whether the specific needs of OSS are covered by the models.

The deployment of OSS is similar to the deployment of commercial off-the-shelf SW (COTS). Both need to be customized to fit the requirements of the adopting organization. Configuration and parameterization are the approaches of choice in this case. If they are not sufficient, customization of the SW code is necessary. With COTS, customizations are limited to customizations utilizing Application Programming Interfaces (APIs) provided by the vendor. With OSS, anyone can modify the source code. This flexibility offers great advantages but also leads to more managerial complexity. Since research on OSS customization within organizations is rare, we first need to identify the different events in the lifetime of an OSS that can occur before we can analyze how well the models for SW development and use support OSS use.

Research on maintenance of OSS does exist. But it covers maintenance processes within the OSS projects (e.g., Koponen and Hotti 2005). To our knowledge, no research on the case of internal OSS maintenance in companies does exist. As a result, the interactions between the process of adaptations in companies and the ongoing development process within the OSS project have not received much attention yet. This intertwined process may already start with the deployment of OSS within the organization. In this context, it is especially of interest whether the below mentioned models can also support such important tasks as OSS configuration and change management within organizations.

1.2 Frameworks for Software Development and Use

SW development, maintenance, and its continuous use are intellectual tasks that are difficult to manage. Given the economic and legal importance of these tasks, they must be controlled and managed. A number of models or frameworks have been developed towards these goals. They should help to produce high quality SW efficiently (Sommerville 2007, pp. 692). Both of these characteristics have often been badly missed in SW development and SW products (Boehm 2006). Most of the management models have evolved based on the experiences gained in many SW projects in many organizations. Practices that led to desired outcomes have been gathered and further improved so that the resulting frameworks are considered to contain best practice. A best practice process denotes a process, which is the most effective and efficient process for a certain task. A bundle of such processes may become the standard for this specific task and can be applied in diverse organizations.

We chose for our research three frequently used frameworks to represent models for different purposes. They contain guidelines which partly relate to the same tasks (e.g., change management).

Any organization that develops SW systems should follow a system development model. Such models support project management from systems analysis through decomposition and integration including quality assurance. An example of such a model is the V-Model where activities are arranged according to the letter V (Sommerville 2007, pp. 110). The use of its German version, currently called V-Modell XT (V-Modell n.d.), is mandated for systems developed by or for the German federal administration (Lange 2009). Many private organizations make use of it as well.

The use of a SW system in an organization can be considered a service to its internal and external users. The framework called ITIL (Information Technology Infrastructure Library) has been developed with the goals of efficient delivery of such services and high service quality. ITIL is a collection of concepts and guidelines for IT planning and operations that are supposed to represent best practices [http://www.itil-officialsite.com].

A third type of models supports the assessment of the capability of an organization to develop high quality SW. The international standard ISO/IEC 15504 (ISO/IEC 15504-5 2006) constitutes an example of such a framework. This standard, often referred to as SPICE (Software Process Improvement and Capability Determination), defines processes grouped in process categories, capability levels which the processes can achieve, and an assessment model which guides the
measurement of processes with respect to their capability. SPICE is especially relevant to SW vendors but can also be valuable to large organizations developing large programs for their own use.

It is not easy for an organization which wishes to achieve the right level of managerial control of IT use to choose the appropriate combination of frameworks given their number, their overlap, differences in terminology and structure (Paulk 2004). We address yet another question in this context as mentioned above: How well do these models and frameworks support the full use of OSS?

2 RESEARCH APPROACH

Given the scarcity of relevant research and the difficulty to collect detailed data through survey research, we decided to observe an OSS adoption and customization process long enough to be able to induct the managerial needs of these processes. Therefore, we chose to follow the paradigm of action research (Avison et al. 1999). Of course, this approach does not guarantee that we will discover all the events that take place in the life of customized OSS but if we observe enough release changes, we should be able to give an initial answer to our research question.

2.1 Action research

Action research is a qualitative participatory method. The researcher becomes part of the project team in order to study the object of research in all necessary detail. It is widely used in the discipline of information systems (IS) as an interpretive research method (Baskerville 1999, de Villiers 2005). Qualitative research in IS is often applied in new problem domains where empirical data is unavailable or available only in small sample sizes. The process of action research consists of four consecutive sub-processes: plan, act, observe, and reflect (Zuber-Skerritt 1993). Our plan consisted of decisions which information on OSS deployment and adaptations to record and what tools to use. Since proper documentation of code versions and changes is a necessary action in OSS use, this was in the same time our “action” part and observation activity. We archived source code as well as change and feature requests. During our research, seven iterations triggered by official releases of the OSS were examined. One external release was not incorporated into the internal code base by the development team. The collected documents were examined in the reflection phase.

Action research, with its root in the behavioral sciences and founded by Kurt Lewin and other researchers in the 1940s (Peters and Robinson 1984) uses a practitioner-researcher relationship and is participative (Avison et al. 1999, de Villiers 2005). The study of an existing product development over several iterations distinguishes this research method from other interpretative research methods, e.g., research during the creation of a new product (de Villiers 2005). Using action research, researchers participate as well as criticize in the process and, therefore, influence it. As a result, action research enhances the practice and is able to reveal new knowledge.

In addition to the study of the internal code development, we also studied code changes in the external OSS community that did not enter the official releases yet. All internal and all external releases were archived for ex-post examination. Minor internal releases were triggered by internal adaptations or non-official external code used in the internal code base; major internal releases were triggered by the aforementioned official external releases.

Close cooperation with the project team allowed us to gain insights regarding several code changes within the official code that were introduced into the internal code base and led to incompatibilities between the official and internal release. These were examined by the project team manually. Since new releases were never adopted completely, files with changes in the official release as well as in the internal code base needed to be updated manually.

2.2 OSS case

Most OSS projects are in constant flux. They follow the “release early, release often” approach (Golden 2005, pp.19-20) because they are not restricted by business practices and strategies of COTS.
New releases may include bug fixes and new features. The constant changes require formalized support processes (Hoyer et al. 2007). The OSS characteristic of continuous change certainly applies to the OSS system we studied. It is a special-purpose web-based OSS Content Management System (CMS) that includes some typical Web 2.0 features. It was adopted and adapted by a small entrepreneurial company. The OSS system was developed within the Pligg CMS project [www.pligg.com] starting in 2005. It was chosen for use in our case in 2006, when our observation immediately started. The CMS instance we studied is online at http://www.colivia.de.

Users of the system can submit news items that are placed in a waiting queue. The news item is usually a short reference to another website. If other users find the news interesting, they can comment on it and vote for it. News that receives votes above a certain limit is placed on the first page which gives it more exposure. Each vote is not necessarily equal. Its weight may depend on the previous activity of the user who is giving the vote. The exact vote calculation is usually not disclosed. The same is true for the calculation of a reputation score for each user. News items are tagged and assigned to groups. Most common tags within a certain time period are displayed in a tag cloud. Such sites are referred to as social news sites. Pligg has also been used for other applications. Some of the sites built with Pligg are http://www.dealigg.com, http://www.ecofuse.com and http://software.intel.com/sites/coolsw/. Pligg is used all over the world, 40,000 users are registered in its support forums.

3 EVENTS IN OSS CUSTOMIZATION

3.1 Software evolution

As a basis for an OSS evolution process in companies, we use the system evolution process (Fig. 1) proposed by Arthur (1988) and amended by Sommerville (2007, p. 540). The SW evolution process is the result of a sequence of several maintenance iterations. Maintenance can be divided into adaptive, perfective and corrective maintenance (Swanson 1976). While corrective maintenance addresses errors found within the SW product, perfective maintenance is used to increase performance and maintainability as well as minimize inefficiencies. Adaptive maintenance is used to adapt SW to a changing environment. Maintenance often starts with the deployment of a SW product in an organization and stops with its retirement (Bennett and Rajlich 2000).

While maintenance has to be seen as a continuing process throughout the life of a SW product, this is contrary to the usual organization of SW tasks in projects. As a result, SW maintenance is usually organized as a sequence of maintenance projects (Kneuper 2003, p. 84f.).

Studies of SW that evolves over time (E-Type products) led to several research papers often referred to as “Lehman’s Laws” (Lehman and Ramil 2001). They include the proposal of continuing change and increasing complexity during the process of use of a SW product as an E-Type product. Here, we focus on the interdependencies between the concurrent external and internal development of an OSS system as well as the influence of the external releases on the internal code base.
3.2 Events during OSS customization

Even before the deployment of a SW system within the company, required changes are identified, their impact is analyzed, the change is planned and carried out resulting in a new system; change requests after deployment initialize the same steps (Sommerville 2007, p. 540).

Based on our research of the OSS CMS customization, a distinction of two process chains in the evolution of an OSS within an organization can be made. Both process chains use the generic system evolution process from Fig. 1 as the basis but include different process steps to establish a new system release. This distinction is due to the differentiation of internal change requests, triggered from inside the company, and external change requests, triggered by external events, e.g., new official releases or bug fixes available in the OSS project’s support forums. A firm may opt to ignore the second kind of change requests, but it then loses over time the free resources of the OSS developer community. Based on this process model, we identified several tasks in the areas of configuration and change management which are required in the case of entangled internal and external customizations of OSS.

Special requirements within the configuration management

Internal source code changes of OSS in a company require the establishment of an internal code base different from the code within the official OSS release. For OSS projects, a situation with two competing code bases would be called a fork; such a situation should be avoided to minimize inefficiencies (Raymond 2001, pp. 72-73). In OSS customization, the configuration management is required to manage the diverse code branches and minimize inefficiencies by supporting a merging of the internal code and new official releases.

For the internal code branch, the configuration management needs to keep track of both internally programmed code as well as imported external code (e.g., a bug fix available within the OSS project’s support forums). Official code versions of Pligg, like in many other OSS projects, are stored in the version control system Subversion (SVN). External code which becomes available between two official releases in SVN, support forums or in another place, and is used for modifications of the internal code tree, has to be treated as internal code until it is integrated into the official release and the official release is integrated into the internal code base. As a result, a distinction between internal and external code is not sufficient in the internal documentation. The origin of external code that is used in the internal version but has not become part of the official release (yet) has to be recorded as well. Any modification to the internal code base may be the cause for incompatibilities between the internal and official release during the next update.

During the observation period, conflicts caused by incompatibilities of internal changes with changes in a new official release occurred in two iterations, while internal adaptations got obsolete in five iterations. As a result, incompatibilities had to be resolved by modifications to the internal code base if the official release were to be adopted.

Special requirements within the change management

In the life-cycle of the OSS CMS we studied, in case of an internal request for change external sources were always checked first to save efforts. The change management was responsible for the search, assessment and possible adaptation of appropriate code. The search included resources provided by the OSS project, in our case the OSS support forums and the SVN repository. Only if no suitable code from the OSS community was found, internal code was developed. In both cases, this new code remained in the internal release at least until a new official release became available. With a new official release available, internal modifications were checked against the new external code changes.

In general, OSS projects use diverse places to document changes made to the SW. OSS users will, therefore, usually need to monitor several places for relevant changes. In addition to communication tools, e.g., discussion forums and mailing lists, code changes are also entered into bug reporting tools (e.g., Bugzilla). In some OSS projects, users and developers may submit all kinds of source code changes, including updates, fixes, and sometimes even new features, rather than only bugs in such
tools (Michlmayr, Hunt and Probert 2005, Koru and Tian 2004). As mentioned above, OSS projects often utilize revision control systems for configuration management purposes. Usually, all source changes will be tracked with these systems. Read access to revision control systems is usually unrestricted so they are an additional resource to search for relevant code.

The retrieval of information regarding new official releases was also a task assigned to the change management as well as the merging of the code bases in case of a new official release. The merging was supported by the configuration management with information about prior releases; also, the configuration management was responsible for the mapping of the branch merging.

We summarize the observations described above in Table 1.

Table 1. Additional tasks for maintenance in case of OSS customization

Code feedback

A task which may be assigned to the change management as well as to the configuration management is code feedback to the OSS project. It was not performed during our action research study, but code feedback can be beneficial to both the company that gives feedback as well as to the OSS project. If internal changes get integrated into the official release, official code can replace the corresponding internal code making later configuration management easier.

4 ANALYSIS OF FRAMEWORKS

All three models were examined based on original documents. The basic structure of each model is given first. Then, we report the results of our analyses referring to the specific chapters.

4.1 V-Modell XT

The V-Modell XT (V-Modell n.d.) is a SW development model widely used in the German government sector. It is divided into nine parts:

- Part 1: Fundamentals of the V-Modell
- Part 2: A Tour through the V-Modell
- Part 3: Reference Tailoring
- Part 4: Reference Roles
- Part 5: Reference Work Products
- Part 6: Reference Activities
- Part 7: Reference Mapping to Standards
- Part 8: Annex
- Part 9: Templates

Figure 2. Structure of the V-Modell XT based on (V-Modell n.d., p. 1)
Within Part 4, relevant roles for configuration management and change management are defined, e.g., Configuration Management Administrator and Change Request Manager. The defined roles are sufficient for configuration and change management in the OSS context.

The view of the V-Modell XT is not limited to internal developments; it does incorporate the assessment and use of external products, even including market surveys of off-the-shelf products (Chapter 4.3 of Part 5). External SW modules are mentioned in Chapter 4.15 of Part 5. Links to chapters with further information within the standard are provided, including a link to make-or-buy decisions. Another relevant part for OSS customization is product evaluation (Part 6, Chapter 3.5); accordingly, external components can be evaluated before they are integrated into the internal code branch as non-official external code.

The possibility of code feedback is contained in the model, but it is based on the assumption that both the supplier and the buyer of SW products are using the V-Modell XT; feedback is provided in form of a Statement of Acceptance (Part 6, Chapter 5.1), which does not really fit in the case of OSS.

The V-Modell XT does support dividing of projects into partial projects (Part 3, Chapter 5.21), but there is no explicit support of ongoing concurrent development using separated code branches. For external SW units, an adoption procedure is defined in Chapter 3.8.12 of Part 6, which also does not reflect the concurrent development during the OSS life cycle. As a result, the handling of the code branches has to be represented via separate baselines or with the official code base carried within a baseline as a special configuration item (CI) within the configuration management. A baseline is a set of all relevant work products for one specific configuration.

In summary, V-Modell XT does include adequate practices for assessment and adoption of external components. It also offers some ideas which could be used for concurrent development in OSS projects in companies. However, it does not offer a consistent treatment of concurrent development.

### 4.2 IT Infrastructure Library (ITIL)

The IT Infrastructure Library (ITIL) is an example of best practices within IT service management.

They are grouped in functions or processes which are themselves assigned to five core volumes in ITIL Version 3:

<table>
<thead>
<tr>
<th>Service Strategy</th>
<th>Service Design</th>
<th>Service Transition</th>
<th>Service Operation</th>
<th>Continual Service Improvement</th>
</tr>
</thead>
</table>

*Figure 3. Core volumes of ITIL Version 3*

Here, the volume Service Transition is especially relevant, as it “covers the broader, long-term change management role, release and deployment practices, so that risks, benefits, delivery mechanisms and the support of ongoing operational services are considered” (OGC 2008). The subsequent statements are based on the official German translation of the OGC Service Transition volume (OGC 2007).

Chapter 3 presents the Service Transition (ST) Principles; best practices and principles are contained here in several policies. Policy 3.2.2 confirms that all changes of service should be done by the service transition; the second best practice requires that internal and external changes have to be distinguished. While this is essential in case of OSS, according to our research it is not sufficient, as in the case of OSS customization with external code which is not part of the official release, three code types have to be distinguished. Policy 3.2.6 concerns the initiation and maintenance of relations to stakeholders. A best practice suggests building relationships with stakeholders (including suppliers). Since the OSS project can be considered a kind of supplier, this relationship can be the basis for feedback to the OSS project. According to a best practice in Policy 3.2.9, any update of a release has to be recorded within the configuration management system. This is in line with the required archival of all changes to CIs.
by the configuration management determined in our research of the OSS project. The inclusion of information about the origin of code is also essential.

Chapter 4 presents ST processes; several processes can be used in case of OSS use and customization in companies. In Chapter 4.1 (Transition Planning and Support) a release policy is detailed (4.1.4.2), recommending specific IDs for any release. It uses Major Release, Minor Release and Emergency Release as typical examples for release types. This concept needs to be extended for OSS use and customization to include a differentiation between internal and external release.

Several relevant topics are contained within Chapter 4.2 (Change Management). Considerations regarding the design and planning of the change management in 4.2.4.2 include the proposal of both a change advisory and emergency change advisory board as well as competences and responsibilities of stakeholders (e.g., suppliers). With suppliers as stakeholders within the change management, the OSS project may be defined as a stakeholder; as a result, code or other feedback to the OSS project can be covered via this stakeholder relationship. In addition, 4.2.6.7 (Review and Closure of Change Records) explicitly mentions feedback to the stakeholders and 4.2.7.3 includes Sourcing and Partnerships within the change management interfaces. Therefore, ST implicitly includes the option to give feedback to an OSS project. The kind of feedback is not specified, this may include revealing experience (e.g., in form of participation in OSS support forums or submission of bug reports) or actual code submissions to the OSS project. In Chapter 5 (ST Common Operation Activities), the introduction of a Stakeholder Management Strategy with respect to suppliers of services and products is mentioned in 5.3.

Chapter 4 also includes definitions of changes, with standard changes defined in 4.2.4.5. A new official OSS release shares several criteria with a standard change, especially a defined trigger. Without a standard process for merging of the new official version within the external code branch with the internal code branch, this particular change will not share the criterion low risk with the standard change and, therefore, remain a special kind of change every time. ST does not provide actual implementation practices for changes; therefore, a detailed change process for OSS needs to be specified within the company.

ST defines typical roles in Chapter 6. Service Asset and Configuration and Change Management are combined as one responsibility; six roles are defined as typical: Service Asset Manager, Configuration Manager, Configuration Analyst, Configuration-Administrator/Officer, Change Management System/Tool-Administrator and Change Manager. Additional tasks and responsibilities can be assigned to these roles for internal use and customization of OSS without need for additional roles.

The configuration management system is specified in great detail in chapter 4, where examples for configuration splitting are given. ST does not, however, specify best practices for the handling of separate code branches in which the same OSS version is concurrently modified by different development teams. Like in the V-Modell XT, the different code branches can be handled as different baselines, or the official code could be defined as a specific CI. The required support for code merging in OSS customization projects is not included within the ST.

In summary, the adaptation process can in part be structured on recommendations of the ITIL framework, but ITIL does not provide advice for the case of concurrent development of the same base version of SW in different locations (i.e., within the OSS project and the company). Copies of the same CI are only mentioned in Chapter 7.3 (technological considerations of the configuration management system), but it is unclear whether this includes separate copies of the same CI.

4.3 ISO/IEC 15504 (SPICE)

The standard ISO/IEC 15504 (SPICE) is an example of a quality management and assessment standard. It incorporates ISO 12207 AMD1 and AMD2, a process reference model for SW life cycle processes. The assessment model consists of 48 processes distributed over three process categories with one or several process groups within these categories (ISO/IEC 15504-5 2006, pp. 3).
SPICE includes three process categories Primary Life Cycle, Organizational Life Cycle, and Supporting Life Cycle. The last process category covers configuration management and change management which are of special interest here. Individual processes within Supporting Life Cycle Processes are grouped in Support Process Groups (SUP). SUPs can be utilized by processes within the Primary Life Cycle and Organizational Life Cycle. For maintenance, SUP.8 (configuration management) and SUP.10 (change request management) are utilized by ENG.12 (software and system maintenance) within the Engineering Process Group.

Ten base practices (BPs) for configuration management are defined for SUP.8. Several BPs cover topics also found within ITIL ST, e.g., configuration management elements (BP 2), baselines (BP 4) and the archival of changes of every configuration management element (BP 7, BP 10). However, BP 3 and BP 8 cover areas relevant to OSS use and integration not found within ITIL ST. BP 3 relates to the development of a branch management strategy. As part of the development of a configuration management, it covers the handling of more than one code branch resulting in developers working on separate copies of the same configuration element. For this case, special quality requirements are in place. Reviews are mentioned as an example of a possible method; the branch management can be supported by configuration management tools. BP 8 covers reports on the configuration status while BP 9 covers the verification of configuration elements. These BPs are especially relevant in case of integration activities and if parallel development or variants are used (Hörmann et al. 2006, p. 198-199). The demand for a verification of the correctness of a baseline emphasizes the particular relevancy of verification in this case.

The actual changes are reflected in SUP 10 (change management). Change management as a support process includes here BPs that encompass the change management process from the development of a change strategy until the review of the actual change. Several BPs focus on the handling of change requests, which are also defined as one of the work products (ISO/IEC 15504-5, p. 55). Within the BPs, there is no explicit reference to external change triggers. Also, none of the BPs includes the explicit possibility of assessment and inclusion of external code.

4.4 Comparison of frameworks

V-Modell XT provides adequate practices for the assessment and adoption of external components but it is unable to represent the intertwined development processes that occur in case of customization of OSS in companies as a whole. Feedback processes are focussed on the traditional understanding of a buyer-supplier relationship.

ITIL covers the areas of OSS customization that are consistent with the customization of closed-source SW, but it does not provide appropriate best practices for the management and merging of code branches resulting from concurrent development in case of OSS customization. Some practices exist as basic approaches but they need to be modified or expanded to match the requirements of OSS customization, e.g., with the introduction of the OSS project as a new stakeholder.
SPICE is less comprehensive in the areas of change management and configuration management; nonetheless, BP 3 within the configuration management support process recommends developing a strategy for branch management, which is essential for OSS customization. SPICE proposes BPs for the relevant process areas but it does not include examples of typical cases as ITIL does.

5 SUMMARY

The possibility to modify the source code in order to custom tailor it to the needs of the organisation is one of the most unique features of OSS. Through action research of the use and customization of an application OSS over several official releases and internal modifications, we identified differences between the customization process of closed-source SW and OSS. These differences were mainly caused by the concurrent development in the OSS project and within the company and by the possibility of use of externally available non-official code.

Our literature review of selected frameworks on good practices in SW development and use revealed that the process of customization of OSS is not sufficiently covered by these frameworks.

Some tasks that were performed within the OSS CMS customization we studied could not be found in any of the frameworks considered, e.g., the differentiation of code according to its origin (internal code, external non-official code, or official release code).

The overall economic benefit of OSS cannot be disputed (e.g., MERIT 2006). If more companies outside of the SW industry would take advantage of its feature of open source, not just of low costs, the benefits for the whole economy would further rise. Companies may be more willing to choose this option if they get adequate support in managing the process of OSS customization. Such support can come from best practice frameworks that are increasingly being used if the frameworks get extended by practices needed in OSS customization.

While our research of OSS customization is limited by the analysis of a single project, it is sufficient to reveal difficulties if ITIL, SPICE, or V-Modell XT are used as they are to manage OSS customization in companies. According to our results, users who want to customize OSS inside a company cannot rely only on best practices included in the observed frameworks. These frameworks particularly do not cover the concurrent and intertwined process of customization which is characteristic for internal customizations of OSS. Extensions of the frameworks have to be made to cover the complete process. We have indicated in the previous section some directions for extension.

Like in SW testing where a test can only detect errors but not prove the correctness of a program, the experience with one OSS customization can just indicate some problems of the frameworks but not necessarily all of them. Therefore, more research on OSS customization in companies is needed to establish best practices in this area.

Abstract

In this paper we discuss the challenges of managing large-scale information infrastructures. Various
management models, such as the IT governance model, propose structured approaches for
management of an organization’s infrastructure. This paper argues both theoretically and empirically
that such an approach to information infrastructure governance has its limitations. The paper is based
on empirical material from three change processes in information infrastructures in the context of
health care. We present case vignettes that illustrate how these processes evolved along unexpected
trajectories, subject to factors beyond the control of management. To conceptualize these phenomena
we draw on literature that conceptualize change as emerging from the meeting between multiple
parallel streams of activities. The interactions between the various streams open up windows of
opportunities that affect the information infrastructure development. We argue that such
conceptualizations more realistically depict how large-scale information infrastructures evolve, and
hence how they can be (or not be) managed.

Information Infrastructure

1 INTRODUCTION

The topic of this paper is management of organizational information infrastructures. Often these
information infrastructures are considered to be relatively stable and thus suitable for strategic
planning (Weill and Broadbent, 1998). Our case study indicates that the assumptions of stability and
manageability are not always in accordance with empirical reality, and consequently that the
prescriptive models for strategic planning (such as IT governance models generally) may be somewhat
optimistic.

The field of IT governance has seen a growing interest over the last 20 years. With the fall of Enron in
2000 and the subsequent introduction of regulation that requires auditing and control such as the
Sarbanes-Oxley Act in the USA and Basel-II in Europe, the field of IT governance experienced a
significant boost, and is currently widely touted and deployed. Substantial research findings on IT
governance became available in the early nineties (Loh and Venkatraman, 1992; Henderson and
Venkatraman, 1993) and became prominent in late nineties especially with the works of Brown (1997)
and Sambamurthy and Zmud (1999). In particular the research of Peter Weill and Marianne Broadbent were important in presenting the topic of information infrastructure management for a broader audience (Weill and Broadbent, 1998). They argue that in order to maximize business value from its investments, a company should conceive also its ICT infrastructure as an investment portfolio and subject it to management, balancing risks and benefits like for any other investment portfolio. Weill and Ross (2004) follow up by advocating business executives to not leave the IT decisions to the IT departments, but to “professionalize” IT governance. They suggest a framework for allocating decision rights and accountabilities in the use of IT. Decision responsibilities/rights are allocated to different groups and mechanisms are defined that formalize the relationships and provide rules and operating procedures to ensure that objectives are met. Six metaphors drawing on political archetypes are used to describe the mix of decision rights: Business monarchy, IT monarchy, feudal, federal, IT duopoly and anarchy.

In their book, Weill and Ross also propose a distinction between five different types of IT decisions related to: IT principles, IT Architecture, IT Infrastructure Strategies, Business Application Needs, and IT investment and prioritization. We want to draw the attention to the postulated relations between them. In order to ensure the realization of business value from IT investments, this model for IT governance stipulates an optimal sequence of actions: Initially IT principles should be formulated to comply with the strategic aims. These principles then comprise the basis for designing the architecture of the organizations information infrastructure. This architecture is then again the basis for investments relating to the information infrastructure. Then, the infrastructure capability enables the specific applications to be built based on business needs (to be specified by the business process owners). Finally, the resulting IT investments (in the investment and prioritization process) are expected to contribute to the strategic goals since they have been derived from the preceding definition of the IT principles, architecture, infrastructure and application needs.

In the next section we present alternative studies of information infrastructures. A significant theme in this strand of research is how IT infrastructures often evolve as a result of contingencies and events that were not planned, thus the actual evolution of information infrastructures often exhibit an unpredictable character. This might affect the possibility for following the structured and sequenced approach suggested by IT governance models, and it may seem that the assumptions about the stability and manageability of its object (organizational information infrastructures) are perhaps too simplistic. In the paper we investigate this topic in more depth, and our research aim is to examine the role of unpredictability versus strategic plans in processes of changing the information infrastructure. Thus, in addition to the studies of information infrastructures, we also review literature on the role of emergence in e.g. processes of strategic planning. We briefly present the well-known Garbage Can Model from organizational theory (Cohen, March and Olsen, 1972), as well as adaptations of it within political science that employ the notions of multiple streams, windows of opportunity and punctuated equilibrium. These notions have also been employed within IS, notably by Orlikowski, and constitute the core elements of our analytic framework of this study.

Following the theory section, our methodology section details how we have combined three independent empirical studies from very different organizations (however, all within health care and all describing infrastructural change processes). The case presentation is organised as three case vignettes where we focus on the process of evolution of the information infrastructure in question. The vignettes are crafted to illustrate the different relevant “streams of activities” that go into information infrastructure evolution. The case vignettes describe the different sources and temporalities of the streams, as well as the consequences when these multiple streams intersect, and the “windows of opportunities” that are opened up. This is followed by the discussion where we indicate the relevance of a perspective on IT governance that tries to balance the influence of structured models for IT governance with the influence of contingencies that tend to be beyond the control of IT management.

Proceedings ECIS 2009
2 LITERATURE REVIEW

2.1 Information infrastructures and strategic planning

Some conceptualizations of information infrastructures emphasize not the manageability, but rather the complexity of such large-scale interconnected assemblages of information systems (Contini and Lanzara, 2008). Within this strand of research, an information infrastructure is seen as a heterogeneous social-technical network, not just a technical communication network. The physical connections and equipment, the technical standards, the conventions of use, the technical and organizational support structures, the organization of work and cooperation are parts of the infrastructure (Hanseth and Monteiro, 1997; Star and Ruhleder, 1996). Such complex networks emerge only over time, not instantly. Consequently their existence is a historical result of long-term processes more than a result of single decisions and consequent plans.

These studies also emphasize how the growth of information infrastructures is shaped by the “installed base” that is already in place. Since the existing information infrastructure provides both resources and constraints for further development, radical and abrupt changes in information infrastructures are rare. Any change or intervention needs to take into account the installed base. These information infrastructures are large and open, heterogeneous, socio-technical networks, where various actors have different types and degrees of influence over the complete information infrastructure. This implies that there may not be a single locus of control over an information infrastructure. This distributed nature of mandate, ownership and agency makes conventional, control-oriented management approaches of limited applicability (Ciborra, 2000). Thus, the notion of cultivation has been suggested as an alternative way to conceptualize management or governance of such processes (Hanseth and Lyytinen, 2004). The element of emergence is central in this conceptualization.

We see a parallel in how emergence is perceived in organization studies. For instance Mintzberg (1989) describe how strategies were seldom implemented in the way they were conceived but rather, were emergent. Mintzberg chose “crafting” as a metaphor when he proposes the following postulates about strategies:

- Strategies need not be deliberate – they can also emerge, more or less unplanned.
- Effective strategies develop in all kinds of strange ways.
- Strategic reorientation happens in brief, quantum leaps.
- To manage strategy, then, is to craft thought and action, control and learning, stability and change.

The concept of emerging strategies becomes especially interesting when dealing with uncertainty of the environment; with instability, complexity and change. Top-down strategizing might work under simple and stable conditions, but when conditions are uncertain, instable and complex, strategy making becomes a bottom-up process (Clegg, 2005). We argue that such socio-technical conditions are increasingly a part of organizational lives in a fast moving global economy, and that this is in particular the case for information infrastructures because they often extend beyond the immediate and local context. Thus the changing environment, such as e.g. technological development, or legislative changes, may significantly impact the organization’s internal information infrastructure’s development. However, not just external conditions challenge the straightforward implementation of strategic plans, also internally in an organization the decision-making processes leading to action have been found to be less structured than expected.

2.2 The Garbage Can Model (GCM): multiple streams and windows of opportunity

The Garbage Can Model of organizational choice, proposed by Cohen, March and Olsen (1972), describes decision making in situations that do not meet the conditions of more classical models of decision making, as preferences are seen as problematic, technology as unclear, and participation...
fluid. Here decisions are seen as the results of arbitrary streams of solutions, problems, participants and choices, temporarily coinciding in “choice opportunities”. These streams follow different temporal logics, and only randomly open up windows of opportunities for decision making. The time it takes, and the problem it solves, all depend on a relatively complicated intermeshing of elements. These include the mix of choices available at any one time, the mix of problems that have access to the organization, the mix of solutions looking for problems, and the outside demands on the decision makers.

In the GCM, a decision is an outcome of several partly independent streams within an organization. Cohen et al (1972) outline four main streams as follows:

1. Problems – The concern of people inside and outside the organization, that might arise over issues of lifestyle; family; frustrations of work; careers; group relations within the organization; distribution of status, jobs, and money; ideology.
2. Choice Opportunities – Occasions when an organization is expected to produce behavior that can be called a decision. Opportunities arise regularly and any organization has ways of declaring an occasion for choice.
3. Solutions. Somebody’s product, which is looking for problems to be solved.
4. Participants. Participants come and go. The distribution of “entrances” depends on the attributes of the choice being left as much as it does on the attributes of the new choice.

Although not completely independent of each other, each of the streams can be viewed as independent happenings in a timeframe. Elements of organizational structure influence outcomes of a garbage can decision process by (a) affecting the time pattern of the arrival of problems choices, solutions or decision makers, (b) by determining the allocation of energy by potential participants in the decision and (c) by establishing linkages among the various streams. Organizational structure changes as a response to such factors as market demand for personnel, and the heterogeneity of values which are external to the proposed model.

According to the GCM, although decision-making should be a process for solving problems that is often not what happens. Problems are worked in the context of some choice to be made, but choices tend to be made when the shifting combination of problems, solutions and decision makers happen to make action possible. This aspect of the theory has been taken up also in fields that aim to explain processes beyond the organization, such as policy making. The formulation of the “multiple streams model” by John Kingdon (1984) has been the most well known example. Kingdon proposes that there arise possibilities for policy change when the complimentary streams of problems, policy and politics converge. In themselves they are not effective, but when either two of them or all three meet, this create openings that Kingdon calls “policy windows” where actual policy change can be effected. This point is again reflected in the punctuated equilibrium model for policy change (Baumgartner and Jones, 1993) which explains stability and change in political systems. This model claims that radical change can happen to seemingly stable systems in cases when windows of opportunity allow the opposition to challenge and overturn the established “policy monopolies” (i.e. institutionalised structures).

The most renowned contributions that apply these notions within Information Systems Research are probably those of Wanda Orlikowski. The concept of “window of opportunity” was employed by Tyre and Orlikowski (1994) who drew the attention to the adaptation period following installation of an IS. Their case study showed that there was a brief window of opportunity in which organizational innovation (exploration and modification of the IS) could be pursued. After some time had gone by, the practices had gotten more routinized, and the window for experimentation and change was closed. Later changes could occur, but in an episodic manner and not continuous and ongoing. In a later paper, Orlikowski (1996) discusses situated change as a metaphor that can capture the emergent nature of socio-technical change processes. She finds well known conceptualizations of change problematic because of their assumptions of stability; this includes notions such as planned change, the technological imperative model and the punctuated equilibrium model. While we may not agree with
her on the primacy of change rather than stability in organizational life, we think that her conceptualisation of change has much to offer. She sees organizational change as resulting from “ongoing improvisation enacted by organizational actors trying to make sense of and act coherently in the world.” (Orlikowski, 1996). This acting happens under the conditions of, among other things, temporal structures (Orlikowski and Yates, 1999). The organizational members align their activities to the stabilized-for-now temporal structures, but they also enact them and can thus possibly change them.

Summing up the theoretical framework, we choose to draw on the notion of multiple streams, which we find particularly relevant for information infrastructures, since they have a heterogeneous make-up, drawing together multiple technologies, usages and interests across a potentially very diverse organization. In addition we find the notion of “windows of opportunity” to be relevant in order to identify events and instances where these streams intersect and allow interventions on the information infrastructures. As information infrastructures are large and complex, they require a certain time period to change. A too brief window of opportunity or one that is inappropriately timed vis a vis the infrastructural evolution processes may not perhaps have the same effect as a longer or well aligned window of opportunity.

3 METHODOLOGY RESEARCH APPROACH

Our empirical material is based on the combination of three independent case studies carried out in a Brazilian hospital, in Norwegian a hospital and during an implementation project of a state-level health information system in Gujarat, India. Thus the material has not been produced on the basis of a common research design, but was combined a posteriori as a result of long-term discussions among the authors on the theme of information infrastructure evolution. These three cases span a wide variety of geographical contexts, organizational scales and infrastructural conditions, and the vignettes we present here have their focus on the temporal evolution of the change processes.

The research approach in all three case studies has been qualitative, and the material presented was collected via interviews, document analysis and on site observation. Our research approach has been interpretative in orientation, aiming both at eliciting our respondents’ perceptions and opinions (Klein and Myers, 1999) and understanding the actual doings in which actors are involved. Following we give additional details on each of the case studies.

The Brazilian hospital is a São Paulo State government agency subordinated to the São Paulo State Health Secretariat. It has over 15000 employees, and has on average 2250000 patient encounters each year. The material from this hospital, collected by one of the authors, is based on interviews conducted in 2007 and 2008 with the coordinator of the IT department at the time of the research, a previous IT coordinator of the same department, one medical doctor and interviews with managers at the State Health Secretary with follow-up information exchange via email. Analysis of documents provided by the IT department has also been important. These documents include strategic plans, as well as hardware and software descriptions, and annual IT reports. Also, documents available in the website of the hospital as well as publications related to the IT department were used.

The Norwegian hospital is a highly specialized university hospital with national responsibilities within complex treatments. It has almost 8000 employees, and treated more than 300000 patients in 2006. The material from this hospital has emerged from a long-term collaboration between the Department of Informatics at the University of Oslo (where two of the authors are employed) and the IT department of the hospital. Dating back to 1996, various student projects followed the activities around the development and implementation of an Electronic Patient Record (EPR) system. In the period between 2001 and 2004 the cooperation was organized as a more structured research program, where interviews and on-site work observations were conducted with representatives from all relevant personnel groups in three different departments as well as with key actors in the IT department and hospital management.

Proceedings ECIS 2009
One of the authors did fieldwork in the state of Gujarat in western India. Gujarat is one of India’s most industrialized states, and has a population of around 50 million. The researcher was taking part in a project aimed at implementing a health care information system for aggregated health data (i.e. not clinical, patient-based data, but statistical information for administrative purposes). The data collection was based on qualitative methods and interpretative approach within an action research framework. Also quantitative data were used as empirical material as far as they affected the field of study. Participant observation was complemented by individual and group level semi-structured interviews, and also by observation of a focus group. Shadowing was another method used to follow health personnel, officers, as well as software developers. An important component of the participant observation concerns the online activity of an INGO (Indian Non Governmental Organization) such as email, mailing list, chat lines, and phone calls; which was very important for understanding the activity and coordination. In addition a number of government records and reports were also analyzed to further gain an understanding both of the Gujarat health organization and its ongoing processes of intersection with the INGO.

4 VIGNETTES

The following vignettes illustrate how strategic planning relates to actual information infrastructure evolution. Our focus is on examining to what degree the planned and managed action are influenced by activity streams that are either central or peripheral to, or even not related to the initial strategic plan. The first vignette (from Sao Paulo, Brazil) illustrates that political actors can play crucial role in shaping public health care organizations’ internal information infrastructures. The second vignette (from Oslo, Norway) illustrates how a hospital relocation process opened up a window of opportunity for a redesign of the information infrastructure, but where the actual realization deviated somehow from the plan. The third vignette (from Gujarat, India) illustrates the way that multiple streams of activities related to the development and implementation of a state-wide information system constituted opposing and non-synchronized demands.

Vignette 1. Redesign of Infrastructure (Sao Paulo, Brazil)

In Sao Paulo, Brazil, the period 1995-2006 was characterized by administrative continuity (i.e. a succession of governors from the same political party) and a continuous strong emphasis on the use of IT. IT became a strategic issue due to a large state modernization program started in 1995. Budgeted resources, complemented by international funds for modernization of the financial system, education, health, environment, police and social services, were used to build a basic communication infrastructure, integrate databases and to create multi service government offices that were perceived by citizens as showcases for a modern government (Reinhard et al., 2006).

It was in this political environment that, in the beginning of 1995, the Board of Directors of a Brazilian public hospital decided to renew the hospital information infrastructure, with integration of corporate information as the main goal. A new Superintendent had recently been appointed and plans for the following years had been planned and presented. The hospital, which was a teaching hospital, comprised 6 Institutes, 2 Auxiliary Hospitals, a Rehabilitation Division and one associated hospital in a campus that housed around 3,000 operating beds. The institutes were distributed in a campus of around 352,000 m² area.

The information systems in the hospital consisted, at that time (1995), of two mainframe computers, local area networks of various sizes and technologies, and hundreds of stand-alone PCs. The two mainframe-based systems were unable to exchange information, both between themselves and with the departmental networks. IT services were provided by a government partner organization and a few service providers. Most IT related decisions were depending on the support of the partner organization.
It was understood that a renewal of the IT infrastructure would require the establishment of a common ground of understanding of the involved effort within all hospital units and institutes. It was important to define what information and which processes should be shared and integrated across internal organizational boundaries. So, an Informatics Committee (IC) was created, formed by representatives of every Institute of the hospital, also, partner organizations and some service providers were also invited to become IC members. The IC established the main guidelines for an IT renewal in the hospital. Mainly due to growing dissatisfaction amongst users with the existing systems, the group decided to build a brand new HIS for the hospital from ‘scratch’, rather than upgrading the existing legacy systems (Moura et al., 1998). The easiest way to expand the installed base would have been a continuity of investments in mainframe technologies, as most of the existing applications were based on this platform. Nevertheless, the new platform was built on a very different conceptualization of information infrastructures. This was not based on the main proposal of the previous IT decision makers from the partner organization, so tensions emerged between the new decision makers and the partner organization. There was a strong support from higher administration all through the process as building the information system was considered a priority of the leadership.

This situation opened a window of opportunity where favourable political will stimulated investments in the hospital’s new information infrastructure, despite the previous IT decision makers’ opposition to the new proposal. In this case the political temporality emerged as a strong factor due to the continuity in the political arena that contributed to the implementation of the renewal proposal in the following mandates. In areas characterized by political instability, projects are often terminated without any explicit reasons. As a consequence of shifts in political parties, new projects tend to be started in order to create references for the current political regime, so that credits are not attributed to previous politicians and the regimes that initiated them. Historically this has frequently been the situation in countries, where political instability was the rule, rather than the exception, for many years. In this case, the window of opportunity was not only opened for new investments but also remained open in the following political mandate. A totally different scene would have been likely within a more instable political frame where this project easily could have been terminated without prior warning.

**Vignette 2. LAN INFRASTRUCTURE (Oslo, Norway)**

During the 1980’s and 90’s the IT infrastructure of a large Norwegian hospital had been evolving in an arbitrary fashion. Different units of the hospital were located in separate buildings, with variable access to network infrastructures. Since the early 1990’s a few mainframe systems had served several administrative purposes, such as a Patient Administrative System, a Personnel System and an accounting system. In 1995 a number of projects aiming at the implementation of central clinical information systems were initiated (an electronic patient record system, a radiological information system and picture archive, as well as four laboratory systems). In addition, entrepreneurial doctors in various specialties had purchased or developed specialized applications for their own treatment and research needs. For instance, the heart surgeons had a database application where extensive information on all surgical interventions on heart patients for a couple of decades had been recorded. This information was invaluable for their research, and could not be recorded in or retrieved from standard EPR solutions. As a result of this and similar systems, the ‘corporate’ application portfolio was increasingly problematic to support and the opportunities for integration of the various systems were also limited due to a lack of standardization.

The whole physical network infrastructure was redesigned from scratch before moving into new facilities in 2000. When the bid for tender was announced in 1997, the new network infrastructure was stipulated to serve more than 4,000 PCs, printers and peripheral devices. In addition centralized management of both hardware and software was to be implemented, including the monitoring of the entire network and all connected devices. Also the application portfolio was somewhat reduced during this move, however most of the clinical specialist systems were maintained under a portal architecture that simplified the users’ interaction with the systems. In general the user’s autonomy with respect to
IT was curtailed, as they could no longer install what they desired on their computers or access Internet freely. The protests against this restriction were significant, in particular from researchers using specialized software. The IT department accommodated the users by offering access through another, separate network for the hospital’s university employees (this was a teaching hospital). This alternative network had a more liberal policy than the hospital’s internal network.

The new facilities was expected to be ready in October 1998, but due to various delays during the building process the actual move was postponed three times, until it finally occurred in May 2000. This meant that initially the IT department had expected to be able to leave behind a lot of the issues associated with the Y2K risk, as old servers and most of the old applications were not supposed to be moved along to the new site. When the move was postponed beyond this point, a risk assessment project had to be conducted and necessary measures taken.

In this example, the redesign of the information infrastructure was coupled with the relocation process which opened up a window of opportunity for radical changes. However, this coupling also backfired, when the relocation was postponed, and the IT department had to devise an ad-hoc strategy to cater for the Y2K issues. Moreover, also the users’ protests’ were taken into account and consequently led to non-planned and more improvised adjustments of the initial strategy.

Vignette 3. Reporting System for aggregated health data (Gujarat, India)

An Indian NGO (hereafter INGO), which was part of an international network dedicated to HIS, was responsible for a local tailoring and implementation in Gujarat, with the support of the local health department. The information system was based on a free and open source framework, and the implementation we report from started in February 2006 and went on until April 2007.

The health information system in question was a system that supported capture and reporting of aggregated data for epidemiological and managerial purposes. The healthcare context was bureaucratic and procedural reporting was the main function of information flow. While the ideology of the INGO was oriented towards supporting action primarily at the primary healthcare level, the implementation followed the existing information flow, more vertically channelled, because it was thought to be the best strategy to get acceptance. The health reporting system thus aimed at replicating the existing organizational structure, where each level aggregates data from the lower one, adds new data and produces its own reports as per predefined national formats. Technological and organizational change would be introduced incrementally. The preferred strategy of the INGO was to start pilots at the district level, customize the system, and then scale up.

The state of Gujarat is administratively divided into 25 districts. Within each district there are Block Health Offices (BHO) which coordinates administrative tasks at the sub-district level, and between the levels of the district and community. In the INGO plan, the computers were placed in the Block Health Offices, as all the Primary and Community Health Centres’ personnel would come to these offices for their information processing activities (including data entry and report generation).

The implementation started with a pilot in the southern part of the state. One computer was installed in each of the five Block Health Office (BHO) that together covered a whole district. In July 2006, a positive evaluation was conducted by the state authorities and a prestigious national management institution.

Indeed, in August - September 2006, southern and central areas of Gujarat had been hit by an unusually violent monsoon, which affected a huge number of victims and heavy material damages occurred in such areas. The positive evaluation allowed the “scaling up” of the HIS to four more districts, for a total of more than twenty BHOs. To avoid any extra burden on health personnel in the affected areas, the IT project was pushed to districts where no emergencies had to be prioritized. Those districts were located in the north-western part of the state, where the heavy monsoon rains and floods had been less intense. Thus all these new districts were far from the first pilot site, where IT
capacity had been developed, and far from the state capital, where decisions were taken, and some office space was made available to INGO. Geographical distances, poor transport infrastructure, and weak coordination made implementation in these new districts relatively slow, as five people had to cover an area of several hundred kilometres (many hours by train). The slow implementation was also not synchronized with quick development of negotiations between the INGO and the commissionariat at top level of state administrators, who were also moved by other pressing concerns for the aid for flooded areas.

Beside contingent problems, sharing of information across vertical health programs such as HIV/AIDS, malaria, tuberculosis (TB) was very poor. During an interview, one of the vertical program’s managers declared that “we [the health program managers] have the population in common, only.” The mismatch between the actual flow of information and State Health Commissioner’s need of gaining an overview of the health organization functioning through information was expressed emphatically by him, who declared “I don’t want a system that merely automates the existing inefficiencies”, adding “what we need is a 2-3 pages report, to take action on”. The starting point in that direction was the definition of indicators for the Reproductive and Child Health National Project. This project, indeed, requires pulling data from different health programs (pre-natal care, vaccinations, HIV tests, nutrition, etc). So, a negotiation to define indicators’ formulas and data access started from the top organizational level. Implementation at lower administrative levels, beginning from districts, was discussed, as well. Due to these different ‘streams of events’ (districts rollout of HIS, indicators definitions), different timeframes were manifesting: while computers still were to be installed in some of the five districts, the commissioner started to push for a “dashboard” of indicators to monitor the health situation. By the term “dashboard”, he referred to a visual representation of the state health situation through graphs and maps; the aim was to have health conditions at a glance. From the health department’s side, this was thought to be useful also for the ongoing disaster recovery, but the timeframes (and the geographical areas involved) were mismatching at that point of time.

5 ANALYSIS

Despite their diversity the case vignettes all show that sometimes information infrastructures evolve in ways not directly resulting from strategic planning. Sometimes strategic decisions can be followed through to implementation, but at other times the evolution of information infrastructures does not seem to directly result from the decisions taken to govern them. In the latter case the II evolution is impacted by from circumstances that are neither controllable nor predictable because they are related to issues beyond management’s sphere of influence. Different streams of activities, often beyond the control of the planners, blend in the formation of emergent strategies. These emergent strategies are related to exploiting situations where the confluence between multiple streams of activities constituted ‘windows of opportunities’. This required adaptive and ad-hoc management action for noting and exploiting windows of opportunity.

In the Oslo case, the relocation process - an event beyond the control of the IT department - opened a large window of opportunity for the IT department to go through with a major restructuring of the hospital information infrastructure. Under any other circumstance, such a radical change would probably have been unfeasible. However, the strategy intended to achieve this had to be amended along the way, due to other contingencies: the clinicians’ exercise of their professional autonomy made it impossible to stick to the intended strategy of a single, centrally controlled network. The department’s effort to harmonize the infrastructure was a solution to a long-lasting messy situation, waiting for an opportunity to make the decision to enforce it. The relocation of the hospital provided such an opportunity. But the clinicians’ significance as central actors in the process proved difficult to ignore, and subsequently a second network was implemented. This was not predicted as a problem or as a solution in the original plans, but was still handled along the way in a manner that became acceptable to all parties. The Y2K problem illustrates the significance of the temporalities when we
deal with such windows of opportunities for infrastructural change. Due to the delays in the relocation process it came to have significant impact on the process.

The São Paulo case presented radical changes in the information infrastructure. As for the partner organization that previously was responsible of the IT infrastructure decisions, the influence in decision-making related to the new infrastructure was reduced. Political will and continuity opened up a window of opportunity and contributed to the implementation and continuity of an infrastructure that was completely different from the existing one. Before this change, it would have been very difficult to predict what the new infrastructure would be. Political stability allowed for continuity of investments in the new infrastructure, but even though the infrastructure developed in a fairly “smooth” way the following years, it is hard to know if this infrastructure will have the same support from the top IT decision makers after forthcoming political elections.

In the Indian case multiple distinct streams of activities intersected. The practical activity on the ground, comprising installation of hardware and software as well as capacity building in pilot health facilities, was delayed due to heavy monsoon rains, geographical distances between the pilots and poor transport infrastructure, which weakened coordination. These activities were also influenced by the request for the development and prototyping of a “dashboard” for health conditions monitoring, due to State Health Commissioner needs. The dashboard implied the definition of health indicators’ formulas and access to data sources (from different health programs) and actual provision of data. Each of these flows had its own temporality. The partial match between them and HIS main stakeholders opened for a limited window of opportunity for system implementation.

By employing the notion of “multiple streams” to empirical studies of information infrastructures in health care contexts, we have emphasized the role of multiple streams of activities as well as how windows of opportunities emerged when these streams converge. These streams intersect in multiple ways, not all of which are expected. These intersections or interdependencies can have quite dramatic impact on assumedly unrelated activities. We argue that models that suggest structured approaches to information infrastructure governance (such as IT governance models) do not emphasize these aspects adequately. We have shown in the case studies that the information infrastructure’s development was influenced by activity streams emerging outside of the organization. Sometimes these streams interact to further management’s plans, such as when the hospital relocation served as a golden opportunity to redesign the LAN infrastructure or when the political stability and investments in IT in Sao Paulo enabled the redesign from scratch of the hospital’s information infrastructure. Sometimes, however, the intersection or interdependencies between the different streams generate unforeseen problems.

The implications of this view is that models that advocate structured approaches to governance need to be complemented with learning-based or adaptive strategies for decision-making and operational action. For instance Hayes and McGee (1998) applied the Garbage Can Model in a study of IS in organizations and acknowledging the constructive power of these processes, they concluded by recommending us to “Look out for and use those garbage cans!” (ibid p.33). Similarly, Fardal and Sørnes (2008) claim that Garbage Can processes are productive at organizational level, and they conclude that:

“[…] acknowledging that decision-making isn’t always a rational process could improve the fit between intended and actual decision-making structures. At last, at the organizational level, GCM decision-making provides sensible IS strategic decisions, meaning that CIOs can focus on implementing the decisions rather than imposing a decision-making rationality that participants do not adapt to” (ibid p. 565).
6 CONCLUDING REMARKS

In this paper we have emphasized the role of multiple streams of activities as well as how windows of opportunities emerged when these streams converge. These intersections or interdependencies can have quite dramatic impact on assumedly unrelated activities. From this perspective, it is no wonder that organizations often experience that they have limited control over internal streams and limited influence on external ones. While the streams can not be managed, organizations can try to manage their outcomes. And they are more apt to be able to do so if the inherent power and importance of these phenomena in organizational decision making is acknowledged. Our major message in this paper is that dealing with the dynamics of information infrastructures requires a balance between planned and emergent strategies and thus continuous learning. Based on this we could formulate the following guidelines for organizational members involved with IT governance:

• Since the intersection of the streams may emerge unpredictably, an organization need to strengthen its ability to predict and detect the windows of opportunities opened. Generally this requires a good understanding of the challenge that information infrastructures pose, as well as a sensibility towards the character of organizational processes. The theoretical streams and concepts presented in this paper can be seen as contributions toward this aim.

• Since the intersections of such streams can represent unique opportunities for change, as exemplified in the empirical cases, the organization also needs to develop agility to exploit them. This requires agility both in the organization and in the IT governance structures:

• Any IT governance model in use should incorporate the required flexibility to leave aside the standard plan it has sketched. Ideally it should have an inbuilt robustness towards adaptive handling of change. For instance, the advice of the IT governance models to distinguish between different types of IT decisions may be sound in general. Sometimes, however, the various areas intersect in unpredictable ways. New application needs may challenge the previous decision of architectural aspects of the infrastructure, for instance. Sometimes external change, e.g. in legislation, may overturn the carefully designed strategic IT principles. How is then this handled by the governance structure in place? If the IT governance model does not incorporate the flexibility required for this kind of deviations, it needs to be overruled and set aside in periods of radical change occurring from the kind of phenomena we have described.

• Usually this kind of flexibility and agility needs organizational slack resources and/or redundancy. Be prepared that the organizational hierarchy may need to be softened up to enable the right participants to exploit the windows of opportunities that may emerge.

The baseline of our message is that the garbage can is there, and windows of opportunities can stay open or close without prior advices. It is thus up to us to choose if we will regard it as a disturbance to our ready made plans, or as a resource in order to reframe plans with unpredicted events.

Abstract

Establishing technologies has brought mixed socio-economic impacts across nations and regions. Researchers have studied the relationships between the establishment technologies and its impacts through identifying innovative processes, major actors, and available resources. However, the challenge to this literature is how less resourced countries have achieved greater prosperity than better resourced countries by establishing Information and Communication Technology (ICT). To understand and analyze this phenomenon, we propose a typology of the configuration of roles and actors in establishing ICT based on an innovation framework. The proposed typology can be used not only to explain different socio-economic impacts among countries or regions, but also to suggest a constructive way in establishing ICT through reconfiguring involved actors in the key roles.

Keywords: ICT establishment, Innovation, Triple Helix Model
1 INTRODUCTION

Technology has been identified as a means to increase economic growth (Fagerberg 1987) and potentially can originate virtuous circles that catalyze factors in the productive process and accelerate the generation and use of new knowledge (Garud & Kumaraswamy 2005, Bresnahan & Trajtenberg 1995). Consequently, the successful establishment of technology can improve standard of living and create positive socio-economic impacts. By establishment of technology we mean development, adoption or adaptation of technology as well as its implementation (Orlikowski 1992).

Certain types of technologies have been called General Purpose Technologies (GPT) due to their pervasiveness, technological dynamism, and innovative complementarities (Bresnahan & Trajtenberg 1995). Information and Communication Technologies (ICT) are one type of GPT that have been widely distributed throughout managerial, productive and communicative processes in the commercial industries, academic organizations, and governments.

ICT is principal to today’s knowledge-based economy and a backbone of commerce (Powell & Snellman 2004, Tripathi 2006). The abilities to manage, store, retrieve and transmit knowledge have positively affected societies and become catalyzing factors in productive and knowledge-intensive processes (Garud & Kumaraswamy 2005). Negative impacts in establishing ICT can be mentioned as well, like large investments without social net benefits or the severe imbalance of technology benefiting only a few parties instead of the whole community (Tyler 1962, Hanseth & Jacucci & Grisot & Aanestad 2006). Some nations or regions have enjoyed more positive socio-economic outcomes from the establishment of ICT, while others have struggled between positive and negative effects or suffered more negative consequences. Because of the central role of ICT and the potentially conflicting consequences for society, we are interested in learning about its establishment process and socio-economic impacts. To do this, we look for an alternative explanation in the configuration of roles and actors involved in the process of establishing ICT.

For the establishment of ICT, we can identify sets of actions, attributes and duties that need to be fulfilled, which we call ‘roles.’ Different actors can play various roles, forming configurations between roles and actors for the establishment of ICT. In establishing ICT within the socio-economic system, three major actors (government, universities and ICT industry) have been identified to perform different roles according to their special abilities and skills (Leydesdorff 2005, Williamson 2005). However, their performance can be defined by political forces or cultural mores instead of efficiency (Hamlett 1991).

The interesting question is why different regions have different socio-economic impacts, even when they develop or adopt the same or similar technology (Fagerberg 1987). According to Resource-Based View (RBV) theories (Barney 1991, Grant 1991), more endowed countries or regions have more resources to invest in developing or adopting technology than poor countries or regions, therefore, countries or regions with more resources can enjoy more positive socio-economic impacts than less resourced countries or regions; nevertheless, we have witnessed instances where one country with similar or fewer resources than others experience more positive socio-economic impacts from the establishment of ICT. For example, relatively less resourced South Korea has enjoyed mostly positive socio-economic consequences from adopting and implementing Code Division Multiple Access (CDMA) technology as its second generation wireless communication technology standard, while countries with more resources at the time like Japan, Taiwan, and Singapore have not had similar positive impacts.

To explore alternative theories to explain the variation in socio-economic impacts among regions, this paper rests on a conceptual framework to propose a map of configurations between actors and roles in establishing ICT. The map can be used to analyze the relationship between ICT establishment and its socio-economic impacts in a given region over time, or to compare different regions. Furthermore, the findings can provide pragmatic ideas about reconfiguring actors and roles in order to decrease the
differences and gaps in socio-economic impacts among countries and regions created by the establishment of ICT.

2 LITERATURE REVIEW

The establishment of innovations in ICT and its socio-economic impacts have been analyzed from a historical perspective (Dudley 1999); changes, interactions and consequences of technology establishment have also been studied (Feinson 2003, Lipsey et al. 1998, Niosi 2002). Dudley (1999) describes how the principal characteristics of ICT (storing, transmitting and reproducing information) have positively impacted economic growth in the period between 1000 Common Era (CE) and 1975 CE. He showed that the decentralization and distribution of information reduced the costs of disseminating information and increased literacy levels. As a result, this phenomenon led to the decentralization of economic activity, and more communities benefited from sharing or generating knowledge and accessing financial support and technological assistance.

Unintended negative effects of technology establishment have been reported as well. Tyler (1962) points out that the presence of technology in productive processes, products, and services affects people’s values, habits, and interests. As a result, we observe more powerful, expensive and destructive weapons, compulsive consumption, or decisions based on ‘efficiency,’ when the problem may not lie in the realms of economics, science or technology. Other negative effects have come as a result of automation, like the replacement of the workforce (Noble 1984), and the concentration of production has had its greater impacts on the less resourced and less skilled companies and workers (Flamm 1988). In general, social, economic and ecological problems have arisen as unintended side-effects during and after the establishment of various technologies (Kingdon 1995).

At the organizations level, mixed results have been reported as outcomes of ICT investments (Dehning & Richardson 2002), nevertheless it has been claimed that such paradoxes can be explained by measurement problems and outdated data (Barua & Kriebel & Mukhopadhyay 1995, Brynjolfsson & Hitt 1996). Seo & La Paz (2008) analyze the dark side of Information Systems, and recommend firms to be aware of the negative impacts of IS and balance both positive and negative side effects for organizational agility. Similarly, Carr (2003) recommends spending less on IT investment and thinking more to generate advantages by having superior understanding of the use of new technology.

Different types of actors play various roles in establishing a technology. For example, in the development of the semiconductor and computer industries in the U.S., the government was a principal actor in the early stages of invention and improvement for the first computers and telecommunications networks by fostering and funding research on defence (Flamm 1988, Ceruzzi 1998, Noble 1984, Denning 1997). History also confirms that the government has been not only the first promoter of innovations, but also was the principal customer of computer technology for statistical data analysis for a long period (Flamm 1988, Ceruzzi 1998). Academia was typically the recipient of research grants and carried out projects to develop and utilize new technology for improvements in productive processes (Noble 1984). Some successful academic projects transformed into venture companies by transferring innovative technologies into commercial products or services, becoming prosperous companies like SUN Microsystems (Ceruzzi 1988). Companies recognized the significance of research and development and kept investing in computer technology. For example, IBM invested strongly in R&D to enhance the processing and storing capacity of the first primitive computers, so IBM could rapidly commercialize and customize its products to meet market needs (Flamm 1988). In this case, IBM as a company in the IT industry played a fundamental role not only in research and development but also in establishing and commercializing the outcomes of applied research (Pugh 1995).

In order to discover the main categories that shape the configurations of roles and actors for the introduction and establishment of ICT, we surveyed the literature of innovation, economic growth, and
the actors of innovation. Our survey is focused on the identification of both roles and actors for the establishment of ICT. We acknowledge that other types of analysis may lead to explain the optimal configurations based on efficiency (see for example Williamson 2005), however, we attempt to set up a framework to describe the actual configurations that can potentially explain the variance in the establishment of ICT across countries or regions, and explain how different countries and regions have similar socio-economic impacts even though their ICT development paths are different (Doty & Glick 1994).

2.1 Innovation and economic growth

Society-wide economic growth is influenced by many factors such as culture, social events, economic, political, and technological forces (Spencer & Murtha & Lenway 2005). Focusing on technological and political factors in economic growth, Lipsey et al. (1998) propose a structuralist growth model. They criticize models of growth for being abstract and intangible in describing how a production function can transform input into economic output. The authors open up the black-box of production function and break it up into four elements affecting economic output: 1) Technology (stock of existing technological knowledge), 2) Facilitating Structure (physical and human capital, production facilities, managerial and financial organization, industrial concentration, financial institutions and financial instruments), 3) Policy Structure (means to achieve public policy such as public institutions), and 4) Policy (expressed in legislation, rules, regulations, procedures and precedents). The social facilitating structure transforms inputs into outputs affected by technology and policy structure. Policy structure is influenced by policy itself. Following this rationale, technological innovations would increase economic growth by adding input into the facilitating structure, and effects would be appreciated on the policy structure and legislation to increase economic performance.

Innovation plays a significant role in economic growth (Denning 1997, Mahdjoubi 1996). The Linear Model of Innovation describes four factors to generate innovation (Godin 2006) – 1) Basic Research conducted by the academia and funded by government or firms; 2) Applied Research, where firms use and test the basic research for practical usage; 3) Development, with firms further developing and customizing products and services for end users; and 4) Commercialization, where firms distribute products and services. According to this model, investment as input in basic research can generate more innovation as the output of the four factors, impacting economic growth (Godin 2006). As Mahdjoubi (1996) points out in his Holistic Innovation Model, innovation is not only the disruptive result of basic research, but it can be the product of continuously improving processes in designing or manufacturing, enhancing supply chain networks, emulating other technology, and acquiring new technology by purchasing licenses or patents. The Holistic Innovation Model specifies more functions in each stage and recognizes feedback between stages.

These models provide a basis in identifying necessary roles in establishing ICT. In the following section, we review the existing literature to categorize actor groups that can play roles in the ICT establishment.

2.2 Actors of innovation

forcing a transformation of each actor and their role (Han et al 2001, Leydesdorff & Meyer 2003, Shinn 2002).

The Structuralist Growth Model, Linear Model of Innovation, and Holistic Innovation Model emphasize various functions to establish ICT and show how different degrees of socio-economic effects can occur depending on those procedures (functions). On a different bracket, investigators concentrate on identifying actors without indicating their roles in conducting different procedures (functions) in establishing ICT (Cohen & Levinthal 1990, Etzkowitz & Leydersdorff 1995, Mahmood & Rufin 2005, Spencer et al. 2005). These two branches of literature focusing on roles or actors in establishing ICT and their socio-economic impacts open up intriguing gaps: (1) what are the major roles played by the various actors and (2) who plays which role(s) in establishing ICT. The latter question brings up the very significant perspective that the same role can vary in its outcome depending on the actor performing it, and such variation may have an impact on ICT establishment.

By reviewing various theories and models, we are able to recognize roles and actors. From the literature, most innovation theories focus on the first role of the academic and private sectors in detecting the needs and solutions of technology innovation. Meanwhile organizational theory and the triple helix model emphasize the role of government as an actor who can play the similar role, which can be achieved mainly through national labs and close linkages with academia. The second most popular role is creating a market and regulations accordingly. This role can be performed by the public or private sector. In order to support technology innovation, the theories of innovation systems, and innovation and economic growth identify the third role – educating potential developers and users, so they can use and apply the innovation. This role can be played by the industry, the academia, or both. Finally, the commercialization and production of a technology becomes the last role to diffuse the technology for mass users. Only the industry actor group can conduct this role according to the holistic model of innovation and innovation systems. Table 1 summarizes these four identified roles and three actor groups.

**Table 1.** Roles and Actors identified in Innovation and Socio-Economic theories

## 3 CONCEPTUAL FRAMEWORK

From our review, we identified three main relevant categories of actors – Government, Universities, and ICT Industry – and four major roles for the establishment of ICT in the socio-economic context: 1) Detection of users’ needs and solutions, 2) Development, production and commercialization, 3) Market creation and regulation, and 4) Learning.

We acknowledge that there are sub-categories with heterogeneous actors, for example, various firms in ICT Industry. However, this study focuses on the macro level in establishing ICT. It means, for instance, that we emphasize the difference between a government systematically leading the detection of needs and solutions and the situation in which companies in the ICT industry compete freely for the detection of needs and solutions in establishing ICT.

We also recognize that the four identified roles (functions) are a simplification of the process of ICT establishment. This process is much more complex and includes many specific roles. As mentioned,
again, our research focus is not how the roles should be completed at the micro level, but what the major roles that should be accomplished at the macro level are, what the possible configurations between actors and roles are in establishing ICT, and whether those configurations have an impact on the measures of ICT establishment. Consequently, this theoretical framework can help researchers, practitioners and policymakers to better explain, analyze, and improve the existing configurations in establishing ICT, so that they can reconfigure the patterns of actors and roles in order to maximize positive socio-economic impacts for the region while minimizing the negative side.

Our overall perspective for the establishment of ICT is a compound of processes connected in a non-linear manner (Mahjdoubi 1996) to first detect users’ needs and solutions, subsequently develop, produce and commercialize ICT products and services in a market created and regulated to foster the use of ICT. One of most effective to complete this process is through education and training developers and users, which ultimately, not only improves performance, but also expedite the technology diffusion. We will examine now each role with the special abilities of the actors who can offer and accomplish the corresponding function.

3.1 Detection of users’ needs and solutions

It is critical to identify the user’s needs and especially to detect the technological opportunities with great potential to generate value (Bond et al. 2003). Once market needs and opportunities are identified, actors think about possible solutions to fulfil these needs and opportunities. The value of adopting technology can be estimated by analyzing the surrounding situation and technological possibility for a solution in the particular socio-economic system (Mahdjoubi 1996, Mahmood et al. 2005). If solutions have been successfully developed and established in other regions, then adoption can be one way to satisfy the need if the culture and technologic-economic platforms allow imitation (Spencer et al. 2005). If no available technology fulfils the needs, innovation is compulsory. This decision is critical, because the investment in innovations may denote an impossibility to shift to alternative solutions when the new technology is in the process of development or production due to high switching costs (Tyler 1962). Government, Universities, or the ICT Industry are able to act as a detector of needs and solutions by conducting studies in national labs, university labs and companies’ R&D divisions (Lazzeretti et al. 2005, Pradhan 2002); the strengths and weaknesses of each actor are:

- **Government**: Governments can have first-hand information from the community when they conduct projects. They sometimes directly survey the population to identify needs. Many governments in developing countries look for solutions in technologies that can be imitated from developed nations, which can be useful in the early stages of innovation (Mahmood & Rufin 2005). Conversely, in a more advanced innovative setting, paternalistic governments may engender passiveness and restrain innovation when making decisions (Spencer et al. 2005). The main weaknesses of governments are the bureaucratic processes that slow procedures while consuming resources and efforts. Additionally, political forces may act based on factors different from efficiency or social welfare (Hamlett 1991).

- **ICT Industry**: Opportunities to open new markets by innovation or imitation are the main incentives for the ICT industry to detect needs and solutions, so companies in ICT industry can be the first mover. However, due to their nature, companies will ignore signals to meet some of the needs unless they expect profit opportunities in the future. Large investments can be risky for companies because technology research and development consume time and resources without guaranteeing a return on investment (Dehning & Richardson 2002). If no economic benefits are expected, the opportunity is not attractive to companies.

- **Universities**: Their traditional primary missions are teaching and research (Etzkowitz 1989). Rigorous research methods can help in identifying needs, solutions and impacts (Nelson 1959, Mahdjoubi 1996, Godin 2006); however universities may be biased in favor of developing basic research rather than applied works. Some universities with entrepreneurial vision have engaged in applied projects, which can present an advantage for this role (Etzkowitz & Leydesdorff 1995, 1998, 2000, Lazzaretti & Tavoletti 2005, Shinn 2002).
3.2 Development, production and commercialization

The mass production of ICT involves the coordination of productive processes to create and deliver value, including the purchase of raw materials or equipment, the use of a skilled labor force, product design, and strategic financial and administrative management (Riches 2003). In democratic systems, production is mainly conducted by private sectors; this may be different in centrally planned economies in which all the productive decisions come from the central government. In addition, we need to remember that the commercialization of technologies can be very specialized in high-tech markets, in which complex technology products require a skilled workforce (Foxall 1988).

- **Government:** Many innovative technologies in ICT have been born in not-for-profit research centers or projects sponsored by governments, such as the Internet and other technologies that were first designed for military purposes (Noble 1984). Governments can be directly or indirectly involved in coordinating and formulating the value network that keeps control over the nation’s resources based on different socio-economic governing systems, which may or may not be more efficient than an open market approach (Mahmood 2005). The perspective of paternalistic governments may be involved in not only production, but also the distribution of social benefits.

- **ICT Industry:** The Industry is commonly the main player for this role. Companies have consistently developed or imitated (adapted or adopted) new ICT to protect and extend their market share. From the market perspective, configuring value networks for production and commercialization is about business objectives, so the successful configuration of value networks in this role is directly related to companies’ prosperity.

3.3 Market creation and regulation

The creation of markets is referred to as the construction of a structure where buyers and sellers can trade (Burton Jr. 1993). In this structure, the public sector plays a significant role in defining policies and rules, which is an important factor in the establishment of technology (Lipsey et al. 1998). This rule will oversee the market to foster transparency and efficiency, keep the market away from monopolistic practices, so it provides justice in cases of policy violation. In this role, the authority with the attributions to create laws and supervise their observance is the government; however, in practice, informal regulations and lobbying forces can also be found. The regulations that a government authorizes can hopefully encourage positive effects while discouraging negative impacts; however, companies in the industry also create invisible self-regulating rules and practices that impact market performance (Williamson 2005).

- **Government:** Governments should pursue a transparent function of markets through the creation and implementation of adequate regulations and policies (Williamson 2005). A well designed structure under the proper regulations and policies will attract more investors and foster good practice, so it will consequently speed up the ICT establishment (Lipsey et al. 1998). We should acknowledge, however, that excessive regulations and policies by the government can slow the process and self-evolving industrial dynamics in establishing ICT.

- **ICT Industry:** ICT Industry can provide feedback to the government to improve regulation that can bring more positive dynamics in the industry. However, this procedure can be influenced by dominant companies in the market for their own advantage rather than for overall socio-economic benefits.

3.4 Learning ICT

The process of learning contributes to establishing ICT in different ways (Smit 2007). One is educating customers to adopt a technology more efficiently and effectively when users search for. Another is training specialists to develop or adapt ICT. The specialists usually learn basic knowledge and gain more sophisticated knowledge through directly developing or adapting ICT (Arrow 1962). The complexity of ICT requires professional skills and training that people can acquire in universities.
or companies they work for (Ross 1967). Governments can foster the info-alphabetization or influence the design of educational curricula; however governments do not directly provide education or training to people to establish ICT.

- **ICT Industry**: ICT development or adaptation is directly related to companies’ fates. Thus, companies invest in training their personnel and supporting research centers to maintain or achieve technical capabilities. Companies also educate and support customers to adopt and use their technology more efficiently or effectively through support centers, conferences, or educational institutes.

- **Universities**: One of traditional university missions is teaching people to become professionals who are able to use and improve technologies (Denning 1997). Universities provide highly skilled personnel not only by teaching them through courses but also by giving them opportunities to conduct applied research in conjunction with companies.

### 4 TYPOLOGY OF THE ROLES AND ACTORS

Doty and Glick (1994), argue that typologies are complex theories that frequently misinterpreted. A typology is different from classification in representing series of logical arguments that connect concepts, constructs or variables, and incorporating multiple levels of theory that can predict variance in dependent variables.

Having identified the fundamental roles and actors needed to establish ICT in socio-economic system, we now introduce the typology of the possible configurations between the roles and actors that shape the establishment of ICT. By studying the configurations of different socio-economic systems, we may find some patterns that help in creating strategies to improve the rates and impacts of establishing ICT, or to identify configuration benchmarks that reveal the most effective organization (Niosi 2002).

In order to build the typology, we will consider one leading actor for each role, so there will be one, two, or three possibilities to fill the leader position for each role. For example, in the role of Detection of user’s needs and solutions, there are three actors (Government, ICT Industry, and Universities) as a potential leader. Table 2 presents the configurations in the form of a menu with four columns that represent the roles; for each role, the potential actors to perform the role are listed in the corresponding column. A total of 24 different configurations \((3 \times 2 \times 2 \times 2 = 24)\) can be formed by identifying one leader for each role. The configurations would identify various patterns, for example, a government performing most roles in the establishment of ICT (Government leading the detection of needs and solutions, the development, production and commercialization, and the market creation and regulation, with academia or IT Industry leading the learning process for ICT establishment). In another instance, ICT industry plays major roles in the process of ICT establishment when the ICT industry leads in all four roles. Other configurations can represent mixed distributions of roles played by actors influenced by market and political forces (Denning 1997).

**Table 2. Configurations Map for ICT Establishment**

For example, in many developed western European countries like Denmark, all roles are led by ICT industry except the role of market creation and regulation (Haekkerup 1999, Shapira & Rosenfeld 1996), while in developing countries like Indonesia, governments has involved in not only the role of market creation and regulation, but also the role of detection of users’ needs and solutions.
(Madanmohan & Kumar & Kumar 2004, Sharif & Sundararajan 1984). Is it coincident or natural? Can poorly performed nations in term of establishing ICT improve their performance by changing the configuration of roles and actors?

The proposed configuration will provide a theoretical basis to answer these questions. This configuration can be used 1) to compare countries and regions that have different socio-economic impacts in establishing the same ICT, and 2) to analyze the historical development of single country or region. By studying the configurations that countries have adopted over time, we are in a better position to explain how various actors can perform differently on a given role and how the performance of actors on different roles impacts the process of establishing ICT. In this way, we may identify patterns that help to explain why and how some countries can sustain their development and have more positive socio-economic impacts than others. In addition, we can find and propose more appropriate configuration for a country through observing and analyzing the evolving configurations of countries.

5 DISCUSSION, LIMITATIONS AND FUTURE RESEARCH

Although this study is a simplified representation of the ICT establishment process, it contributes to knowledge by identifying the major actors and roles and suggesting a holistic way to analyze their intertwined relationships which can be further used to describe patterns and benchmarks in establishing ICT. The proposed framework provides an alternative explanation that complements existing theories about technology adoption, diffusion, innovation and the socio-economic impact of establishing ICT. We acknowledge as a limitation that empirical information may not always identify one leader for each role, but roles may be performed collaboratively (or competitively) by many actors; however, this paper introduces the concept of the configuration that affects the establishment of technology.

The 24 theoretical configurations introduced in this study are based on all possible combinations of actors and roles defined; however, we may find a smaller subset of configurations in practice, which opens up a whole new avenue for future study in recognizing and describing what are the factors that produce the different configurations and their impacts. In this vein, researchers can survey nations and regions to identify how many configurations of roles and actors there actually are, whether there are patterns that can be categorized by geographic regions or economic levels, and how the configuration of roles and actors can be reshaped over time in order to improve the establishment of ICT. Researchers, practitioners and policymakers can use the proposed framework from evaluating current configurations to designing strategies for reconfiguration that stimulate positive impacts while repressing negative effects in the ICT establishment.

For future research, we can test, confirm, and improve this proposed framework through empirical studies based on quantified and qualified data. Based on further empirical analysis, researchers and practitioners can develop recommendations for the strategies of ICT establishment that can provide more specific and practical roles for governments, universities and companies.

Abstract

The growing relevance, scale, and complexity of Business Intelligence (BI) entails the need to find agile and efficient solutions for the coordination of maintenance and release processes – under consideration of the heterogeneity of the involved units on the IT and the business side. The finance industry with its mature BI infrastructures and its highly turbulent business environment is a forerunner for these developments. Based on a survey among BI users in the finance sector, relevant problem areas in the BI service provision are identified and structured. A series of qualitative interviews among banks and insurance companies is used to gain further insights into approaches for dealing with the related issues. The studies uncover several advantages of a central “BI Competency Centre” (BICC) as well as levers for effectively structuring the interfaces between BICC, IT, and user interface.

Keywords: Business Intelligence, Empirical Study, Governance, Service Orientation
1 RELEVANCE

In recent years, Data Warehouse (DWH) based infrastructures for management support have grown tremendously in relevance, scope, and scale. The integrated approaches they are built upon are usually referred to as Business Intelligence (BI). In more and more cases, BI reaches out to all business functions and managerial levels and is turning into an integral segment of the business (Baars and Kemper 2008). On the one hand, these developments open up significant business potential. On the other hand, however, they come at the price of increasing costs and a constantly rising technical and organizational complexity. These challenges need careful management that includes a thorough reconciliation of technical and application oriented requirements (Hughes 2008, Miller 2006). The issues are more severe in the domain of BI than in the operational IT because BI applications are required to embody ever changing business semantics and versatile analytical needs (Finger 2008, Moss 2006). Many organizations have reacted by establishing specialized units for running and supporting BI solutions – central BI “centres of competence” (BICCs). In general, BICCs act as linking pins between the user side and the infrastructure provision (Miller 2006, Unger & Kemper & Russland 2008). However, it is yet unclear under which conditions a central BICC is to be preferred over a decentralized approach with BI units spread across different user departments, how to distribute competencies among the user, IT, and the BICC side, and how the respective interfaces need to be crafted under consideration of the constant stream of system modifications and re-designs (Eckerson 2006, Geiger & Hill & Ton 2007, Strange & Hostmann 2003).

When tackling this issue, the literature on IS (de)centralization provides a rich body of rationales for deriving the spectrum of basic organizational options. However, the respective sources are not geared at the particular characteristics of the BI domain and are thus hardly applicable without further modifications (Boddy 2005, Gordon & Gordon 2004, Haag 2003, Inmon 2005, Inmon 2006, Kimball 2002, Laudon & Laudon 2005). It is yet unclear what the core priorities are in the BI domain with respect to the involved users, the IT and the BI units (Kleese & Winter 2007). There are also several relevant BI characteristics to be considered, e.g. the need to built data structures that feed both unit specific analyses and cross-departmental reporting applications, or the blurry distinction between “routine” changes (e.g. modifications of established data sets, often in form of so called “data cubes”) and more far reaching requirements (e.g. in case such modifications involve the integration of new source systems or require a higher load frequency).

This contribution deals with these issues by deriving a service-based concept for the distribution of tasks within the systems maintenance and the release development phases of BI solutions. It gains insights from application oriented research conducted with insurance companies and banks. Financial organizations have been pioneers in the realm of BI for a long time and thus come both with a rich experience base and comparatively mature solutions (Kleese & Winter 2007). Furthermore, external pressures are especially salient in this industry due to the volatility of the business environment. As will be discussed in the final section, most of the core conclusions are expected to be invariant to industry peculiarities because the underlying qualitative rationales are not affected.

Due to the novelty of the phenomenon in discussion, the research is of an explorative nature (Schwab 2005, Yin 2009). It encompasses an explorative quantitative study on the prioritization of BI maintenance and release development processes as well as a series of interviews in the finance industry that provides insights into the options, possibilities, and challenges of their organization. The results motivate the draft of a concept that aims at overcoming remaining shortcomings of a BICC approach by distinguishing three classes of services.

2 CONCEPTUALIZATION

The presented results focus on the financial sector. The financial sector is commonly understood to encompass all those organizations that are primarily dealing with the allocation, management, acquisition and investment of monetary resources and thus with all kinds of matters related to money and the financial markets (Howells 2007). Among others, companies in the finance sector include full service banks, insurance companies and investment trusts (Moormann 2007). The relevance of BI in
these organizations is driven not only by the fact that information is usually a core product but also by a number of pressures both from the regulatory and from the market side. Recently, developments like the subprime crises (Blundell-Wignall 2008) or the growing number of natural disasters are additionally fostering the need for an agile reporting and analysis infrastructure that provides a comprehensive overview on internal and external developments – based on integrated data pools. (Moormann 2000). It does not come as a surprise that finance sector organizations, and banks and insurance companies in particular, are among the most avid users of advanced BI infrastructures. The finance sector can thus be treated as an epitome for current developments in the BI domain (Kimball 2002, Moormann 2007).

This contribution deals with the organizational interfaces between the participants involved in the maintenance and release development for BI solutions. Here “maintenance and release development” is understood to encompass all types of alterations on an existing solution (IEEE 2008). Maintenance is used for minor changes that can be dealt with in near-time within the established reporting structures. Release development adheres to the definition of a project. In the light of the presented aims, the scope of this research is confined to changes that are involving the user department and that lead to modifications relevant for and perceivable from the user side. Among other activities, this excludes backend optimizations, the versioning of data management tools or redesigns of transformation logic that is not visible from the frontend (Baars & Horakh & Kemper 2007).

The studies that led to this contribution are embedded in a larger research context that tackles BI organization and its IT support (Baars & Horakh & Kemper 2007, Horakh & Baars & Kemper 2008, Unger & Kemper & Russland 2008). The fundamental research objective was to identify viable options for the design of the interface between users, the BI units and/or the IT department in order to effectively cope with perceived shortcomings or to pursue desired enhancements. Due to the dearth of research into the subject, it was tackled according the paradigms of exploratory research (Schwab 2005) and addressed with two complementary studies that have been conducted in the first half of the year 2008: A descriptive, quantitative survey to get a first overview on fundamental priorities and a series of qualitative interviews that was geared at a more in-depth understanding of the subject matter.
shortcomings in the BI area on the one hand and demanded enhancements on the other. The results are used to structure and guide the further exploration which is achieved by the interviews.

A pivotal factor that needs to be introduced for a valid interpretation of the interviews is the type of requirement that is dealt with in a particular system change. It was expected that different types of requirements would lead to different ways of dealing with them and gaining an understanding of those relations was a major part of the study. The second group of insights deemed to be relevant pertained to rules and regulations that had been imposed and their respective relevance. To grasp relevant causal and temporal relationships, questions on the concrete experiences behind the chosen design options were introduced. All this should condensate in the actual design of processes and projects for maintenance and release development. The resulting conceptual framework is depicted in Figure 1.

3 PRIORITIZATION – QUANTITATIVE EXPLORATION

The questions on the prioritization were covered as part of a wider online survey. As depicted in the conceptual framework, they encompassed an investigation of the type of BI organization, and of shortcomings and demands for enhancements regarding BI service provision. From about 11,000 addressees who were contacted via personalized emails, 1,519 followed the link to the survey web page. A total of 97 persons from the finance sector filled out all questions relevant for the discussed research. The sample was gathered from a list of experienced BI practitioners from IT departments (19 respondents), dedicated BI units (19 respondents), and BI user departments (59 respondents). Due to the explorative nature of the study, the results were primarily approached with descriptive statistics and used as a means for hypothesis generation rather than hypothesis testing (Schwab 2005). All results where checked with Chi-square tests for significance – based on a significance level of 10%. Due to the qualitative design and the sample size, differences in the results will also be discussed when they are not statistically significant but nevertheless lead to insights into potential differences among the groups. The shortcomings and demanded enhancements that were identified to be most relevant with respect to the overall study will be discussed in the following two sub-sections.

3.1 Shortcomings

Two questions addressed the shortcoming side of the framework: The participants were asked to select the three most pressing issues in for BI maintenance and release development respectively. The lists of 9 choices each were compiled based on BI literature and prior field experience. The differentiation of the results according to the type of organizational unit exposed diverging views on the shortcomings in BI maintenance.

Striking is the difference in the evaluation of data quality which was – in line with results from similar studies – the issue that heads the overall list of chosen shortcomings: Only a minority (16%) of the respondents from IT units considered data quality to be among the top-three relevant issues, while participants from user departments chose this item in almost half of the cases (46%). In contrast, the number for the BI units topped 60%. When evaluated with a Chi-square test, these differences also prove to be significant with respect to the chosen significance level (p=0.077). This result can be interpreted as an indicator for the distance of the IT staff from the use context on the one hand and the underestimation of data quality related efforts by the users on the other. In a BI unit, however, data quality related issues converge and culminate. A possible similar discrepancy might exist regarding the diversity of the analysis systems. This item was declared slightly more often to be a problem in the business departments than in the BI and IT units. A reason could be that tool integration is primarily driven by handling the frontend.

Interestingly, about a third of the respondents in the BI and business units selected missing functionality as a core issue while the result for IT is zero (significant with p=0.054). Again, this reveals a lack of insight of IT into the application side.

The IT seems to be a little more conscious of an insufficient coverage of informational needs (42%), which a slightly lower percentage of users (32%) and only a minority of the BI unit respondents (12%) considered to be an issue. A possible explanation could be that IT has an overview on all potential data sources while the user department is not yet fully aware of those possibilities. Being situated between
IT and user department, the BI unit has the best vantage point over the actual information supply and demand. A different result comes up for the lack of integration into the IT-backend which neither for the IT (16%) nor the user department (24%) ranks among the most frequently selected issues while still 32% of the BI unit saw this as a challenge. Although the results are not statistically conclusive yet, they again might hint at the tendency of the IT and business departments to underrate the conceptual challenges that go along with the integration of heterogeneous business semantics.

Regarding the release development for BI applications, 61% of the participants from the user side complained about an unsatisfactory time budget [of the BI providers] to support the user departments. In contrast, 28% of the IT and BI unit participants considered this to be of particular relevance (significant with p=0.067). This can be interpreted as another indicator for diverging priorities: The providers act according to a defined prioritization and under consideration of available resources. As lower prioritized requests have to wait, business departments are left unsatisfied. This goes in line with the occurrence of development backlogs which are considered critical by all three groups with item selection rates that vary between 30% and 40%.

Not surprisingly, only a small group (16%) of participants from IT considered lack of maintenance and release knowledge in IT to be a problem. When contrasting this with the values for the user departments and for the BI units (together 36%), one can suspect that the IT might indeed overrate its abilities. Similar, about 20% of the BI and user units complained about a lack of models for agile development, while the number is a little lower for the IT side with 16%. Regarding the item lack of management support, the results are consistent across all groups (about 30%).

It is obvious that the views of the participants vary – and in some cases (data quality, functionality, time budget to support user departments) even significantly. Several answers indicate that the full impact of BI is most comprehensively grasped in the BI unit. This can not only be explained by the hinge function of the BI unit between the user and the IT side but also because of its degree of specialization. Ideally, the different priorities that surface in the answers are reconciled by flexible organizational concepts that – where possible – leverage the different awareness of issues among the groups.

3.2 Demanded enhancements

The second aspect of interest pertained to opportunities for enhancing the value of BI. The questionnaire covered this in two questions with 9 choices each.

With respect to the maintenance side, a functional requirement holds a top rank: 63% of the dedicated BI units demanded more degrees of freedom in the data analysis applications. This wish was not shared uniformly: On the user side, only 47% selected this item (and only 21% in IT). A possible interpretation is that the BI side rated this issue from the information production perspective (generation of reports) while the answers of the users reflect a more passive, consumption oriented view. This would also explain why this result is not corroborated when it comes to the question of data mining: About half of the users (47%) demanded such systems but only 21% of the BI units and only 11% of the IT. On the content side, there was a perceived need for analyses across business function that was seen by both the BI and the user side (each about 40%) – but not in IT where only 16% selected this item. Obviously, BI users see demand for more in-depth and more far-reaching insights – although not necessary in tandem with more degrees of freedom or even a higher number of tools.

Shared wishes are a higher degree of integration of external data (around 35%) and portals as single point of contact (around 30%). Portals have a slightly higher importance for the BI while data integration is more important for the user departments.

With respect to organizational measures, a better data quality management dominates the answers of all three types of organizations. This result is consistent with the shortcoming side.

Regarding release development, the item business departments should be given more room to implement their own solutions is of special importance. This option was demanded by 49% of the participants from user side, and surprisingly still by about 25% of both the BI and the IT participants (a significant difference with p=0.050). Obviously, despite all proclaimed trends to concentrate IT...
development, there is a remaining need for decentralized activities that is especially felt in the user departments. Mirroring this against the issues of backlog and unsatisfactory time budgets, a potential to find a shared solution to issues of fast and flexible development is discernable. It is equally noteworthy that rules between business department and IT is not once selected by respondents from IT units (16%) while user participants chose this in 44% of the cases (significant with p = 0.053).

On the structural side, an integration of a BICC for future projects was demanded by about 40% of the BI units and by slightly fewer participants from user departments. The fact that a BI unit has been established does not necessarily mean that it also takes over the role of a BICC and is tightly integrated into the company. The answers from IT only reached a mark of about 20% - a result that might again signal an underrating of problems by the IT. A similar situation can be found when it comes to the wish for faster implementation which is conceived to be a problem by 35% of the participants from business and BI units but only for 10% of the IT participants (significant with p=0.075).

Service orientation and better data loading processes were of some relevance, although the numbers are not particularly illuminating. Yet, the service orientation (in the sense of delineating, providing, and managing customer-oriented services in the sense of IT service management) is seen as a building block for the implementation of the concept that is derived here.

In conclusion, the results provide some ideas for designing the interface between the units: They indicate that there is a need for a differentiated, carefully governed division of labour that allows bringing together seemingly conflicting requirements regarding the management of data quality, fast reaction times, more responsibility for the user departments, and providing cross-departmental solutions. The BICC stands at the core of this.

4 DESIGN OPTIONS – QUALITATIVE STUDY

For the qualitative case interviews (Yin 2009), a total of ten companies from the finance sector with mature BI infrastructures were selected. Their business model, type of BI organization, number of users, and BI experience (measured in years of usage) is presented in Table 1. In each case, interview partners from dedicated BI units were selected – to capture the more holistic view of BI units that became visible in the survey. This encompasses both centralized and enterprise-wide BICCs (4 cases) as well as specialized BI units that report to a user department and are part of a decentralized BI approach (6 cases). Each of the interviews lasted between 60 and 110 minutes. The interview questionnaire contained qualitative, open questions that were structured around the conceptual framework that has been introduced in section 2.

Table 1. Characteristics of examined cases

As illustrated in Table 2 and Table 3, the results were aligned with the identified challenges and opportunities for enhancements. Marked with a “-” are cases in which the identified challenges still remain unsolved or where the opportunities are not yet grasped while the “+” indicates the availability of an approach to deal with the various subjects. It is noteworthy that most of the companies with a centralised BICC (cases 1-4) have found at least partial solutions to most of the problems. In fact, it can be derived from the interviews that centralised and decentralised BI departments follow different strategic trajectories: The centralised BI departments show a strong focus on questions of efficiency while their decentralised counter-parts are primarily occupied with the fulfilment of the business departments’ requests. Units that report to user departments naturally have weak points when it comes to the consolidation of the diversity of analysis systems or tackling a lack of integration into the IT-
Moreover, centralised BI departments have also come up with ways to turn the discussed demands into reality. In the following sections, the different approaches are discussed in further detail.

### 4.1 Challenges and approaches to deal with them

#### Diversity of analysis systems

In the study, an unhealthy diversity of analysis systems only occurred in companies with a decentralised BI organization. The central BICCs were able to impose regulations that constricted the range of tools to a defined set. Furthermore, they guided or supported the user departments when it came to developing new releases or adapting existing ones – and in the process managed to curb or prune uncontrolled growth.

Cases 1 and 2 are prime examples for imposing a defined and confined set of tools. The interview partners from these companies also emphasized the resulting opportunity for systematically building up knowledge about the maintenance and the development of the respective applications.

The picture is totally different for decentralised BI units which primarily adhere to the wishes of the separate departments: This approach fosters heterogeneity between different solutions. The company of Case 9 can act as an example for the resulting issues: The interview partner described experiences with handling the constant stream of new tools introduced – tools which all needed to be connected on the IT side and that brought about massive issues regarding the built up and maintenance of the required knowledge base.

#### Lack of integration of BI-solutions into the IT-backend

A centralised BICC also has advantages when it comes to the integration of BI-Solutions into the overall IT architecture. Because of their size and role they are able to react swiftly to BI-relevant
changes on the IT-backend. This can be illustrated with Case 2: Although BI and IT units were independent subsidiaries they established well defined processes to cope with changes on the IT-backend. Conversely, decentralised BI-Departments are usually neither important nor big enough to be integrated into the workflow of the IT-backend. This can even lead to a situation where relevant changes on the IT-backend are not communicated to the BI units at all. Examples are the companies in the Cases 8 and 10 which both struggle with insufficient information on changes of the backend infrastructure. Independently of the organizational variant, the integration into the workflows of the IT department is crucial.

Unsatisfactory time budget of the BI providers to support the user departments

A best practice for allotting time and space can again be found in the centralised BICC: Implementing separate budgets for release development and ongoing maintenance tasks. This dual-budget approach has been implemented in all 4 BICC cases. Especially in Case 10, the lack of such a distinction was a root cause for all sorts of problems – even minor changes to the systems had to undergo the steps for the set up of a formal project. In consequence, dual budgets support flexibility.

Development backlogs

Backlogs have been dealt with successfully both in some centralised and decentralised units. As the answers on the experiences and the resulting rules and regulations show, a well defined requirements engineering alongside a communicated prioritization is the practice of choice. Such an approach had been implemented in all four BICC cases as well as in the companies 5, 7 and 9. In Case 9, this was complemented by the use of agile development methods that actually embedded developers in the department.

Lack of maintenance and release knowledge in IT

The case studies support the assumption from the quantitative exploration that a centralised BICC is – due its very design as a mediator – best suited to get a comprehensive overview of both the user and the IT needs. BI units in user or IT departments usually do not see both sides of the coin. This leads to problems like insufficient budgets for creating sustainable concepts or the tendency of IT to prioritize changes on the BI systems very low, even if they have a huge impact on the company. The companies described in Case 8, 9 and 10 face these problems.

No models for agile development

Only the company in Case 9 applied a model for agile BI development that guided the release development. It is noteworthy that this company had introduced several standardized processes between the user department and the IT to curb efficiency losses and foster cost reduction. An issue that still awaits a solution is the handling of data integration processes. At best, a combination of agile BI development with defined processes and a BICC driven coordination is leveraged.

4.2 Opportunities to realize demands for enhancements

Options for business departments to implement their own solutions

As discussed above, the idea of supporting professional system development within the user departments can be achieved in a setting like Case 9 which is based on a high degree of decentralization. In case of a more centralised approach, a central BICC can open up carefully crafted options that allow trained members of the user department to design their own reports or analysis cubes. This solution relies on extending BICC competencies to trained power users. It has to be mentioned that only the BICC in Case 2 was able to offer training services for such purposes.

Data quality management and data loading processes

All centralised BICC had already been able to systematically introduce rules and guidelines to improve data quality management and data load. As discussed above, the decentralised BI departments in four out of six cases had not yet been equally integrated into the IT workflows. This aggravates the problems as it leads to a frequent lack of information.
**Integration of a BICC**

Even though they were not always familiar with the term, the centralised BI units found in the study conformed fully to the understanding of a central BICC. These units had created well-structured processes and responsibilities for data ownership or requirements engineering. A remaining problem for these BICCs is the time it takes to deliver solutions for the user side.

**Faster implementation**

The acceleration of changes and the increasing rate of release development projects still pose problems for all but two of the companies. Small and specialized BI units like the decentralised BI department in Case 9 with its own DWH have an edge in this regard because they can act immediately and without much coordination effort. This situation can barely be transferred to enterprises which are in need of a core data warehouse that spans department borders. Changes to the core DWH naturally take time as they usually involve a larger number of stakeholders. Up to now there is no solution implemented in the examined companies for churning out such modifications in a short time frame.

**Service orientation**

The central BICCs have all started to plan, develop or deploy dedicated BI services. The company in Case 1 has already developed several services, while the company in Case 2 is right in the process of service specification. In contrast, most of the decentralised BI departments have not even thought about introducing services – which is not surprising as they are woven together with user departments and will by design not push a higher degree of bureaucracy. The exception to the rule is, again, Case 9. Here BI development services are used as building blocks in the agile development model.

**Rules between user department and IT**

All those companies that have implemented a BICC have also defined a set of rules. Actually, implementing a BICC as an organizational entity naturally involves the definition of rules and responsibilities – the establishment of a central BICC fosters regulation. In contrast, companies with a decentralised approach struggle much more with the definition of rules because too many parties with heterogeneous systems and requirements have to be factored in. That does not mean that this is an impossible endeavour: two decentralised companies succeeded in that regard and came up with rules that govern the interface between IT and BI. The company in Case 9 only has rules for ramping up new applications while in Case 7 strict rules had been dictated by the IT side that had to be followed by all decentralised BI units. There is a catch: In Case 7, the development times are as slow as if they would be when following a centralised approach.

**5 CONCLUSIONS**

The presented results show that there is a particularly strong case to establish a central BICC which coordinates the BI tasks of maintenance and release development and that acts as a mediator between IT and user departments. Although it is certainly not impossible for decentralised BI organizations to enforce enterprise-wide stipulations that govern tasks like data quality management, clear requirement prioritization, a definition of allowed analytical systems or the integration with the backend systems, this is much harder to achieve in decentralized environments. Likewise, the IT cannot easily take over the role of a BICC as it lacks its “dual-view”. Actually, the very set up of a central BICC is not possible without the parallel introduction of at least some rules that define the interfaces between IT, user, and BI unit. The exception to this logic is Case 9 where the solution is facilitated by a narrowly confined scope of the supported solutions and a separated single-purpose DWH. Notwithstanding, the definition of agile release development processes based on defined services achieved in this enterprise has to be regarded as groundbreaking. This is of particular interest for changes that are required to be inserted relatively quickly – which is especially relevant for the finance sector.

Ideally, the need for agility can be reconciled with the rationales that foster centralization and regulation. Both Case 9 and the four BICC cases offer a powerful lever to tackle this seemingly impossible task: The definition of BI services and the design of BI service oriented management concepts. A map of self-contained services helps to break down the complex tasks of BI maintenance from a service-user perspective and to distribute the services across different units. By grouping the
services based on their different needs for centralization, a hybrid of a decentralised and a centralised approach can be designed. As the experiences with the backend-systems highlight, it is recommendable to also add “informational veins” which transport messages on events at the backend (e.g. changes in the source system) or at the application side (e.g. new analytical requirements) – implemented e.g. by supporting infrastructure workflows or interfaces that are adhering to the Service Oriented Architecture (SOA) concept. Flexibility on the technical side supports agility on the application side.

Based on these considerations, it is proposed here to distinguish between three classes of services that are differentiated by the criteria participating partners and possibility to be based on well defined and technologically supported processes. This draft of a service based concept aims at exploiting the potential of decentralized self-services as far as possible without impeding the potential of a BICC to foster integration, governance, and efficiency. It is visualized in Figure 2.

Figure 2. Service classes and responsibilities

Class 1 refers to technical changes that can be tracked with workflow software and executed jointly by the IT department and the BICC in a semi- or even fully automated fashion. Examples encompass modifications to the report layout or in the calculation of performance indicators. This type of service needs to be handled at the provider side, but – due to its standardized nature – can be triggered from users in a self-service fashion. Streamlining such activities supports fast response times for standard changes while leaving data quality and backend integration tasks in the hands of the BICC. Furthermore, when system supported, it also fosters transparency e.g. regarding prioritization and front-end-integration – all of which are core concerns of the user side.

Class 2 addresses tasks that have repercussions through the whole system and involve more than one user department. Even in case of being well defined, these tasks cannot be equally automated as they involve negotiation and bargaining activities. Also, the initiative for starting a Class 2 service might just as well come from the BICC, e.g. in case of identifying new opportunities regarding data usage. Separating Class 2 from Class 1 services further increases a transparent prioritization and backlog handling while at the same time utilizing the role of the BICC as a coordination and communication hub between the different departments and the IT side. A careful handling of Class 2 type services can be expected to facilitate data quality management, the integration of external data sources, and the systematic built-up of cross departmental solutions.

Class 3 involves the maintenance and release development for individual solutions which are totally evading any kind of standardisation, e.g. the design of a prototype for a new class of analytical systems. These are separate projects which are naturally dealt with by a team of representatives from the user department and the BICC side. They might later trigger Class 2 or Class 1 services – when a designed system is going to be embedded in the overall BI infrastructure. Such services need to be dealt with altogether manually as there is no template to apply.
Figure 2 visualizes the three classes and gives some examples.

6 DISCUSSION AND OUTLOOK

Trailing the ever growing size and relevance of BI infrastructures, the subject of “BI organization” is likely to come further into focus as well. The presented results provide explorative insights into a particular variant of a BI organization: A dedicated and central BICC – a “Business Intelligence Competence Centre”. As has been shown, the establishment of a central BICC can for several reasons support a more professional development and maintenance of BI solutions. Its weaknesses primarily lie in transparency and reaction times – as known from other centralized IT approaches. To address them, a concept has been drafted that distinguishes between three classes of BI services which allow for a differentiated and staged approach to professionalization.

The concept is understood to be a first building block to an agile and IT supported BI development. It is conceived to be built on a defined service management concept and to be technically supported by a SOA architecture. In further steps, the presented results need to be fleshed out, coupled with concepts for BI service management and SOA and be validated by the use of prototypes.

Limitations of the study lie in the need for deeper and more solid statistic evidence, in the requirement for additional qualitative validation steps, and in the confinement of the exploration to the finance sector. Regarding the empirical data, the presented results are understood as a rather broad first step which is not meant to provide final and comprehensive results. However, together with the conclusions derived from the qualitative study they deliver some grip for the design of a much more sophisticated quantitative empirical instrument. Besides, additional interviews might help to gain further insights into possible applications areas, particular restrictions and additional options regarding the implementation of the concept.

The sectoral limitation should also be scrutinized. However, while the finance industry indeed brings a specific set of BI requirements (e.g. real time data feeds from trading systems) and unique BI applications (e.g. for risk management or data mining), the presented arguments are equally valid for other businesses as well. An exception is the need for very fast development cycles. But in times of complex global turbulences it can be expected that on a mid term time horizon this type of setting will become relevant for most other businesses as well – with the finance sector again becoming the forerunner in the domain of BI solutions.

Abstract

An appropriate use of various pedagogical strategies is fundamental for the effective transfer of
knowledge in a flourishing e-learning environment. The resultant information superfluity, however,
needs to be tackled for developing sustainable e-learning. This necessitates an effective representation
and intelligent access to learning resources. Topic maps address these problems of representation and
retrieval of information in a distributed environment. The former aspect is particularly relevant where
the subject domain is complex and the later aspect is important where the amount of resources is
abundant but not easily accessible. Conversely, effective presentation of learning resources based on
various pedagogical strategies along with global capturing and authentication of learning resources
are an intrinsic part of effective management of learning resources. Towards fulfilling this objective,
this paper proposes a multi-level ontology-driven topic mapping approach to facilitate an effective
visualization, classification and global authoring of learning resources in e-learning.

Key words: Ontologies, Topic Maps, E-learning, Knowledge Management
AN ONTOLOGY-DRIVEN TOPIC MAPPING APPROACH TO MULTI-LEVEL MANAGEMENT OF E-LEARNING RESOURCES

1 INTRODUCTION

E-learning is “the delivery of educational content via electronic media” (Tastle, White & Shackleton, 2005) (p. 242). To improve the effectiveness of e-learning, the constructivist learning paradigm (Papert, 1990) proposes utilizing multiple student-centred learning strategies including collaborative learning, explorative learning, adaptive learning, and concept mapping for facilitating the smooth transferring of knowledge in knowledge construction. While these strategies do assist learners with their knowledge construction, they also create a problem of information overloading due to an enormous amount of learning resources generated (Vivek, Steven, Dennis, Gretchen, 2007). Such information overloading prevents learners from effectively wading through this superfluity of information in an e-learning environment. As a result, a well-organized representation of course concepts, learning resources, learning tools for facilitating the effective and efficient use of learning resources is essential for successful e-learning.

Numerous developments have emerged using ontologies and semantic web technologies for addressing these problems (Jin et al., 1999, Nejdl et al., 2002, Anderson & Whitelock, 2004, Sampson et al., 2004, Dicheva & Dichev, 2006, Gasevic & Hatala, 2006). These developments, however, have not yet been fully incorporated into the existing e-learning scenario due to the challenges involved in implementing them. Existing e-learning websites are still predominantly based on the first generation of learning management systems (LMS) such as blackboard, WebCT, Top class, Learning space, Virtual Laboratory, FirstClass, Moodle and others. These systems do not support for effective management of e-learning resources (Hatem, Ramadn & Neagu, 2005). The reason for this is that these systems are created for human and machine readability but not for computer understandability. To effectively manage learning resources, improving machine understandability and enabling intelligent information processing are critical.

Semantic web is a promising solution to enable intelligent web-based information processing (Berners-Lee, Handler & Lassila, 2006). Realizing the potentials of semantic web technologies in education, initiatives using semantic web technologies in e-learning started in late 90’s (Jin et al., 1999, Nejdl et al., 2002, Nilsson, Palmer & Brase, 2003). The major argument for this is that the availability of massive information is of no use, unless the ‘right information in the right context with the right level of details to the right person at the right time’ (Holger, 2003) is delivered. There are further developments towards addressing the problems of information representation, retrieval and reuse including topic mapping (Mizoguchi, 2004, Vatant, 2004, Dicheva et al., 2006) and resource description formatting (RDF) (Garshol, 2004, Yang et al., 2006).

Regardless of these developments in using topic mapping and ontologies in e-learning, very little or no evidence is presented to confront specific issues that online learners face. These critical issues include simple and flexible visualization (Dicheva, Dichev & Dandan, 2005b) and representation of e-learning resources, single point access to all learning resources (Dicheva et al., 2005c), and quality assured sustainable resources for reusability (Brase & Nejdl, 2003). The need to address these issues is further reinforced by the recognition of the stakeholders on the critical importance of a proactive use of diagrammatic representation of course content and effective management of learning resources for successful e-learning (Sridharan, Deng & Corbitt, 2008).

This paper proposes a novel approach for topic visualisation, representation and authoring features to fulfill specific e-learning requirements by extending our earlier work on the identification of critical success factors for sustainable e-learning (Sridharan et al., 2009). In particular, this paper introduces a new dimension to knowledge representation of learning resources based on pedagogies employing topic mapping paradigm. This helps learners create their mental models by choosing the learning path
based on their learning styles and preferences and allows them to follow a step-by-step process in their knowledge accumulation processes. Furthermore, the proposed approach enables a sustainable learning object repository, proactive contribution of learning resources with authentication facility.

The remainder of the paper is organized as follows. In Section 2, the research questions and significance of the research are covered. A description of the theoretical background followed by a brief review of related work is presented in Section 3. An ontology-driven topic mapping approach is presented in Section 4. Finally a summary with future research is included in Section 5.

2 RESEARCH QUESTIONS

A massive amount of learning resources is generated through various pedagogic strategies in the current e-learning environment. Some of these resources are generated using disparate learning tools such as discussion forums, e-mails, chat, open courseware materials, useful links etc. Such a rich collection of learning resources provides learners with numerous opportunities for reinforcing and strengthening their learning through effective knowledge construction. It, however, comes with various shortcomings including (a) ineffective use of available learning resources, (b) absence of facilities to capture valuable tacit and explicit knowledge generated, (c) scarcity of time and effort required by domain expert to capture and maintain these resources, and (d) deviation of learners from their mainstream learning activity while trying to interact with multiplicity of tools and technologies associated with an online course.

Against this background, the main question for this research is ‘how to realize effective transfer of knowledge through efficient capturing, eliciting, organizing, authenticating, retrieving and reusing learning resources in an e-learning environment?’. Following this question, several subsidiary questions can be defined as follows: (a) How to represent resources in a way that is easy and fast for learners to intuitively comprehend the course concepts? (b) How to provide a single point access to course resources and tools supporting various learning strategies? (c) How to represent the retrieval results in an organized manner based on pedagogic strategies? (d) How to create sustainable learning resources through global authoring of learning resources with authentication facilities?

To answer these questions, this paper proposes a multi-level course visualization and representation approach through considering an ontology-driven single point entry to e-learning resources through topic mapping. The proposed approach has the following specific features including (a) simple multi-level representation of course material both graphically and textually using topic mapping in a taxonomical manner with provision to expand and collapse based on the selection of a branch by the learner, (b) provision of one point access to both course related resources and tools associated with various learning strategies to prevent learners lost in information ‘space and technology’, (c) provision of easy and fast access to context-specific quality learning resources and tools through navigational topic maps or query-based topic maps, (d) presentation of retrieval results in a pedagogically classified style with freedom for learners to choose their own learning path, and (e) facilities for populating new resources and associated ontologies by participants, pending approval from domain experts using simple easy to use interface through topic maps-based graphic or text navigation.

The proposed approach mutually benefits both learners and teachers in many ways. Learners benefit through effective knowledge absorption through step-by-step course visualization, effective presentation of context specific annotated learning resources and freedom to choose the right resources for learning based on their level and style. A single-point access to all course-related resources prohibits learners from being side tracked from the mainstream activity. Learners can derive a sense of satisfaction to see their contribution appreciated and added to the authenticated learning object repository. Maintenance and sustainability of the learning object repository are made easy as this approach facilitates global contribution with quality check. This ensures that domain experts can focus their efforts towards authenticating rather than populating the repositories for reuse.
3 RELATED STUDY

The constructivist learning paradigm promotes the use of intuitively visual interfaces such as concept mapping (Novak, 1998) and topic mapping (Pepper, 2000) for effective learning. Visual representations are powerful mechanisms for materializing meaningful learning process (Gershon & Eick, 1995, Le Grand & Soto, 2000) in learning environments. Concept mapping is a “technique for representing knowledge in diagrams called ‘knowledge graphs’, which are networks of concepts with relationship between them represented respectively by nodes and links” (Novak, 1998). Concept maps are invented with the objective of externalising the understanding of a domain by learners and experts.

Topic maps represent a collection of topics, their relationships and their information sources. Topic mapping provides a mechanism for intuitively representing course concepts and their relationships between the concepts. In addition, to enable fast and easy retrieval of resources, topic map facilitate merging of electronic indexes similar to back of book index. These indexes are however, derived from multiple sources and anchored to actual resources, but kept separately.

Three key concepts are involved in topic mapping including topics, associations and occurrences (Pepper, 2000). Topics representing concepts are the syntactic constructs processable by machine. Relationships between concepts are determined by the associations with grouping of concepts without any implied direction. Occurrences are a way to binding topics to relevant resources. Such occurrence can be a resource reference such as the uniform resource locator, pdf, doc, audio, video or a string value such as population in a country. Figure 1 gives an example of a topic map in a database course.

![Figure 1. Example of Topic Map with topic, association and occurrence](image-url)

Knowledge management is emerged to enhance the organizational performance through the synergy of people, process and technology and to address the problems of information overload. It is commonly referred to as a systematic process of acquiring, eliciting, organizing, representing and retrieving organizational information and knowledge (Nonaka, 1998, Duffy, 2001). In the current e-learning scenario, learners are often confronted with more learning resources than they can deal with or handle using various pedagogic strategies. To tackle this problem of information overload, embracing the principles of knowledge management in conjunction with the semantic web technology is imperative.
for successful management of e-learning resources. The semantic web is an extension of the current World Wide Web, which envisions intelligent information processing (Berners-Lee, Hendler & Lassila, 2001).

Ontologies are “an explicit specification of a conceptualization” (Gruber, 1995) (p.908). It is the “vocabulary for expressing the entities and relationships of a conceptual model in a domain along with semantic constraints” (Obrst and Liu, 2003). Ontologies are “the metadata schema providing a controlled vocabulary of concepts” (Maedche et al., 2002). Ontology is a document that formally defines the relationship among terms (Berners-Lee et al., 2006). It provides a mechanism to communicate between people and computers through a shared understanding of resources in a domain (Davies and Fensel, 2002).

There are two popular technologies for ontology construction including RDF and topic mapping. Topic mapping and RDF technologies, however, are developed with slightly different flavours for fulfilling similar objectives. Garshol (2004) asserts, “topic maps were created to support high level indexing of sets information resources to make the information in them finable. RDF, on the other hand, is intended to support the vision of semantic web through providing structured metadata about resources and a foundation for logical inferencing”. Both technologies aim at realising the semantic web vision of machine processability by annotating, associating between concepts and attaching more semantics. Topics maps are an ISO (International organisation for standardization) standard developed in 2001. RDF is a W3C (world wide web Consortium) standard developed in 1997. Web ontology language (OWL) built on RDF is the new W3C recommendation for ontology construction with facilitates for effective reasoning capabilities by consistency checking through inference rules such as transitivity, symmetry etc.

Much research in topic mapping has been done in knowledge visualization (Le Grand & Soto, 2001, Dicheva et al., 2006), knowledge retrieval (Yang, 2003; Garshol, 2004; Shin et al., 2006), knowledge capturing (Dicheva and Dichev, 2006), and managing and reusing repositories (Ahmed, 2000; Dicheva et al, 2005). Several interactive graphic navigating tools and techniques for visualization through topic mapping have been developed (Mondeca, 2001, Fluit, Sabour & van Harmelen, 2002, Alani, 2003, Dicheva et al., 2005b). For instance, Topic Maps for Learning (TM4L) (Dicheva et al, 2006) provides support for graph view, text view and tree view of learning repositories. Ontopia navigator (2001), Mondeca’s topic navigator (2001), techuila’s (2001) Topic Maps for Java (TM4J) dynamic visualization (2001), and Alani’s (2003) visualization tool (TGVizTab) provide variations to existing knowledge visualization methods. Addressing the readability of a graph in a complex domain, Munzner (1997) proposes hyperbolic geometry to display large numbers of nodes in the screen. Le grand and Soto (2000) propose an interactive topic mapping visualization tool to represent semantic graphs in three dimension spaces. Nevertheless, automatic generation of graphic visualization using these tools becomes rather cumbersome and incomprehensible for a novice learner, especially in a complex course domain. In this regard, Le grand (2001) recommends topic mapping metrics to deduce efficient positioning of node to enable quick scrutiny of topic and explore the relevant ones in detail. Fluit (2002) proposes grouping instances in clusters according to their classes, while Ahmed (2000) suggests different layers of details in a topic map to display general information and to explore into details once the specificities are identified. The proposed approach adds a new dimension to knowledge representation by including topic maps based presentation of learning tools and resources based on the pedagogic classification.

Yang (2003), Shin (2006), and Vivek et al. (2007) use topic maps to enhance the retrieval of learning resources for overcoming the limitations of key-word based search engines. Yang (2003) presents mechanisms to improve the retrieval results from collaborative learning repositories in semantic retrieval of concept model (SRCM). Shin (2006) proposes conversion of topic maps and RDF metadata for effective retrieval online. Vivek et al. (2007) investigate ways to improve information retrieval capabilities in e-learning. Nevertheless, presentation of retrieved results is equally important for learners to get the best out of the resources through effective classification of retrieved results.
Dicheva (2006) builds an ontology-driven learning repository using topic mapping in TM4L ontology editor, whereas Yang et al. (2006) propose a topic map-driven visual authoring tool (XRVAT) for constructing ontologies. Ahmed (2002) examines the potentials of topic maps as an interface to multi-user document repository. Realising the problems of identification of topics and relationships between them, Dicheva et al. (2005a) highlight the importance of identification of minimal ontology using topic maps. However, facilitating global authoring with quality check is crucial aspect for creating a sustainable learning object repository, which is not given sufficient thought in the literature.

It is evident from the literature that a concerted effort is directed towards tackling the problem of information overload in managing e-learning resources, employing the next generation of web. Visualisation, retrieval and authoring of resources and associated ontologies using topic map is a significant development towards effective management of resources in a distributed environment. Nonetheless, generation of topic visualisation through these approaches become very cumbersome and incomprehensible, especially for a novice learner seeking to acquire knowledge in a complex domain. Besides, not much attention is paid to the representation of retrieved resources generated from multiple pedagogic strategies, which is equally important. Furthermore, global authoring, with authentication facilities, is very critical to create a sustainable learning object repository by capturing both tacit and explicit knowledge for reusability. Finally, single point access to not only to learning resource, but also learning tools will enhance the effectiveness of learning by enabling the learner to focus on the learning activity. Towards filling these gaps, this paper extends the existing research for tackling these specific aspects in an e-learning context. These aspects are simple multi-level presentation and representation of retrieved results through visual graphs, authenticated global authoring of learning resources and single point access to all learning resources including tools associated with various pedagogies.

4 AN ONTOLOGY-DRIVEN TOPIC MAPPING APPROACH

4.1 Motivation

The support for this study comes from our earlier work on evaluating the critical success factors for sustainable learning (Sridharan et al., 2009). This qualitative study entailed interviewing 29 academic staff involved in the e-learning domain from a wide range of function areas including the strategy and policy division, the library resource management division, the technology and media division and, the teaching experts in an e-learning environment. The objective of this study is to identify the critical success factors intertwined within pedagogies, technologies and management of learning resources in an e-learning environment. The critical success factors identified in the study include appropriate choice of pedagogies, proactive use of technologies supporting pedagogies, understanding the pedagogical principles behind technologies, appreciating and exploiting the full potentials of various technologies supporting pedagogies, effective management of learning resources through selected metadata and ontologies and, more importantly synergising pedagogies, technologies and management of learning resources for sustainable e-learning. However, it was apparent, that there are some
practical difficulties which prevent teaching staff from incorporating these factors in reality for enhancing the e-learning effectiveness. Some of the prohibiting factors identified in the study include ineffectiveness of LMS, lack of time and effort, lack of interest, problems associated with knowledge sharing etc. in proactively employing the identified critical success factors in reality. This paper addresses the specific problems related to proactive use of concept mapping technique as a pedagogical strategy, associated technologies and effective management of learning resources through ontology-based topic map approach.

In this direction, this research aims to propose a novel approach for extending the topic visualisation, representation and authoring features to fulfil specific e-learning requirements. The proposed approach consists of five modules to facilitate effective management of learning resources, namely student module, domain expert module, ontology module, authentication module and learning resources module. To comprehend the process involved in each of these modules, a motivating scenario is given in the following with a detailed explanation of functionalities of each of the modules.

4.2 Typical Scenario

To illustrate the proposed ontology-driven topic mapping approach, we take a typical learning scenario, where the learner is required to accomplish a task for fulfilling the course objective. Let’s take an example where the learner is expected to finish an assignment on normalization in a database course before a short deadline which is approaching. The learner is required to gather as much knowledge as possible to complete the assignment before attempting or posing any queries or doubts related to assignment. In the current e-learning set-up with LMS, the learner has to wade through multiple sources, multiple paths, and multiple modes to accomplish the task. In this scenario, despite spending a lot of time and effort, it is highly likely that learner either got side-tracked or missed some important aspects due to ineffective organisation and presentation of learning resources.

4.3 Student Module

Student module facilitates a systematic presentation of topics, resources and tools in an organised manner using topic maps to enable step-by-step knowledge acquisition process for fulfilling the task. This module contains facilities for viewing the entire course in multi-levels with more details in a particular sub-topic shown on demand by the learner. Basic association types namely pre-requisite, co-requisite and follow-up concepts are represented. Learners have a choice of navigating through textual and graphical modes. Both text view and graphic view would contain the semantic overall view of the course to construe the main concepts represented by nodes in a course at a glance. Each node will have four options namely expansion, view resources, search, append within the chosen sub-topic.

By choosing the expansion option, the chosen branch will expand. The next level of details will be provided in both text and graph view. Alternatively choosing view resources option will generate a page with three frames as shown in Figure 2. The top frame of the page will contain a topic map of classified resources (such as basic learning material, collaborative learning resources, interactive learning resources, concept maps creation facilities etc.). The middle frame contains an annotated version of all relevant resources related to the chosen node from the learning object repository enabling the learner to decide their learning path. The bottom frame will contain all related tools associated with the chosen pedagogic strategy. The generated result will contain aggregated resources of all the topics based on the semantic relationship between topics represented by ontologies in the chosen node. Search option will generate the same result with classified representation of resources using both the key-word and semantic relationships from ontology structure. In addition, if learners find the resources presented to them have not clarified their understanding, they can access the query tool based on a simple web interface from the same knowledge representation sub-section to pose queries. This will automatically be directed to domain experts and peers without the need to go outside the learning space. On the other hand, if learners either found a very good learning resource or have...
some queries relating to the chosen node, they can populate the learning object through a similar interface along with metadata and ontologies.

This module is linked with the ontology module and the learning object repository module for facilitating effective retrieval of context-specific learning resources. In this approach, the course structure is pre-determined and remains relatively static with the objective of keeping it simple and comprehensible to a novice learner. The ontologies and learning resources at the back end is dynamic with facilities for uploading new resources with associated ontologies. Considering that topic maps are powerful for visual representation and navigation capabilities, the use of XML (extended make-up language) based topic maps (XTM) technology is proposed for this module deriving basic knowledge structure from ontologies.

Figure 2. A multi-level learning resources visualization and representation

In the given scenario, the learner chooses the relevant node namely the normalization concept using this approach and then selects the option of viewing aggregated results or going into further details. By clicking on the view option, the system presents a categorized list of all resources on normalization and the supporting tools. The presented resource result is classified into basic resources, resources from collaborative learning such as frequently asked question, interactive learning resources such as self-test quiz and problem-based learning resources, explorative learning resources (such as open course ware material, additional reading material, useful links with annotation), tools for constructing mental maps such as concept map tools and tools for practicing problems (intelligent tutoring systems) or self-testing their knowledge. The learner can either choose aggregated result to show all resources in the chosen node and choose a specific category based on the stage of learning and preferences and styles of learning. The chosen resources will be rendered in a new page in detail with facilities for tracking of completed sections.

4.4 Domain Expert Module

The domain expert module consists of simple web 2.0 based friendly interfaces for manually creating, updating, deleting topic maps along with learning resources and ontologies. The same interface is used for posting queries and answers to queries, which will automatically be added to the learning repositories after quality check by domain experts. Apart from this domain experts can create some inference rules to create automatic authentication of learning resources either based on the author, source and other selected key elements. This module is constrained by ontology module and authentication module.
4.5 Ontology Module

The ontology module is at the back end of the system anchored to both the visualization module and the learning resources module. This module comprises of four types of ontologies such as context ontologies, structure ontologies, domain ontologies and pedagogy ontologies. When a node is chosen or a keyword-based query is entered, the ontology base is activated to get additional information for both retrieving and classification of resources before presenting it to the learner. Using Protégé OWL, the representation of disjoint classes to assert a concept can not be instance of more than one class, consistency checking through a reasoner, and adding value restrictions can be effectively executed. Also, OWL is powerful for inference due to its expressivity and stricter rules such as transitivity, symmetry, functional properties etc. Due to these reasons, use of OWL is proposed for this module. A sample ontology construction using Protégé Owl is given in Figure 3. All the complex relationships between concepts and inference rules are included but concealed to the learner. This complex semantic relationship between concepts enables effective retrieval based on the semantically related concepts and representation of organized results.

![Figure 3. A sample construction of ontologies using Protégé OWL](image)

4.6 Authentication Module

The authentication module is anchored to the domain expert module and the learning resource module. It facilitates either an automatic quality check based on the inference rules schema created by experts or sending alerts for domain experts to check for quality before committing the resource in the learning object repository.

4.7 Learning Resources Module

Finally the learning resources module contains heterogeneous learning resources which are anchored to student module, domain expert module, ontologies module, and authentication module. Use of
XTM technology is recommended to represent this module. All relevant quality learning objects are included, irrespective of the type and source of resource. The resources could be an audio, video, outside link, discussion material, question and answer, example, definition etc.

5 CONCLUSION AND LIMITATIONS

Having built on our earlier work in evaluating the critical success factors for sustainable e-learning (Sridharan et al., 2009), we in this paper have introduced a novel approach to overcome some of the practical difficulties in the process of embedding some of the critical success factors identified in our earlier research for successful e-learning. Specifically, we have addressed the problems associated with using concept mapping techniques, effective representation of learning resources, sustainable and reusable management of learning resources through ontology-driven topic maps in e-learning websites. This leads to some key contributions to the domain of e-learning including multi-level topic visualisation, resource representation using topic mapping, and authenticated global authoring of learning resources with critical ontologies. Furthermore, we have proposed a novel approach that is capable of recommending a single point access to not only learning objects, but also course related tools using a single interface, wherever applicable, to avoid learners losing track of their mainstream activities.

In this paper we have proposed to blending topic maps and OWL for presenting the course in a simple and comprehensive manner through topic mapping and concealing the complexities of semantic relationships in a course behind OWL ontologies. To fulfil the objective of effective presentation of course structure in a simple and comprehensible manner, a multi-level presentation of course through topic maps is pursued. To help learners grasp the basic knowledge before exploring the details of a course, high level overview of domain knowledge is proposed with expansion and collapsing facilities. To effectively represent retrieval of learning resources, this paper proposes a topic mapping based classification of resources based on pedagogies used in a course incorporating semantic annotations. To enable successful and sustainable management of learning resources, this approach proposes mechanisms for populating new resources and associated ontologies within the topic-maps based framework pending quality check by experts.

The study is limited in a number of ways. Firstly, this study is based on the outcome from a qualitative study based on a small sample size. As a consequence, generalization across the learning community is not possible. Secondly, evidence of support for such an approach is one sided as the learning community, other key stakeholders in e-learning environment, are absent. Thirdly, the success of this approach requires the identification of critical metadata and ontologies for creating a sustainable learning object repository, which has not been identified. Finally, various options and mechanisms for either developing a stand alone system or integrating with LMS and content management have not yet been explored.

Future direction for this research requires more in-depth study incorporating learners’ view is critical for wider acceptance of this approach. In addition, identification of critical ontologies from teachers and learners perspectives to effectively implement a system-based on topic maps is crucial. Based on the results, development of a prototype with functionalities for presentation, representation, retrieval, authentication, inference and populating mechanisms is necessary to implement in reality. In addition, identification of mechanisms for keeping track of individual learners’ progress by representing completed topics in one colour and yet to complete in a different colour within the topic map paradigm will enhance the use of the tool.

EXPLORING THE DEVELOPMENT OF SOCIAL ALIGNMENT WITHIN AN INNOVATION CONTEXT

Tadhg Nagle, University College Cork, Ireland
William Golden, National University of Ireland, Galway

Abstract
There has been increasing attention in IS literature around the technology-business relationship and the concept of social alignment. However, little attention has been given to how or why social alignment should be developed. Further examining the concept this paper explores the development of social alignment within an innovation context. Using canonical action research the study is based within an innovation network. Primarily focusing on four organisations, a lack of social alignment was diagnosed. In particular, it was found the business executives did not fully understand the potential of the new technologies available. An intervention was then planned to facilitate the organisations in utilising a business model framework for developing social alignment by creating a common understanding between the business-technology executives. The study which took 24 months to complete involved over 110 hours of primary data. The results highlight the positive impact of the business model framework in developing social alignment. However, it was found that the business model framework alone is not enough to develop social alignment within an innovation setting. Careful thought should be put into who facilitates the development of social alignment and a shared understanding, as CTO’s are often too caught up in day-to-day operations to fulfill the role.

Keywords: Social Alignment, Business Models, Shared Understanding

1 INTRODUCTION

The importance of alignment has been frequently noted (Avison et al., 2004). So much so, it has been viewed as a core component to the theory and practice of IS strategy (Galliers & Newell, 2003). Using a framework set out by Horovitz (1984) for the process of strategic business planning, Reich and Benbasat (1996) converged alignment research into two dimensions of business and IS/IT alignment: (i) intellectual and (ii) social. The intellectual dimension, which was developed from the work of Henderson and Venkatraman (1989) refers to the existence of a high-quality set of interrelated business and IS/IT plans (Reich & Benbasat, 1996; Tan & Gallupe, 2006). However, given that the majority of research is positioned within the intellectual dimension (Tan & Gallupe, 2006), it is evident that the lack of senior executives in the formulation of IS planning and the presence of internal inhibitors to use IS strategically, demonstrates the deficiency with this approach to IS/IT alignment (Kearns & Lederer, 2000). To aid understanding on how to overcome this problem, this paper focuses on the social side of alignment, which has been highlighted as a potential solution (Feeny et al., 1992).

This paper begins by defining the concept of social alignment and subsequently proceeds to highlight the compatibility of the business model as a tool for creating a shared understanding; thus developing social alignment. Furthermore, the paper describes the business model concept as defined by Osterwalder et al. (2005) and in particular notes the untested proposition by the authors, which puts forward the business model framework as a platform for common communication and shared understanding. Justifying the use of canonical action research the paper proceeds to highlight the suitability and relevance of the Industry Led Research Project (ILRP) that bounds the innovation network within which the study is based. In addition, along with the description of the implemented action/intervention, the findings collected from the diagnosis and evaluation stages of the research
methodology are outlined and analysed. Finally the findings are discussed highlighting the main
conclusions from the study.

2 THEORETICAL GROUNDING

2.1 Business Models

The use of the term ‘business models’ within academic literature became particularly noticeable
during the dotcom era (Osterwalder et al., 2005). This association has been explained by the business
model concept taking a central role in describing how organisations should compete in the digital
economy (Lee, 2001; Seddon et al., 2004). This link is further supported by views that Internet
technologies have challenged conventional methods of value creation and also generated a wide
knowledge gap between IT developers and organisational stakeholders (Schmid, 2001; Gordijn &
Akkermans, 2001). However, persistent confusion over the domain during the period earned it the
label of being the “most discussed and least understood aspect on the web” (Rappa, 2001).

Since then a strong vein of research has developed around using business models in communicating
the “core logic”, “business system” or value creation within an organisation (Linder & Cantrell, 2000;
Petrovic et al., 2001; Auer & Follack, 2002). More process-oriented definitions declare that a business
model is a “story that explains how an organisation works” (Magretta, 2002) and the first step in
gathering requirements for business information systems (Gordijn & Akkermans, 2001). In addition to
these broad comprehensive descriptions, there has been an accumulation of business model definitions
detailing its primary components and possible interrelationships (Pateli & Giaglis, 2003). One such
eample is the highly recognisable definition given by Timmers (1998), stating that a business model is
“an architecture for the product, service and information flows, including a description of the
various business actors and their roles; and a description of the potential benefits for the various
actors; and description of the sources of revenues”.

However, like the definition stated by Timmers (1998), many descriptions of a business model list
numerous components which has nullified their attempts to clear confusion and inversely added to the
ambiguity around the domain (Pateli & Giaglis, 2003). As a result, more recent approaches at creating
a universal definition of a business model have incorporated a methodology of synthesising large
quantities of past research. In an effort to find the most common components in a business model, two
individual studies create a list of components using the criterion that the component had to be
mentioned by at least two authors (Osterwalder et al., 2005; Shafer et al., 2005). Between the two
studies the framework put forward by Osterwalder et al. (2005) has been more widely accepted by the
practitioner community. Summarising the framework, Table 1 highlights the nine components, which
are grouped by Product, Customer Interface, Infrastructure Management and Financial Aspects.

<table>
<thead>
<tr>
<th>Grouping</th>
<th>Business Model Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Product</td>
<td><strong>Value Proposition</strong> – overall view of an organisation’s bundle of products and services</td>

2.2 Social Alignment and Shared Understanding

Evidence has shown that while technology executives view both alignment of business with technology and alignment of technology with business as being very important, non-IS executives only deem the alignment of IS with business planning as being important in gaining competitive advantage (Kearns & Lederer, 2000; Byrd et al., 2006). This is a serious misjudgement, as both types of alignment ensure that senior executives from business and technology give greater commitment to strategic IS resources and gain a strong understanding of each other domains. This results in more effective use of IS resources towards improving organisational performance (Reich & Benbasat, 1996; Kearns & Lederer, 2000). Thus, in order to develop and maintain a mutual/shared understanding between business-IS executives, research efforts began to focus the social side of alignment in the early 1990’s (Feeny et al., 1992).

Social alignment is defined as “the level of mutual understanding and commitment to the business and IT mission, objectives, and plans” (Reich & Benbasat, 1996). Further developing their research framework, Reich and Benbasat (2000) divide the social alignment dimension into short-term alignment and long-term alignment. Short-term alignment is defined as the “state in which business and IT executives understand and are committed to each other’s short-term plans and objectives”. The key factor in determining short-term alignment is the shared knowledge between business and IT executives. More recently, researchers have used the terms convergence, mutual understanding, shared understanding, and shared cognition synonymously to indicated a state where a common ground of comprehension is reached on a certain topic (Johnson & Lederer, 2005). Moreover, with similar emphasis on a shared understanding, long-term social alignment is defined as the “state in which businesses and IT executives share a common vision of the ways in which IT will contribute to the success of the business unit” (Reich & Benbasat, 2000).

With respect to this paper, a number of studies have shown that strong social alignment yields multiple benefits for innovation. Firstly, research has shown strong social alignment has a significantly positive effect on innovation (Jansen et al., 2006). In particular Landry et al. (2002) highlighted that marginal increases in social alignment contribute more than any other explanatory variable in increasing the likelihood of innovation in organisations. In addition, Jansen et al. (2006) discovered that managers might develop “densely” connected social relations within their organisations to increase its ambidexterity and found that informal coordination mechanisms are more important than formal coordination mechanism for developing both exploratory and exploitative innovation.

Moreover, the findings of Subramaniam and Youndt (2005), found that an organisations social alignment enables its ability to develop incremental and radical innovations. In fact, without good social alignment the knowledge and skill held by individuals had a noted negative effect on radical innovation. Practical implications discourage the employment of highly independent experts who are reluctant to share their ideas with their colleagues, as this is counterproductive. In addition, as specialists within a function tend to have similar backgrounds, experiences and career path opportunities, they usually have a specialised language and perspective that may not be easily understood by members outside their department or research unit (Hutt et al., 1995). However, instead of eliminating specialisation that is necessary for focusing on different elements of the technology or market (Dougherty, 1992), innovation management must build communication bridges or shared knowledge between different departments. In a study done by Mom et al. (2007) it was found that information flows from managerial peers positively related to their exploratory activities. From this, numerous unique views of technology can come together to form a vision of how the technology can meet market requirements (Bond & Houston, 2003). Nonetheless, a paucity of such tools that enables clear and shared communication around innovation projects has been highlighted (Christensen et al., 2008).
One of the major aims of alignment methodologies is to get IT and business managers to the same table (Booth & Philip, 2005). This may increase social alignment by increasing the communication between the different departments, however, recent studies have shown that these communication links need to be frequent to create a common understanding within an organisation (Johnson & Lederer, 2005). Furthermore, it has been known that frequent communication alone is not enough. Using a strategic management quote, “one can brief a reluctant manager endlessly without accomplishing anything, unless one comes to realize his hidden resistances and strives to bring them up to consciousness in some way” (Churchman & Schainblatt, 1965). Heretofore, there is a need for a common language of words or symbols that create a positive social influence as different environments, most often than not, use different languages (Reich & Benbasat, 1996). Once this is achieved a synergy of shared knowledge is created (Nelson & Cooprider, 1996), overcoming the problem of having executives on different levels of understanding (Reich & Benbasat, 1996; Bassellier & Benbasat, 2004). Unfortunately, outside the practical suggestions of increased collective encounters (Tan & Gallupe, 2006; Feeny et al., 1992) or formal reporting systems (Preston et al., 2006) there is a scarcity of research in examining the mechanisms and process through which social alignment can be achieved (Cohen & Toleman, 2006).

However, linking the use of business models in developing social alignment, Osterwalder et al. (2005) specifically posits “the business model concept helps increase the mutual understanding between the business and IT/IS domain. It creates a common language and shared comprehension”. However, the Osterwalder et al. (2005) paper is purely theoretical and even though the framework has been widely adopted by the practitioner community, there has been no rigorous validation of any of propositions put forward in their paper. As a result this paper focuses on:

**RQ: Investigating the effectiveness of a business model framework in developing social alignment, within an innovation context?**

3 RESEARCH METHOD

Analysing the different research methodologies, action research stands out as a strong choice as it not only merges theory and praxis but also uniquely “associates research and practice, so research informs practice and practice informs research synergistically” (Avison et al., 1999). In summary “action research strives to marry rigor to relevance by conducting scientific research in the setting of a real world problem”. Taking this into account, action research has been deemed as being very suitable for the IS domain as: (i) IS is a highly applied field “almost vocational in nature”, (ii) action research is highly clinical and puts the researcher in a helping role, (iii) the aim of action research is to produce highly relevant findings which is an important factor in the significance of IS research (Baskerville & Wood-Harper, 1998). Throughout the twelve different types, canonical action research is the most widely accepted form of action research (Kock, 2004). Using the Susman and Evered (1978) five step model of: (i) diagnosis, (ii) action planning, (iii) action taking (intervention), (iv) evaluation, and (v) reflection, the researcher collected data over a 24 month period.

Another reason why action research was chosen is that the researchers were externally involved in the Industry Led Research Project (ILRP) within which the study is based. This project enabled an existing network of primarily four eLearning firms to gain access to substantial R&D resources. Ranging in size from 20 to 150 employees, the organisations had individual revenues of up to €15 million around that period. In addition, all of the organisations are primarily involved in the industry (compliance and regulation eLearning sector) on a European and/or global basis and are in existence between 10 and 20 years. Their customers primarily involve the pharmaceutical, high-tech, financial and hospitality industries. Starting in 2006 the ILRP partnered the organisations with a research institution, which specialised in Web 2.0 and semantic technologies. As a member of the institution the researcher was able to collect primary data for over 24 months of the project, in which the eLearning organisations faced the technological disruption of Web 2.0. Summarised in Table 2, over 110 hours of primary data was collected from multiple sources and multiple informants using
interviews and participant observation. In order to answer the research question the action taking (intervention) was carried out over six months and involved the researcher demonstrating how the business model could be used as a communication platform. This was done at a number of open days but also on a one-to-one basis with the organisations. In total, 17 semi-structured interviews were undertaken, lasting between 45 – 90 minutes. Participant observation was used throughout the 24 months in gathering data from inter-organisational meetings and open days. Even though the meetings were not as formalised as interviews the researcher was still able to collect data by asking questions or noting points of information that complied with the questions asked in previous interviews. Furthermore, on more than one occasion meetings were conducted over a full business day. Open days also consisted of one to two day events where all of the organisations in the innovation network were invited to one location to discuss current issues and topics associated with the network. Finally, analysis of company/industry reports and press releases that applied to period and organisations in question were also used to triangulate data used in the study.

4 FINDINGS

Primarily focusing on the data gathered in the diagnosis and evaluation stages of the action research methodology this section highlights the findings of the study. In particular, the cause and effect of poor social alignment is outlined in the diagnosis section. Furthermore, the use of the business model as a communication platform is evaluated with regard to its impact on social alignment between the business and technology domains of the organisations.

4.1 Diagnosis

While collecting data during the diagnosis stage of the project, it became apparent that the participation of the eLearning organisations was significantly lacking. When the project started it was assumed that the eLearning organisations would become actively involved in developing the innovative technologies researched within institute. However, this was not the case. To encourage participation from the organisations open days were conducted. These consisted of presentations and demos of the research being accomplished. However, after they had taken place there was no observed increase in participation between the eLearning organisations and the institute. Such was the lack of participation, the Programme Director (Enterprise Ireland) felt that after the ten months of the project, the likelihood of any of eLearning organisations commercialising any of the research was exactly same as when the project started.

Analysing why the open days did not work it was identified that all the attendees to the open days were all people involved in the technology side of the organisations. In particular, it was highlighted by the Director of Informatics (Enterprise Ireland) who had the responsibility of overseeing 3-5 similar ILRP’s. With in depth experience of such initiatives the Director of Informatics pointed out that “the typical person that shows up to the open days 2-3 times a year, tends to be the technical people from the companies. That’s all well and good and they maybe getting value from it. But at CEO level, in order to keep them supporting their techies ..... it’s really important and useful for them to see this is
how it (technology research) might change how they do things.” This in turn “allows the technical guys the space and the time for them to stay involved in the project”. This clearly shows that there was a breakdown in communication between the technology and business sides of the organisations. Furthermore, it demonstrates that the business executives did not have enough information to fully grasp how the technological research could potentially impact on their business. As a result they had no reason to commit resources to the innovation initiative.

Originally, the fact that the participants were technologists was not seen as a problem, as it was assumed that they were in the best position to communicate the opportunities back to their counterparts or CEO of their organisation. However, the early open days were dominated by discussions on deep technological topics such as: SCORM (most widespread eLearning standard) compliance, privacy, security and the incompatibility of the new compared to those used in industry. Moreover, the majority of these discussions focused on the immediate obstacles rather than exploring potential opportunities through the new technologies. Furthermore, with all the discussions of the open days focusing on technological issues, very little business issues were discussed. In addition, it was found that even though the attendees found the open days useful when they reported back to their respective managers they got little or no response. Highlighting this fact, one of the regular attendees stated “the open days have been great but when we go back and report to our managers, they tend to glaze over it” (R&D Engineer, Company A). This is not surprising as the report would have consisted mainly of technological issues with very little information of the business opportunities being afforded to them by the project. In a sense, the attendees communicated the progress of the project in a totally different language and with information that was not deemed relevant.

Further analysing the communication methods used in the eLearning organisations uncovered a high emphasis on financial analysis around strategic activities and exploring new technologies. As noted by the Director of Informatics (Enterprise Ireland), when creating a vision for the organisation, they usually put it in “financial terms”. In addition, as noted by the CTO of Company C, communicating the benefit of exploring or investing in new technologies through financial models is often not possible. He stated, “imagine how hard that is to sell to the CEO”, when explaining a case when he needed to invest in research activities without being able to calculate the financial terms of the activity. In fact there is evidence that each of the CEO’s communicated strategies in financial terms. From the perspective of Company A, their strategy was to become a $100 million company. In order to fulfil this vision the CTO saw his role as making the technology as efficient as possible. As stated by the CTO (Company A), “the technology part of that (strategy) will not be too different from how we do it today…..do more of the same better faster”. Furthermore, the CTO clearly noted that “as long we have a business case to hang around it (technology investment) the CEO isn’t too concerned about what we do”. Company D pursued the strategy of monetising any effort across their clients through their services model. This was evident in a meeting with the CTO as he said he would only be able to participate in the project if he was able to demonstrate an “aggressive return”. In addition, Company B pursued a compound growth rate of 35% and similar to Company D would participate if substantial gains could be financially identified.

4.1.1 Summary of Diagnosis

Summarising the data gathered, it was found that the organisations had a communication breakdown that was impacting on their ability to create a shared understanding and shared vision. In an effort to overcome this obstacle a planned intervention to use the business model concept as defined by Osterwalder et al. (2005) was initiated. Consequently, it was predicted that with the business model as a communication platform the technology side would be better able to communicate the opportunities of the project with their business counterparts. In particular, it would allow the CTO’s better describe the potential of the new technologies being developed within the institute but also better demonstrate the potential impact of not developing the technologies. This would further enable the CEO’s better understand the business potential of the technologies and also get the CTO’s to explore aspects of the
new technologies beyond that of immediate technological obstacles. This would in-turn, increase participation in the project and allow the technology to explore new possibilities within the project.

4.2 Evaluation of Intervention

From an overall perspective the intervention and use of the business model was a success. The proceeding open day after the intervention showed a marked increase in participation by all the organisations. Furthermore each of the four firms committed to future participation. Company B wanted to get more involved in mobile devices and creating a future technology roadmap around that area. Company D brought one of their customers to the open day and noted very high interest in commercialising some of the technologies in the institute. Finally, Company A expressed keen interest in the area of new forms of learning assessment. The increased interest from the eLearning organisations was also noted by members within the institute. It was the first time that they felt the organisations had got actively involved in the project. From Enterprise Ireland’s perspective they were also satisfied with the results. the Programme Director reflected on the chances of some research being commercialised, and said “Not that I thought it was impossible but when we started off it was a ninety-one shot and now its still not passed the fifty-fifty mark but is more sixty-forty. But there was a chance that it would have never got off the ground and stayed at nine-to-one”. Also the Programme Director directly stated that we had “achieved our first objective…now there is more than just an awareness (by the e-Learning organisations) of whats going on”. However, he did also note that the eLearning organisations “were still in that firefighting mode … they are still driving their current business and they are all succeeding in that but that’s not giving them any bit of time to look that bit further down the road”.

Having noted the evidence of success it was important to attribute that success back to the intervention. During a meeting with the Programme Director (Enterprise Ireland) he discussed the reasons he felt were the cause for the increase in participation in the project. Firstly, the Programme Director felt that the business model intervention gained the buy-in from the upper level management of the eLearning organisations. As he stated “the priority was to open the eyes of the companies…. I think we definitely achieved that”. However, it was noted that this was not done by closing the divide between the technology and business functions but by directly communicating the business value of the technologies directly to them. Furthermore, there is evidence to demonstrate the intervention directly impacted on the participation of the eLearning organisations in the project. The Programme Director felt it “made it easier for the rest of the open days as they will be supported by their senior executives”. Secondly, he stated that after the intervention many of the “senior commercial guys” began to see opportunities in the eLearning market relating to the technologies being developed in the institute. Thirdly, he specifically noted that “from a CEO level they would have appreciated that you have helped them understand the need for a continuous method for their R (research) along with their D (development)”. Further endorsing the intervention and highlighting its effectiveness, the Director of Informatics (Enterprise Ireland) made the business model a compulsory component of future ILRP’s.

Success from the business model intervention was also quite evident within the companies themselves. While interviewing the CTO in Company A he said “you have the (CEO) all fired up about it (the project) and I don’t know what you did. It will make it a lot easier for us to have conversations” with the institute. He also noted that the CEO was “quite bullish” about the project and without the intervention the CEO “would have struggled to map that (the project potential) back into the realities of what we want to do over the next two years”. Directly after the intervention, Company D saw an innovative opportunity with one of their biggest customers (multinational – over 14000 employees) and brought their Chief Learning Officer from the US to the next open day. This highlighted the fact that senior managers began to see opportunities from the technology and began to take action in utilising the research. This was a very positive result for the project as there was a risk that the eLearning organisations would think the technologies had very little practical applicability. After the intervention, there is clear evidence to show that the CEO of Company C began to take notice of the new shift in eLearning. In a meeting he explicitly stated, “I am really intrigued in this formal/informal
learning and it scares the hell out of me a little bit”. The CEO also added that he saw “definite opportunities for companies like us” within the Web2.0 domain. This is a particular case in point, as it is coming from a company that saw very little value in the new technologies. They firmly believed that their customers would not be willing to pay for extra layers of functionality in their product.

As the evidence suggests there is a strong link between the intervention and the increased participation and innovative behaviour of the firms. However, further evaluation of the intervention shows that none of the eLearning organisations implemented the business model framework as a way of common communication platform for creating a shared vision after the intervention. Investigating why Company A didn’t use the business model framework, the R&D engineer found that it did give “some good use cases on how to apply the technologies” but for the most part was “boring”. He further stated that “it will be easier (to communicate the value) when we get to see pieces of the technology”. At that time the CTO was also having problems in communicating the value of the technologies. In an interview he explicitly stated having a problem in “getting a better handle on just what is it that you (research institute) are doing that might benefit us”. It was clear he was having a problem with this as he reiterated “it’s hard to tie all this together, unless you have the vision of where it ends up”. Interactive Services were having the same problem. Their CTO was also finding it difficult to tie all the new technologies together to form a business case or vision to communicate to the CEO and customers. He pushed the need to have “real problems to glue the technology together”. Furthermore, it was deemed that use cases were more appropriate for method for the CTO’s to communicate the value of the technologies. As a result, both ThirdForce and Intuition collaborated on generating use cases to aid the rest of the organisations to better see the potential of the technologies and understand how they could implement them in an industry specific scenario. Both companies dedicated a resource to the task and a number of use cases were developed that covered the pharma, financial and hi-tech industries. However, as noted by the Project Leader within the Institute, “they did not go far enough with the use cases” and failed to push the boundaries of what was possible. Nevertheless, after these use cases had been developed the organisations were “able to visualise” (CEO, Interactive Services) the technologies in an actual real life scenario.

4.2.1 Summary of Evaluation

Outlining the key findings Table 3 summarises the evaluation of the intervention. Above all the business model framework clearly communicated the potential value of the technologies being developed in the research institute, which in-turn gave increased freedom to the CTO’s and technology personnel to get more involved in the project. Evidence pointed to increased commitment to the project from the organisations, the cause of which can be linked back to the business model intervention. However, this all resulted from actions taken during the intervention. One of the objectives was to show the value of the business model framework so that the CTO’s would utilise it as a common communication platform. However, there was very little evidence that CTO’s utilised the business model framework. One of the main reasons was that the CTO’s were more interested in understanding how to apply the technologies to current real life use cases rather than exploring the future possibilities. This is consistent with the general modus operandi of the CTO’s as they were constantly dealing with day-to-day technological issues.

Table 3: Summary of Key Findings
5 DISCUSSION AND CONCLUSIONS

As stated by Reich and Benbasat (1996) one of the key influencing factors of social alignment is the type of communication used in the formulation of a shared understanding/vision. However, within the findings the use of financial analysis as a common language created a number of issues between the business and IT/IS domain. The primary issue was that while the CEO’s of the organisations used financial analysis to define strategies and objectives, the CTO’s primarily discussed technological issues relating to current products. This highlighted the increased effectiveness of the business model framework as a communication platform. However, increased scrutiny of the findings uncovered the impact of the researcher in the intervention as a factor in developing the shared understanding. Yet this was not the sole reason for the observed impact as the research had been involved with the organisations through the open days with little success. This would show that even though the business model framework was not adopted it did increase the impact of the external agent and vice versa.

The findings show that the business model framework clearly demonstrated value of the new/innovative technologies to the CEO’s of the eLearning organisations, which in turn increased their commitment to the initiative. One of the key reasons why the business model was more successful in communicating the value of new technologies than the financial analysis methods is that it did not exclude vital information in an effort to oversimplify the potential value. As highlighted by Christensen et al. (2008) using financial modelling can exclude the impact of not investing in innovative projects. In line with the research of Chesbrough and Rosenbloom (2002) this study demonstrated that the business model was able to map the financial and technological domains. Furthermore, the study shows that the business model was able to present possible opportunities that could be exploited by the eLearning organisations themselves or their competitors. In doing so the CEO’s were able to see the potential of the new/innovative technologies but also the risk in not assigning resources to exploring these technologies. In effect, the findings demonstrate the suitability of the business model as a communication tool between business and technology roles, particularly within an innovation setting. More specifically, the study supports research such as Amit and Zott (2001), which demonstrates the business model as a strong tool in presenting the value created within an eBusiness environment.

Within the findings, the success of the business model intervention in enabling the communication of the potential value of the new/innovative technologies is linked and substantiated through the marked increase in participation by the organisations. However, the key goal of the intervention was to create a common communication platform that would facilitate social alignment in the organisation and support the development of a shared understanding/vision. Nevertheless, the business model failed to become a common communication platform for the organisations. For the business model to become a common communication platform, it needed to be adopted by the CTO’s as they were the main connection between the research institute and the eLearning organisations. It has long been known that excellent business/technology relationships within an organisation require the technology representatives to “promote IT as an agent of business transformation” and to “contribute beyond the IT function role” (Feeny et al., 1992). Moreover, some have shown the inability to do this is at the onus of technology representative of the organisation (Lutfman et al., 1999). Yet, this study demonstrated that after the intervention little effort was made in developing a shared vision/understanding, utilising the business model or any other communication platform. Further analysing the success note during the intervention, its main benefit was that it provided a suitable tool that could be used for building a shared vision and understanding through a common communication platform. Moreover, the intervention demonstrated how the business model framework could be used and provided one shared vision for the eLearning industry. The key question is why did the organisations positively respond to the actual intervention but ultimately fail to implement the business model and further develop a shared vision after the intervention was completed?
One explanation can be found by discussing the main difference between the period during the intervention and period after the intervention. The two main differences between these two periods include: (i) the facilitating role of building the vision was not undertaken by either the CTO, and (ii) the industry vision was primarily built using an external viewpoint during the intervention. With regard to the first point, during the intervention the role of building the shared vision was undertaken by the researcher. The aim was that after the intervention this would be continued by the CTO. However, this did not happen. One reason for this is that the role of building a shared vision has been viewed more suitable for person outside of the technology domain. Literature has documented the need of an “organizational architect” to work with both technologists and strategists to grow the organisational and technological capabilities needed to build a vision (Sauer & Willcocks, 2002). Notwithstanding the fact that Sauer and Willcocks (2002) do not specify that the role should be performed by somebody external to the organisation. They do advocate the need for a participant that sits outside both the technology and business domains to build a mutual understanding between the two. This would explain the failure of technologists to facilitate the building of a shared vision after the intervention. Furthermore, the findings would suggest that placing the onus on the technologists (CTO’s) to build a shared vision (Luftman et al., 1999; Cohen & Toleman, 2006) or placing the onus on both technologists and business executives to understand the issues of their counterparts to build a share vision (Kearns & Lederer, 2003; Luftman & Kempaiah, 2007) is not an optimal solution within an eBusiness or innovation setting.

Furthermore, the second point which highlights the fact that the industry vision built during the intervention came from a viewpoint external to the eLearning organisations is also significant. In particular, external input is not discussed in Reich and Benbasat’s (2000) research on the factors of social alignment. Their research primarily focuses on internal communication between the technology and business roles of the organisation in order to build a shared cognitive map or shared vision. However, literature within the innovation domain and specifically around exploring opportunities has noted the need for cognitive diversity. In particular, Gilsing and Nooteboom (2006) highlight the fact that organisations that open up to a variety of insights are more successful than those who did not. Furthermore, they note that cognitive diversity or external input is especially important when an organisation is going from a stage of exploiting current technologies to exploring new technologies (as was the case with the eLearning organisations). In addition, in their model of absorptive capacity Zahra and George (2002) posit the need for social integration mechanisms to build a shared understanding but also the need for external input to feed into that understanding. Again this would indicate that an organisation that needs to build their absorptive capacity or ability to internalise new technologies need external input in building a shared vision.

In effect, this study has shown that the business model acted as a better tool for both codifying external knowledge and integrating it socially than financial languages. However, using the business model as a communication platform alone is not enough to increase the social alignment and build a shared understanding/vision between business and technology, as advocated by Osterwalder et al. (2005). The research highlighted that the external agent had an effect on the development of social alignment. This would infer that within an innovation setting, careful thought should be put into the person who is going to fulfil the role of implementing the business model as a communication platform. However, it must be reiterated that the business model framework did have a significant impact as the external agent was involved with the organisations before the intervention with no observed impacts.

Abstract

Online research maps are websites that present information about certain research activities in a
structured manner. Institutions like universities, states, or individual researchers use them as knowl-
edge base to identify and communicate “who knows what” and “where can the respective information
be found”. Furthermore, these items are used as a research marketing measure, stressing the impo-
tance of this kind of portal. However, research maps differ in their range of functionalities, their re-
spective naming, their target audience and so on. Thus, it is an exhausting task identifying and choos-
ing the right set of functionalities. Our goal is to offer a template for the creation of common practice
online research maps. For this purpose, we present a reference model and describe its development
process. As preliminary measure, 66 research maps have been carefully analysed with respect to the
formerly mentioned aspects. Derived from the results of our analysis, common practice was identified
and used as basis for developing a reference model for online research maps. For development pur-
poses, an existing language for describing internet portals was chosen and adapted to suite the re-
quirements of describing research maps. The reference model presented in this article was then evalu-
ated in a multi-methodical procedure.

Keywords: Web Site Analysis, Reference Modelling, Conceptual Modelling, Knowledge Transfer.
1 MOTIVATION

These days, main deficiencies in information supply are no longer caused by lacking availability of information but rather by information overflow and high complexity in information processing (Porter & Millar 1985). This problem is addressed by the research area of knowledge management, which elaborates on how to identify, gain, generate, disseminate, utilise, and retain knowledge (Probst & Raub & Romhardt 1999). Knowledge management is not only a success factor in business but it is also of highest importance for researchers and research networks. This paper addresses the above stated deficiencies by supporting the development of online research maps.

Online research maps are Internet-based knowledge management instruments, which present research activities through answering different questions, like (a) “who is conducting the research?”, (b) “what is being researched?”, (c) “what results have been achieved?”, and (d) “who is paying for the research?”. Research maps give a general overview of the involved parties, research topics, and achieved results, trying to emphasise existing mutual relationships. These relationships can be, for example, of geographical, organisational, financial, or causal nature. Online research maps can significantly reduce the effort put in the search for knowledge assets and the respective experts due to structured – often visual – representation (Eppler 2001). Thus, online research maps facilitate getting familiar with an unacquainted research area. Furthermore, the database of the research map can be quantitatively analysed to identify research gaps. By giving an insight into the research activities of an organisational unit, research maps are not only a knowledge management instrument but can also be used as a marketing instrument to make own research results available for public. For instance, the U.S. National Cancer Institute uses an online research map (http://www.cancermap.org) to “connect the dots between all researchers involved in pancreatic cancer research to speed the development of national strategies and to leverage resources for pancreatic cancer research”.

While using and hosting an online research map yields certain advantages, their development can be an exhausting undertaking when conducted manually in a try-and-error manner. As organisations conceive their individual solutions independently, much work is carried out redundantly. In many cases, research organisations’ budgets limit the effort that can be brought into the development of a research map. Especially in this case it is important for those organisations to get support designing the functionality and structure of their internet portal.

Reference modelling has been proven a successful means of knowledge transfer through capturing common-practise solutions for information systems development (for detailed information about the advantages of reference models see e.g. vom Brocke 2007; Frank & Strecker 2007; Fettke & Loos 2007). Our goal is to develop a reference model for online research maps, which can support constructors during the conceptual phase of a development project of an online research map.

Hence, there are two major research questions we address with our paper.

(1) What functionalities and structures should be included in the reference model for online research maps to capture common practise?

(2) How can this common practice be graphically represented by a modelling language?

Our development process of the reference model includes the collection and analysis of existing websites, the choice and adaptation of an appropriate modelling language, data-driven reference model construction, and finally the evaluation (cf. Figure 1). The remainder of this paper proceeds correspondingly. In Section 2, we present our explorative analysis of existing online research maps. It consists of an online-based search for websites, their analysis, and identification of implemented functionalities. Furthermore, as the naming of these functionalities varies from website to website, we establish a common vocabulary for the used functionalities. In Section 3, a modelling language appropriate for online research maps is chosen, adapted, and specified by a language-based meta-model. Section 4 covers the creation of our reference model, which is conducted in an iterative way. In the following
section the evaluation of our reference model is discussed. On the one hand, the model is validated against randomly selected websites. On the other hand, we evaluate the applicability of our model to a concrete real-life situation of research map construction. In Section 6, we conclude with an outlook for further application and evaluation activities as well as for important contributions of the reference model to other research questions.

![Diagram](image1.png)

**Figure 1: Development Process of the Reference Model**

## 2 EXPLORATIVE ANALYSIS OF RESEARCH MAPS

As a preliminary step, typical functionalities of research maps had to be identified. These functionalities should serve as basis for the selection of an appropriate modelling language. Thus, from July to August 2008, an analysis of existing research maps was conducted. For this, the search engine Google (http://www.google.com) was used to retrieve results for keywords like “research map” (and other corresponding English terms) and “Forschungslandkarte” (and other corresponding German terms). For each term, the first 250 results were analysed whether or not they belong to a research map. Besides many links leading to pages just providing information about research maps or solely providing links to them, 76 research maps were identified as being adequate for our analysis at the first moment. However, 9 of them were offered as print media and one of the web based research maps did not deliver the required login information in time. This led to a total of 66 research maps analysed, originating from eight different countries. Most of them (42) originate from Germany, another 10 from the United States. The remaining 14 maps originate from several European countries. Each of the 66 research maps was scanned for functionalities it provides. As the naming of the research maps’ functionalities differ, coding them with common terms was required. Once functionalities for a certain research map were identified, they were recorded in a contingency table. This enabled us to identify common expressions and aggregate them thematically (cf. Table 1). For this, every term found on a certain online research map and identified as being relevant was assigned to one of the 52 defined functionalities. Those again were aggregated to another set of 12 classes, characterising them in a more general manner. Furthermore, for common understanding we defined the meaning of each of the functionalities and counted their absolute occurrences (#Freq.) and their percentage share (%).

</table>
For this article, common German expressions were translated to English (marked with *). Terms in quotation marks serve as placeholders (e.g. “Text” stands for “English” or “German” (ID 28), “Icon” stands for the respective flag symbols). After having built the overview, we created a screenshot of each research map and tagged it with the respective term (cf. Figure 2). Thus, documentation of the assignment results is available. As an example for the assignment, the research map of the “Johns Hopkins Center for Global Health” (http://research.hopkinsglobalhealth.org/researchmap.cfm) provides the functionality Project Map, which was coded with the respective term Knowledge Asset Map (ID 04). As another example, About the Center was coded with the term Portal Operator (ID 32).

3 ADAPTATION OF A MODELLING LANGUAGE

A necessary task during the reference modelling process is the selection and – if necessary – adaptation of an adequate modelling language (Becker et al. 2008). For websites, various approaches towards modelling requirements definition are proposed, which can be differentiated into three branches of development (cf. Figure 3). One group of approaches originates from data modelling and is based on Entity-Relationship Models (Chen 1976). Other approaches primarily derive from Hypertext Modelling (Garzotto & Paolini & Schwabe 1991; Halasz & Schwartz 1994). A further branch of development comprises object-oriented approaches (Rumbaugh et al. 1991; Rumbaugh & Jacobson & Booch 1998).

![Image of Figure 3: Modelling Approaches for Web Applications (Brelage 2006)]

The extended World Wide Web Design Technique (eW3DT) by Scharl (1998) was chosen for the construction of the reference model for research maps. The crucial advantage of eW3DT was the fact that reference models for internet portals have already been constructed using this modelling language (Scharl 1997). Thus, this modelling language is intended to be partly reused in the context of this paper. Furthermore, this modelling language incorporates all required elementary model constructs provided by the other modelling languages. eW3DT distinguishes the five website element types page, interaction, index, menu and file, which can be either static or dynamic. In contrast to static web elements, the content of dynamic web elements may vary depending on the time being accessed. A website structure is modelled by establishing relations between website elements using different connection types. The contents of single website elements can be refined in sub-models. The analysis as presented in Section 2 revealed requirements that made it necessary to adapt eW3DT. The meta-model in Figure 4, for which we used an extended version of the ERM data modelling language (Chen 1979), illustrates the project-specific extensions to eW3DT. Derived from the functionalities of the class analysis (cf. Table 1, IDs 19-21), the reference model is required to be able to describe the content-related structure of reports that should be available in the research portal. Thus, the new element type Web-OLAP represents a quantitative report that is available on the research map and may also be manipulated through the OLAP operations: rotate, slice, dice and drill-down respectively roll-up.
Concerning the extension of the meta-model for the specification of analysis reports, the model constructs that are commonly used in modelling languages for the functional specification of OLAP systems have been adopted (Bulos 1998; Golfarelli & Maio & Rizzi 1998; Holten 2003). The content-related specification of OLAP reports is defined by values of columns and rows which determine a two-dimensional projection of a navigation space. Navigation spaces are made up of dimensions and dimension scopes (e.g. date defined by year, institution defined by country and research theme defined by topic); and systems of metrics (e.g. number of research results). Thereby, the navigation space clarifies which metrics should be analysable according to which structure of dimensions. The design relying on rows and columns determines the tabular structure of the report. If the element type Web-OLAP-Report is being marked as dynamic, the report is generated from the database on demand and thus can contain different metric values at different access times. If the report is static, however, its contents remain the same regardless the time the web portal is accessed. By specifying additional attributes of the Web-OLAP element, the available OLAP operations can be chosen. Further information functionalities were identified empirically, some of which pointed out that indices are frequently used in research portals to give an overview of various entities, like institutions, people, and topics. Within the extension of the meta-model, the element type index is intended to be assigned to different
dimensions – respectively dimension scopes – which can also be used within the context of report-based analysis. For example, by using this meta-model extension it is possible to express that the index directory of institutions is presented in different ways, e.g. ordered alphabetically/geographically or by Institution Type/Area of Research (cf. Figure 6). Besides the hierarchically structured index navigation, it should be possible to search throughout thematically separated areas, e.g. via full-text search. For this purpose, the additional element type search has been included. By defining a navigation space, the content-related restriction of a supported search can be specified.

Another extension to the meta-model was motivated by the fact that in eW3DT database symbols are assigned to the element type interaction in order to specify that data is collected or provided during this interaction. As decisions are to be made concerning the naming and structure of databases, we used data clusters to specify this data in our adapted eW3DT variant. The data clusters are excerpts of an Entity-Relationshipship Model (ERM). The ERM excerpts describe the data addressed in the interaction from the requirements definition point of view. Thereby, a consistent application of reference modelling in requirements definition is guaranteed. However, this abstracts from the way the data is physically structured in the database and from the database itself.

4 A REFERENCE MODEL FOR RESEARCH MAPS

With the functionalities identified in Section 2 and the modelling language as prerequisite for the creation of the reference model at hand, we chose an iterative process for building its structure. During the first iteration step, a set of five research maps, which provided a considerable amount of functionalities, was analysed regarding their structure (cf. Table 2). For each functionality the respective web element type (Page, Menu, Index, Search, Web-OLAP, File and Interaction) as Static or Dynamic, and the links between them (Dynamic, Static, Including, or Representing) were chosen. If necessary, additional functionalities were included and placed at an appropriate position.

Table 2: Iteration Steps for Building the Reference Model

The first iteration step consisted of ten research maps being compared to the model originating from the initiation step. Ten functionalities had to be additionally included and placed in an appropriate position in the model. Others had to be repositioned. During the second iteration, only three more elements had to be included.

During the third iteration, no more additional elements were required and no repositioning had to take place. Thus, we defined the result as our reference models first version (cf. Figure 5). The greyed out elements in Table 1 express, which functionalities of the initial list were left out in the reference model either because not more than five percent of the analysed research maps included them, or because
they were very domain-specific and not of any value for research maps belonging to different domains.

Figure 5: Reference Model Proposal after Three Iteration Steps

The reference model all in all consists of 148 elements and is divided into 14 sub-models, describing subordinate contents. If not accessing the research map via a deep link, e.g. by using a link provided by a search engine, the user enters the research map via the Homepage (level 1.0). There, elements of level 1.1 are included and immediately presented. For maximum impact, on this level the user should be enabled to choose his preferred Language. Furthermore, the Objectives of the map should be presented to give a quick overview about what the site is about. The interactions Intranet Login and Feedback communicate the possibility to get in contact with the operators by sending annotations or proposals for corrections. By entering a secured area, the (active, thus not visiting) user gets the possibility to contribute to the research map, a necessity e.g. for research networks or communities. A file Privacy Policy generates trust and informs about how the operator deals with members data and their profiles. Content Search enables the user to search the content of the research map by keywords. To send the URL of one of the page to interested third parties, the interaction Recommend this Page can be used. The Site Map gives an overview of the structure of the web portal whereas the Disclaimer is a serves as legal insurance.

Web site elements on level 2.0 can be accessed from the homepages navigation menu. Figure 6 illustrates this for the menu Institution, which consists of a dynamic element Directory of Institutions and an element Institution Search.
Institutions

Figure 6: Sub-Model of the “Institutions” Menu

Similar to the menu Institutions, 14 more sub-models were created. A condensed description of all available sub-models is listed in Table 3:

<table>
<thead>
<tr>
<th>Sub-model</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Analysis</td>
<td>This sub-model contains four dynamic Web-OLAP-Applications. Each application is configured to its special scope. The Web-OLAP-Applications Project Analysis, Area of Research Analysis, Institution Analysis, and Publication Analysis will generate significant reports.</td>
</tr>
<tr>
<td>Career Center</td>
<td>Four dynamic indices in the sub model Career Center exist. Each index contains domain-specific information, external links for further information, e.g., Vacancy, Further Education, Academic Studies, and Professional Training.</td>
</tr>
<tr>
<td>Events Calendar</td>
<td>The dynamic index Events Calendar announces events, exhibitions, workshops, and advanced trainings related to the area of research. An external link to an organisers website lets users sign up for an event.</td>
</tr>
<tr>
<td>Institutions</td>
<td>This sub-model lists research institutions alphabetically, geographically or by type of institute. One institute is characterised by its Contact Data, Profile, Main Research Area, involved Members of Staff, Publications, Projects, Patents, Awards, Cooperations, Special Equipment and handled Methods. For large numbers of registered institutions, an Institution Search should be implemented.</td>
</tr>
<tr>
<td>Intranet login</td>
<td>This sub-model contains a menu Intranet linking to two interactions: One interaction manages the administration of user data, the other interaction manages the administration of content data like Projects, Research Results, Publications, and Events Calendar.</td>
</tr>
<tr>
<td>Links</td>
<td>The static or dynamic index Links is a link collection to external websites related to the research portal.</td>
</tr>
<tr>
<td>Media</td>
<td>The dynamic menu Media contains three dynamic indices and one static page. The page Press Contact keeps contact data for press only. The index Press Release lists press reports chronologically. Older reports will be stored in the index Press Archive. The third index Podcasts enables users to play audio and video documents related to the portal. Additionally, there is a possibility to subscribe to the Newsletter.</td>
</tr>
<tr>
<td>Portal Operator</td>
<td>This sub-model consists of five static pages. A Profile describes the portal operator with his core competences, the service offering and philosophy. The History of a firm will be presented as well as its Organisation. Pages with Contact data and Directions are in this sub-model, too.</td>
</tr>
<tr>
<td>Professionals</td>
<td>The sub-model Professionals consists of a Person Search and an Index of Professionals. One professional is characterised by his Contact Data, membership to an Institution, Profile, Main Area of Research, Publications, Projects, Patents, and Awards.</td>
</tr>
<tr>
<td>Publications</td>
<td>A publication is characterised by its Publication Status, Type of Publication, Title, Location, Publisher, Year, Authors, Project, Research Area, Institution and URL. The index Publications lists data sets sorted by time, type or author. Categorial filters in a Publication Search could be used to specify database requests.</td>
</tr>
<tr>
<td>Research Funding</td>
<td>This sub-model includes an index with information about Funding opportunities.</td>
</tr>
<tr>
<td>Research Maps</td>
<td>Maps facilitate the search process in an area of research. Knowledge Asset Maps and Knowledge Structure Maps are modelled as Web-OLAP-Reports. Web-OLAP-Reports are being real-time-generated from the database, so they will be up-to-date permanently.</td>
</tr>
<tr>
<td>Research Projects</td>
<td>This sub-model contains the index of Research Projects which will be described by a Title, a realising Institution, Participants, a Description, its Duration, Keywords, used Methods, Research Results, Cooperations, Financial Supporters and its Project Status. A powerful Project Search helps to control the project data sets.</td>
</tr>
<tr>
<td>Research Results</td>
<td>One or more research results could originate from one research project, so research results are outsourced in its own sub-model. The index of Research Results lists all data sets alphabetically. Using Search Research Results, the output could be limited and sorted by categories. One result will be described by its Title, its publishing Institution, Contact Person, Description, Classification, Keywords, URL its mapping to a Research Project, its situation of Patent Registration, Financial Supporters, its Status, and Publications.</td>
</tr>
</tbody>
</table>

Table 3: Descriptions of the Sub-Models’ Contents
5 EVALUATION OF THE REFERENCE MODEL

Having built the reference model, we chose a multi-methodical approach for our evaluation, initially starting off with testing the abilities of the reference model against a random sample of ten of the remaining research maps. During this, we found out that no more website elements had to be added to the reference model to completely describe the sample. This can be interpreted as an indicator for the reference model completeness. Subsequently, we used the reference model as accompanying measure for the creation of a research map from scratch. By doing so, we wanted to evaluate its usefulness in day-to-day business. The map that was to be set up was on order of an international research network, settled in the domain of information systems. It can be accessed via the URL http://www.forschungslandkarte-hybridewertschoepfung.de. The research map generally required the ability to present information about research artefacts created by the members of the network. It was also required to describe the artefacts with different dimensions, list the respective contact person and additional downloads, if available. For reporting purposes, the dimensions should be analysable by an OLAP system.

The reference model successfully served as a guide for the discussion on and the choice of functionalities implemented for the portal. The artefacts of the research maps are analysable with the OLAP system IBM Cognos by their dimensions. During the next step, we called the users of the research map for participation by filling in a paper-based questionnaire about the applicability and usefulness of the elements provided. No negative comments regarding the content of the portal were given, however the naming of the website was questioned, which, however, was not subject to the application of the reference model anyway.

Furthermore, we conducted semi-structured interviews with seven users. All in all, they too found the research portal to be complete in regards to the requirements. Besides successfully describing the required content, the reference model turned out to be helpful during the creation process of the research map. For a detailed description of how this process can be evaluated, see Frank (2007). However, up to this point, all personnel except third party users of the research map developed are known to the authors and therefore – although leading to very good results – their judgement has to be questioned. Thus, in the next step, the reference model will be used during the development process of a research map for clients personally not known to the authors.

6 OUTLOOK

The reference model in its as-is state seems to be able to completely describe most of the research maps, which are available online. However, as motivated in Section 5, the fourth step of the evaluation phase still has to be taken, which will be done in a larger scale project with participants that are not acquainted or connected to the authors in any way. For this, the reference model will be handed over to the research map development team. The authors will accompany the whole process and observe the reference models applicability for both the choice of elements and the process of developing the research map. The result of this analysis should provide the means for a further adaptation of the modelling language and an even more suitable definition of functionalities. By doing this, another iterative process will be started, improving the reference model’s significance (cf. Figure 1). The reference model serves as basis for a larger scale empirical analysis, encompassing more online research maps. As prerequisite for such an empirical analysis, it is important to define adequate criteria for coding the objects of investigation. Here, the reference model for research maps comes into play by offering criteria in terms of functionalities and common expressions. Once collected, further results should be expected from this data pool:

(1) By being able to work with a larger number of results, we should be able to identify different types of research maps. Concluding from the sample analysed in Section 2, it seems that there are different purposes for which research maps are set up. Firstly, single researchers use the maps as online documentation of their own work. These kinds of maps are very limited in their number of functionalities,
the number of research domains covered and the number of people accessing the site and contributing to it. Secondly, organisations like universities or sponsors set up research maps to either present their own research results or those of the supported projects. The amount of users accessing and contributing to this kind of map is naturally considerably larger. Furthermore, the research map might cover more than one research domain. Due to the larger amount of stakeholders, the demand for functionalities, too, will be higher. Thirdly, research networks use research maps for sharing their results among each other similar to organisations. In opposite to them, there is no need for a central institution managing the research map. Once empirically identified, these different types of research maps might lead to clusters of functionalities connected to them. If this should succeed, the reference model could be enriched with meta-data, specifying for which type of research map the respective functionalities are relevant. This would greatly simplify the choice of functionalities for a certain kind of map, as the adequate set could be derived from the selection of a certain configuration parameter (Becker & Delfmann & Knackstedt 2007).

(2) Another application scenario of the empirical data collected is the construction of a maturity model (Nolan 1979; de Bruin et al. 2005) for research maps. A similar approach addressing portals in general was proposed by Baroni de Carvalho & Ferreira & Choo (2005). A quantitative analysis can show which functionalities are typical for different degrees of maturity. Assuming that the maturity model consists of five – as widely used – stages, it is our expectation that our reference model corresponds with level three, implying a medium level of maturity. While research maps can be considered as knowledge management instruments, such a maturity model is a specific kind of a knowledge management maturity model as e.g. proposed by Freeze & Kulkarni (2005).

Abstract

Online social networks are gaining increasing economic importance in light of the rising number of members. The numerous recent acquisitions priced at enormous amounts illustrate this development. Therefore, the growing relevance of online social networks in science as well as in practise revealed the need for adequate valuation models, which take into account the networks’ specific characteristics. Thus, this article develops an economic model for valuation of online social networks. The model allows the evaluation of whether the purchase prices on the market, which recently amounted to millions, are justifiable. Finally, the practical application of the model is illustrated by an example of the major European online social network XING.com.

Keywords: social networking, customer relationship management, business case.
1 INTRODUCTION

One of the most important current changes with regard to the use of the Internet is the transformation of passive information users into active actors, which increasingly create the content of the World Wide Web (WWW) themselves. Along with these changes, the economic impact of established media declines and experts predict heavy socio-economic and political implications (Bernoff et al. 2008). A main driver for this development is the active use of online social networks, where people are connecting and communicating more and more online with one other (Kazienko et al. 2006, Gross et al. 2005). Networking sites such as Facebook.com or XING.com not only provide a technical platform to establish and maintain relationships between users, but also enable users to present themselves to a wide public and to make visible their own social networks (Boyd et al. 2007). This emergent technical and social phenomenon generates an increasingly important economic impact and has spurred enormous attention among researchers and practitioners.

Thus, media and IT companies have been acquiring recently online social networks for considerable amounts to adapt their business models to the new environmental conditions and to reorganize their companies for the future. In 2005, for example, the media company News Corp. acquired the online social network MySpace.com for US $ 580 m. Two years later Microsoft paid US $ 240 m for a 1.6% minority interest in the online social network Facebook.com. The extrapolated value of this company thus amounts to staggering US $ 15 bn. This trend can also be observed in Germany: following a bidding war with the publisher Springer, the German publishing company Holtzbrinck acquired the online student network StudiVZ.de for approximately € 85 m (Sievers et al. 2008). However, the enormous purchase prices for online social networks are also considered critical and experts compare the situation with the dotcom bubble over the turn of the millennium: Martin Sorrell for instance, CEO of the WWP Group – the world’s largest communications services group (and one of the six largest advertising holding companies) –, is cited in the Financial Times Deutschland seriously questioning the valuation of Facebook.com at US $ 15 bn (Lambrecht 2008).

This makes clear, that the important question of how online social networks can be valued using well-founded valuation methods has not yet been answered. Therefore, the objective of this paper is first to develop an economic model for the valuation of online social networks, which takes into account the specific characteristics of these companies, and second to illustrate the practical application of the model to the online social network XING.com using only publicly avaiable data. The paper is structured as follows: In section 2 we define and describe online social networks as a current phenomenon. In section 3 we briefly review the existing valuation approaches to online social networks, before we develop our own quantitative approach in section 4. The practical use of the new model is extensively illustrated by an example of the major European online social network XING.com in section 5. The last section summarizes the results and suggests areas for further research.

2 ONLINE SOCIAL NETWORKS: A CURRENT PHENOMENON

Although Facebook.com was only established in 2004, today more than 90 m people get together in the digital friendship network (Agarwal et al. 2008). This is only one example of how online social networks – aroused by the web 2.0 boom – have evolved into a new, mostly free of cost, mass medium where users\(^1\) present themselves to a wide public and voluntarily reveal parts of their privacy. Beside the exponential growth of online social networks there is a growing realization that online social networks are not simply forums in which individuals congregate. Rather, “these networks create

---

\(^1\) The terms customer, member and user are used synonymously.
substantial value for the individuals who participate in them, the organizations that sponsor them, and the larger society in multiple ways” (Agarwal et al. 2008). The community idea itself, which was long known and extensively researched especially in the field of social sciences (see Bagozzi et al. 2006) and in social network analysis in general (Milgram 1967, Granovetter 1973, Watts 2003), took on new dimensions with the development of the Internet and the emergence of online social networks. In this context, this article focuses mainly on the users’ integration in the online social network (e.g. number of contacts etc.) and the consequences in regard to the economic valuation.

We generally perceive an online social network as a set of actors, which are represented by nodes, and a set of edges (ties) linking pairs of nodes (Adamic et al. 2003, Kazienko et al. 2006, Bampo et al. 2008). The edges represent connections between actors and describe social interactions or relationships. The nodes and edges are usually presented by a graph (Hanneman et al. 2005), as shown in Figure 1. This visualisation especially highlights so-called hubs (Bampo et al. 2008), i.e. actors who have a particularly large number of connections to other actors.

![Elements of an online social network](image)

**Figure 1. Elements of an online social network**

In the following we define – according to Boyd et al. (2007) – an online social network in particular as a web-based service that enables ”individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system” (Boyd et al. 2007). Thereby, the aspect of networking, i.e. establishing and maintaining relationships between users, is prevailing. However, relationships are not as tangible as those from the real world (Kazienko et al. 2006). Currently, there are a lot of online social networks both for business (e.g. Doostang.com, LinkedIn.com or Xing.com) and for private purposes (e.g. Facebook.com, MySpace.com or StudiVZ.de), focusing on different target groups. Moreover, they differ in size and who can see your profile and how much of it is visible as well (Howard 2008). While most of the key technological features are fairly consistent, the culture that emerges around online social networks varies (Boyd et al. 2007). Furthermore and in addition to the fostering of individual contacts, the community idea is actively lived over forum and group functions.

At the moment many online social networks are basically funded through advertising proceeds. An extension of the business model that includes user fees, is therefore a great challenge for coming years (Pauwels et al. 2008). Critical both regarding the introduction of user fees and in particular the economic valuation of online social networks is the fact that the individual benefit of members considerably depends on the number of members within the online social network. For instance, if a part of the members leaves the online social networks, the individual benefit of the remaining members consequently decreases. On the other hand, every new additional contact of a member raises his or her barrier to leave the network. Such characteristic effects have to be considered when attempting a valuation of online social networks.
3 RELATED WORK

Researchers and practitioners have written a plethora of articles and books on the valuation of firms in general (see Koller et al. 2005, Brealey et al. 2008, Damodaran 2002). However, according to the predominant view in literature standard business valuation approaches are very restricted in their ability to value young, fast growing companies in a dynamic environment, such as Internet companies (see e.g. Gollotto et al. 2003). Reasons are, for instance, the backward orientation using traditional financial balance sheet figures (e.g. liquidation value, substantial value, (adjusted) book value), a lack of acceptance and application in business matters (e.g. real option approach), a lack of academic foundation (e.g. venture capital approach), and the limited history to draw on for future cash flow projections and the handling of just negative cash flows (e.g. discounted cash flow approach).

What makes the economic valuation of online social networks even more difficult is the fact that customers, relationships between customers and the resulting network effects – and therefore intangible assets (especially social capital e.g. Kazienko et al. 2006) – represent a major part of the firm value than assets being currently reflected on the balance sheet. Hence, the value of each customer and the integration of the customer in the online social network as well as the growth of the network have to be considered explicitly to get a reasonable estimate of the firm value. Established standard business valuation models do not sufficiently consider these aspects yet. However, in recent years new approaches (e.g. for the services sector) have been developed, which take into account the value of customers as the most important factor for a firm’s valuation (cf. e.g. Gupta et al. 2004, Bauer et al. 2005, Krafft et al. 2005). Although these models are still based on the discounted cash flow approach, the focus has shifted from the projection of cash flows on a company level to the projection of cash flows obtained from the existing and future customer relationships.

The basic idea behind these valuation methods is measuring the value of the customer base by summing up all discounted cash flows (in and out cash flows) arising from all existing und future customer relationships. The obtained value of the customer base represents the entire value of the discounted operating cash flows of a company. Finally, the value of the customer base “and all cash flows generated from non-operating assets yield the overall value of the company” (Bauer et al. 2005). This change of perspective is quite beneficial for the valuation of online social networks. Although several methods of customer-based valuation have been developed which take into account important aspects, we are not aware of any approach so far that is applicable for the valuation of online social networks. A significant aspect which has to be taken into account when evaluating the customer base of online social networks is considering the number of individual contacts. This is crucial, since the loyalty of a customer strongly depends on the integration into the online social network, as every additional contact of a customer raises the barrier to leave the network (see Algesheimer et al. 2006). The online social network XING.com, for instance, reports that well-connected users have (due to network effects) a higher retention rate (i.e. they are less inclined to leave the network) and lead to a higher activity among users (XING, 2006).

Based on these premises, we develop a model for the economic valuation of online social networks considering the findings from previous research in customer-based valuation and network theory.

4 DESIGN OF THE ECONOMIC MODEL

The long-term value of online social networks is largely determined by the value of the network’s customer relationships, since tangible assets usually play a tangential role. Hence, the online social network’s existing and future customers provide its most reliable source of future revenues. Thereby the value of all existing and future customer relationships is denoted as the customer equity (CE) (Blattberg et al. 1996, Rust et al. 2004). To determine the value of a single customer the widely accepted customer lifetime value (CLV) approach is used, which is similar to the discounted cash flow
approach in firm valuation (see Koller et al. 2005, Damodaran 2002). CLV is defined as the present value of all existing and future cash flows generated by a certain customer (Berger et al. 1998).

Incorporating the CLV approach for determining the value of the online social network, we first partition all existing and future customers into different cohorts $c$ (with $c=0, 1, \ldots$), where $c$ denotes the period in which the customer joined or will join the online social network. Then customers are referred to as $i=1, \ldots, N_c$ for each cohort $c$, whereas all existing customers at the instant of valuation are assigned to cohort $c=0$. With this notation, an online social network’s CE can be expressed as the sum of discounted CLVs of all existing (cohort 0) and future (cohorts 1, 2, \ldots) customers:

$$CE = \sum_{c=0}^{\infty} \frac{\sum_{i=1}^{N_c} CLV_{c,i}}{1 + d^{f}},$$

where $CE$ denotes the total value of all existing and future customer relationships, $CLV_{c,i}$ the CLV of customer $i$ of cohort $c$, $N_c$ the number of customers in cohort $c$ (with $N_c \in \mathbb{N}$) and $d$ the periodical discount rate (with $d \in \mathbb{R}^+)$.

In order to determine the CLV of customer $i$ of cohort $c$ ($CLV_{c,i}$), we obtain the present value at the beginning of period $c$ of all cash flows $CF_{c,i,t} \in \mathbb{R}$ that the online social network expects to receive from the customer over the entire relationship (Berger et al. 1998). Assuming $T_{c,i} \in \mathbb{N}$ as the duration of the customer’s relationship (for existing customers: remaining duration) and index $t$ as the period of the customer relationship (for existing customers: period since the instant of valuation), $CLV_{c,i}$ can be expressed as follows:

$$CLV_{c,i} = \sum_{t=0}^{T_{c,i}} \frac{CF_{c,i,t}}{1 + d^{f}},$$

where $CF_{c,i,t}$ denotes the cash flow in period $t$ of the customer relationship for customer $i$ of cohort $c$ and $T_{c,i}$ the duration of the customer relationship for customer $i$ of cohort $c$.

However, the implementation of Equation (2) is not easy, as it requires detailed information regarding both the future cash flows $CF_{c,i,t}$ and the duration of the customer relationship $T_{c,i}$ for every single (future) customer. Therefore, we use a common approach to bypass the estimation of the concrete duration of the customer relationship $T_{c,i}$ and consider retention rates $r_{c,i,t}$ (cf. for example Berger et al. 1998, Gupta et al. 2004). The retention rate $r_{c,i,t}$ of a customer $i$ of cohort $c$ for a period $t$ (with $t \geq 1$) is defined as the (conditional) probability that the customer remains in the online social network in period $t$, given that the customer has been a member in the previous period ($t-1$). Thus, an undifferentiated approach calculating average retention rates for the whole customer base is often used. To avoid this, we compute individual retention rates for each customer, considering his or her individual degree of interconnectedness in the online social network. Assuming that the online social network is modelled as an undirected graph (see Figure 1), where members are represented by a set of nodes and communication relationships (also known as contacts) by a set of edges linking pairs of nodes (Bampo et al. 2008), the number of incident edges of a node $i$ represents the number of

2 Strictly speaking all determined values are expected values. For simplification we avoid to state all determined values as expected values.

3 An edge respectively a contact between two members exists technical if and only if one of the members has confirmed the contact request of the other.
members customer \(i\) has a connection to or keeps in touch with. This can be expressed in terms of the period \(t\) through the variable \(e_{c,i,t} \in \mathbb{IN}\). Regarding the estimation of the individual retention rate \(r_{c,i,t}\) for customer \(i\) the following requirements have to be fulfilled\(^4\):

R.1 For a customer \(i\) with a larger number of contacts the individual retention rate should be ceteris paribus, higher than for a customer \(j\) with less contacts (lock-in effect). This results in a strict monotone increasing retention rate function of the number of contacts (i.e. \(e_{c,i,t} > e_{c,j,t-1}\) implies \(r_{c,i}(e_{c,i,t}) > r_{c,j}(e_{c,j,t-1})\)).

R.2 An additional contact – i.e. an increase in the number of contacts by one – leads to a ceteris paribus less marginal change in the individual retention rate of customer \(i\) with a larger number of contacts than in the individual retention rate of a customer \(j\) with fewer contacts. This results (in combination with R.1) in a decreasing marginal utility of the number of contacts in regard to the retention rate (i.e. \(e_{c,i,t} > e_{c,j,t-1}\) implies \(r_{c,i}(e_{c,i,t}+1) - r_{c,i}(e_{c,i,t}) < r_{c,j}(e_{c,j,t-1}+1) - r_{c,j}(e_{c,j,t})\)).

These requirements as a starting point, we intensively searched for appropriate functions. The arctangent based formula (3) fulfills both requirements R.1 and R.2 for all numbers of contacts \(e_{c,i,t}\) and can therefore be used for our purpose. We compress the arctangent function (\(\arctan\)) to restrict the obtained values for \(r_{c,i}(e_{c,i,t})\) to the interval \([0; 1]\). Then the individual retention rate for a customer \(i\) of cohort \(c\) in period \(t\) can be defined as a function of the number of contacts as follows:

\[
r_{c,i,t}(e_{c,i,t-1}) = \frac{\arctan(\alpha_{c,t} \cdot e_{c,i,t-1})}{\pi/2},
\]

where \(r_{c,i,t}\) denotes the retention rate for customer \(i\) of cohort \(c\) in period \(t\), \(e_{c,i,t-1}\) the number of contacts of customer \(i\) of cohort \(c\) in period \(t-1\) and \(\alpha_{c,t}\) the calibration factor for the number of contacts in period \(t-1\).

Note that the parameter \(\alpha_{c,t} \in \mathbb{IR}^+\) is used to calibrate the model in regard to the empirical observed average retention rate of the particular period \(t\) of the customer relationship (the empirical observed average retention rate can be interpreted as the fraction of customers that had been members for \(t-1\) periods and remained in the online social network in period \(t\)). Figure 2 illustrates the function \(r_{c,i,t}\) of the number of contacts \(e_{c,i,t-1}\) for some selected values of the calibration factor.

![Figure 2. Retention rate as a function of number of contacts](image)

Taking into account the customers’ individual retention rates \(r_{c,i}(e_{c,i,t})\) we can derive Equation (4) for the CE of an online social network\(^5\). Since the future numbers of contacts of a customer \(i\) are

\[\text{CE} = \sum_{t=0}^{\infty} \frac{r_{c,i,t}}{1+r_{c,i,t}} \cdot (1-e_{c,i,t}).\]

\(^4\) Cf. e.g. Varian (2003), where a detailed literature overview of network effects is given.

\(^5\)
unknown, his or her recent number of contacts has to be used for a forecast. We will demonstrate a corresponding procedure as well as how to determine all other parameters of the model in detail in the following section using the case of XING.com.

\[
CE = \sum_{c=0}^{\infty} \sum_{j=1}^{N_c} \frac{CLV_{c,j}}{(1+d)^j} = \sum_{i=0}^{\infty} \sum_{l=1}^{N} \frac{CF_{c,i,l} \prod_{l=1}^{i} r_{c,i,l} (e_{c,i,l})}{(1+d)^j}
\]

Finally, assigning the approach of Bauer et al. (2005), we have to add up the value of the non-operating assets and to subtract the value of all non customer-specific costs as well as the market value of dept to obtain the corporate value of an online social network. However, according to empirical research, for some companies, the CE is “a useful proxy for firm value” (Gupta et al. 2004). In order to demonstrate the valuation, the following section illustrates the practical application of the model to XING.com, one of the largest and well-known online social networks in Europe.

5 APPLICATION OF THE ECONOMIC MODEL

In this section, we illustrate the application of the model designed in the preceding section and determine the corporate value of the online social network www.xing.com (referred to as XING) on January 1st 2008. As XING is a publicly listed corporation (IPO in 2006), we can resort to data published in the annual reports from 2006 and 2007 for our valuation. This ensures a better transparency and traceability. To avoid a blanket valuation of XING based on average values and the disregard of essential information such as the customers’ individual degree of interconnectedness, we drew a sample of 1,000 customers (Premium Members) on December 31st 2007. By choosing the members randomly (using the search for “random members” provided by XING), it is assured that the sample is really characteristic for the whole network. Based on this data, we determined each customer’s individual CLV considering the individual number of contacts and the initial year of registration in XING. In a final step, we derive the corporate value from the CE.

5.1 The online social network XING

The online social network XING was founded in August 2003 under the name OPEN Business Club and is one of the leading online social networks within the realms of professional online networking platforms in Europe. At the end of 2007, XING counted over 5.7 m members worldwide. These customers use XING to find useful business contacts, new business opportunities, employees, jobs and ideas by posting a profile on the Internet platform. In addition to the free of cost Basic Membership, XING offers a Premium Membership for a monthly fee of € 5.95 which is the backbone of the business model and booked by 362,000 members (December 31st 2007). Besides these membership fees we disregard additional revenue generating sources like banner-ads and e-commerce in a first step as so far these sources of revenue are not crucial to the XING business model.

---

5 As it is not possible to draw a conclusion of the customer’s individual retention rate directly after his or her initial registration to the online social network (t=0) an average value for the rate \( r_{c,i} \) is used. For \( t>1 \) see (3).

6 We assume that all Premium Members joined the network on January 1st within their year of registration. Note that the year of registration is publicly available for each member (cf. www.xing.com).

7 In 2007 94% of XING’s revenues were generated by Premium Memberships (Xing 2007).
5.2 Determination of the parameters of the model

Determination of the number of members

Starting from the IPO at the end of 2006, XING reports a compound annual growth rate (CAGR) of XING’s Premium Members of 64% (Xing 2007). As corporate cash flows are almost exclusively generated by Premium Members, we only consider Premium Members’ cash flows in our model. Nevertheless, Basic Members contribute indirectly to the value of the online social network: On the one hand they are “potential contacts” for Premium Members and therefore increase the attractiveness of the network. On the other hand Basic Members are also “potential Premium Members” in future periods. However, a projection of a compound annual growth rate for Premium Members of 64% seems to be not reasonable. For instance, mature Internet companies like Amazon, Ameritrade, Capital One, eBay, and E*Trade usually show compound annual growth rates in the range of 15% to 25% (Gupta et al. 2004) and a survey of the Global Industry Analysts Group (Xing 2006) projects an annual growth rate of 21.1% for chargeable Internet services in the next years. Moreover, from 2007 to 2008 the number of online social network users increased by 25% to 580 m users worldwide (ComScore 2008). Thus, we adjust the annual growth rate for XING to 25% for the years 2008 to 2010 (cf. Table 1). For the subsequent time period up to 2017, we project a more conservative growth rate of 10%. Beyond the year of 2018 we do not assume any network growth for XING, i.e. numbers of new members and numbers of members leaving the online social network are the same.

</tr>
</tbody>
</table>

Table 1. Number of Premium Members of XING 2006 to 2010 (cf. Xing 2007)

Determination of the individual retention rates

As described in section 4 retention rates for \( t \geq 1 \) represent the probability that a Premium Member generating cash flows up to period \( t-1 \) will still be a Premium Member in period \( t \). First of all, we determine average retention rates \( r_{0,t-1} \) for the Premium Members derived from the published fraction of members still remaining \( t \) years (or periods) after their year of registration (cf. Table 2). As the Premium Membership fees for XING are payable in advance, we assume that all customer cash flows are generated at the beginning of a period. Considering this, we derive an average retention rate of 100% \( (r_{0,1}=100\%) \) for the first year of membership (=first period), as all new customers generate cash flows in their first year. For the second year we consequently consider only those customers, that are still Premium Members of the online social network after one year \( (r_{0,2}=82\%) \). Furthermore, the average retention rate for the third year \( r_{0,2,3} \) is determined as 93% \( =76%/82\% \), as 82% of Premium Members remain after their first year of membership in the online social network (paying members in \( t=2 \)) and 76% of Premium Members after their second year of membership (paying members in \( t=3 \)). Starting from year 4 onwards, we assume \( r_{0,t} \) being constantly 99% \( =75%/76\% \).

</tbody>
</table>

Table 2. Rate of remaining Premium Members and average retention rates

In a second step, to account for the individual degree of interconnectedness of each Premium Member, we determine individual retention rates based on the actual number of contacts \( e_{g,t-1} \) of a Premium Member and on the calibration factor for a specific period \( a_{t-1} \) (cf. Equation (3)). For the determination of the calibration factor, we use the average retention rate. In detail, we choose \( a_{t-1} \) so that the overall
average of the individual retention rates for period \(t\) (i.e. the average of all \(r_{0,i,t}(e_{0,i,t-1})\)) corresponds to the observed average retention rate for this year of membership \(r_{0,2,t}\) (cf. Table 2: e.g. 82% for the second year of membership). The results of this calibration for the periods 1 to 3 are illustrated in Table 3. For further periods we do not need this calibration factor, as starting from period 4 onwards we assume constant individual retention rates.

<table>
<thead>
<tr>
<th>Period (t) (year of membership)</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calibration factor for period (t) ((\alpha_t))</td>
<td>0.0643</td>
<td>0.1560</td>
<td>0.4170</td>
</tr>
</tbody>
</table>

Table 3. Calibration factor for the calculation of the individual retention rates

To calculate the individual retention rates for the existing customers (using Equation (3)) not only for the next period \(t\) (based on \(e_{0,i,t-1}\)) but also for further periods \((t+1, t+2, \ldots)\) we have to forecast the individual number of contacts \((e_{0,i,t}, e_{0,i,t+1}, \ldots)\). For this projection, we calculate in a first step the average number of contacts depending on their individual period of membership \(t\) (e.g. 126 for the second period after registration). Thereon, we derive average growth rates respectively. For example we obtain an average growth rate of 29.9% \((=126/97-1)\) from \(t=1\) to \(t=2\). The rates are presented in Table 4, whereas these are only relevant for the periods 1 to 3.

<table>
<thead>
<tr>
<th>Period (t) (year of membership)</th>
<th>1</th>
<th>2</th>

<td>29.9%</td>
<td>82.5%</td>
<td></td>
</tr>
</tbody>
</table>

Table 4. Average growth of the number of contacts

Finally, we can determine the individual retention rates using the calibration factors \(\alpha_t\) (cf. Table 3), the individual information about the year of registration (to determine period \(t\)), the current number of contacts and the average growth rates of contacts (cf. Table 4). The latter is essential for the forecast of the individual number of contacts in the following periods. Table 5 illustrates individual retention rates exemplarily for Premium Members A1 and A2.

<table>
<thead>
<tr>

<td>150</td>
<td>93.4%</td>
<td>195</td>
<td>97.9%</td>
<td>356</td>
<td>99.6%</td>
</tr>
</tbody>
</table>

Table 5. Example for the calculation of individual retention rates

For better understanding, we show the calculation following the example of A2: Customer A2 has \(e_{0,A2,1}\)=150 confirmed contacts at the end of his first year of membership. Using the calibration factor \(\alpha_1=0.0643\) and Equation (3) we determine the individual retention rate \(r_{0,A2,1}(e_{0,A2,1})=arctan(0.0643\cdot150)/(\pi/2)=93.4\%\). Hence, the probability that A2 still remains Premium Member in the next period (i.e. in 2008) is 93.4%. For the calculation of the individual retention rate of A2 for 2009, we project the number of contacts by the end of 2008 as follows: \(e_{0,A2,2}=150\cdot(1+29.9\%)\approx195\). This leads to a individual retention rate of \(r_{0,A2,2}(e_{0,A2,2})=arctan(0.1560\cdot195)/(\pi/2)=97.9\%\). The individual retention rates of further years (e.g. for 2010) can be calculated analogically. For the determination of retention rates of future customers, we have to use average numbers of contacts (cf. Table 4) as their individual numbers of contacts are unknown.
Determination of the cash flows

The revenue generated per Premium Member is € 5.95 per month, which accounts to € 71.40 per year. In order to project future cash flows, we determine in a first step the EBITDAM-margin (Earnings Before Interest, Tax, Depreciation, Amortisation, and Marketing) based on figures published in the annual report 2007 (Xing 2007) in the amount of (€ 6.894 m+€ 1.651 m)/€ 19.609 m≈43.6%. Due to the negative margin of the previous year and the long-term rather truncating growth we use a more conservative margin which is extrapolated to a constant figure of 35%. With regard to the amount of marketing spending we have to rely on an assumption, as we could not find precise information in the annual reports about the allocation to existing and to new customers. Therefore we follow the often used rule-of-thumb (cf. Greenberg 2001) and assume that it is five times more expensive to win new customers than to keep existing ones. Taking into account the customer distribution of existing and new customers in our sample of 2007 (55% of the sample are existing customers and 45% are new customers), we allocate marketing-spending of € 8.14/year for new customers and € 1.63/year for existing customers. Following these, we determine the cash flow per Premium Member amounting to $ CF_{c,i,1} = \text{€ 71.40} \times 35\% - \text{€ 8.14} = \text{€ 16.85}$ for the first year of membership and to $ CF_{c,i,t} = \text{€ 71.40} \times 35\% - \text{€ 1.63} = \text{€ 23.36}$ for the following years ($t>1$).

Determination of the discount rate

Due to the dominating equity financing of XING, we assume in a simplified model that the weighted average cost of capital (WACC) is solely based on equity. The cost of equity capital is derived by applying the after-tax CAPM using the average yield of a 10-year European government bond of 4.4% for the base rate (European Central Bank 2007). Applying a common used income tax rate of 35% the tax adjusted risk free rate accounts to 2.86%. Furthermore we assume an expected risk premium of the stock market after taxes of 5.5% (Stehle 2004). Taking into account that online social networks bear more risk than traditional software companies and the fact that XING is relatively small, we increase the published beta-factor of 1.27 for software-companies (Drukarczyk et al. 2007) to 1.48. In summary after applying the after-tax CAPM, we derive a discount rate of 11% (=2.86%+(5.5%\times1.48)).

5.3 Key findings of the application

Applying the economic model to XING, we obtain a CE of € 219.14 m. The value of the existing members sums up to € 63.89 m. In contrast, the value of the future members consists of the discounted cohort values of all acquired members up to the year 2026 (amounting to € 151.77 m) and of the discounted terminal value (amounting to € 3.48 m). Table 6 gives an overview of the key findings. With our results we help investors to make well-founded investment decisions on the basis of public available data. If we take into account that further residuals such as the value of the non customer-specific cash flows, fixed costs that are not attributable to the individual customer and the value of the non-operating assets are negligible, the corporate value equals the CE. Comparing this value with the market capitalization in the amount of € 229.89 m on January 1st 2008, we can state only a slight difference of 4.7% from our findings. This difference can be explained on the one hand by general volatility of the stock market and divergent estimation of valuation parameters by the stock market. On the other hand we neglected additional revenue sources such as advertisements, e-commerce or merchandising products as these sources of revenue are (so far) not crucial to the XING business model. Therefore a stock price of € 44.21 at the instant of valuation seems to be reasonable.

---

8 This extrapolation is consistent with the projected EBITDA-margin according to the XING guidance.
9 As cash flows $ CF_{c,i,t}$ are generated at the beginning of each period, we discount the values contrary to Equation (4) by $t-1$ periods and assign acquisition payments to period $t=1$. In period $t=0$ there are no cash flows.
10 XING shows equity of € 41.5 m and long-term debt of € 0.85 m in 2007 (Xing 2007).
11 From the year 2018 on we assume a net growth of zero relating to the number of members. Therefore the cohort values are almost constant from the year 2027 on, so that we can take a terminal value based on the perpetuity.

Table 6. Key findings of the application to XING

6 SUMMARY

The increasing economic relevance of online social networks and the numerous recent acquisitions priced at enormous amounts revealed the need for adequate valuation models. However, traditional valuation approaches are restricted in their ability to value young, high-growth online social networks in a dynamic environment. Thus, we developed an economic model for the valuation of online social networks taking into account their specific characteristics. The model allows the evaluation of whether the purchase prices on the market, which recently amounted to millions, are justifiable. The practical application of the model was illustrated by an example of the major European online social network XING. The results show that the model fits quite well, as the results of the model were in the range of the market capitalization of XING at the instant of valuation. For the practical use of the model, we illustrated that, although some assumptions within the application to XING were necessary, public available data in connection with specific market data are sufficient to get reasonable results. These results help investors to make well-founded investment decisions. However, future research has to focus on the application of this approach to other business models of online social networks, as only membership fees are the core basis of XING’s revenue model were currently considered in a first step. For example, for online social networks without membership fees, it is possible that people do not unsubscribe but simply do not use it (passive users with low or no value for the company). In this case, it could be a good idea to check the number of contacts added or the number of accesses in a certain period of time instead of the customers’ number of contacts as an enhancement of our model.

Furthermore, we assumed average retention rates for future customers so far. This assumption could be released by accepting more computational complexity for the determination of the customers’ individual retention rates. This can be achieved through network simulations of the development of the individual number of contacts. We are currently working on taking into account these aspects.

REVEALING KNOWLEDGE NETWORKS FROM COMPUTER MEDIATED COMMUNICATION IN ORGANIZATIONS

Abstract

In today’s knowledge driven economy, knowledge is considered to be the key factor in defining the success of an organization. We have learned that knowledge is residing in the informal network of the organization. Hence, to improve performance, it is the informal knowledge network that should be examined and developed. For this purpose, social network analysis is increasingly applied in business contexts. This is, however, a new domain, which is still in development. This paper aims to aid in this development by researching how representative knowledge networks can be revealed in organizations. While surveying is a common first option to capture an organizational network, this technique may not always be suitable. Communication sources (e.g. e-mail) may provide an alternative, however, we do not know to what extent these sources can represent the actual knowledge network. This paper examines a Dutch IT services organization. Here, a web-survey among the employees baselines the knowledge network, which is compared to 3 communication networks from the same organization, captured by means of e-mail, telephone and SMS (Short Message Service) communication (also known as text messaging or texting). A comparison is made by means of correlating the network matrices and by comparing essential network properties. Findings show that only the e-mail network is significantly representative for the baselined knowledge network. This exercise is exploratory in nature as only one organization is examined, but comprehensive with regard to the richness of data that is available for examination. From our findings we gain insight in the extent to which networks, captured from e-mail, telephone and SMS archives can represent an organizational knowledge network.

Keywords: Informal network, Learning network, Advice network, Social Network Analysis, Mail analysis
1 INTRODUCTION

Knowledge management is widespread in organizations and involves the management of knowledge processes concerning generating, sharing and using knowledge (Davenport & Prusak, 1998). Typically, there are two approaches toward knowledge management: codification and personalization (Hansen, Nohria & Tierney, 1999). The first approach assumes that knowledge within the organization can be made explicit and stored within information systems such as knowledge repositories. Hence, knowledge should be retained so that it is available for re-use. The second approach considers organizations as transactive knowledge systems where knowledge is exchanged between individuals (Wegner, 1987). In this approach, knowledge management focuses on stimulating the interaction between individuals so that knowledge diffusion takes place throughout the organization.

The personalization approach has gained more attention of researchers in recent years. Part of this research focuses on the pattern of knowledge interactions that we refer to as knowledge networks (Hanssen, 2002). A visual representation of such a knowledge network consists of nodes that represent the employees of an organization while the links between these nodes represent the knowledge exchanges between these employees. This contextual specification is the main difference between a social network and a knowledge network: a knowledge network is a social network regarded from a knowledge perspective. A useful method for studying these networks is Social Network Analysis (SNA) as it supports both qualitative and quantitative network research (Wasserman & Faust, 1994; Cross & Parker, 2004). Network data that is required for this research is typically collected using surveys or in some instances using interviews. In a survey, a respondent is asked about his/her knowledge exchange relations with his/her colleagues within the organization. Aspects of the relation that can be of interest include the type of knowledge that is exchanged, how it is exchanged, and how frequently it is exchanged. A disadvantage of surveys is that, especially for large surveys, it takes considerable time from the respondent to fill out the survey and that high response rates are required to do qualitative analysis in case studies (Helms, 2007; Teigland, 2002). Consequently, there is hardly any longitudinal analysis of knowledge networks as it requires that a survey is sent out several times during a certain period.

To overcome these issues, some researchers analyze e-mail traffic within organizations as a source for collecting network data (e.g. Tyler, et al., 2005). The advantage here is that because respondents do not need to fill out a survey, the response rate is 100% and longitudinal analysis becomes possible by examining consecutive time frames. A limitation, however, is that the assumption with analyzing e-mail traffic is that e-mail communication is representative for communication that concerns knowledge exchange. Principally, this idea is not wrong as knowledge is an act of personal interaction by means of communication. But this communication does not only take place through e-mail messages. Face-to-face communication is also an important means for getting knowledge across (Lock Lee & Neff, 2004). Furthermore, e-mail messages are not only used for knowledge exchange but for instance also for coordinating tasks and personal messages (Whittaker & Sidner, 1996). Next to e-mail traffic, other communication sources may be applied to overcome the issues of capturing an informal network by means of surveying. One alternative is by means of tracking telephone conversations within an organization. Also, tracking text messages (texting), further referred to as SMS messages (Short Message Service), may be a valuable source for capturing the informal network of the organization.

This paper intends to examine the extent to which networks that are created from sources such as e-mail, telephone and SMS communication are representative for the knowledge network of an organization. We define our research question as follows:

“To what extent are networks, captured from computer mediated communication sources representative for the knowledge network of an organization?”
The need for this research initiative stems from the fact that the analysis of knowledge networks is becoming a more popular instrument in both science and management. Data capturing by means of surveying knows several limitations that data capturing from computer mediated communication sources does not have. The latter form of data capturing always yields a 100% participation, covering the full network, and it supports longitudinal analysis opportunities. If this research can indicate if and to what extent computer mediated communication sources are suitable to represent knowledge networks, it enables new possibilities for analyzing networks for both science and business.

The remainder of this paper is structured as follows. In section 2 this research is embedded in its theoretical background. Section 3 elaborates on the research method and approach. A case study were networks are captured and compared is introduced and a comparison approach of the networks is elaborated upon. In section 4 the results of the case study are provided, based on the proposed measuring and comparison approach. In section 5 our findings are discussed and conclusions and limitations are provided.

2 THEORETICAL BACKGROUND

A knowledge network concerns the knowledge management activities (e.g. knowledge creation or sharing) that take place among people in an organization. When focusing on a particular knowledge management activity, several types of knowledge networks can be distinguished. Two types of knowledge networks that are often distinguished in literature include learning networks (cf. Skerlavaj, Dimovski, Mrvar & Pahor, 2008) and advice networks (cf. Borgatti & Cross, 2003). Both types of knowledge network are included in this research and described in more detail below. Furthermore, the role of communication in knowledge exchange is briefly explored, which finally leads to the idea to use communication data stored by technology supported media as a source for collecting data on knowledge networks.

The traditional, cognitive view on learning assumes that learning is a mental process within the heads of individuals (Hustad, 2007). In this view, learning is separated from doing in practice and therefore neglects what can be learnt through experience and collaboration. More recent views consider learning as a social process of mutual engagement and relate learning explicitly to practice. Two major accounts in this field are the work by Lave & Wenger (1991) and Brown & Duguid (1991). Based on their studies, they introduced the concept of Situated Learning and Learning in Working respectively. The concept of situated learning is based on master-apprenticeship relationships where apprentices learn and master a practice through legitimate peripheral participation. Peripheral participation means that the apprentices start participating by performing relatively easy tasks and with low risk to the practice, i.e. in the periphery of the practice. During the execution of his tasks, the apprentice engages with and is coached by more experienced practitioners in the practice. If an apprentice is successful, i.e. he is learning, he gets more responsibilities until he finally becomes a master himself.

In this research, we refer to the learning relations between employees in an organization as knowledge networks (Skerlavaj et al., 2008; Palazzolo et al., 2006). Knowledge that is exchanged in learning relations typically involves tacit knowledge and consists of skills, experience and attitudes. This makes knowledge exchange difficult and therefore not every type of knowledge exchange is as effective as another. More active learning approaches, e.g. guided problem solving or guided observation, are preferred as they result in richer knowledge transfers from the master to the apprentice (Leonard & Swap, 2005; Davenport & Prusak, 1998). Richer knowledge transfers results in a higher level of knowledge exchange and therefore contribute to a deeper understanding of the practice. The goal of learning networks is to increase and preserve the knowledge and competence level of employees in the organization, which should ultimately result in a better performance of the organization (Skerlavaj et al., 2008).
Advice networks refer to the idea that employees are dependent on the knowledge of others to execute their job (Cross & Parker, 2004). In that case, it is important to know who knows what and to have access to these people so that they can be asked for advice when needed (Borgatti & Cross, 2003). Cross, Borgatti & Parker (2001) defined five different types of advice that can be sought: Solutions, Meta-knowledge, Problem reformulation, Validation, and Legitimation. These types indicate the intention for seeking advice from a colleague. Providing advice takes place by exchanging knowledge, however, this knowledge exchange is considered to be different from knowledge exchange in a learning network. In the case of an advice network, the goal is to transfer just enough knowledge so that the advice seeker can solve his problem. Hence, more passive learning approaches for knowledge exchange can be used such as directives, rules of thumb or pointers to information sources (Leonard & Swap, 2005). Besides knowing who knows who and having access, it is also important that you can tap into this knowledge quickly (Cross & Parker, 2004). The speed of knowledge exchange is referred to as velocity (Davenport & Prusak, 1998). It is defined as the time between contacting a colleague and finally receiving the requested knowledge from this colleague, either directly from him or via him from another colleague. The higher the velocity of the knowledge exchanges in the advice network, the better it is for the job performance (Hansen, 2002).

Communication is a vital mechanism when it comes to exchanging knowledge in learning as well as advice networks (Palazzolo et al., 2006). It is through communication, consisting of for example discussions and asking questions, that an apprentice can learn from a master. Furthermore, communication is also the basis for asking advice from colleagues. Several media are available for communication and hence for knowledge exchange in learning and advice networks. Basically, two types of media can be distinguished: Face-to-face contact and technology supported media. According to media richness theory (Daft & Lengel, 1986), the selection of the right medium depends on the richness of the knowledge that needs to be exchanged. Consequently, it might be wise to use different media for learning and asking for advice as the richness of the knowledge transfer in both cases is different. Research shows that people have a strong preference for face-to-face contact when it comes to exchanging knowledge (Cross et al., 2001; Smith & McKeen, 2003; Lock Lee & Neff, 2004). All studies reported that computer supported media such as e-mail, telephone or intranet have a lower preference. It is not just that face-to-face contact is the best medium per se but also that other factors are involved why people prefer face-to-face contact. These factors include trust and social cues for example (Wenger, McDermott & Snyder, 2002; Hooff, De Ridder & Aukema, 2004). But it is not just a matter of selecting the best medium, but using several media at the same time as they reinforce and support each other (Davenport & Prusak, 1998). Hence, it is likely that people will use several computer supported media to support face-to-face contact. Based on this assumption, it might be worthwhile to explore to what extent data about knowledge network relations can be retrieved from the computer supported media that store data about communication.

E-mail is a computer supported medium that is more frequently used to capture the social network of an organization (e.g. Tyler, Wilkinson & Huberman, 2005) and a variety of tools exist that support capturing a social network from e-mail data (e.g.: Gloor (2004), Edwards (2005), Mika (2005) and Viegas, Golder & Donath (2006)). E-mail is argued to be a plausible source for capturing a social network. Farnham, Portnoy & Turski (2004) for example reveal that the people we mail most are also the people we tend to work with most. This does, however, not argue for the fact whether e-mail data may also be applied to capture a knowledge network. Hence, it is relevant to investigate to what extent e-mail data, along with other computer mediated communication sources, such as telephone communication and SMS messages, are plausible as sources to capture the knowledge network of an organization.
3 RESEARCH METHOD

3.1 Approach & Sample

In order to examine the research questions, a comparison was made between an advice and a learning network on the one hand and 3 communication networks on the other hand, derived from e-mail traffic, mobile phone calls and SMS messages. The choice for these networks stems from the availability of data in our sample. A case study was conducted in a Dutch consultancy firm in the IT services sector. The firm consists of 68 employees, of which 41 were included in our sample due to their participation in the survey. Of these 41 employees, 10% is female. Moreover, the sample is divided over 6 functional areas (e.g. management, consultancy) and 3 levels of seniority (junior, medior, senior). The case study was conducted in June 2008, a non-holiday period, boosting the representativeness of the networks while no colleagues were unavailable. The scope of the data collection was 1 month. Most employees in our sample are geographically separated in their daily work. Therefore, these employees heavily rely on computer mediated communication media such as e-mail, telephone and SMS to communicate with each other.

3.2 Data collection

The data for the advice and the learning network was collected by means of an online web-survey that was specifically created for this research. In the survey, employees were asked to indicate to what extent they give advice to each other and to what extent they learn from others. Both questions could score on a 5-point scale, ranging from “sporadically” to “intensively”. From the survey results, two adjacency matrices were created: an advice network and a learning network. The scores that each respondent provided for 1..n colleagues were placed in the cells of an adjacency matrix where each respondent is represented by a row and each colleague by a column. The cells were the row and column match the same person were not taken into account. While no advice or learning (score: 0) was also denoted in the adjacency matrix, a matrix is always squared. Eventually, before the calculations were performed, the 2 matrices were recoded. The 5 points in the scale were reduced to 4 points, cancelling out the 1 on the scale, leaving a scale of 2-5. This was done after an examination of the scores in the web-survey. About 50% of the respondents indicated a connection to all other respondents of at least 1 on the scale, meaning that these respondents indicated that they at least sporadically contacted all other respondents. The other 50% of the respondents did not indicate this connection of at least 1 on the scale to all other respondents. This distortion was solved by removing the 1 on the scale. The communication networks (e-mail, telephone and SMS) were not recoded.

For the respondents that participated in the survey, we also collected data about their e-mail, telephone and SMS communication. For this purpose, the Exchange server was accessed to extract one month of e-mail communication data and mobile phone bills were accessed to extract telephone and SMS communication data. Both the data from the Exchange server and the mobile phone bills were applied in a data mining application that was specifically designed and developed for this research, called ESNE: E-mail Social Network Extraction. The application uses the header data of e-mail messages (the “from” and “to” headers). The content of the messages (body data) was discarded due to privacy regulations in our organization of study. Also, the application supports filtering of the e-mail messages. Filtering was applied in various ways. First of all, the data was filtered for a specific time frame of 1 month. Moreover, an upper bound was defined for mass e-mails. Messages that were sent to over 20 recipients were filtered out from our research. It is argued that these e-mails do not represent personal communication as is the case in an advice and a learning network. No lower bound was defined. Different from other tools, our application also filtered out automatically generated messages (e.g. an out-of-office reply) and all senders and recipients external to the company, leaving
only the communication between employees, as again is the case in an advice and a learning network. Similar to other tools (e.g. Holzer, Malin & Sweeney (2005) and Bird et al. (2006)), the application also supports finding aliases. The application scanned all employees on their first and last name and provided possible aliases for each employee (i.e. different mail addresses). All possible aliases were manually linked to an employee or discarded by a manager from the organization. The application itself does not support the visualization of a social network from the data but it is capable of creating adjacency matrices from the e-mail data in the format of the social network analysis software used in this research (.ntf file to import in Cyram Netminer 3.30a). The .ntf file contains both the adjacency matrix and an attribute table containing actor attributes that were derived from employee data managed in the application. This way, an adjacency matrix was created from the filtered e-mail data (including aliases) from June 2008. The weight in the adjacency matrix is expressed by the amount of e-mail messages exchanged between two actors.

Likewise, two adjacency matrices were created from the telephone and SMS data. The application filtered the telephone data to exclude all but mobile phone calls from and to the employees of the focal organization. Also, calls that lasted less than 10 seconds were filtered out. Concerning the SMS data, only the messages that were sent from and to employees were included. The weight in both matrices is again expressed by the amount of calls or messages exchanged between two actors. All matrices i.e. the advice and learning matrices from the web-survey and the e-mail, telephone and SMS matrices from the analysis tool, were manually combined to one file containing the 5 matrices, identical in size and actors, and one attribute table to be used in our social network analysis software.

3.3 Measures

In order to investigate the differences between the networks, a means to compare the networks is required. In the comparison process, the networks that were captured by means of the web-survey were treated as a baseline. It is argued that these networks represent the actual advice and learning network of the organization, as these are the only networks where the employees indicated their relations themselves. In comparison: the e-mail, telephone and SMS networks are a result of communication, moreover than an indication of relations by the employees themselves.

For the comparison between the networks, a two-way comparison format is proposed. First, the networks are compared by means of correlating the matrices. Correlation coefficients can indicate the extent to which the matrices of the networks are similar to each other. The correlation coefficients can be calculated over either the non-weighed (binary) data and the weighed data. The first calculation indicates similarity when only observing whether actors are tied or not. The second calculation indicates the similarity when also taking into account the weight of links between actors. The correlation coefficients for the non-weighed matrices are calculated using the Jaccard coefficient. This coefficient is based on only the existing relations in a matrix and neglects the non-existing relations (i.e. it matches the 1 and neglects the 0). For the weighed matrices, the Pearson’s correlation coefficient is applied. For all correlation measures, a QAP permutation test (Borgatti, Everett & Freeman, 1992) is applied with 2,500 iterations in order to support the significance of the correlation scores.

In the second way of comparing the networks from our comparison format, the networks are compared by means of calculating and comparing network properties that tell something about the structure of the networks. By comparing the networks by means of their properties, further insight can be gained in the equivalence of the networks. For comparing the network properties, we use a number of well-known network measures (derived from Hanneman & Riddle (2005)) that cover different aspects of network structure. An overview of the the network properties that are examined is provided in table 1. For a more elaborate description of the network properties, the reader is referred to Hanneman & Riddle (2005)).

4 RESULTS

4.1 Matrix correlations

In table 2 and 3 below, an overview is provided of the correlation coefficients between all five networks. For the QAP permutation test, in all cases the $p >= observed$ values were .000, indicating that all results are significant. For the Pearson correlations of the weighed matrices, the significance is expressed by either * or **.

As can be derived from table 2 and 3, the correlation coefficient between the advice and learning network indicates that both networks have no specifically high overlap. From this fact we may conclude that it is plausible to interpret the correlations of the e-mail, telephone and SMS networks to the advice network separate from the correlations of those communication networks to the learning network. A clear decreasing trend is visible for the similarity between the survey networks (advice and learning) and the communication networks, decreasing from mail, to telephone, to SMS. This trend applies for both the non-weighed and weighed data and for both the advice and learning network. Another result from the calculations is the fact that the weighed communication network matrices show higher scores than the non-weighed communication network matrices, meaning that e.g. the e-mail network is more similar to the advice and learning network if the weight of the links is taken into account. The e-mail, telephone and SMS networks tend to be more similar to the advice network than to the learning network. However, these differences are only minor.

4.2 Extended mail network

From our findings from the matrix correlations, we learned that of all communication networks, the e-mail network is the most similar to the advice and learning network. Therefore we decided to extend the research concerning the similarity between the advice and learning network on the one hand and the e-mail network on the other hand. It is argued that the timeframe of one month that is applied in this research may yield that the e-mail network is less similar to the advice and learning networks than it could be if the timeframe is extended. Therefore, the timeframe of the e-mail network was extended to 6 months, from January to June 2008. From this data, a new network, the extended e-mail network, was constructed using the data mining application (ESNE). The extended e-mail network was then correlated against the advice and learning network. Again, the $p >= observed$ values were .000 in all cases, indicating that all results are significant. The results from these calculations are incorporated in table 2 and 3 above.

The results show a different outcome for the non-weighed than for the weighed data. The non-weighed data shows that the extended e-mail network is less similar to the original e-mail network that consists of only one month of data. However, the difference between the scores from the non-weighed and the weighed data are minimal. On the other hand, the weighed data does indeed show that the extended e-mail network is more similar to both the advice and learning networks than the original e-mail data of one month.

4.3 Network properties

In table 4 an overview is provided of the scores from 11 network properties that are commonly used in social network analysis. The scores are calculated for all basic weighed networks (i.e. the extended e-mail network is excluded from our scope here).
The network properties displayed in table 4 show different scores for the different networks. For most network properties, the same trend can be visualized as with the matrix correlations. Of all communication networks, it is again the e-mail network that most resembles the advice and learning networks. The telephone network is less similar to the advice and learning networks and the SMS network even less. This trend does, however, not apply for the reciprocity network property. An explanation for the deviating reciprocity value in the e-mail network may be that of all forms of communication studied in this research, e-mail is typically a medium of bilateral communication, i.e. an e-mail is typically replied to with another e-mail. This way of communicating is not found in media such as telephony or in an advice or learning network, where one instance of communication already involves both sender and receiver. The matrix correlations showed that the e-mail network, which is the communication network that most resembles the surveyed networks, is more similar to the advice network than to the learning network. In the case of the network properties, however, the e-mail network is more similar to the learning network than to the advice network. Again, these differences are only minor. This does, however, not apply for the centralization properties, where the in-degree centralization index of the e-mail network is far more similar to the advice network and the out-degree centralization index of the e-mail network is far more similar to the learning network.

5 DISCUSSION & CONCLUSIONS

5.1 Discussion & conclusions

This paper intended to examine to what extent computer mediated communication in organizations may be representative sources for capturing and analyzing organizational knowledge networks. As the analysis of organizational networks is becoming an increasingly more important management instrument, there is a need to continuously improve the analysis method. While capturing network data by means of surveying knows several limitations, the analysis of computer mediated communication...
sources may provide a promising alternative. In the Dutch IT services organization were we conducted our case study, 6 networks were captured: the advice and learning network by means of surveying and 4 communication networks from e-mail traffic (1 month and 6 months in length), telephone conversations and SMS (text) messages. Consequently, a comparison between the networks was conducted by means of two comparison approaches: correlating the network matrices and comparing basic network properties, applied in social network analysis. Results from the matrix correlations show that only the e-mail network (both the original and the extended network) is significantly representative for both the advice and learning network. The telephone and SMS network are only slightly representative to the advice and learning network. The results from the network property calculations support the findings from the matrix correlations to a large extent. A secondary finding is the fact that the extended e-mail network has a mixed effect on the quality of representativeness of the original e-mail network. While the weighed extended e-mail network is more representative to the learning and advice network as its weights are more representative, the non-weighed extended e-mail network is less representative for the advice and learning network. This is probably caused by a distortion due to introducing new relations in the extended e-mail network that were not present in the original e-mail network and also not in the advice and learning network. This distortion may be removed by defining a minimum amount of messages sent between two actors before including the relation in the network (recoding the data). Although this examination was only conducted in one organization, the richness of the data proved worth to investigate how the computer mediated communication networks resemble the advice and learning network that provided a baseline for the knowledge networks in the organization of our case study. We may conclude from our research that a network based on e-mail traffic proves to be a valid representation for a knowledge network when conducting knowledge network analysis if surveying the focal organization is not an option.

5.2 Limitations

Probably the most important limitation on our research is the fact that this research was conducted in only one organization. Therefore, we cannot conclude on the repeatability of our findings in other organizations. It is, however, imaginable that it is quite a challenge to find multiple organizations that are willing to participate in a survey and also provide access to their Exchange server (e-mail) and to provide mobile phone bills (telephone and SMS). This is the reason that this research was addressed as an exploratory case study research. Another limitation is that the scales used in the data capturing process for the 6 matrices were not normalized. The advice and learning networks consist of a 5-point scale, whereas the e-mail, telephone and SMS networks were based on the amount of messages or calls. However, the analysis of the matrix correlations lowers the effect of this limitation as the coefficients calculated over both the weighed and non-weighed networks are similar to a large extent. A final limitation is the fact that the telephone and SMS networks could not be captured for 100% of the data. This is due to the fact that the telephone bills were partially concealed. This was done by the provider of the telephone network and cannot be altered. In the telephone network 20% of the data was removed and in the SMS network 9% of the data was removed due to concealed data (anonymous calls and SMS messages). Because the blocked entries on the telephone bills are spread over all of the actors, it is false to conclude that the measured indicators deviate by 20% and 9%. The percentages only decrease the amount of calls and messages, they do not remove 20% and 9% of the links. From the existence of concealed entries it is, however, evident and fully in line with the findings of this research that telephone and SMS networks should not be favored as a surrogate for the advice and learning network of an organization.
5.3 Acknowledgements

We would sincerely like to thank Professor Robert A. Hanneman (University of California, Riverside) for his help on structural equivalence measures for matrices and on the interpretation of the significance of the results of our paper.

ANALYZING COMMUNITY CONTRIBUTIONS TO THE DEVELOPMENT OF COMMUNITY WIRELESS NETWORKS

Abdelaal, Abdelnasser and Ali, Hesham, College of Information Science and Technology
University of Nebraska at Omaha, Omaha, NE 68182, {aabdelaal, hali}@mail.unomaha.edu

Abstract

Community wireless networks (CWNs) have emerged as collective actions achieved by many communities worldwide to access the information highway. Developing autonomous CWNs depends, in large part, on community contributions that may include time, money, efforts, expertise and computer resources. However, there is a lack of instruments for measuring such contributions, as well as the outcomes of these networks. This study uses the social network analysis analytical approach to model, measure and analyze community contributions in the development of their wireless infrastructures. In particular, we model community contributions as a two-mode (or bipartite) graph composed of two sets of nodes: the first represents a set of community contributors and the other represents a set of wireless networks. The edges between these two sets stand for the inputs of contributors. Their contributions include volunteering time and manpower, sharing their wireless nodes with community members, donating money, donating hardware, providing technical support, and developing open source software for the network. The model is used to analyze these tangible and intangible forms of contributions. We hope this study provides a better understanding and sounder measurement of the role of communities in developing these emerging common wireless infrastructures and similar digital collective actions.

Keywords: community wireless networks, social network analysis, collective actions, common systems

1. INTRODUCTION

The phenomenal growth of community wireless networks (CWNs) has captured the attention of a broad range of academicians and professionals in several disciplines and practical fields. CWNs are socio-technical crucibles where community resources are shared, mobilized and reproduced to build a common telecommunication infrastructure. Numerous communities have built autonomous wireless infrastructures using their own resources to join the information society. The majority of these networks provide free, or affordable, Internet to community members. In other words, CWNs have been built by the community, as an outgrowth of private WLANs, for the community. We argue that CWNs could serve as a third solution, in addition to the private and public solutions, for achieving digital inclusion (Abdelaal and Ali 2009a). Consequently, scholars recognize them as wireless commons achieved by collective actions (Abdelaal and Ali 2009b; Bina and Giaglis 2006; Damsgaard, Parikh, and Rao 2006; and Sicker, Grunwald, Anderson, Doerr, Munsinger and Sheth 2006 and Negroponte 2002). The term collective actions refers to the voluntary collaboration of group members to construct a common project (Olson 1971:pp7). Literally, a collective action requires a collectivity, or a group of people, which collaborate to achieve an action (Sakurai 2002). Along this notion, developing collective wireless networks, require a motivated and committed group of agents, sometimes organizations, with shared objectives who contribute to these networks for the well-being of the community at large (Abdelaal and Ali 2007; Quinn 2006; Bina and Giaglis 2006 and Camponovo and Cerutti 2005). These agents may include local residents, open source software (OSS) developers, students, technology vendors, municipalities, civil rights activists, developing agencies and researchers.

Agents of a social structure are those who participant in converting both tangible and intangible resources into negotiable offerings (Allee 2008). The agents of CWNs could be classified into three categories: beneficiaries, contributors, and isolated actors (Abdelaal and Ali 2008). Beneficiaries are individuals who gain from these collective networks. Their benefits may include obtaining free Internet access, donated old PCs, technical
Expertise, exposure, and/or other social gains. Contributors are those who donate to the network. Their contributions may include providing manpower or technical skills, donating money or used equipment, sharing their wireless nodes with others or boosting the publicity of the project (Quinn 2006 and Drunen, Koolhaas, Schuurmans and Vijn 2003). Scientists and practitioners emphasize that engaging community members and employing their resources are essential to building and sustaining these community-driven ventures (Siochru and Girard 2005; and Sandvig, Young, and Meinrath 2004 and Bina and Giaglis 2006). Isolated actors, within the proximity of the network, are those who neither benefit from nor contribute to the network. These isolated actors include the “have-nots” or those who are digitally disconnected. The subject matter of this paper is the contributions of the agents of CWNs to the development and operation of these collective actions. CWNs provide community members the opportunity to contribute (e.g. money, time, expertise, computer resources) and develop innovative applications, software, and hardware for their communities (Powell 2006). In this study, we use the term contributions to refer to the tangible and intangible resources or assets provided by community members to build and maintain CWNs.

Despite the exponential growth of these networks, closely linked to the deregulation of the 2.4GHz spectrum, there is a lack of empirical studies and quantitative methods that investigate their resources and outcomes. For instance, previous attempts, mostly case studies, have conceptual and instrumental limitations. Our objective is to complement previous literature and develop a quantitative model, supported by empirical evidence, for community contributions to CWNs. Hopefully this model would guide future research and help policy makers and community developers to promote this innovation. Such collective projects, we believe, require new perspectives to treat their resources and outcomes for the following reasons:

1) CWNs are built and operated by flows of tangible (e.g. money, hardware) and intangible (e.g. knowledge, efforts, and software) contributions from community members. Since these contributions are provided for free, it is difficult to measure and aggregate them using conventional measures. Therefore, it is hard to comprehend the contributions of these resources to the overall cost of the project;
2) Most of these networks are not official organizations, but rather loosely affiliated groups or collectivities;
3) As with other collectivities and collaboration groups, it is not easy to track the contributions and benefits of participants. This problem is exacerbated if the diversity of stakeholders of CWNs is considered; and
4) Community contributions, and the benefits of CWNs, are usually provided outside the market mechanism. Therefore, it would be useful to convert them into negotiable market values in order for researchers to control such factors and for practitioners to manage their networks.

Therefore, paying special attention to this emerging form of collective actions is warranted and developing quantitative models or metrics for their variables is necessary to advance this intellectual stream and accumulate related knowledge. The developed models, or artifacts, should be efficient and general enough to encompass different types of involved actors and acknowledge their contributions and benefits. The key question we address is:

How can we measure the role of communities in developing their wireless networks?

Social network analysis (SNA), depends on graph theory, is used to answer this question. Answering this research question is important for understanding how community resources are mobilized and reproduced to achieve collective actions, taking advantage of digital innovations. This would be a first step towards advancing CWNs as a third solution to integrate the society in the information age. This analytical approach has been used to study a wide-range of similar networks such as computer, social, biological, chemical and transportation systems (Hanneman and Riddle 2005 and Peter, Scott, and Wasserman 2004). Sufficient modeling and analytical details are provided so that researchers and practitioners can apply the adopted research approach in their own investigations. This study is part of a larger research project whose objective is to investigate the tension between these emerging socio-technical networks and their societies. Investigating the tension between "structure and agency" or "macro and micro" is one of the key intellectual themes in sociological inquiry (Hanneman and Riddle 2005). It is important to note that this paper is an extension to a previous work that proposes a conceptual framework of community contributions to CWNs (Abdelaal, Ali and Khazanchi 2009b). In this previous work, we
treat community contributions as collective actions mobilized by the social capital in the community. In another work, we explore the role of these networks in achieving digital inclusion for their communities (Abdelaal and Ali 2009a). In particular, we also discuss their size, capacity, service charging, and finances. We also provide a thorough review of literature related to their outcomes.

The rest of this paper is organized as follows: section 2 discusses the literature of the role of communities in building their wireless networks and briefly reviews similar work that uses SNA to study complex networks. In section 3, we present our research methodology. In section 4, we propose our model. In the fifth section, we use the proposed model to compare and classify CWNs. Section 6 discusses the significance of research and suggest ideas for future work.

2. LITERATURE REVIEW

The notion of community and information commons have attracted the attention of a large number of Internet scientists (Lesser, Fontaine and Slusher 2000). Although there is an extensive research on collaboration in the domain of the Internet, very little empirical work has focused on the creation of telecommunication infrastructures as outcomes of such collaboration. In other words, a small body of research, mostly qualitative, addresses how CWNs are built. For instance, Damsgaard, Parikh, and Rao (2006) describe CWNs as wireless commons. They define wireless commons as a group which share their private WLANs to create a common resource and open it for others. The authors point out that the group members might have conflicts of interest or they may overuse such a common resource. Misusing or overusing common resources is a classical problem in social science known of the tragedy of commons. They discuss the causes and the preventions of this tragedy in the domain of the wireless commons or CWNs. Sicker, Grunwald, Anderson, Doerr, Munsinger and Sheth (2006) use simulation tools to study the relationship between the network capacity and the number of users to examine if the wireless commons are misused. They use the density, usage patterns, environmental conditions, and application demand as assessment parameters. Battiti, Cigno, Sabel, Orava, and Pehrson (2005) call these networks open access networks. According to the authors, the main advantage of CWNs is fostering win-win partnerships between actors, increasing freedom of choice for users and providers, decreasing costs and expanding service coverage. Along this line of research, we also consider CWNs as a form of collective or common projects (Abdelaal and Ali 2009a and Abdelaal, Ali and Khazanchi 2009b).

Best and Maclay (2002) identify six factors that must be considered for designing a self-sustainable CWN: costs, revenue, networks, business models, policy, and capacity. Camponovo and Cerutti (2005) classify the actors of CWNs into four categories: (1) those who share their access points with others; (2) the beneficiaries of these networks who obtain free Internet access; (3) the Internet service providers; and (4) the regulatory authority that sets the regulations to govern the use of the spectrum. Bina and Giaglis (2006) use the concept of collective actions to explore the motivations of participants of CWNs. Mandviwalla, Jain, Fesenmaier, Smith, Weinberg, and Meyers (2006) identify the following stakeholders: underserved individuals, municipalities, schools, small businesses, nonprofit organizations, community groups, utility companies, healthcare providers, and state and federal governments. This study focuses only on the inputs of such stakeholder to CWNs. We discuss the outcomes of these networks in Abdelaal and Ali (2009).

Scholars point out that such inputs may include volunteerism, money and hardware donation, providing technical support and developing OSS for the network.

For instance, Quinn (2006) discusses the role of community engagement, volunteerism, OSS, and donated computer hardware in the development of three CWNs in the Chicago area (United States). The author also
proposes a guide to help practitioners in this regard. Similarly, Drunen, Koolhaas, Schuurmans and Vijn (2003) point out the importance of community contributions in building and maintaining the Wireless Leiden network in the Netherlands. According to the authors, such contributions include low-cost network interfaces, OSS, home-built antennas, and voluntary manpower and technical skills. We model and analyze these types of community resources used to build the investigated CWNs. Using a case study, Shin and Venkatesh (2008) suggest that community participation should continue through all the developing stages is essential for the sustainability of CWNs. They also identify four groups of stakeholders emerged around this network: the Kutztown municipal authority, technology vendors, the project team and the community. They argue that inputs of citizens, as lay designers, are important for the success of CWNs. Powell (2006) discusses contributions of volunteers to British Columbia Wireless. Their contributions include site surveys, hardware hacking, software and content development, technical support and legal and regulatory research.

Reviewing previous literature, we highlight the following drawbacks:
1) The types of community contributions, to CWNs, adduced in previous literature are plausible and supported by evidence from case studies. However, they are not categorized and attributed in terms of quantitative variables that could be controlled. This is important for guiding future research, allowing for comparison, and accumulating knowledge; and
2) There are no conventional instruments or common approaches to measure the tangible or intangible resources and outcomes of CWNs.

Similar to our analytical approach, Jackson (2003) discusses several examples of economic applications of graph theory. These applications include obtaining information about jobs from social contacts, exchanging goods between market actors, and contracting trade agreements. Gale and Kariv (2007) propose a graph model for financial networks where nodes represent traders and weighted edges represent the probabilities of trade between them. Souma, Fujiwara and Aoyama (2005) model the Japanese shareholders network using a directed graph where nodes represent companies and edges represent activities, ownership and governance. Spulber and Yoo (2005) use graph concepts to develop a pricing policy for telecommunication services. Their proposed pricing policy takes into account the impact of changes in one node on the entire system, particularly on the economies of scale. Tesfatsion and Pingle (2003) use graph concepts to examine the effects of a non-employment payoff on network formation and behaviors of workers. The authors model the interactions between networks of workers in a form of a directed graph. The vertices represent the workers and employers. Edges denote to the work flows between workers and employers. In our pilot study, we use data from the Omaha Wireless Group to describe CWNs as socio-technical networks where each network is composed of two graphs: wireless network and a social network served by this wireless network (Abdelaal and Ali 2009b). We argue that the interactions between these two graphs impact different aspects of CWNs. Evidently, graph theoretic concepts and SNA is a sounder analytical approach for studying CWNs as value networks.

2. RESEARCH APPROACH

As with similar emerging phenomena, there are no standard research approaches or widely-recognized empirical studies on CWNs. This is mainly because the CWNs movement is large and diverse, geographically dispersed, and informally structured. In addition, CWNs are not well-defined and practitioners and researchers usually mix between them and similar networks such as municipal wireless networks and commercial Wi-Fi hotspots (Abdelaal and Ali 2009b). It is, therefore, difficult to collect high quality data about the transactions of all actors. To avoid these problems, we collected 2-mode network data using a survey instrument during the annual International Summit for Community Wireless Networks (ISC4WN). The collected data represents a network of “affiliations” between different categories of community contributors, by their inputs to develop the network, and their CWNs. In other words, this data describes which type of contributor (e.g. volunteer, money donor, OSS developer, etc.) is affiliated with which CWN and how much he/she contributes. Another quality of the data is

2 The International Summit for Community Wireless Networks was held in Washington, DC, U.S., May 28th to the 30th, 2008. Its objective was to explore the opportunities and challenges of CWNs.
that it represents 16 networks from different parts of the world. The data describes ties between two sets of nodes at two different levels of analysis: a set of CWNs on the micro level and the community members on the macro level. The third quality of the data lies in reflecting diverse opinions of CWNs developers and advocates who attended this annual summit. We posted the survey online and sent its link to those who could not fill it during the summit. We received 41 responses and eliminated the incomplete ones. The survey questions are designed to ask respondents to choose the types of contributions their networks receive from their communities. We categorized six distinctive facets of contributions (or variables): volunteering time, money donation, hardware donation, technical support, sharing access points, and developing software for the system, as shown in Table 1. These variables are used as proxies for community resources, or contributions. In order to study collective actions in a quantitative manner, we need to identify a collective action to examine and construct variables that represent this action (Sakurai 2002). These variables have been identified based on extensive review of literature, three years of experience working with the Omaha Wireless Group and discussions with leaders of CWNs. Seven individuals examined the clarity and relevance of the survey questions to the measured constructs. The literature and collected data shows that there are other types of contributions such as obtaining the necessary political support and promoting the awareness of the benefits of the project. We excluded such contributions for simplicity. Again, we use graph theory concepts to study how communities, by their contributions, create CWNs. A graph is a mathematical model consisting of two sets V and E. V is a set of nodes called vertices connected by a set of links (or E) called edges. Graphs have been used to represent many similar complex networks and solve related problems (Peter, Scott, and Wasserman 2004). The SNA and the UCINET software is used to visualize, measure and analyze the data. We adopt this approach for its efficiency in representing network data in a compact and systematic manner, suitability for computation processing, capability of using theories and concepts of graph theory and ability to infer patterns of relations between actors in a mathematical manner (Hanneman and Riddle 2005). For more details about concepts, measures and suitable data for 2-mode networks (or bipartite graphs), we refer readers to Hanneman and Riddle (2005) and Borgatti (2008).

Table 1. A matrix of the contributions of CWNs actors

The investigated observations are transformed into a data matrix in which each observation, or a CWN, occupies one row and each variable, or type of contribution, occupies one column. Table 1 summarizes the data collected about these variables. Three kinds of intangible resources, or community contributions, have been distinguished in the realm of CWNs: the cooperation of volunteers, the technical expertise of computer specialists and the
