ePublications@SCU is an electronic repository administered by Southern Cross University Library. Its goal is to capture and preserve the intellectual output of Southern Cross University authors and researchers, and to increase visibility and impact through open access to researchers around the world. For further information please contact epubs@scu.edu.au.
ECIS 2009
The 17th European Conference on Information Systems

INFORMATION SYSTEMS IN A GLOBALISING WORLD: CHALLENGES, ETHICS AND PRACTICES

8-10 June 2009
Verona, Italy
Welcome to ECIS 2009

ECIS 2009 -- Benvenuti a Verona!

Welcome to the 17th European Conference on Information Systems, ECIS 2009, organized jointly by the Department of Management in the Faculty of Economics at the University of Verona, and the Information Systems and Innovation Group of the Department of Management at the London School of Economics and Political Science.

Since its beginning in 1993 ECIS has grown to become the largest and most prestigious Information Systems conference in Europe, attracting scholars from all over the world.

In contrast to past conferences ECIS 2009 does not have specialist tracks, but differentiates only between full research papers and research-in-progress ones. Of 697 submissions, 248 papers will be presented at the conference. In addition, ten excellent panels enrich the programme.

Renewing the traditional structure of the conference required different and more substantial support from the community. We relied on Research Paper Chairs Sue Newell and Edgar Whitley, Research-in Progress-Chairs Nancy Pouloudi and Jonathan Wareham, and Panels Chair Lars Mathiassen, 250 Associate Editors, countless reviewers, and Carla Marisa Bonina for handling the submission process. To all we are very grateful for their excellent work!

We further extend our thanks to the Chairs of the Doctoral Consortium, Gabriele Piccoli and Erica Wagner.

The conference would not be taking place without the enthusiastic support provided by Antonio Cordella and Cecilia Rossignoli, Organisation Chairs, and Lapo Mola who managed the Local Organisation.

A special thank is also for Cinzia Bonomo from Sistema Congressi, Anna Maran and Alessandro Zardini from University of Verona for their support and help in making this event possible.

Finally, we "thank" our delegates, presenters, and session chairs, who will be the real protagonists of the conference.

We are sure the programme and the quality of the participants will make ECIS 2009 in Verona a very memorable event.

Marco de Marco, Claudia Loebbecke, Leslie Willcocks

Conference Co-Chairs
Conference Committee:

Conference Chairs
Professor Marco De Marco (Catholic University, Italy)
Professor Claudia Loebbecke (University of Cologne, Germany)
Professor Leslie Willcocks (London School of Economics, UK)

Research Paper Chairs
Dr. Edgar Whitley (London School of Economics)
Professor Sue Newell (Bentley College, USA)

Research–in–Progress Chairs
Dr. Jonathan Wareham (ESADE, Spain)
Dr. Nancy Pouloudi (Athens University of Economics and Business, Greece)

Panels Chair
Professor Lars Mathiassen (Georgia State University, USA)

Doctoral Consortium Chair
Dr. Gabriele Piccoli (Università di Sassari, Italy)
Dr. Erica Wagner (Cornell University, USA)

Organisation Chairs:
Dr. Antonio Cordella (London School of Economics, UK)
Dr. Cecilia Rossignoli (University of Verona, Italy)

Local Organization
Dr. Lapo Mola (University of Verona, Italy)
Associate Editors, A big thank you!

On behalf of the ECIS 2009 programme chairs and organizing committee we would like to thank you for all your excellent work in acting as an associate editor for ECIS 2009.

This year, we received 680 submissions - up from 566 last year. Nevertheless, because of your excellent work, we were able to make decisions on all of the papers in the normal timescale and notified authors of the decisions on their papers following the programme committee meeting held in Verona in early March.

Around 35% of the papers were accepted and the programme for the conference is now available online at http://www.ecis2009.it/programme.htm.

An important part of the review process is providing an opportunity for the reviewers and associate editors to see how their perspectives, insights and reviews relate to those of the others involved in the process as well as to the final decision on the paper. This allows all involved to learn from the review experience.

The functionality for doing this on Manuscript Central is a little awkward, but if you logon to MC in the usual way, you can now view the full reviews, AE commentary and chair’s decision for all papers you were involved with.

Best wishes

Edgar, Sue, Nancy and Jonathan

Programme at a glance

SUNDAY, JUNE 7, 2009
09.00 - 17.00 ANCILLARIES:

- OPEN SOURCE AND INNOVATION WORKSHOP
  - Workshop Co-Chairs,
    - Tony Cornford, ISIG, LSE
    - Maha Shaikh, ISIG, LSE

- ESWIS: EUROPEAN STUDENTSWORKSHOP ON INFORMATION SYSTEMS
  - Workshop Co-Chairs
    - Valentina Albano, LUISS Guido Carli, Rome
    - Stefano Za, LUISS Guido Carli

- INVESTIGATING THE POSSIBILITIES OF GREEN IS
  - Workshop Chair
    - Helen Hasan University of Wollongong, Australia

- GLOBAL SOURCING MANAGEMENT WORKSHOP
  - Workshop Chair
    - Leslie Willcocks, ISIG, London School of Economics
    - Eleni Lioliou, ISIG, London School of Economics

**ECIS2009**

Proceedings ECIS 2009
DETAILED PROGRAM
### MONDAY PAPERS

**ROOM T4**

#### FROM 11.00 TO 12.30

**SESSION 2**

**E-GOV 1**

**SESSION CHAIR**

PingZhang

**THE CHIASMUS OF DESIGN: PARADOXICAL OUTCOMES IN THE E-GOVERNMENT REFORM OF UK CHILDREN’S SERVICES**

Dave Wastell, Nottingham University Business School, UK; Susan White, Dept. of Applied Social Science, University of Lancaster UK; Karen Broadhurst, Dept. of Applied Social Science, University of Lancaster UK; Chris Hall Centre for Applied Childhood Studies, University of Huddersfield, UK; Sue Peckover Centre for Applied Childhood Studies, University of Huddersfield, UK.

**APPLYING LESSONS LEARNED FROM COUNSELLING: ON NURTURING RELATIONS IN DESIGN PROJECTS**

Diego Calzà, University of Trento, Department of Sociology and Social Research, Italy; Claudia Cattani, eTour, Italy; Gianni Jacucci, University of Trento, Department of Sociology and Social Research, Italy.

**DESIGN CRITERIA FOR PUBLIC E-SERVICES**

Annie Röstlinger Linköping University, Dept of Management and Sweden; Stefan Cronholm Linköping University, Dept of Management and Engineering, Sweden; University of Borås, Business and Informatics Sweden.

#### FROM 14.00 TO 15.30

**SESSION 11**

**GOVERNANCE 2**

**SESSION CHAIR**

Ferdinando Pennarola

**IT-CONTROLLING IN FEDERAL ORGANIZATIONS**

Andreas Schwertsik Technische Universität München, Germany; Petra Wolf, Technische Universität München, Germany; Helmut Krcmar, Technische Universität München, Germany.

**HOW GERMAN HOSPITALS GOVERN IT – AN EMPIRICAL EXPLORATION**

Felix Köbler, Technische Universität München, Germany; Jens Faehling, Universität Kassel, Germany; Jan Marco Leimeister, Technische Universität München, Germany; Helmut Krcmar, Technische Universität München, Germany.

**TOWARDS A SERVICE GOVERNANCE FRAMEWORK FOR THE INTERNET OF SERVICES**

Christian Janiesch, SAP Research CEC Brisbane, SAP Australia Australia; Michael Niemann, Multimedia Communications Lab, Technische Universität Darmstadt, Germany; Nicolas Repp, Multimedia Communications Lab, Technische Universität Darmstadt, Germany.

#### FROM 16.00 TO 17.30

**SESSION 30**

**PROJECTS AND OPEN SOURCE**

**SESSION CHAIR**

MahaShaikh

**INFORMATION TECHNOLOGY AND THE FIRST-LINE MANAGER’S DILEMMA: LESSONS FROM AN ETHNOGRAPHIC STUDY**

Joao Vieira da Cunha, Joao Vieira da Cunha Faculty of Economics, Universidade Nova de Lisboa; Andrea Carugati, Andrea Carugati Århus School of Business, Århus University.

**THE RELATIONSHIP AMONG DEVELOPMENT SKILLS, DESIGN QUALITY, AND CENTRALITY IN OPEN SOURCE PROJECTS**

Donato Barbagallo, Politecnico di Milano, Dipartimento di Elettronica e Informazione, Italy; Chiara Francelancli, Politecnico di Milano, Dipartimento di Elettronica e Informazione, Italy.

**DO BEST PRACTICE FRAMEWORKS FIT OPEN SOURCE SOFTWARE CUSTOMIZATION?**

Steffen Kessler, Institute of Information Systems, Philipps-Universität Marburg, Germany; Paul Alpar, Institute of Information Systems, Philipps-Universität Marburg, Germany.
### Session 3: Socio Collaboration (11.00 - 12.30)

**Session Chair:** Aurelie Lequercq

- **Bitching, Bouncing and Brawling - How Backchannels Brought Colour to Conference Calls**
  - Benjamin Eaton, The London School of Economics and Political Science, UK

- **Development and Validation of a Model for Assessing the Success of Employee Portals**
  - Nils Urbach, European Business School (EBS), Germany; Stefan Smolnik, European Business School (EBS), Germany

- **Exploring the Impact of Real-Time Communication on Media Choice in the Context of Distributed Work**
  - Aleksi Aaltonen, The London School of Economics and Political Science, UK; Benjamin Eaton, The London School of Economics and Political Science, UK

### Session 16: Service Innovation (14.00 - 15.30)

**Session Chair:** Tillo Bohmann

- **The Emergence of a New Form of IS Offshore Enterprise – The Modern Hierarchy**
  - Brian Gannon, University of London, UK; David Wilson, University of London, UK

- **Internal Markets as a Sourcing Option for the Delivery of IS Services: Improving Outsourcing and Insourcing**
  - Jacques Bulchand-Gidumal, University of Las Palmas de Gran Canaria, Facultad de CC.EE. y Empresariales, Spain

- **Sourcing and Automation Decisions in Financial Value Chains**
  - Matthias Henneberger, FIM Research Center Finance & Information Management, University of Augsburg, Germany; Arne Katzmarchik, FIM Research Center Finance & Information Management, University of Augsburg, Germany; Stephan Müller, FIM Research Center Finance & Information Management, University of Augsburg, Germany; Frans-Matthis Pleie, FIM Research Center Finance & Information Management, University of Augsburg, Germany

### Session 25: Social Networks 1 (16.00 - 17.30)

**Session Chair:** Janice Sipior

- **Simmelian Ties, Organizational Justice, and Knowledge Sharing in Virtual Workgroups**
  - Zhi Wei Ho, National University of Singapore, Singapore; Klarissa Chang, National University of Singapore, Singapore

- **Web-Enabled Boundary Spanners and Their Role in the Knowledge Flow Network**
  - Eoin Whelan, University of Limerick, Ireland; Brian Donnellan, NUI Galway, Ireland; Robin Teigland, Stockholm School of Economics, Sweden; Willie Golden, NUI Galway, Ireland

- **Re "Design Networks" Shaped by Their Own Outcomes? Coordination Processes between Actors and Artefacts**
  - Francesco Bolici, OrgLab-DIAM, Cassino University, Italy; Francesco Virili, OrgLab-DIAM, Cassino University, Italy

**Nominated for the Claudio Ciborra award**
# Tuesday

## Session 37
### BPR1
#### Requirements on IT Business Value Measures for Mobile-Integrated Business Processes
- Kai Habermann, University of Augsburg, Augsburg, Germany
- Key Pousttchi, University of Augsburg, Augsburg, Germany

#### Teaching Case Influences of Six Sigma 'R' Embracement and Abondonment
- Wasana Bandara, Queensland University of Technology, Australia
- Diana Heckl, Frankfurt School of Finance & Management, Frankfurt am Main
- Michael Rosemann, Queensland University of Technology, Brisbane, Australia

**Chair:** Dianne Cyr

## Session 42
### Web 2.0
#### Modelling Use Continuance in Virtual Worlds: The Case of Second Life
- Stuart Barnes, Norwich Business School, UK

#### The Moderating Role of Utilitarian/Hedonic User Motivation on User Behaviour Towards Web 2.0 Applications
- Hsia-Ching Chang, National Taiwan University, Taiwan
- Lunghwa University of Science and Technology, Taiwan
- Chen-Ya Wang, National Taiwan University, Taiwan
- Seng-Cho T. Chou, University at Albany, State University of New York, USA

#### Discussion of Functional Design Options for Online Rating Systems: A State-of-the-Art Analysis
- Axel Winkelmann, University of Koblenz-Landau, Koblenz, Germany
- Sebastian Herwig, University of Münster, ERCIS, Münster, Germany
- Jens Peepelbuess, University of Münster, ERCIS, Münster, Germany
- Daniel Tiebe, University of Münster, ERCIS, Münster, Germany
- Jörg Becker, University of Münster, ERCIS, Münster, Germany

**Chair:** Aleksi Aaltone

## Session 58
### ISD 2
#### Towards a Research Framework for a Human Development-Based "Bottom of the Pyramid" ICT Development Strategy in South Africa
- Walter Brown, Monash University, South Africa
- Irwin Brown, University of Cape Town, Cape Town, South Africa

#### Recognizing Work Priorities and Tasks in Incoming Messages Through Personal Ontologies Supplemented by Lexical Clues
- Roger Tagg, University of South Australia, Adelaide, Australia
- Prashant Gandhi, University of South Australia, Australia
- Raaaj Srinivasan Kumara, University of South Australia, Australia

#### The Emergence of Language Consensus - Intensifying Language Interaction in Information Systems Development
- Marianne Corvera Vargas, Goethe University, Frankfurt, Germany

**Chair:** David Sammon
ROOM T5

FROM 11.00 TO 12.30
SESSION 33
Social Network 2
SESSION CHAIR
Carol Saunders

VALUATION OF ONLINE SOCIAL NETWORKS – AN ECONOMIC MODEL AND ITS APPLICATION USING THE CASE OF XING.COM
MARTIN GNEISER, University of Augsburg, Augsburg, Germany; JULIA HEIDEMANN, University of Augsburg, Augsburg, Germany; MATHIAS KLIER, University of Innsbruck, Innsbruck, Austria; CHRISTIAN WEIÄ, University of Augsburg, Augsburg, Germany.

REVEALING KNOWLEDGE NETWORKS FROM COMPUTER MEDIATED COMMUNICATION IN ORGANIZATIONS
JURRIAAN VAN REIJSEN, Utrecht University, The Netherlands; REMKO HELMS, Utrecht University, The Netherlands

ANALYZING COMMUNITY CONTRIBUTIONS TO THE DEVELOPMENT OF COMMUNITY WIRELESS NETWORKS
ABDELNASSER ABDELAAL, University of Nebraska, Omaha, USA; HESHAM ALI, University of Nebraska, Omaha, USA

FROM 14.00 TO 15.30
SESSION 44
e-GOV 3
SESSION CHAIR
Dianne Wigand

UNDERSTANDING CITIZENS’ BEHAVIOURAL INTENTION IN THE ADOPTION OF E-GOVERNMENT SERVICES IN THE STATE OF QATAR
SHAFI AL-SHAFI, Brunel University, UK; VISHANTH WEERAKKODY, Brunel University, Business School, UK

DOES THE ANSWER LIE IN COLLABORATION? – A CASE STUDY ON E-GOVER
BJÖRN NIEHAVES, University of Münster, (ERCIS), Muenster, Germany; JÖRG BECKER, University of Münster, (ERCIS), Muenster, Germany; KEVIN ORBACH, University of Münster, (ERCIS), Muenster, Germany

THE (MISSING?) VALUE OF IT IN PUBLIC ORGANIZATIONS - THE CASE OF THE SWEDISH RESCUE SERVICES
JAN LJUNGBERG, Gothenburg University, Gothenburg; Sweden; JANE FRISK, Gothenburg University, Gothenburg, Sweden

FROM 16.00 TO 17.30
SESSION 56
ADOPTION CASE
SESSION CHAIR
Andrea Pontiggia

DECISION MODELS AND THE ADOPTION OF WIRELESS TECHNOLOGY
GREGORY GIMPEL, Copenhagen Business School, Denmark.

ACCEPTANCE PROBLEMS OF AMBIENT INTELLIGENCE AND MOBILE TECHNOLOGIES IN HOSPITALS IN INDIA AND GERMANY
TYGE KUMMER, ESCP-EAP Berlin, Germany; MARKUS BICK, ESCP-EAP Berlin, Germany; RAJ GURURAJAN, University of Southern Queensland, Australia

WHY INFORMATION TECHNOLOGY IS NOT BEING USED FOR FINANCIAL ADVISORY
PHILIPP NUISBAUMER, University of Zurich, Zurich, Switzerland; GERHARD SCHWABE, University of Zurich, Zurich, Switzerland

# Room T7

## From 11.00 to 12.30
### Session 34
**Open Innovation**

*Session Chair:* Pat Finnegan

- **Presenting Data for Team-Based Decision-Making in Agile Information Systems Projects**
  - Kieran Conboy, National University of Ireland, Galway, Galway, Ireland; Thomas Acton, National University of Ireland, Galway, Ireland; Raija Halonen, National University of Ireland, Galway, Ireland

- **Enabling Open Innovation: Proposal of a Framework Supporting ICT and KMS Implementation in Web-Based Intermediaries**
  - Sven Carlsson, Lund School of Economics and Management, Lund, Sweden; Vincenzo Corvello, University of Calabria, Rende, Italy; Piero Migliarese, University of Calabria, Rende, Italy

- **Digital Libraries as Information Organizations. The Re-Unfolding of the Memory/Information Paradox**
  - Attila Marton, London School of Economics and Political Science, London, UK.

## From 14.00 to 15.30
### Session 50
**BPR 2**

*Session Chair:* Francesco Bolici

- **The Effect of Information and Communication Technologies, Workplace Re-Organization and Trade on the Demand for Employees Skills: A Comparative Analysis of Greek and Swiss Enterprises**
  - Euripidis Loukis, Federal ETH Zurich, Switzerland; Spyros Arvanitis, University of the Aegean, Island of Samos, Greece

- **Counteracting Forces in Implementation of IS-Enabled Global Business Processes**
  - Møyfrid Sannarnes, University of Agder, Kristiansand, Norway; Bjørn Munkvold, University of Agder, Kristiansand; Kim Andersen, Copenhagen Business School, Howitzvej, Denmark

- **An Approach to Assess the Implementation of Business Process Management in Enterprises**
  - Michael Rohloff, University of Potsdam, Potsdam, Germany

## From 16.00 to 17.30
### Session 61
**E-Commerce 1**

*Session Chair:* Annemette Kjaergaard

- **Would I Use My Personal Blog for Commercial Exchange?**
  - Wee-Kek Tan, National University of Singapore; Chuann-Hoo Tan, City University of Hong Kong, Kowloon, Hong Kong; Hock-Hai Teo, National University of Singapore

- **Consumers’ Perception of Control over Online Information Disclosure. An Electronic Focus Group Study**
  - Mirella Lahteenmäki, Helsinki School of Economics, Finland; Johanna Bragge, Helsinki School of Economics, Finland; Anne Sunikka, Helsinki School of Economics, Finland

- **File-Sharing – A Threat to Intell**
  - Bo Andersson, Lund University, School of Economics & Management, Lund, Sweden; Paul Pierce, Lund University, School of Economics and Management, Lund, Sweden; Markus Lahtinen, Lund University, School of Economics & Management, Lund, Sweden

A Review of Ethical Theory in the ‘Upper Echelons’ of Information Systems Research

Bull, Christopher,
Business Information Technology and Management Science,
Manchester Metropolitan University Business School, Manchester M1 3GH, UK,
c.bull@mmu.ac.uk

Abstract
Despite some notable and rare exceptions and after many years of relatively neglect (particularly in the ‘upper echelons’ of IS research), there appears to be some renewed interest in Information Systems Ethics (ISE). This paper reflects on the development of ISE by assessing the use and development of ethical theory in contemporary IS research with a specific focus on the ‘leading’ IS journals (according to the Association of Information Systems). The focus of this research is to evaluate if previous calls for more theoretically informed work are permeating the ‘upper echelons’ of IS research and if so, how (Walsham 1996; Smith and Hasnas 1999; Bell and Adam 2004). For the purposes of scope, this paper follows on from those previous studies and presents a detailed review of the leading IS publications between 2005 to 2007 inclusive. After several processes, a total of 32 papers are evaluated. This review highlights that whilst ethical topics are becoming increasingly popular in such influential media, most of the research continues to neglect considerations of ethical theory with preferences for a range of alternative approaches. Finally, this research focuses on some of the papers produced and considers how the use of ethical theory could contribute.

Keywords: Information Systems Research, Information Systems Ethics and Ethical Theory

Introduction
Information Systems Ethics (ISE) is an important economic, social, cultural and political topic. This research argues for the development of ISE for the similar reasons that are offered for IS (Davis 2000; Baskerville and Myers 2002; Paul 2007a; Paul 2007b) and because IS phenomena are not always well represented by general ethics, business ethics or the various branches of computer ethics. However, the development of ISE should also appreciate some important work in adjacent fields e.g. computer, information and internet ethics (Wiener 1948; Parker 1968; Weizenbaum 1976; Johnson 1985; Moor 1985; Floridi 1999; Tavani 2007), the rare but notable exceptions within the field of Information Systems (IS) (Walsham 1996; Banerjee, Cronan et al. 1998; Adam 2001; Introna 2002; Wagner and Newell 2004) and capitalise on the renewed interest being shown by the International Conference on Information Systems (ICIS) in 2008 and the European Conference on Information Systems (ECIS), 2008 and 2009. The development of ISE is also important given the relatively poor historic coverage of such work, especially in terms of the quantity of research and of considerations of philosophical ethical theory (Walsham 1996; Smith and Hasnas 1999; Bell and Adam 2004), which is somewhat surprising given the interest in other IS topics e.g. politics and power (Markus 1983; Knights and Murray 1994; Jaspersen, Carte et al. 2002; Howcroft and Light 2006; Avergou and McGrath 2007). Furthermore, the need to develop ISE is also important given the increasing economic, social and political significance of IS. In terms of developing ISE, there are various views on how to proceed. Some have long called for more considered reflections of philosophical ethics in IS (Walsham 1996) and others have argued for ethical theories based on ‘less abstract’ approaches (Smith and Hasnas 1999). In 2004, the response had been fairly disappointing (Bell and Adam 2004).
The focus of this research is to follow such studies and assess if more research is being devoted to ethical topics in IS research beyond the specialist media e.g. Ethics and Information Technology and conference e.g. ETHICOMP, and CEPE etc. This research will evaluate the quantity of work published in some of the ‘upper echelon’ IS journals and how such work is considered. This paper is structured as follows; first, in order to understand the broader context of the research questions a brief overview of what is meant by philosophical ethical theory and some of the main developments in computer, information and IS ethics are presented. Next, the paper presents two views in relation to ISE research (Walsham 1996) and (Smith and Hasnas 1999). This is then followed by a review of ISE work published in the ‘upper echelon’ IS journals (according to the Association of Information Systems) from January 2005 to October 2007 inclusive, in the following journals; Management Information Systems Quarterly, Information Systems Research, Management Science and the Journal of Management Information Systems is considered. Finally, the paper critically reflects on the nature of such research in light of the criteria adopted within this review.

**Ethical Theory**

It is beyond the scope and purpose of this paper to evaluate the full complexities of philosophical ethical theory. Many contemporary sources offer good overviews of the main ideas associated with ethical theory (Johnson 1985; Johnson and Nissenbaum 1995; Walsham 1996; Tavani 2007). However, for the purposes of clarifying this research, ethics relates to the study of morality and the use of such theories in judging issues of right and wrong (Gert 1998; Gert 1999; Tavani 2007). Some claim that there are three moral systems; religious, legal and philosophical ethics (Tavani 2007). Philosophical ethics is an informal system where sanctions are often socially orientated e.g. disapproval or ostracism (Tavani 2007). Within philosophical ethics there are a range of diverse and well established ethical theories. The most popular theories are; deontological (duty-based acts) (Ross 1930; Kant 1988), utilitarianism (consequential-based acts) (Bentham 1948), contract or rights-based acts (Hobbes 1972) and virtue (character-based acts) (MacIntyre 1985).

**The Development of Ethical Theory in IS Research**

Historically, some of the most interesting contributions toward an idea of ISE have been made by those working within adjacent academic fields and by a few notable exceptions from those within IS research. The shaping of ISE from the adjacent academic fields may be explained (to some extent) by the relative infancy of IS and of interests in other subjects. Such work includes; Wiener’s texts on the likely impacts of computers on society (Wiener 1954), Maner’s early work on privacy, crime, and dependency (Maner 1980), both Moor’s and Johnson’s work in relation to clarifying computer ethics (Johnson 1985; Moor 1985), Floridi’s philosophical development of information ethics (Floridi 1999; Floridi and Sanders 2002) and Tavani’s work in cyber ethics (Tavani 2007). Within IS, there have also been a few rare notable contributions; Walsham’s use of philosophical ethics to reflect on the limitations of professional codes of conduct (Walsham 1996), Adam’s contributions on gender issues (Adam 2001), Introna’s work in respect of new media (Introna 2002) and some observations of the ethical nature of packaged software systems (Adam and Light 2004; Wagner and Newell 2004; Adam and Bull 2008). However, whilst many have made some useful contributions to the development of IS (Banville and Landry 1989; Baskerville and Myers 2002; Paul 2007a) and other (broadly similar) topics are much healthier (see comments made in respect of the literatures on politics and power earlier, it is somewhat surprising that previous ‘calls to arms’ (see earlier comments) have struggled to ‘take-off’. So what has happened to ISE since?

In order to assess the condition of ISE, this research conducted an evaluation of ethically related work published in the ‘upper echelon’ IS journals (according to the Association of Information Systems) from January 2005 to October 2007 inclusive. These dates are
appropriate as they follow on from the work of other reviews. This research recognises the debates about journal quality and the nature of such media e.g. would such work be submitted to such publications etc. However, this research is ongoing and for the purposes of scope it begins by evaluating the following publications; Management Information Systems Quarterly (MISQ), Information Systems Research (ISR), Management Science (MS) and the Journal of Management Information Systems (JMIS). This review process used the search engine Business Source Premier / EBSCO in conjunction with some independent evaluation of the data to produce its results. The search began by seeking to find any work that was identified as covering ethics (this may or may not be a Key term). This resulted in finding just 5 papers (see table 1).

Table 1: All Papers That EBSCO Highlights As Covering The Term ‘Ethics’

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table 1 highlights the neglect in IS of the word ‘ethics’ as a key term. However, this doesn’t necessarily mean that ethical considerations are this scarce. In order to proceed further this review used more specific terms in the study of ethics and referred to the bodies of knowledge in ISE, computer, information and internet ethics in order to be guided on such topics. The ethical topics that appear to generate significant interest are; trust, privacy, piracy and moral hazard. However, whilst the primary focus is based on these four issues, many papers also cover issues such as; IS development, E-Commerce and outsourcing etc. Using these four key terms almost 50 papers appear to be retrieved, this again is slightly misleading as one paper may cover more than one topic (see table 2).

Table 2: The Number of Papers That EBSCO Highlights As Covering The Additional Terms; Trust, Privacy, Piracy and Moral Hazard

</table>

After some necessary interpretation of the papers, they were reduced to 32 papers that were deemed to be appropriate to this research (see table 3). This research finds that some human intervention in the use of search engine technologies is necessary for the following reasons. There was some occasional retrieving of inaccurate data e.g. a search for ethics and MISQ also located a paper for the Journal of Computer Information Systems. There was some retrieving of the same paper for a range of topics due to the broad nature of some of the research coverage e.g. covered many themes. Finally, some papers found were not appropriate to the topic e.g. not always IS papers etc. The 32 papers in table 3 are evaluated against the following criteria; investigating if calls for more ISE work have materialised, if so,
what is the nature of the research produced and why and how it is theoretically treated, either support for the use of philosophical ethics (Walsham 1996) or alternative ethical theories (Smith and Hasnas 1999).

**Two Theoretical Approaches in ISE**

Walsham highlights that whilst IS literature sometimes considered ethical issues, there is little in the way of grounding such work within general ethical theory. In addition, he questioned the ‘objectives and value’ of such work. Walsham went on to provide a concise outline of the main theories from normative ethics which he used to re-evaluate the ACM ‘Code of Ethics and Professional Conduct’ of 1992. Whilst Walsham acknowledged the difficulties in creating such codes of ethics, he welcomed such work as helping to guide practitioners and considered much of it to be ‘thoughtful and useful’. However, his research seeks to demonstrate how the use of ethical theory could have produced a more ‘informed and thoughtful reflection and debate’. This is highlighted by examples of some limitations within the Code; unresolved conflicts between duties and goals, problems in what constitutes good (virtuous) IS practice, and little focus in relation to the rights of groups. Walsham concludes by reiterating the value of ethical theory and the role that IS academics can play in making such theories more accessible and explicit in their work. He also highlights that the work of ISE is not restricted to IS but also has important implications for ‘society at large’.

Smith and Hasnas’s also called for more work in ISE and highlighted various problems in such research e.g. the different trajectories of IS and ethical development. They also discuss the problems of such an IS ethical vacuum. However, they seek to focus on the role of IS/IT in business. One of the main claims within the paper is that IS are not an ethically neutral entity, this is supported with an interesting case study of Blockbusters selling customer data to direct marketing companies, described as a well intentioned strategic initiative but conceived in ethical ignorance which resulted in several unforeseen negative responses. In addition, they also call for a more philosophical approach in ISE. However, unlike Walsham, they are somewhat wary of the applicability of philosophical ethics to IS practitioners. Ethical theories are perceived to be ‘too abstract’, not easily accessible to people from a business, engineering, computer science or IS background;

> “Unfortunately, the doctrines of philosophical ethics are highly abstract and are essentially meaningless to one with little or no philosophical training”  
> - Hasnas and Smith (1999), p. 112

They seem to remedy this problem by diverting away from philosophical ethics for a more ‘accessible’ form of ethics e.g. theories of business ethics; stockholder, stakeholder and social contract theory. Although it also acknowledged that such theories are barely used in IS, despite their more accessible / practitioner nature. In summary, despite the recognition of the importance of ISE, we have two fairly similar views on how to proceed, for grounding or considering more research within ethical theory. In the next section, the paper examines the response within the ‘upper echelons’ of contemporary IS research to such previous and high profile calls.

It is beyond the scope of this work to critically evaluate the detailed content of all papers retrieved. However, it is desirable to discuss many of the general themes that emerged. Table
3 outlines the papers studied including the titles (sometimes abbreviated), topics and journal references. In addition, the table outlines the three main evaluation criteria:

- Is ethics or morality acknowledged as a key term (y) or not (n) (column p1)
- Are the terms trust, privacy, piracy and moral hazard acknowledged as a key term (y) or not (n) (column p2)
- Are ethical issues considered by ethical theory (y) or another theoretical concept (n) (column p3)

</table>
The general findings arising from table 3 in this study are as follows. Whilst there is only one paper that explicitly uses the term ethics (P6), it is clear that many papers (28 out of 32) do explicitly use terms that are popular in ethical research such as; trust, privacy, piracy and moral hazard. It is also clear that whilst it may not always be recognised, that more ethically related work is of interest to IS scholars and is permeating the ‘upper echelon’ journals. Also such research is covering a broad range of diverse topics. However, whilst there may be some significant interest, no papers use ethical theories to consider such emerging IS phenomenon. Subsequently, none will make a philosophical contribution that can challenge any of the established theories used, again somewhat distant from developments in information ethics (Floridi 1999; Floridi and Sanders 2002). Disappointingly, almost all of the authors are moving even beyond Smith and Hasnas’s diversion of philosophical ethics approach (Smith and Hasnas 1999) and by-passing ethical theories completely. This review also unearthed some other findings that also appear to drift beyond previous calls. The majority of the papers prefer to focus on micro-level research, rather than considering many of the broader social issues and there were also some interesting methodological choices and rationale.

In specific terms, in respect of meeting all of the criteria specified in table 3, only one piece of IS research could be said to have succeeded (P6), although there are some theoretical disparities with this work. Paper 18, listed ‘moral hazard’ as a key term, proceeded to highlight a number of potential ethical issues within online reputation mechanisms, but then...
decided to by-pass grounding the work within an established ethical framework. Paper 19, briefly acknowledged the specific ethical and legal implications of its topic, for instance, industry attempts at controlling the illegal downloading of music through peer-to-peer technologies however the work then proceeded to analyse this topic from a market-based perspective.

In terms of the analysis of topics, the issues of trust and privacy are of the most interest. This is perhaps due to the nature of IS developments on the significance of E-Commerce. The issue of piracy is perhaps the most ethically orientated, although the philosophical and empirical ethical issues are relatively neglected. Whilst paper 6, met all of the criteria, there are several other interesting observations, some acknowledged by the authors themselves (Moores and Cha-Jan Chang 2006). Moores and Chang acknowledge some problems with the scope of their research e.g. the testing of an established model within a specific practitioner related context. Thus, the work finds that software piracy is a major economic concern (for those who own such intellectual property), that certain individuals in certain contexts do recognise that pirating is an act of infringing intellectual property and that individuals often don’t judge such acts to be too morally wrong to refrain from such acts. In addition, there are some other interesting observations in relation to the choice of research methods e.g. the use of student sampling within a specific geographical and cultural context. Such methods are somewhat problematic especially in terms of generalisation e.g. society at large. Despite the inevitable problems of representation, student sampling methods were a surprising popular practice in many of other papers (P1, 4, 27, 28 and 30). Some of the problems are somewhat acknowledged in paper 6, but the method is still justified on the basis that students are a ‘prominent source of piracy’? The problems of student sampling are less acknowledged elsewhere (P4, and 27).

Another paper (P19) also specifically acknowledges the ethical dimension arising from the development of digital technologies (peer-to-peer) and the desire by the music industry to prevent illegal sharing. However, whilst this is appreciated, the authors seek alternative approaches to improve our understanding. A similar approach is used in paper 16, where the authors argue that piracy in digitally experienced goods can be positively moderated through the use of realistic marketing and increased sampling and neglect to understand the phenomenon from an ethical perspective. Furthermore, ethics is relegated further and the issues are explored within a marketing strategy solution, a theme that is also developed in other work (P1, 4, 21, 27, and 30).

The research on privacy, moral hazard and trust are also based on micro-level issues and again neglect the use of ethical theory. In terms of privacy, paper 1 and 21 address a professional audience. The papers relating to trust are diversely grounded; e.g. papers 4, 27 and 30 are in reasoned action theory and marketing, paper 10, in psychological contract violation and papers 27, 28, 30 and 32 in trust building theory or marketing. Another interesting piece of research (based on the evaluation criteria for this research) is on trust. Paper 18 (Dellarocas 2005) also uses the term moral hazard as a Key term and the paper sometimes refers to its ethical dimension. The research examines the construction of online reputation mechanisms which deal with seller reputation based on customer feedback. The research is based mostly on the website eBay but also through comparisons to others e.g. Amazon. The paper highlights some broader economic and moral issues of reputation in online environments and explores how effective such reputation mechanisms are designed and managed (or not). The research offers some interesting insights into some of the various flaws within such mechanisms, with some detailed explanations as to why such flaws could be significant. Again like some of the IS research on piracy, this research is developed within a specific context but it attempts to consider several broader social implications.

Finally, this review also highlighted some other generic issues, which may be explained by the popularity of certain authors, some of whom have been very prolific, and their favoured
approaches. In addition to the popularity of student sampling, there was an overwhelming tendency to use quantitative or semi-quantitative methods rather than qualitative methods, including papers 1, 4, 6, 8, 16, 18, 19 and 30, on-line or other survey data was also popular e.g. papers 1, 10, 18, 28 and 32, with noticeable contrasts in terms of the levels of participation and response e.g. papers 1, 10 and 32.

The Use of Ethical Theory in This IS Research

The previous section of this paper largely evaluated the published articles against some fairly interesting but specific criteria. Also the work is evaluated within the authors chosen frameworks. This research now seeks to make a modest contribution by seeking to reflect on how some of the various papers could be with the use of a more explicit ethical theoretical position. Again for the purposes of scope it is impossible to reflect on all of the papers listed, thus what follows is an analysis of the most popular topics covered e.g. piracy and trust. Also the research can only restrict the reflection to a few ethical theories, these being that of deontology (duty-based) and utilitarian (consequentially-based) considerations.

In general, in terms of the issue of piracy (papers 6, 8, 16 and 19), the use of a deontological framework could help to explore why individuals feel that they have a duty not to pirate digital goods. Also do individuals perceive that they have conflicts of interest when conducting such acts and which duties do they subscribe too and why? In terms of utilitarian issues, questions could focus on the individual consequences and if people are concerned about conducting often illegal acts, and if not, why? In terms of the digital music piracy issues covered in paper 19, the authors seem to accept that file sharing is almost inevitable and that many individuals seem to share their files regardless of the multifarious risks involved? Even if such a scenario appeared to be true for many individuals, then such issues may represent such a change in human morality and moral reasoning to question the validity of using such established theories relating to duty and consequence-based ethics, particularly if such ideas are relevant in guiding us in understanding contemporary phenomenon? This methodological position appears to be somewhat similar to the analysis of the technical problems of piracy discussed in paper 16. Thus the approaches prescribed by the authors to the problems of piracy e.g. better marketing and sampling of goods, don’t seem to resolve the root-cause moral issues involved in why people pirate goods and again seems to except such actions as an inevitable feature of contemporary life.

Perhaps the most potentially fruitful paper for a more explicit consideration of ethical theory is Paper 18 on the issue of trust with its focus on reputation mechanisms at e-Bay (and Amazon). Whilst this paper raises several interesting issues and insights into the power of reputation mechanisms in online environments, the work also raises several alternative questions. Some of the neglected questions of interest could be the following. What does such research say about the duties of governance in regulating such new forms of commercial organisations? What accountability issues are raised for online operators in such moral hazard problems? Should online operators devote more resources to predict or manage the moral hazard problems more effectively? Finally, what are the moral, social and legal responsibilities or implications arising from the mass publication of potentially erroneous information within an online reputation mechanism?

Strengths and Weaknesses of this Research Paper

The objective of this research is to make a modest contribution to considerations of the condition of ISE. Some of the weaknesses in this research are as follows. Firstly, the findings are only based on four leading IS journals further research will review other leading journals. Also, although the AIS list was chosen to select the ‘upper echelon’ journals, there are many disagreements about the worth of such ranking systems. Secondly, those engaged in ISE research may actually prefer to target other well respected journals for a variety of reasons e.g. such media may be considered to be more accommodating to such research, although our
research highlights that ethically related topics are now permeating the mainstream, ‘upper echelon’ media. Thirdly, selecting papers that conform to a notion of ISE is also a subjective activity. Others (including the authors of the selected papers themselves) may disagree with the papers identified. Fourthly, because the papers on ISE were purposefully selected, such heightened scrutiny may misleadingly distort the actual strengths or weaknesses of such work. Finally, it is worth remembering that the chosen papers are being judged primarily against a specific set of criteria used for this research and only occasionally against the objectives they sought to develop. It is not the intention to criticise such work but to focus on how a different theoretical treatment may also be considered.

In terms of the strengths of this research, the review does offer a relatively rare contemporary insight into the condition of ISE, particularly in some of the ‘upper echelon’ media. Given the broader significance of IS, it is important to reflect on the condition of ISE research. Although the focus on such journals presents some problems in terms of representation, this specific focus is useful because such work (rightly or wrongly) is likely to be influential to others in IS and other academic fields. Furthermore, the findings from this study challenge those who believe that the appropriate home for ISE research is within specialist media and not necessarily within the ‘upper echelon’ IS media. Such media are increasingly sympathetic to ethical topics, even if this research supports many of the earlier findings (Walsham 1996) (Smith and Hasnas 1999) (Bell and Adam 2004) that authors continue to find an interest in such topics but choose to by-pass interpreting them within a more explicit ethical theoretical framework. Finally, this research also highlights some of the problems associated in conducting such research and some of the problems of an over-reliance on search engine technologies. It also sought to focus beyond reviewing just key term and abstract submissions to also offer some detailed considerations of full paper research submissions. Finally, one of the main strengths of this research is to go beyond highlighting what exists but also try to show what could be? This is demonstrated by the reflections on how such empirical data may be informed (or not) by a reformulation within ethical theory for some of the publications scrutinised.

**Conclusion**

This research has sought to respond to previous calls for a more informed development of ISE research, particularly in relation to considerations of ethical theory in empirical work. Historically, ISE research has been somewhat neglected from mainstream or ‘upper echelon’ media, which is surprising given the support and relative popularity for topics such as: power and politics etc. The historic development of ISE has been influenced by some rare but notable exceptions within IS and by academic work in adjacent fields. Those within IS tend to target their work in either specialist or more sympathetic media.

This contemporary review (2005-2007) of work published in the ‘upper echelon’ IS media highlights that it is something of a myth to believe that such media are inappropriate vehicles for ethically related work. Many ‘leading’ IS journals (and conferences) are increasingly valuing the importance of conducting more ISE related research, perhaps due to the presence of a range of digital technologies that appear to raise an array of interesting ethical challenges. However, whilst such developments are welcome, there appears to be some significant problems in indentifying or appreciating the ethical potential of such research and thus a failure to respond to previous calls to ground such work within ethical theories either in terms of Walsham’s call for more philosophical considerations or Smith and Hasnas’s call to use less ‘abstract’ ethical theories. This research also suggests how the use of such neglected ethical theories may illuminate existing empirical research. Finally, this research is an ongoing and will seek to build further on these initial findings.

Abstract

In spite of the economic downturn, demographic factors are expected to continue to produce a labour shortage particularly in the Information and Communications Technology (ICT) sector. In Canada, the sector has signaled that critical skills shortages exist in certain areas although the extent of these shortages is the subject of much debate. While economists have suggested that by the year 2011, all labor force growth in Canada will come from immigration, research has shown that immigrants often face barriers to full employment. Similarly, women are under-represented in ICT and face a range of barriers to employment and advancement. Increasingly, both government and industry have asserted that more effective “management of diversity” could help alleviate the skills shortage. To date, research has focused on barriers to entering the workplace but less has focused career satisfaction even though there is evidence to suggest that these may have significant impact on employee retention and productivity. The role of demographic factors is complex. For example, in Canada, while all immigrants are not visible minorities and all visible minorities are not immigrants; recent immigrants are more likely to be visible minorities. In addition, the intersection of variables, such as gender and visible minority status, complicates the analysis. Our study examines demographic factors affecting career satisfaction among 7110 managers with a minimum of 10 years experience in nine large Canadian companies in the Information Communications and Technology Sector. We found that the gap between visible minorities and white/Caucasian respondents in perceptions of career satisfaction and factors affecting it, to be larger than the gap in perceptions of male and female respondents. More work is needed to address these issues if the ICT Sector is to effectively deal with the skills shortage.

Keywords: Information Systems Professionals, Job Satisfaction, Gender

Proceedings ECIS 2009
1 BACKGROUND

Increasingly government, the private sector and industry organizations are suggesting that effectively managing diversity is, at least in part, the solution to addressing the global labour shortage. Pointing to demographic shifts including the aging baby boomers and declining fertility rates, the Royal Bank of Canada (RBC) has noted that 100% of labour market growth in Canada in 2011 will come from immigration.

From an economic point of view, how well Canada continues to meet the challenges of diversity will determine our future success in attracting talented immigrants as global competition for talent intensifies with the aging of Western societies...in the face of potential labour shortages, employers will miss out on opportunities for growth unless they recognize the potential of all groups in Canadian society (RBC, 2005).

The study also points to the under-employment of women, who are under-represented in certain sectors and occupational groups. Strategies to increase the participation of immigrants, women and other under-represented groups have been advocated to ensure that Canada competes effectively in an increasingly globalized economy.

The problem seems to be exacerbated in the Information and Communications Technology (ICT) sector, where for over a decade industry leaders have been talking about the skills shortage (Boisvert, 2007). There is little doubt that enrolments in computer science and engineering have declined. The Information and Communications Technology Council, for example, estimates that new computer science and engineering graduates which will meet 49%-75% of demand (approximately 7,585 positions) annually (ICTC, 2008). “A new survey shows that a growing shortage of IT skills has put upward pressure on salaries as employers choose experienced workers over graduates....a continuation of what [IT World Canada] calls a “sobering trend” will hurt economic growth and productivity “across all industries” (CBC, 2007). While enrolments of women in other professions — medicine, law and business administration — now exceed males, the percentage of female enrolments in computer science and engineering are declining at a time when their participation in other disciplines is increasing. Female enrolment in computer science is the only discipline where the percentage of women is lower than it was in 1992-93 (ICTC, 2007). Some groups, such as the recently formed, Canadian Coalition for Tomorrow’s ICT Skills, have suggested that increasing the participation of women in engineering and computer science will help address the skills shortage (Ibaraki, 2008). Others, such as the Information Communications Technology Council (ICTC) have emphasized the importance of immigration in filling the gap, with approximately 7,588 immigrants with ICT skills entering Canada annually (ICTC, 2008).

Scholars and industry analysts alike have considered the under-representation of women in the ICT sector from a variety of perspectives. Sue Rossner systematically outlines no fewer than ten different theoretical perspectives to women and technology in the workforce (2006) and stresses the importance of being self-reflective. Liberal feminism, for example, focuses on employment, access and discrimination issues and ways to identify barriers and overcome them. Other approaches, explores ways in which the social shaping of technology has been constructed in ways that exclude women. For example Adam et. al (2006) suggest that Information Technology (IT) skills are gendered requiring women to distance themselves from their own identities. Ramsey & McCorduck (2005) explore issues related to professional identity in the face of systemic stereotyping, dualism, and devaluation. Essentialist approaches assumes all women are united by their biological characteristics and focus, for example, on women’s reproductive role and its implications or on skills and aptitudes considered female. Structural approaches focus on revealing the ways in which patriarchy constrains and focuses on the need for structural and systemic changes. Post-modern feminism questions the very notion of common female experience and posits the notion of multiple identities that are highly context specific. Rossner also describes existentialist, psychoanalytic, racial/ethnic feminism, post-colonial and cyber
feminism. While one might take issue with her categorizations, it is clear that theoretical perspective framing the exploration of this issue shapes the way in which questions are formulated and methods applied. Our study is situated in what is often described as a liberal feminist tradition, based on the assumption that barriers exist to women (and other under-represented groups) which can be identified and addressed to increase participation and advancement in the workplace. We do, however, acknowledge that there are other questions that might be asked.

Currently in Canada, while women are 47% of the workforce, they are only 29% of ICT workers. Females represent only 9% of engineers and 16.7% of programmers compared to 36.8% of analysts and 60.8% of graphic designers and illustrators. (Gunderson et al., 2005). Based on secondary research and interviews with key informants, a study entitled "Diversity – The Competitive Edge: Implications for the ICT Labour Market", (ICTC, 2007) examined barriers to women in the ICT sector. It suggested complex factors affecting participation of women in ICT. Socialization and early education affect the self efficacy and confidence, the development of preferences and choices. Systemic barriers in schools include pedagogical approaches to science and mathematics which are insufficiently applied and the absence of role models, negative perceptions of computing and related work including the “nerd” stereotypes and notions that ICT work is programming. Systemic barriers in post-secondary institutions are similar and have been well documented as creating a “chilly climate” for female engineers and computers scientists (Wasburn and Miller, 2006). In addition, there have been barriers identified to finding employment which include closed recruitment processes and narrow definitions of skills and requirements. Within organizations there are issues related to career advancement, access to training, mentoring, exclusion from informal networks, the absence of role models, stereotypes, communication and negotiation styles and work-life balance issues. Some literature also considers broader socio-political-cultural forces and practices which form the institutional environment of organizations but these issues receive limited attention (For a summary of these see ICTC, 2007).

There is also evidence of under-utilization of immigrants and visible minorities in Canada. While all immigrants are not visible minorities and all visible minorities are not immigrants, recent immigrants are more likely to be visible minorities (Palameta, 2004) and represent a growing proportion of the Canadian population. The data suggest that immigrants tend to be unemployed in spite of their education and technical skill levels. Visible minorities in Toronto face higher unemployment rates than non-visible minorities, although they are more likely to be university educated. There is evidence of under-representation in the ICT sector. Immigrants are 20% of the workforce but only 5% of ICT workers. Visible minorities are 13% of the workforce but only 10% of ICT workers (ICTC, 2007). On average, Visible Minorities experience a 15% wage disadvantage and a 13% earnings disadvantage compared to White/Caucasians (Hum & Simpson, 1999; RBC, 2005). They also face a range of barriers to career advancement (Reitz, 2001).

Similarly, the barriers specific to IEP’s included, “inadequate information about the labour market and processes prior to immigration, settlement and job search challenges, inadequate communications/cultural skills, systemic barriers in employment practices, inadequate support in the workplace”. Based on the barriers relating to lack or inadequate workplace support, this paper attempts to examine the subjective perceptions of employees at work.

To date in Canada, there has been much empirical research on the barriers to immigrants on entering employment but much less on the career progression of visible minorities and immigrants. The evidence suggests that immigrants who are also visible minorities face particular challenges not just in

---

1 In Canada, the term “visible minority” refers to a person who is not an Aboriginal person, who is non-Caucasian in race or who is “non-white” in colour, as defined under the Employment Equity Act. The following population groups comprise the total visible minority in this study: Arab, Black, Chinese, Filipino, Japanese, Korean, Latin American, Middle Eastern, South Asian, South Asian, West Indian, Southeast Asian, West Indian, and multiple visible minority (referring to those respondents who identified as belonging to more than one visible minority group).
terms of obtaining employment but even after they are employed. Similarly, there has been considerable research on women in technology but limited large scale empirical work. As well, we are interested in the inter-relationship of multiple demographic variables, in particular, gender versus visible minority status.

This study draws on previous work on the under-representation of women and immigrants in the ICT sector as well as the extensive body of literature on career success and satisfaction. For example, Cox and Nkomo (1991) reported that women and minorities have lower levels of objective career success than white males. Harter et al. (2002) found that career satisfaction among immigrants and visible minorities is lower and has a significant impact not only on employee performance and retention but also on organization’s productivity and profitability. Greenhaus et. al. (1990) studied 828 manager/supervisor pairs and found that blacks reported having less job discretion and lower feelings of acceptance than whites. They also reported receiving fewer promotions and being less satisfied with their careers and were more likely to report negative organizational experiences than whites. Igbaria and Wormley (1992) who focused on the IT profession found evidence that Blacks receive less career support than whites and tended to have lower levels of met expectations and lower levels of career satisfaction than whites.

Given the focus the concerns in the ICT sector about the talent shortage, a better understanding of the factors affecting career satisfaction and organizational commitment is important to understand how to retain well-qualified, productive employees. A variety of factors affect employee satisfaction (Auster, 2001). Research also suggests that employees who are satisfied with their careers are more engaged and thus be more likely to contribute to achievement of organizations’ success (Harter et.al., 2002).

2 RESEARCH QUESTIONS

Our study explores five inter-related questions including:
1. Are there differences in organizational commitment between visible minorities versus white Caucasian and male versus female employees in Canadian ICT firms? Are there differences in career satisfaction between visible minorities and white Caucasian employees in Canadian ICT firms. Are there differences between males and females?
2. Are there differences in perceptions of relationships with managers and colleagues between visible minority and white Caucasian employees in Canadian ICT firms. Are there differences between males and females?
3. Are there differences in perceptions of career advancement and development between visible minority and white Caucasian employees in Canadian ICT firms. Are there differences between males and females?
4. Are there differences in perceptions of diversity and inclusion practices between visible minority and white Caucasian employees in Canadian ICT firms. Are there differences between males and females?
5. Are there differences in perceptions of educational attainment and credentials between visible minority and white Caucasian employees in Canadian ICT firms. Are there differences between males and females?

3 METHODOLOGY

This paper utilizes survey data collected as part of a larger study that examined career advancement of visible minorities in corporate Canada (Catalyst et. al., 2007). Over 17,000 pre-managers, managers, professionals and executives from 43 organizations responded to an online survey between October 2006 and February 2007 - a response rate of 29%. The survey asked a range of questions pertaining to demographic, human capital, subjective and objective attributes and perceptions. Of these, 6,783 respondents were employed in ICT sector companies and we have analysed these results below. Of the
full-time employees who responded, 54 percent were male and 50 percent possessed some forms of university education. The average tenure with their respective organizations was 11.4 years, at an average age of 41.7 and an average salary of $90,775. There are no discernable differences based on the demographic characteristics between the selected sample and the employees who completed the survey with the exception of salary. About 60 percent of the respondents included in the final sample earned $40,000 or more, compared to only 55 percent of all the respondents to the survey.

4 FINDINGS

All of the survey findings presented below have undergone both t-tests and Chi-square tests, and were found to be significant at p<0.05.

4.1 Organizational Commitment

Most respondents, whether visible minority (87%) or not (90%), indicated that they identify with their organizations core values. Similarly, visible minorities and non-visible minorities both agreed that they were proud to tell others that they are part of their organization (86% and 85% respectively), as well as being willing to put in a great deal of effort beyond what is normally expected to help their organization. As can be seen in Figure 1 below, female (85%) as compared to male (80%) respondents were more inclined to stay with their organization, however visible minority respondents (78%) were less inclined than white/Caucasian respondents (84%) to stay with their organization.

![Figure 1. Respondents perceptual intent to stay with their organization.](image)

4.2 Career Satisfaction

While 72% of male respondents indicated they were satisfied with their overall career progress, 79% of females indicated their satisfaction. In contrast, only 65% of visible minority versus 78% of white/Caucasian respondents were satisfied with their overall career satisfaction. Similarly, 65% of female respondents compared to 57% of male respondents were satisfied with their goals for income, as compared to 64% of white/Caucasian versus 51% of visible minority respondents. The perceptions of achieved goals for development also differed between men (60%) and women (69%) as well as white/Caucasians (67%) and visible minorities (52%). The gap (6%) between female (73%) and male (67%) respondents’ satisfaction with the progress they had made toward meeting their overall goals for the development of new skills was smaller than the gap (9%) observed between the white/Caucasian (72%) and visible minority (63%) respondents. Table 1 below presents the statistics of the key questions pertaining to the satisfaction of females versus males, as well as white/Caucasians versus visible minorities.

4.3 **Relationship with Managers and Colleagues**

Most respondents indicated that their manager provides them with helpful feedback, although women (73%) were more likely to agree than men (71%), while white/Caucasians (72%) were more likely to agree than visible minorities (70%). There is a significant gap in the perceptions of managerial efforts to learn about their employee’s career goals, between female (78%) compared to men (74%) and white/Caucasians (77%) compared to visible minority (72%) respondents. Similarly, white/Caucasian (89%) respondents compared to visible minority (85%) respondents and female (89%) respondents compared to male (88%) respondents, indicated that they receive the support they need from other co-workers to meet their work objectives. As can be seen in Figure 2 below, the gap (2%) between female (76%) and male (74%) respondent’s indication that their colleagues include them in informal networking is smaller than the gap (11%) between visible minority (66%) and white/Caucasian (77%) respondents. Most white/Caucasian (96%) and visible minority (91%) respondents indicated that their colleagues treat them with respect but, again, white/Caucasians were more likely to indicate this.

4.4 **Career Advancement and Development**

When asked to comment on whether they believed “who you know” was more important than “what you know”, a higher percentage of visible minority respondents (70%) compared to white/Caucasian (60%) respondents agreed, in contrast to 63% of females compared to 62% of male respondents. This reveals a significantly larger gap between white/Caucasian and visible minority respondents (10%), than the gap between men and women respondents (1%). Furthermore, an even greater disparity is revealed between white/Caucasian and visible minority responses to the statement that “people tend to recommend people of their own ethnicity for high visibility assignments”, where just less than 1/3rd of the visible minority respondents agreed with the statement, opposed to no more than 1/10th of the white/Caucasian respondents. A greater number of visible minority respondents (45%) believed that they are “held to higher performance standards than their peers”, compared to white/Caucasian (33%) respondents, while there was no difference between the responses of female (36%) versus male (36%) respondents. As can be seen in Figure 3 below, there is a much larger disparity (17%) between visible

![Figure 2. Respondent perceptions of their colleagues inclusion of them in informal networking.](image-url)

![Figure 3. Career advancement and development.](image-url)
minority (54%) and white/Caucasian (37%) respondents in their perception of how few role models there are for them in their organization, than the gap (3%) between male (40%) versus female (43%) respondents.

![Graph showing respondent perceptions of the amount of role models for them in their organization.]

### 4.5 Diversity and Inclusion in the Workplace

Even though there are slight differences in the gaps between male (72%) and female (69%) respondents, and white/Caucasian (72%) versus visible minority (67%) respondents, around two-thirds of all respondents indicated that their organization strives to create a climate supportive of all individuals. Inversely, the gap (11%) between the perceptions of visible minority (18%) and white/Caucasian (7%) respondents that that their organization devotes too little resources to diversity programs, was much larger than the gap (1%) between male (9%) and female (10%) respondents. Visible minority respondents (34%) also agreed to a lesser extent than white/Caucasians (46%) as compared to females (41%) versus males (45%) that their senior management demonstrates a strong commitment to cultural diversity. Of those who indicated whether or not their organization has programs, policies and practices that support the attraction, retention, development, or advancement of visible minorities, 81% of men versus 81% of women (no difference) and 88% of white/Caucasians compared to 59% of visible minorities (29% different) indicated that their organizations had programs, policies and/or practices. Table 2 below presents the statistics of the key questions pertaining to diversity and inclusion in the workplace.

### 4.6 Attainment and Recognition of Education Credentials

More than half of the visible minority respondents (63%) had a bachelors degree or higher, while less than half of the white/Caucasian respondents (45%) had a bachelors degree or higher. Furthermore, men (53%) are more likely to have bachelor degrees or higher than women (44%). This uncovers a greater education gap between visible minorities and white/Caucasians (18%) than that realised...
between male and female respondents (9%). Table 3 below outlines the breakdown of the levels of education attained by each of the respondent categories under analysis.

Table 3. Educational attainment of survey respondents.

Of the education earned, only 6% of female and 9% of male respondents earned at least some of their education outside of the United States, Canada, Australia, New Zealand, France, Germany or the United Kingdom, compared to only 2% of white/Caucasian versus 23% of visible minority respondents. Also, 44% of visible minorities compared to 25% of white/Caucasians, and 43% of males compared to 33% of females, believe that their education credentials are recognized as being less than their Canadian equivalent.

Recognition of foreign credentials is one of the biggest barriers identified by respondents in the study, as 31% of respondents felt that their education was being underutilized by their organizations. While the results of the survey show that men to women and white/Caucasian to visible minority responses differ the biggest variance is found in comparing visible minorities to men and women. As this is a survey of professionals who have been in the sector for an average of 10 years, survivor bias is an issue. That is, the respondents are women and visible minorities who have persevered in spite of the barriers that they face.

4.7 Overall Findings

While the survey assessed perceptions, it does suggest significant gaps between the satisfaction and perceptions of fairness in the workplace between visible minority and white Caucasians. Specifically, we found:

1. Visible minorities show less organizational commitment than white Caucasian employees in Canadian ICT firms. There is also a gap between male and female respondents but it is smaller and, perhaps unexpectedly, females are more committed than males.

2. Visible minorities show less career satisfaction than white Caucasian employees in Canadian ICT firms. There is also a gap between male and female respondents but it is smaller and women are more satisfied than men.

3. Visible minorities show less favourable perceptions of their relationship with managers and colleagues than white Caucasian employees in Canadian ICT firms. There is also a gap between male and female respondents but it is smaller. Once again females show more favourable perceptions than males.

4. Visible minorities show less favourable perceptions of career advancement and development than white Caucasian employees in Canadian ICT firms believing that its “who you know, not what you know”. There is also a gap between male and female respondents but it is smaller with females more likely to subscribe to this view.

5. Visible minorities show less favourable perceptions of diversity and inclusion practices than white Caucasian employees in Canadian ICT firms. There is also a gap between male and female respondents but it is smaller.
6. Visible minorities perceive that their educational attainment is less valued than white Caucasian employees in Canadian ICT firms. There is also a gap between male and female respondents but it is smaller with females likely to be more satisfied. The fact is that the gaps between visible minority and white/Caucasian satisfaction, is substantial. What was perhaps most unexpected was that in general female respondents were more likely than males to indicate that they were satisfied. This may suggest that differences in expectations or that the barriers to visible minorities are greater than those faced by women. Of particular note is that the expressed commitment to diversity in many of these organizations, particularly at the senior level, contrasts with the perceptions of many visible minority respondents. Not surprisingly, white Caucasian respondents appear to be less aware of these issues.

4.8 Initiatives to Promote Diversity in the Canadian Workforce

While there is a gap between white/Caucasian and visible minority respondents, employers reported a range of initiatives aimed at supporting full employment of immigrants and visible minorities. As noted above, there are also a plethora of initiatives aimed at attracting and retaining under-represented groups in the industry (ICTC, 2007). Companies are also undertaking targeted outreach to immigrants and visible minorities. For example, Nortel Networks has been a sponsoring company of INROADS, a non-profit organization that aids in the training and development of young people of colour for professional careers in business and industry. It offers multi-year summer internships, year-round coaching, and training activities. In addition to sponsorship fees, corporate sponsors are expected to provide a professional internship opportunity each summer for an intern and to consider hiring the intern for full-time employment upon graduation. Toronto Region Immigrant Employment Council (TRIEC) is a multi-stakeholder council which offers services for skilled immigrants matching them with established professionals in the same field. While the control group (without a mentor) got jobs more quickly, their searches were less focused and the employment they secured was in general labour, assembly, security, data entry and telemarketing earning $8-22 per hour. In contrast, the mentored group spent more time researching companies and landed more interviews. They earned an average of $55,000. More than half (55%) of those in a mentoring relationship, found jobs in their field of training through TRIEC’s Career Bridge program (TRIEC, 2006).

Once they are recruited, companies have a range of programs aimed at supporting under-represented groups in the workplace. For example, Nortel includes diversity and employment equity compliance training as part of all its management training. Gennum Corporation, a Burlington, Ontario-based medium-sized company in the semiconductor market, reports that approximately 20% of employees have emigrated from other countries. The company offers mentoring programs, language and communications skills programs on site. Celestica has adopted the Electronic Industry Code of Conduct, a voluntary code that commits participants to ensuring that they and their first-tier suppliers do not engage in “discrimination based on race, colour, age, gender, sexual orientation, ethnicity, disability, pregnancy, religion, political affiliation, union membership or marital status.”

Finally, and most challenging, are initiatives aimed at shaping societal views. Hireanimmigrant.com for example, is a campaign aimed at challenging assumptions and stereotypes through a provocative series of television advertisements. One for example, features two south Asian men discussing an applicant for a job. “But his degree is from Canada”, “His only experience is Canadian”, “And then there is his accent”, “Why are we even looking at him?” It concludes. The advertisement attempts to confront many of the stereotypes and discriminatory views of Canadians. However, the impact of such social marketing efforts is often uneven. While such campaigns may or may not be effective, there is little doubt that systematic attention to the representations of under-represented groups in the media is critical. Large companies can use their spheres of influence to help shape the media representations of under-represented groups and to use their purchasing power.

Barriers to full participation for under-represented groups can be overcome, and that effective programs share certain characteristics and approaches (Matton & Hernandez, 2004). Specifically,
successful workplace diversity initiatives hinge on committed leadership, defined goals/targets or measures of effectiveness, strong diversity professionals, employee involvement and ties to performance evaluation, as well as data to identify, quantify and communicate progress and challenges. At the same time, organizations operate within a social context. There are broad social and cultural factors, including stereotypes, which shape perceptions and expectations, and which must be addressed. Better data and more research on current practices will help advance our understanding of processes for developing strategies which “fit” in particular contexts. “Best practices” which are innovative, make a difference, have a sustainable effect, and can be replicated and applied in other contexts need to be further explored.

4.9 Implications: Towards an Integrated Approach

Discussions of diversity have proposed conceptual models of change. For example, the notion of the “diversity continuum” (Friday and Friday, 2003, Gilbert, et. al., 1999) is based on the assumption that organizations move through a stages on the path to becoming inclusive. Others have proposed that different sectors and companies within those sectors are at different stages along a “diversity curve” (Cukier et. al., 2007). For example, large telecommunications services tend to be higher up the continuum because they are federally regulated, female dominated, consumer-market oriented, knowledge intensive and relatively profitable. Given the complex and inter-related existence of barriers, we suggest that an ‘ecological’ model of change which considers the complex interactions among individual factors, group factors, organizational factors and societal factors which shape choices, create barriers and facilitate opportunities. The model is adapted from public health (McLeroy et. al., 1988) and proposes complex, iterative, interactions between individuals, groups, organizations, institutions and society. The core belief is that no element exists within a vacuum but is influenced and influences other actors. We propose this model in order to address one of the major gaps which has been identified in the literature to date on diversity – that is the relative lack of research exploring the institutional environment of organizations or the larger socio-political-cultural context of organizations. Efforts must address factors at the individual, organizational and societal levels.

At the individual level, focused programs aimed at equipping members of under-represented groups – with the knowledge, skills and attitudes that will increase their chances of success are essential. Within organizations critical issues include:
- A well defined business case and explicit policy on diversity/employment equity
- Senior executive support;
- Targeted recruitment/retention/promotion programs;
- Open and transparent recruitment and promotion policies
- Employee training and communication;
- Diversity performance objectives and targets ideally tied to compensation;
- Maternity/parental benefits and measures to support work-life balance
- Mentoring, networking and support opportunities;
- Implement supportive work practices and culture (eg. work life balance, mentoring, networking)
- Alignment of management of suppliers/procurement policies
- Systems to track diversity data;
- An accountability framework, eg. Public reporting on diversity issues (Jantzi Research, 2007; Catalyst and the Diversity Institute, 2007; ICTC, 2007)

At the societal level, better policies and programs are needed to support immigrants and other under-represented groups. But more importantly perhaps, vigilance is needed to address the stereotypes and hidden barriers that limit both aspirations and opportunities. Our study suggests that while there is strong evidence to suggest that immigrants and other under-represented groups could help address the ICT skills gap, more work is needed to fully utilize their skills.

Abstract

Many intervention programmes to encourage greater female participation in computer education and careers have been conducted in the last twenty years. These intervention programmes take considerable time, effort and money to design and implement. If success were to be measured by an increase in the percentage of female students undertaking computing courses then these programmes would have to be considered a failure. This paper describes a research project which examined fourteen intervention programmes in detail. From the perspective of the programme champions each of the intervention programmes was considered successful, even when this success was restricted to specific areas or limited to small groups of individuals. Formal evaluation appeared to have been an afterthought rather than a priority of many of the programme champions. Some programmes appeared to be less effective due to the lack of targeted and clear goals or predetermined evaluation criteria. It is recommended that during the initial planning phase for intervention programmes a clear objective is to consider what a successful programme would look like and what the evaluation criteria would be. Further work is needed to understand how intervention programmes can be better designed and evaluated so that their impact and success can be expanded.

Keywords: Gender, Computing, Recruitment, Intervention programmes, evaluation.

1 INTRODUCTION

Gender imbalance in specific discipline areas, or occupations, becomes a problem when the gender spread has a detrimental effect on some sections of society. For both men and women there are areas of the workforce where either dominates and one of these areas is computing. The early history and development of computing included significant contributions from women but as the discipline has evolved the number of women entering the profession has declined. While the computing profession is still relatively young it employs over a quarter of a million people in Australia yet less than 20% of these workers are women.

The philosophical viewpoint taken in this paper is that the field of computing has been socially constructed as a male domain and therefore while women are capable of taking their place in this field, at present, they are choosing not to. Lazowska (2002, p. 11) suggests that of the many reasons why we should be working to increase the number of women in computing ‘the selfish reason is the most compelling one: the quality of the solutions we achieve is enhanced by the diversity of the individuals contributing to these solutions’. This paper presents a research project which examined fourteen intervention programmes and reports on the achievements of those programmes. The criteria used to
measure success and the characteristics of those programmes that were regarded as successful are presented and discussed.

2 BACKGROUND

If women are not part of the technology solution design then it is unlikely that technology will represent their needs or their family’s needs. As Borg (2001) reflected technology for the future will depend on the designers, builders and controllers as well as those who use it.

... involving women in technology - how it is taught, learned, created and used - benefits everyone. .... It’s about bringing the talents of technical women leaders to bear on developing more competitive products and finding solutions to problems that impact our lives, our nation and our world. (Anita Borg Institute for Women and Technology, n.d.)

Woszcynski, Beise, Myers and Moody (2003, p. 1585) express the concern that without sufficient women in the computing workforce development of ‘technology pursuits may focus more on doing things faster, and less on doing new things that reflect alternative perspectives’. This was also the focus behind the creation of the Virtual Development Center in 1999, a programme of the Anita Borg Institute for Women and Technology. The authors highlight the importance of technology for improving the human condition generally and then pose a number of critical questions:

But what are the problems technology is attempting to solve? Whose priorities are represented? How much of technology truly benefits the world’s peoples? Who are the creators of technology? The creators of most of our current technology, however, represent a narrow stratum of the world’s population – North American males. (Anita Borg Institute for Women and Technology, n.d.)

Wulf (1998) explains that with a gender imbalance in the engineering workforce ‘we limit the set of life experiences that are applied, and as a result, we pay an opportunity cost, a cost in products not built, in designs not considered, in constraints not understood, in processes not invented’. This is equally true of computing and consequently computing is another area where gender imbalance is of concern and needs to be addressed. To ensure that technology is useful for all, a diverse blend of people is needed to design, develop and implement new systems (Camp 2001). Camp (2001) argues that to create better technology more women are needed to be incorporated in development teams as they bring different perspectives, different points of view and different ways of solving problems thus broadening the systems development process. Without women in the computing workforce the different perspective, priorities and operating styles women bring to the design and development of systems is lost (WSET 1995) resulting in systems that may not be useful to the whole population.

The impact of the absence of women in design and development can be best illustrated by examples:

- Margolis and Fisher (2002) report on a voice-recognition system which was calibrated to male voices only and therefore not able to hear women’s voices. A video conference system built around this software, where the camera automatically focused on the person speaking, could not hear the women and therefore the women were also not seen.

- Tests conducted on the first airbags showed that they saved lives. However, once in use, women and children were injured and even killed by inflating airbags. A study reported in the American Journal of Public Health described how the induced injuries from airbags were ‘disproportionately borne by female drivers’ (Segui-Gomez 2000, p. 1575). The original design team had been made up almost exclusively of men (Coonan 2006) and the initial tests had all been conducted with a 50-percentile male crash-test dummy, which was the size of the average American male (Nikkel n.d.). If there had been more women involved in its development, the fatal flaws in the airbag may have been avoided.

There are also examples from science and engineering which ‘show how a product–design group that is not representative of its users can go wrong’ (Margolis and Fisher 2002, p. 3):
• Artificial heart valves were sized exclusively to the male heart by a mostly male design team (Margolis and Fisher 2002).
• The theories about the preventative benefits of taking one aspirin a day were tested on 22,000 men (Kolata 1990) but reported in such a way that they applied to both men and women (Pear 2000).

Yet men and women can respond differently to the same drug (Buring 2000).

Although these examples highlight mainly physical and physiological differences, the creation of technology and computing environments that benefit all of society requires diverse perspectives in developmental and organisational areas also. Brown (2007, p. 334) concludes it ‘is not that men are incapable of representing women’s interests, but that men generally lack the necessary experiences to consistently and competently raise issues that tend to concern women more than men’. Unless more women are employed in computer design and development, these products and services are unlikely to meet the needs and desires of approximately half the population. The current loss of available knowledge from women in IT development can only be considered to be a loss for society as a whole.

Women need to be actively involved in all levels of these new technologies that have such immense potential for social change.

3 THE COMPUTING EDUCATION PIPELINE

Valenduc et al. (2004, p.10) argue that ‘Professional ICT skills are required in the ICT industry and in related jobs in the user industries, in order to create, develop, implement, repair or manage ICT tools (hardware, networks and software)’. Consequently the acquisition of appropriate computing skills and qualification via education is necessary.

Right along the education pipeline, from primary school to secondary school to tertiary institutions there are fewer girls choosing to study computing. In Australia, as in other countries, this issue was first identified as of concern in the early 1980s. The Australian government set a target that, by 1995, 40% of students within tertiary computing courses would be female (DEET 1990). This prompted a range of strategies to encourage the uptake of computing studies by female students. In Australia, as elsewhere where this same imbalance is an issue, numerous intervention programmes aimed at encouraging more female students to consider computing and successfully complete courses have been conducted. Initiatives have ranged from mentor programmes, the production of videos, special classes for female students, curriculum changes to create a more inclusive curriculum, to the running of workshops and computer camps (Greenhill et al. 1997b; Craig et al. 1998; Clayton and Lynch 2002). Intervention programmes have also been created to equip students with the necessary skills needed to work in this field. Other programmes have aimed to provide the necessary contacts to obtain jobs; while yet others have focussed on how to obtain career recognition and for support to stay in the industry.

Statistics however show no improvement in the rate of participation of females in this industry and anecdotal evidence suggests that these intervention programmes have not been as successful or effective as was anticipated. If success is measured, albeit simplistically, by the current percentage of females in tertiary computing courses, then the programmes must be seen as a failure with a decline from 27.2% in the 1990s (Lang 2003) to less than 20% of current tertiary computing students being female (DEST 2008). This view however is too simplistic, as there is no way of knowing what the percentage of females in computing would have been without the intervention programmes. The government’s target level of 40% has, however, certainly never been reached.

This raises questions about the efficacy of the intervention programmes, given the considerable efforts of many to raise the level of involvement of females in computing. Were any of the initiatives successful? How is success defined? How can success be measured?
4 THE RESEARCH METHOD

The aim of this research was to investigate gender-equity intervention programmes, focusing on the enrolment and retention of female students in computing courses in Australia, over the last twenty years. A collective case study of 14 individual intervention programmes was undertaken. Each of these cases was a concentrated inquiry into a particular intervention programme: Each case was investigated individually to try to understand its complexities (Stake 2000).

Research questions included:
- How did, or do, these programmes operate?
- To what extent have these programmes been successful from the initiators perspective?
- To what extent have these programmes been evaluated by those initiating the programmes?
- What criteria were used to measure success?

Data was collected via detailed document and artefact analysis and by in-depth interviews with the instigator/leader of each of the programmes. The analysis of each individual case was followed by a cross-case comparison.

Within the context of qualitative case study research in the computing discipline, the number of case studies (14) is consistent with other research (Orlikowski and Bardoudi 1991). Myers (2002) queries why more than one case is actually necessary but Miles and Huberman (1994) suggest cross-case analysis enhances generalisability as a multiple-case design will deepen the understanding and ability to explain what has occurred. Herriott and Firestone (1983 as cited in Yin 1994, p. 45) suggest that the evidence from multiple cases is more compelling and therefore the study will be more robust than one of single-case design.

Miles and Huberman (1994) suggest that a multiple-case study requires clear choices about which cases to include within the study. The intervention programmes which became the case studies for this research were selected on the following basis:
- One of the programme’s objectives was to increase the number of females who were part of the computing field.
- The programme could be made up of one or more projects however the programme needed to be a sustained activity.
- The principal champion/instigator of the programme was prepared to participate in this research.
- The programme and projects could be completed or be ongoing.
- The programmes were chosen to provide diversity in location and focus.
- How long the programme ran for, it was assumed longer term programmes would be more successful.

Intervention programmes have been conducted by three different types of entities in Australia; educational institutions, government bodies and industry groups. Eight cases were selected from universities, three from government bodies and three from industry groups. A greater number of case studies were chosen from the university sector than the other sectors due to the proliferation of such activities in this sector.

For each case study the programme leader or a major contributor was interviewed. However additional interviews were conducted for five of the case studies either because there were joint programme leaders or another major contributor was available and willing to be interviewed. A total of 19 interviews were conducted. For four of the case studies two people were interviewed and in one instance a third person was interviewed. Interview times ranged from approximately 60 minutes to 100 minutes in duration. For privacy reasons the interview participants are identified by pseudonyms and will be referred to as the programme’s champion in further discussion. Additional data for each case study came from the detailed study of documents and artefacts (consisting in total of 40 published and 10 unpublished papers, 17 reports, 32 surveys, 6 videos and 12 websites). These
documents/artefacts were investigated for detailed descriptions of the intervention programmes in context, as well as evidence of evaluation or the absence of evaluation.

Easterby-Smith, Thorpe and Lowe (1995) suggest that analysis of in-depth interviews initially requires the researcher to become familiar with the material and then to reflect upon it. Familiarisation of the data was strengthened via thorough re-reading of the transcripts. A set of themes and sub-themes important for understanding what was going on then began to develop. The interview transcripts were subsequently incorporated into NVivo 7 software. While such software can support the analysis of qualitative data, by searching, linking, marking and so on, it can not undertake the analysis and decide what all the text means. As Weitzman and Miles (1995, p. 330) explain; computer ‘software will never ‘do’ theory building for you…. but it can explicitly support your intellectual efforts, making it easier for you to think coherently about the meaning of your data’.

The documents and other artefacts collected also underwent the stages of familiarisation and reflection. Videos were watched, websites were explored, and support materials examined. In NVivo a ‘notes section’ was created, one for each of the case studies, and relevant facts and reflections were recorded as the researcher investigated the artefacts thereby creating a chain of evidence. Next other documents (such as evaluation reports, grant applications and research publications) were carefully re-read and entered into NVivo. This process brought together all the data for analysis, regardless of its source, into one NVivo project file enabling sorting, searching and linking. Having all the data in one project file within NVivo also enabled the creation of a meta-matrix as described by Miles and Huberman (1994) to facilitate an analysis for patterns in responses and opinions. Yin (1994) agrees that this approach is a good method for analysing multiple-case study data.

5 THE RESULTS

5.1 The Programmes

Of the fourteen case studies explored eight studies centred on programmes developed in academia through universities, three were state government initiatives, and three were developed by industry bodies (see Table 1). The geographic locations of these organisations span the entire breadth of Australia. At the conclusion of the research, six of the programmes were still highly active but in eight activities have stopped, or were operating only at a minimal level.

Table 1: Case Study Activity

While the United Nations Development Report (2004, p. xii) advocates that the ‘critical starting point for achieving gender balance in the ICT sector is tertiary level education’, work by Clayton, Cranston, Crook, Egea, Lynch, Orchard, Robinson and Turner (1993) has provided a broader framework which identifies three stages where it is possible to influence the participation by females in computing courses and the computing profession. The first stage of the framework is the Pre-tertiary stage where the focus is on intervention programmes for primary and secondary girls. The Tertiary stage has a focus on decreasing the attrition rates for tertiary female students. The final stage of Post-tertiary is aimed at women in the workforce or returning to the workforce.

University and industry involvement commenced with a focus on only one of Clayton et al.’s three stages, but with a growing awareness of the magnitude of the issues the programmes evolved to incorporate interventions at more stages. Eight of the case studies conducted projects at all three
stages, five conducted intervention projects at two stages, with only one University’s focus remaining on just one stage (see Table 2). It is interesting to note that all groups conducted activities at the pre-tertiary stage. Some programmes concentrated their efforts equally across all stages whereas some focused their activities more at a particular stage. The stage at which the majority of the activities were focused is regarded as the major focus of the programme. A minor focus refers to less activities being directed at that target audience.

Table 2: Focus of Intervention Programmes

![Table 2: Focus of Intervention Programmes](image)

5.2 The Programme Achievements

Some of the intervention programmes were still relatively new (3 years old), and some had been operating for a lengthy period of time (up to 20 years). Examples of the extent and variety of the achievements by these 14 case study entities are described in the following section. An indication of the number of participants at various events is also provided.

In total more than 40 separate Girls in Computing Days or Role Model events were conducted with 14,000 girls, 500 educators, 200 parents and 200 role models participating in these events. More than 200 girls from nine locations throughout one state participated in one multimedia workshops. At least four separate computer camps were conducted for secondary girls; and more than 150 computer clubs now run in schools including one which is being conducted wholly online.

Outcomes of many intervention programmes included the creation of resources such as; a ‘How to’ kit for Girls and ICTs role models events; A ‘Practical Ideas’ booklet for Teachers regarding Girls and ICTs which was distributed to all schools within one state; and ‘Mentoring as a Career Guidance Activity’ resource kit. Other resources produced included six videos, 12 separate websites including one which contained more than 70 pages and had received more then 34,700 hits over a two year period.

For industry women there were five national women in computing conferences conducted as well as two state-based women in computing workshops. More than 20 professional development (PD) sessions were delivered to more than 400 teachers.

Scholarship/awards/bursary schemes now exist where they did not before.

Media exposure and publicity has been generated with ‘Girls and ICT’ articles appearing in numerous school and parent magazines, teacher journals as well as in local and national newspapers. Further, an awareness-raising campaign directly reached 23,044 students in 370 schools across one state, and indirectly reached thousands more.

There were additional projects and achievements, which are too numerous to list, that were more local and specific. Some examples include four girls taking up or intending to take up ICT careers as a result of participating in one particular event; all eleven Year 10 students at one school who participated in intervention events indicated that they intended to take at least one science and/or IT subject in Year 11; 30 students and seven teachers from six secondary schools attended a breakfast with ten female ICT mentors from a local Council.

There are also achievements that are harder to quantify. For example in a number of schools it was noted that there appeared to be an increase in ICT skills and confidence by girls in using ICTs amongst participating girls. Girls were also more willing to take a leadership role in the use of ICTs. In some
schools there was an increase in understanding of the many possibilities and options in ICT study paths and careers. Students also felt they were 'cared about', a sense of 'belonging' assisting with their retention in courses. In universities an improved curriculum and/or an improved learning environment was developed and numerous supportive communities were created enabling networking and mentoring programmes to be conducted. For industry women better networks between entities and therefore better distribution of key information occurred. Workplace strategies have been shared and professional development activities carried out.

As can be seen from these examples, these intervention programmes resulted in considerable achievements with many activities conducted and large numbers of participants involved. Can these programmes therefore be considered successful?

5.3 Criteria used to measure success

Credible evidence, be it qualitative or quantitative or both, should be gathered to evaluate the success of a programme. While formal evaluation was not undertaken of many of the activities within the programmes the evidence upon which the champions evaluated the programmes is summarised in Table 3. Similar activities have been grouped together and duplicate criteria have been removed.

</tr>
<tr>
<td>▪ Creating relationships between groups: industry, education and government and forming networks</td>
</tr>
<tr>
<td>▪ Students going on to enrol in specialist ICT subjects in later years of schooling and going on to apply for scholarships</td>
</tr>
<tr>
<td>▪ Inspiring girls to set up their own computer club</td>
</tr>
</tbody>
</table>
### Improving the Curriculum
- Gender analysis of students’ results in relevant subjects; retention rate of girls

### Mentoring / Support Community / Networking
- Number of participants/members in the community; membership growth and participation numbers at events conducted; the level of engagement of participants
- Level of activity by the community: Number of activities; scope and range of activities.
- Anecdotal feedback and informal comments from participants
- The amount of time girls used the extra hardware provided. The number of participants who sought references from participating staff members or other support and who kept in touch after graduation
- Programme/group becomes embedded and participant/student driven
- Visibility of the group
- Number of students/participants who ‘opt out’
- Level of activity on discussion board
- Amount of sponsorship received and organisations taking part
- A champion emerges from the group

### Overall Pre-tertiary Initiatives
- Increase in the percentage of girls amongst enrolling tertiary computing students.

### Public Speaking Programme
- Students encouraging others to participate and perceived change in students’ confidence levels

### Residential Summer School
- Change in awareness of the tasks required by a ‘typical computing professional’ and change in interest in studying ICT and interest in a career in ICT. This leading to students choosing to enrol in tertiary ICT courses; the number who went to Uni X.
- Anecdotal feedback from students, facilitators and staff, during the camp and afterwards.
- Students returning to their school and speaking about the camp
- Peer evaluation from team members and other colleagues
- Extensive coverage in the media

### Web sites/Video/Resources
- Number of web site hits; Growth of the website
- Another department/organisation using the video/resources. Circulation of materials amongst teachers at the secondary school
- Others recommending the resources.

### Women-only workshop / Conferences on Women in Computing
- Answers to ‘What did you like about today? What changes would you suggest for the next event?’
- Number of participants; Engagement of participants during the day
- Whether all sectors (education, industry, government) were represented

### Tertiary Orientation Camp
- Student comments during and after the camp; Interaction of students when back at University
- Participants reported gaining a sense of ‘belonging’; retention rates in the courses.

### Other
- Number of referred papers
- Change in the culture of the organisation including a commitment by the organisation demonstrated by a budget line entry and support within the organisation
- Uptake of recommendations from gender audit
- Becoming known as the university of choice for girls wanting to do a computer course
- Equity awards received

---

**Table 3: Evaluation Criteria**
5.4 Defining a Successful Programme

When is an intervention programme a success? How can we measure this? For the staff involved with the intervention programmes at Uni5 success for their intervention programme was defined as passing the subject Computing 101 for the girls who participated in the activities (Uni5_documents). Megan (Uni1) on the other hand suggested that success would need to be broader than one subject and would look like ‘maintenance of numbers in my courses’. For Lesley (Ind2) success required the girls to actively follow up the opportunities that they were made aware of during the role model events:

That they have accessed some of the resources that were indicated from that event, that they have linked up with mentors, that they have done something about joining a computer club or at school the next year, signing up for enrolments in courses, or that they have taken back to their school, this kind of information. That they have encouraged other girls to do things or starting their own club at school, that they have just taken it further and influenced other people in what they have done as well. Because there is a sphere of influence when something can be really significant, not just the 30 girls that are there on the day, it is that whole explosive chart. If 10 of those girls get really affected by the day, and they go and impact other people, it is that classic nuclear explosion outwards. (Lesley_Ind2)

Kerrie (Uni7) suggested that success would be that the girls who attended the summer school would take up ‘careers around technology’. Similarly Jodie (Uni6) suggested that programmes were a success if they changed attitudes:

To see the kids taking the appropriate subjects in senior school to broaden their horizons and then, maybe the icing on the cake, would be to see them into a university or a TAFE college to do IT and then the tip would be to see them here. Jo and I don’t get up there and say Uni6 is good. We don’t need to. That is implicit in the whole programme. (Jodie_Uni6)

For one of the intervention programmes still in its early stages, success focused on the implementation of the programme:

Success will look like having an active web presence, having some sort of mentoring support group within the faculty of ICT that the girls are running, that they are active. Even if it is only four lunches a year, it is something. Having guest speakers, that sort of thing. … Success will be the group running, success will be having organised and built up a relationship with some feeder schools. (Sarah_Uni3)

Gov1 defined success by quantitative results; within a short period of time 30% of state primary schools and 70% of state secondary schools will have participated in Girls’ and ICT initiatives. Additionally 35% of state secondary school students enrolled in ICT subjects would be female (Gov1_documents). For Debbie (Gov3) success revolved around all three stages of Clayton’s framework; participation, retention and the advancement of women in ICT:

For me as a group I am hoping that we achieve a couple of things. One is that we really do get more women into ICT. There are three areas that we are focussed on. I hope that we actually bring more in at an earlier stage into the industry. I hope we can show that we are actually retaining more women and not losing them. Most importantly the reason to retain them is for them to actually progress through the industry so that we actually get more senior women managers, we get more people into positions of leadership that then can make a difference rather than being seen as not in areas of authority or influence. (Debbie_Gov3)

5.5 Were these Programmes Successful?

From the perspective of the programme champion each of the programmes implemented by the case study entities was seen as a success. All the interviewees, when asked whether they considered their programmes a success, said ‘Yes’ though a number of the respondents then qualified their answer;
I think all the events were successful, it depends how you are measuring the success. (Clair_Gov1)

Yes. We tried to measure it quantitatively and we couldn’t. We couldn’t relate anything really to the programme but our qualitative work tells us that women students perceived that the programme was just great and that is enough for me. (Alison_Uni5)

Almost all of the respondents talked about individual instances of having made a difference in one persons’ life and that this was enough to make the programme a success;

Yes. I know that I personally have touched lots of women’s lives from that point of view. That satisfies me but does it really justify the amount of time and effort that I have put into it? I don’t care. Really you cannot always measure things by the direct and tangible benefits so to me if we supported an activity and it made the difference between no girls going into a course and one girl going in I would be quite satisfied with it...(Stacey_Ind3)

While nobody described any of the projects or programmes as failures or unsuccessful, not all responses were completely positive:

There is no doubt that the success of the intervention programme depended largely on the personalities and qualities of the senior women students. Naturally some were better at the task than others. (Uni5_documents)

Partial only. I doubt if I move on that it will last independently. The paradox of the majority gender taking no ownership of the issue persists in this Faculty. We have not been able to affect staff perceptions. (Sarah_Uni3)

It was successful to a certain extent I think but only in a limited way, as far as we know. There was some form of evaluation done but there was so many confounding variables that it really didn’t show a clear influence in decisions made by the girls. (Kerrie_Uni7)

6 DISCUSSION/CONCLUSION

Currently there exist a wide range of programmes that have the potential to increase the participation of females in computing and there is some evidence that these programmes have worked locally. This paper describes a research project which examined fourteen intervention programmes in detail. These programmes were conducted by government departments, industry groups or university departments throughout Australia.

The results indicate that it is clear that one type of programme does not suit all situations and that the characteristics of programmes differ widely. The target audience varied from students, at all levels of education, to women in the workforce or returning to the workforce. Different levels of resources and support were accessible for each of the programmes. While the study showed that programmes differed in various ways some common issues and characteristics emerged:

- Difficulties in measuring intangible and qualitative benefits such as increased confidence
- A focus on implementing programmes
- A lack of focus on planning and evaluation of the programmes
- The dependence on the programme champions including personalities, time available, etc
- The need for management support and buy-in from others in the host organisation was seen as critical for programmes.

There were some identifiable explicit measures of success expressed by programme leaders. These include:

- Participants actively following up the opportunities that they were made aware of during programme activities.
• Participants taking up a career in computing. This included concepts of retaining women in computing careers and getting more women into leadership roles in the computing industry.

• The degree to which management and staff of organisations hosting intervention programmes provide mentoring and support both within the programmes and afterwards.

Most of these measures had not been quantified by the programme champions. This appeared to be due to a lack of initial planning of goals and evaluation criteria but resourcing issues also seemed to play a part. A programme was considered successful by all of the programme leaders if it had made a difference, no matter how small, and even if it was only in specific areas or for small groups of individuals.

The study indicates that intervention programmes currently have some identified measures of success depending on the type of programme and the participants. Although these measures were largely self-reported, they are key to understanding the success of the programmes.

The analysis of the findings indicates that for intervention programmes to be successful they need to be structured, targeted and well planned. They also need to have clearly defined goals and evaluation criteria that can be used to assess the programme at various milestones. The evaluation criteria should be considered in the early stages of the planning of the programme and not just after the programme has been completed. Further work is required to understand how intervention programmes can be better designed and evaluated so that they can be successful and have greater impact.

Ultimately, for intervention programmes to be considered successful, given that the purpose of the programmes is to increase participation, then the participation rate of women in computing education and the computing industry needs to rise. For the knowledge-based society of the future this is necessary in order to reflect the diversity of perspectives across the whole of society and to ensure that the development of computing and information systems is based on the broadest range of solutions available. The current lack of multiple viewpoints in computing and IT development and the loss of available knowledge from women, and potential women, in the computing industry can only be considered to be a loss for society as a whole.

Abstract

This paper presents a detailed ethnographic study of the design problems of a major national IT system in UK child protection and welfare services. The implementation of the Integrated Children’s System (ICS) has disrupted social work practice and engendered growing professional resistance, prompting a fundamental review of its design. Marshall McLuhan’s concept of chiasmus is a central feature of the analysis presented here of the tribulations of the ICS. Chiasmus refers to the tendency of any system, when pushed too far, to produce unintended contradictory effects, and is an intrinsic feature of the behaviour of complex, socio-technical systems. The dysfunctions of the ICS provide a pertinent, large-scale example. The ICS constitutes an attempt, via technological means, to re-organize child welfare services in the UK. Whilst aimed at improving child safety, the ICS has had the opposite effect of increasing the potential for error. This chiasmus has been exposed through the multi-site ethnography reported here, which shows how rigidly designed processes, enforced by IT systems, force social work professionals into unsafe investigative and recording practices which put children at greater risk. The paper ends by proposing an alternative approach to design, based on proven socio-technical precepts, emphasizing the principles of minimum critical specification, user-centeredness and local autonomy.

Keywords: Integrated Children’s System, socio-technical systems, child protection, child welfare, user resistance, chiasmus, user-centred design, performance management, audit.
1 INTRODUCTION

Every process pushed far enough tends to reverse or flip suddenly. Chiasmus – the reversal of process caused by increasing its speed, scope or size (Marshall McLuhan, The Book of Probes, p222)

Chiasmus is an integral property of designing, especially so for the design of organisations. In medicine, the general principle is familiar enough: too much of the “active ingredient” harms, even kills, the patient; indeed, the Greek for remedy (pharmakon) also means poison, as Derrida (2004) archly notes. Chiasmus emphasizes the indeterminacy of design, especially in the context of complex systems, where the presence of multiple, interacting variables means that outcomes are inherently non-linear and unpredictable; it thus furnishes a much-needed antidote to simplistic cause-effect thinking. When designing organisations, structure is the active ingredient, and achieving the optimum dose, the golden mean, should be the pre-eminently concerned of the designer: too little structure risks anarchy, too much can bring on bureaucratic sclerosis. As Argyris puts it ‘All organisations are designs… managers specify ahead of time the jobs and roles of the players as completely as possible without the specifications being so complex that they immobilise performance’. The socio-technical theorists propound the same wisdom: “details of a work system should not be overspecified in advance. Sociotechnical analysis proceeds by specifying… only those things that must be defined: the minimum critical specification” (Pava, 1983). Weick (1987) makes much the same argument, expressing it in terms of the right balance between centralisation and decentralisation.

In this paper, we present a cautionary tale where an excess of structure produced a chiasmus, i.e. a reversal of the desired organizational outcome. We will examine the vicissitudes of a major national IT project, the Integrated Children’s System (ICS)\(^1\), in UK child protection and welfare services. The failings of the ICS were thrown into sharp relief by the tragic and brutal death of a 17 month old child (“Baby P”) in the London Borough of Haringey in August 2007. The trial of the child’s mother, boyfriend and another man, which concluded in November 2008, was widely reported in the British press and caused considerable moral outrage. Reports drew attention to the deficiencies of the ICS and the role it had played. An article in the Guardian newspaper of 19th November (p. 7) is typical of the coverage. Entitled “Child protection stifled by £30m computer system”, the article highlighted the vast amount of time taken filling out forms on ICS and the pressures created by the system’s deadlines, together acting to “restrict the time available for family visits”. The urgent need to review the design of ICS has been designated as a key priority for the Social Work Force\(^2\), a body set up by the Government to review all aspects of social work training and practice in response to the Baby P tragedy. Further indications ICS’s deep-seated troubles are reflected in recent reports of industrial unrest, such as the following from the Unison trade union to which many social workers belong:

UNISON wishes to draw attention to the seriousness of the problems being experienced by social work staff with the Integrated Children’s System. The problems appear to be fundamental, widespread and consistent enough to call into question whether the ICS is fit for purpose…. we have reports of a number of industrial disputes or collective grievances brewing or underway and in many more cases staff are voting with their feet and not using the system when they can get away with it (Unison, 2008).

\(^1\) ICS is not a standard software package as such. Rather it is a standard specification, comprising a set of data requirements, a process model, and a reference set of a data collection forms (exemplars), against which suppliers can develop “compliant” software implementations (Cleaver et al., 2008). A number of ICS software products exist purveyed by a range of vendors, either as adaptations of extant systems, or as de novo packages. ICS was originally conceived in 2000. Its development evolved over a number of years, before “roll out” on a national basis from early 2007 onwards. Although there is an espoused emphasis through its development on piloting and incrementalism, our research has found that, in practice, its design has been highly centralised, led by a small group of senior civil servants and expert advisers. Input from social work practitioners has been very limited and feedback from the field has had minimal impact on its design; oft-heard are tales of requests to simplify the exemplars, for instance, going routinely ignored. Adverse reactions from practitioners have been dismissed as “teething problems” rather than symptoms of fundamental design flaws (see Cleaver and Walker, 2004).

\(^2\) As a result of the research reported here, one of the authors (SW) is a member the Task Force
In this article, we shall tease out the fatal flaws in the design of ICS, flaws which were responsible for the chiasmus of a system designed to enhance child safety seemingly having the contrary effect. These paradoxical outcomes are subtle though, only to be brought to light by careful, ethnographic analysis of the local adaptations of practice arising from the user/technology interaction. It is important to be clear that these failings are not, at root, failings of the IT per se, but of the rigid workflow regime and the excessively complex assessment forms which the technology embodies. Having said this, there is no doubt that the all-pervasive nature of the electronic medium has enabled these arrangements to be more efficiently and comprehensively enacted than would have been the case with a paper-based system, and with less flexibility and “wiggle room” for workarounds and other improvisations.

As a major national initiative directly aimed at transforming social work practice, ICS is worthy of investigation in its own right. We also believe that the problems inherent in ICS are by no means unique, and that there are lessons to be learned for the design of systems in general. These lessons are especially relevant in the context of public sector reform where technology features so centrally as the instrument of “modernization”, with e-Government now installed as a global phenomenon (Wastell, 2006). In child welfare, an important focus for such reform has been the need to increase child safety, through the formalisation of organizational procedures and their enactment by technology.

Our main interest has centred on the interface (the “front door”) between social services departments and other agencies (e.g. police, health services), and with the general public. We draw attention to the short-cuts that the ICS appears to necessitate, given the procrastinuous timescales and excessive audit requirements it imposes. Imperatives to safeguard children and support families appeared at odds with the new modes of e-governance and associated performance targets. Equally, the standardised but tortuous assessment forms appeared to engender a range of problematic recording practices. Whilst new tools and methods can clearly play a role in risk management, we will argue that the design of an effective system needs to be based on the needs of users and on a thorough understanding of their working practices. Only this will provide a secure basis for determining the appropriate balance between structure and autonomy.

2 MODERNISING INITIAL ASSESSMENT

In recent years, practices at the front-door of statutory children’s services in the UK have been subject to significant ‘modernisation’ efforts, aimed at improving their safety and efficiency. In 2000, The Framework for the Assessment of Children in Need and their Families was introduced (Cleaver and Walker, 2004) which clearly defined the initial statutory response as a distinct stage in the assessment process (Horwath, 2002). Since its advent, the importance of initial assessment practices has been further reinforced by the public inquiry into the death of Victoria Climbie (Laming, 2003) which heavily criticized the social services department involved (Haringey again) for failings in their referral and assessment processes.

Initial assessment (IA) emphasizes the importance of the first professional response, especially the need to see the child at the earliest point. The Integrated Children’s System (ICS) has accordingly been designed to ensure that workers rigorously follow the various steps specified in a formally defined “model” of the assessment process, leaving behind an indelible, electronic trace for audit purposes (i.e. showing that the correct procedure was followed). A standardized IA form prompts workers to collect information in a systematic way, with the expectation that the data so-garnered will contribute usefully to further assessment. Consistent with the universal application of “Performance Management” throughout the UK public sector (Bevan and Hood, 2006), a burgeoning range of targets and associated timescales have been also stipulated. Within 1 day of a referral being received, social service departments are mandated to make and log a decision about the requisite response. When an

3 We use “technology” in its widest sense to encompass formally-defined procedures and methods (administrative technology) as well as physical machinery, such as the ubiquitous personal computer.
initial assessment is deemed necessary, this must be completed within 7 working days, including the requirement to see the child.

Despite these changes, errors continue to occur, not just concerning the risk of serious harm to children but indications have also been found that “children in need” and their families are not receiving appropriate help (Bostock et al., 2005). Our impoverished understanding of these continuing difficulties arises from a key limitation in the evidence-base. There has been a general tendency within the extant social work research literature to bracket off the technological from the human elements of practice. The present study represents an inter-disciplinary collaboration between social work and IS academics. It proceeds from the general principle that to develop a more effective approach to risk management in child welfare, it is important to conceptualise the ICS as a socio-technical system of inter-related human and technological components, and to draw on relevant ideas from systems theory for enhancing safety. We develop this argument in the next section.

3 THE SYSTEMS APPROACH TO ERROR MANAGEMENT

There is a substantive body of work that argues for such a systems approach to error management (Reason, 1997; Munro, 2005a; Bostock et al., 2005). Reason (1997; 2000), perhaps the most well known exponent of this standpoint, argues that errors in human systems have their origins “not so much in the perversity of human nature as in upstream, systemic factors” (p768, 2000). Coining the notion of “latent conditions for error”, he argues that the analysis of errors in organizational settings should focus on general systemic weaknesses, rather than mistakes made by particular individuals on particular occasions. Such latent conditions refer to generalized, immanent characteristics of a designed system (typically non-obvious and unintended) that increase the overall risk of errors occurring in the operational situation. In aviation, for instance, efforts to automate pilot functions were based on the premise that this would improve safety (Norman, 1990). However, by displacing the pilot from the “control loop”, his/her grasp of what was currently going on in relation to the status of airplane was necessarily eroded. Such reduction of “situational awareness” provides an example of a latent condition of error, a direct but paradoxical consequence of infelicitous design. When the pilot was obliged to take over control in exceptional conditions, the likelihood of mistakes could be increased and indeed several serious accidents were attributed to this aetiology (Norman, 1990).

An extensive quotation from Reason (2000, p.769) provides a useful summary of the main features of the concept. Designating latent conditions as the inevitable “resident pathogens” within the system, he goes on:

They arise from decisions made by designers, builders, procedure writers, and top level management… All such strategic decisions have the potential for introducing pathogens into the system. Latent conditions have two kinds of adverse effect: they can translate into error provoking conditions within the local workplace (for example, time pressure, understaffing, inadequate equipment, fatigue, and inexperience) and they can create long-lasting holes or weaknesses in the defences (untrustworthy alarms and indicators, unworkable procedures, design and construction deficiencies, etc). Latent conditions, as the term suggests, may lie dormant within the system for many years before they combine with active failures and local triggers to create an accident opportunity.

From a systems perspective, approaches to error management that focus on individual breaches of procedure or unwanted aberrations of human conduct will be limited in delivering safer worker practices. Individuals are fallible and will always err, the trick is to design safe systems which minimize the likelihood and the consequentiality of such inevitable failures. A systems perspective requires that more attention is focused on minimizing “the number of latent conditions in the system that can contribute to user error” (Lowe, p.2, 2006).
Another core systems concept we shall draw on is the Law of Requisite variety. In his classic paper on the design of “high reliability” systems, Weick (1987) makes the point that failures inevitably occur when “the variety that exists in the system to be managed exceeds the variety in the people who must regulate it”. Pithily the Law proclaims “Only variety absorbs variety”. This, of course, is the exact opposite of the principle of standardisation, which in the limiting case provides for the same response whatever the input. Rules, policies and procedures are all abstractions and intrinsically lack variety; intelligent human agents provide the necessary “variety amplifiers” (Beer, 1994) which enable bureaucratic systems to work effectively.

In the heavily regulated regime of UK children’s services, requisite variety has necessarily been attenuated and the latent conditions for error are all too readily found. Work volumes create severe pressures in most settings. It is estimated that, on average, some 300 referrals must be processed every month by the typical children’s services department. Teams are legally bound to respond to referrals; they receive no extra compensation or flexibility regarding staff sickness levels, rather targets must be met whatever the particulars of local context or individual case. Pressures are further compounded by the widespread problem of recruiting and retaining experienced staff. Where referral rates are high and resources are constrained, trade-offs are inevitable between urgent child-protection work and assessments leading to more general forms of family support. The general aim of this paper is to draw attention to the unsafe practices that the ICS appeared to necessitate in its demand for rapid case disposals dictated by standardised procedures, and exacerbated by the work pressures and conflicting imperatives that apply in the operational situation.

4 THE FIELD-WORK AND FINDINGS

The project comprised a multi-site ethnographic study, based in five local authorities in England and Wales and drawing data from 15 social work “initial assessment” teams. The five local authority areas comprise: a London borough (Metroville); a county council (Shire); a metropolitan borough in the North of England (Westford); a unitary authority (Seaton); a Welsh rural authority (Valleytown). The field-work began in 2007 and is still underway. Informed by appropriate standards for ethical research, the ethnographies have involved various levels of engagement across the sites. Everyday interactions between team leaders and social workers, middle and senior managers have been observed as well as more formal meetings. In total, we estimate that this has amounted to around 240 days of observation and analysis of everyday practice at the time of writing, supplemented by the inspection of key documents and case files. In addition, a total of 10 focus groups and 60 formal interviews have also been conducted. Transcripts and fieldnotes have been uploaded to a dedicated project web-site to allow the research team to share and discuss the data. Regular meetings have been held to examine and validate emergent themes, supported by group email exchange and discussion. Through these means, we have ensured that the pattern of findings reported below provides an accurate depiction of the situation across the five sites.

Each of the five initial assessment teams is tasked to respond to initial contacts and referrals that come by way of telephone calls, faxes, emails, multi-agency assessment forms etc. These various external contacts cover the range from reports of serious injuries to children, more uncertain concerns about children’s welfare, right through to simple requests for information and advice. In all sites, there is increasingly little opportunity for a “customer” to walk in and directly request help, rather all approaches are mediated through some form of “front of house” customer service interface, either

---

4 The Law was coined by the British psychiatrist W. Ross Ashby, one of the founding fathers of the systems movement, in his Introduction to Cybernetics (1956). Imagine a system (e.g. a family) to be “controlled” in the sense that we seek certain desirable outcomes (e.g. children do not suffer harm and achieve their full potential). Variety simply denotes the number of different “states” that the system can be in, which in the case of a human system (e.g. a family) is both large and dynamic. All families are different and the variety of the social care system must therefore possess a comparable degree of variety (repertoire of responses) in order to deal effectively with this variety.
centralized or within the team. Whilst practices varied across our sites, we found a number of distinct commonalities reflecting the influence of the performance management elements of ICS, and the concomitant preoccupation of staff with maintaining “workflow”. Workers consistently claimed that it was easy to lose sight of the primary activities of supporting families and safeguarding children, to the second order activities of targets and audit. In the rest of this Section, we will focus on the latent conditions for error created by this administrative regime embodied within the ICS. We illustrate these risky adaptations in the sub-sections that follow, limiting our report to three discrete aspects of the initial assessment process, (i) accepting a contact/referral (ii) making further enquiries and seeing the child and (iii) the completion of the IA record.

4.1 Accepting a contact/referral

Our assessment teams reported variable referral rates, ranging from 80 to figures significantly higher than 300 per month. In all but one site, far more contacts/referrals were received than could be managed. The requirement for an initial decision within 24 hours necessitated a rapid but not necessarily reliable response, and where workloads are high, the potential for error is clear:

Admin worker: ‘The phone will be ringing continuously, you put the phone down and it rings straight away... one comes and another one comes... and your mind just gets frazzled, I might have written 5 or 6 pages of A4 paper ...and when I come back to reading them, it’s all looking a bit messy... I can’t quite make out what I’ve got down...’

Such pressures created significant anxieties for experienced staff workers, who understood that the pace of work created less than ideal conditions for practice, but there was also evidence of ‘speed-practices’ becoming habituated and normalized, especially in newer staff. For staff higher up the hierarchy, it was critical that only a manageable number of referrals were actually allocated for initial assessment. In the extract below, taken from one of our busiest teams, the team leader makes clear her reasons for clearing contacts by the end of the day, with the mandate for her actions directly invoking the exigencies of managing work-flow dictated by performance timescales.

Team leader: ‘There are 50 contacts in your inbox... you are under pressure because you have to clear them by the end of the day ...and the question of whether you are more likely to close them in these circumstances? Well yeah... so, really we are looking to close cases not open them... that’s why we work to the highest thresholds’

The IT systems maintained the pace of work, typically by providing digital reminders of deadlines and timescales. In one site, we found an ‘e-tracking device’ in the form of traffic lights, which informed workers about how much time was left before the specific episode was deemed out of timescale. In another site, ‘higher management’ were planning to print out weekly graphs of levels of attainment in meeting targets, alongside tables exposing individual failures.

In order to manage the volume of referrals, we consistently observed the presence of well established ‘general deflection strategies’ that included: strategic deferment, i.e. sending the referral back to the referrer to ask for more information; and signposting, deflecting the case to a more ‘appropriate’ agency. Whilst such adaptations are sensible if proportionate, the inherent risks are also clear. Where insufficient time precluded the pursuit of more detailed information from a referrer, other decision-making heuristics came into play. These included the routine categorization of anonymous referrals as malicious (indeed referrals from neighbours and family members were also often treated as suspect). We were told that children aged over 13 were routinely ‘NFA-ed’ (an outcome of no further action was recorded) on the basis that these young people ‘must have lived with these concerns for a long time and be quite resilient’. Similarly we found questionable methods for dealing with domestic violence notifications through automatic letters generated without any attempt at investigation. In general, we found that well-intentioned, but very busy workers, became habituated to such methods of rationing, with little time to reflect on such rationales and the risks they entailed.
In the following extract, the worker indicates how the imperative to prioritize a case already categorized as child protection (S47, i.e. section 47, Children Act 1989) required that she give less priority to an incoming referral, which also sounded malicious. Although she acknowledges her lack of knowledge, she justified her decision as follows:

*Social worker:* ‘I’ve got this S47 and actually this family are in crisis and I want to put support in for them, before I worry about this other family that don’t even know I’m coming, because it’s an anonymous referral from a neighbor... and you think, well OK, I don’t know if there’s a real risk or not, but from reading it, it sounds a bit malicious, well this family, actually are about to fall apart if you don’t put something in’

In order to manage workflow, we also observed some ‘safer’ locally-improvised methods for meeting timescales, that generally amounted to holding a case open for ‘review’, but logging the IA as complete on the system so as to meet the target. In cases where the seven days had not provided sufficient time to establish confidence about the child’s welfare, this ‘review space’ could enable further information to be gathered. However, such workarounds, even when they are constructive, by their very nature can only survive while they remain undetected by the gaze of senior management.

4.2 Making further enquiries and seeing the child

A number of cases will get through the first layer of filtering and be allocated to a social worker for initial assessment, which will include making further enquiries and seeing the child. At this second stage, we also found short-cuts in operation. There was a tendency to abort an assessment whenever the ‘opportunity’ arose. In the case of the referral from a grandmother below, the routine treatment of referrals from family members as potentially suspicious, and that the health visitor had seen the child, together enabled swift disposal of the case.

*Team leader:* ‘Being a bit cheeky...we contacted the health visitor and said when did you last see the child and lucky enough the health visitor had seen the baby recently and it wasn’t as bad as the grandmother had alleged... so we didn’t take it any further, no further action’

The tempo and volume of work, together with the 7-day target for IA completion, were widely reported as making cases at this second stage equally susceptible to partial analysis and rapid disposal.

*Social worker:* ‘If it’s not looking that serious...sometimes you don’t get all the information and the temptation is then to take a short-cut and maybe not contact the school, or because the school are on holidays you say I think I’ve got sufficient information to make a decision- NFA’

Needless to say, school holidays are not factored into the 7 day timescale! Neither are parents and children who are not at home, nor health visitors who are on sick leave and so forth. These factors necessarily interrupt the expeditiousness of the assessment process, but the system offers no accommodating room for manoeuvre. Thus, timescales can create perverse incentives to dispose early on the basis of incomplete information. Whilst in many cases, an “NFA” decision may be quite appropriate, our file analysis of open cases did find a common pattern of repeated initial assessments of escalating severity, before the case eventually found its way through the front-door.

Front-line team managers played a key role in the operation of ICS. In some teams, acutely aware of the possibility of error, managers worked closely alongside new recruits to defuse their inevitable frustrations and induct them into ‘local methods’ which would enable them to get them to the best out of ICS. However, we also found some tension between workers and their managers regarding the primacy of meeting targets. For example, in a particularly pressurized team, managers described their frustrations with workers spending too much time ‘social chatting’ or needing lessons in ‘diary management’; such critical attitudes would seem likely only to exacerbate anxiety in work that was already stressful enough. Invoking ‘safeguarding’ could buy a worker more time, but only in cases where there was a clear moral mandate to set aside the all-important target. The degree of assertiveness required to challenge the performance system could also lead to overt conflict:
Social worker: ‘My manager said to me “why haven’t you finished that yet?”… and I said “well the health visitor hasn’t called me back”… and they said, “well no, if you’ve decided that it’s family support, then the outcome won’t change, whatever they say”. I said “I disagree” and of course that information informs my assessment, I’m not putting my name to that.’

Where workers were juggling between the completion of IAs and serious cases needing to progress for further investigation, ‘NFA’ was described as a welcome relief. Again, we see the latent potential for errors in this expediency; in the busiest of teams and in spite of the good intentions of workers, time precludes, for example, getting back to the referrer to inform him/her of a decision, which closes down any immediate challenge to the categorization. Seeing ‘the child’ is a central and critical part of initial assessment. However, even in relation to this imperative, we found worrying short-cuts, as the following extract illustrates:

Social worker: ‘My new manager…she comes back and says, it [the IA] doesn’t say have you seen the child, it says “has the child been seen?”, you can put “yes” and then make it clear that the teacher has seen the child. I thought hmm… what’s the point me even doing an assessment if I haven’t seen the children’

Children are not easy to ‘see’ under the conditions of initial assessment, for a variety of reasons. First, there is a requirement to see all children irrespective of a ges, but older children can be difficult to track down. Second, ‘seeing’ should involve talking to the child alone to make an assessment of the child’s development and needs, but this can be hard to achieve within 7 days in a single visit. With initial response to telephone calls increasingly mediated by administrative staff and home visits curtailed to a single visit, the space between help-seeker and help-provider is steadily widening. Skilled workers might attempt to reduce this space, but for many, in the absence of knowledge derived from face-to-face work with families, they fall back on readily auditable, bureaucratic justifications, often offered by fellow professionals, which invoke missed health appointments, school attendance problems and the like.

4.3 Completing the record

The standardized initial assessment record invites workers to comment on a range of factors relating to the child, his/her parents or carers and the presenting concerns. A general observation across our sites was the paucity of information recorded on the actual IA document. In one site, we examined 65 records of individual children; the scantiness of the information, compounded by the difficulties of piecing together fragments of narrative scattered across multiple boxes, made it very difficult for the reader to construct a holistic picture of the child and his/her family. The IA record presents as a rather badly designed tool, requiring copious information that is difficult to glean from one home visit and from other professionals; it thus invites workers to discard the majority of its sections as irrelevant.

With not unsurprising consistency, we found an expedient method of ‘front and back-ing’ (or ‘back-to-back-ing’) had spontaneously sprung up across all our sites, wherein middle sections of the document were omitted altogether:

Researcher: ‘So what about the middle of the document, because everyone seems to miss this out?
Social worker: What middle document?
Researcher: You know, practitioners are concerned with the referral and the outcome on the back, but what about all those pages in between about the child?
Social worker (laughing): To me well… yes, there is a page about the child, I would always put in something, depending on what the child is like…I would always put something in, but in IA you wouldn’t…this is initial assessment’

It was clear that workers were trying desperately to make the form fit their work. Whilst most practitioners welcomed the general principle of electronic recording, the IA was not only overly long.

---

5 The initial assessment form is typically 10 pages in length. Apart from the usual administrative fields for structured data, there are well over twenty free text fields addressing the developmental status of the child and relevant environmental factors: including the child’s ‘social presentation’ or ‘self-care skills’, the ‘family’s social integration’ etc.
but the standardized questions and sub-headings were not easily adapted for this or that case (c.f. White et al. 2008), so workers went straight to ‘analysis’ of ‘that dreadful form’, putting ‘nothing-in-between’. Scrolling through the pages of the record ourselves, we found it difficult to distinguish between the material typed by workers and material already on the form, i.e. the numerous sub-headings and explanatory notes provided. Workers have become experts with the copy-and-paste function, as material is regularly and mechanistically repeated. In addition, the principle that for every family, a record of each child was required, tended to encourage practitioners to produce a general homogenizing account that ‘fitted’ all the children.

**Social worker:** ‘If I know that the IA is more than likely going to turn into no further action, and I know that after I’ve had my conversation with the family, then I will massage the information on each of the children and talk in plural “the children presented”’.

Whilst workers were clearly attempting to work-around the excessive audit demands of ICS, to salvage some time to spend with families, even the most perfunctory response to audit left too little time for the real work of face-to-face communication (Peckover et al. 2008; White et al. 2008). The speed with which workers attempted to complete the IA record also meant that errors of recording were common. In the busiest teams, such errors were compounded when ‘students’ (for example) were asked to catch up with recording cases they knew nothing about! Whilst workers were aware of these errors, they also reported that it was difficult to make corrections as material was ‘locked down’ in the system after 24 hours. After that period, a worker would have to seek special permission to undertake corrections. This stricture, entirely rational in the logic of rigorous audit, is however hardly conducive to good practice. Very obvious errors, such as putting a case note in the wrong file might prompt such requests, but simply improving wording was just too much trouble, though vital to the comprehensibility of the record, especially for other professional readers.

## 5 DISCUSSION

The Platonic approach can be described as Utopian engineering, as opposed to … piecemeal engineering. The Utopian approach is the more dangerous… the Utopian engineer will claim that mechanical engineers plan even very complicated machinery as a whole and that their blueprints cover not only a certain kind of machinery, but even the whole factory…. (Karl Popper, The Open Society and its Enemies, 1999)

Since the Laming report (2003) there has been a very significant reconfiguration of children’s statutory services in the UK. Rigorous information recording and performance management are the mantras of this brave new world; however it is important that the tools we provide for our workers are fit for purpose (Munro, 2005b). We would argue, however, that the increased audit demands of ICS, together with on-going resource constraints, have served to increase the burden on front-line workers (Peckover et al., 2008). From our analysis, it is clear that the design of the modernized initial assessment system of children’s services, embodied within the ICS, is not only flawed, but that its dysfunctions provide the latent conditions for error. In response to the intractability of the IA process, the workers in our study had devised a range of artful “work-arounds”. However, errors are inevitable in the context of such expediencies, which have been extemporized to maintain an overly rigid workflow. An excessive zeal for structure and standardization has thus engendered a reversal of the intended outcome. A chiasmus has been produced in which, rather than improving safety, the latent conditions for failure have been exacerbated and risks increased.

The short-cuts that have been fashioned in the “electronic cage” of the ICS typically take the form of early categorizations based on incomplete information, or the fudging of details of a ‘home-visit’, and so on. As illustrated in our ethnography, it is preferable to dispose of a seemingly nebulous referral in the face of the more immediate performance demands of the ICS. But it is often just those kinds of referrals that appear to be irrelevant, or somebody else’s business, that can provide the warning signs of a more serious malaise (Laming, 2003). Scarcity of resources will inevitably mean that giving priority to one part of the system, the most immediate, will result in cuts in another. It is no surprise to
have found that workers pursue opportunities to deflect incoming work, and dispose of cases on the basis of superficial analysis, or fall back on fallible heuristics such as “it’s probably malicious”. In social services, priority needs to be given to reduce the distance between workers, family and community which many studies have cited (by both service users and front-line workers) as central to good practice (Pithouse and Holland 1999; Gray, 2002). We have seen that the performance-driven ICS only detaches the professional further and further from the possibility of meaningful engagement with service users, offering instead a scientistic veneer of codes, risk scores and metrics.

Lipsky’s concept of the “street level bureaucrat” (Lipsky, 1980) emphasizes the importance of professional discretion in front-line practice in the public services. Lipsky saw such discretion as essential in order to get the job done: “the situations they face are too complex to reduce to prescribed responses”. This is simply a reflection of the ineluctable writ of the Law of Requisite variety: discretion is not some incidental feature, it is fundamental to the operation of any “viable system”, and of particular importance in designing reliable systems for risky environments where failure is highly consequential (Weick, 1987). In a different context, Bourdieu (2003) makes the same point in defining the ability to improvise, to adjust responses to local, situated contingencies, as being the hallmark of competent practice. In the IS field, Ciborra (2002) also exalts improvisation in the modern organisation, as the artistry needed “to fill the gaps of planning, cope with unexpected consequences, with events and situations that do not fit the planned hierarchical procedures” (pp. 153-154).

The findings we present are controversial and are presented in a designedly polemical tone. We draw attention to the multiple opportunities for errors on the part of front-line social work professionals that are exacerbated given the current configuration of initial assessment process and its technological embodiment in the ICS. Performance management (the paraphernalia of targets and indicators) is designed to enhance rather than inhibit quality performance, yet our study has found this regime paradoxically worsens the latent conditions for errors. Whilst it is tempting to berate the maverick professional who subverts correct procedure, it is important to remember that there are “good” organizational reasons for such behaviours, i.e. they are an attempt to reconcile the competing elements of the ICS with imperatives to safeguard children and to support families. The latter role, however prominent in current welfare policy, is particularly vulnerable. Perhaps the real tragedy of ICS is that in busy teams, demands to support families will inevitably be subordinated to pressures to maintain workflow.

Although this paper challenges the huge investment in systems of performance management and IT, we are not arguing for a wholesale Luddite abandonment of new modes of governance and new technology. The remedy, we believe, lies elsewhere, in a radically different approach to design. Radical it would seem for present times, in the public services at least, though hardly ground-breaking; rather the reclaiming of an older design wisdom, sundered-off, ignored, or never encountered. Sociotechnical systems design (STSD) embodies much of what we have in mind. Core principles of STSD include: user participation, minimum critical specification and the optimization of local autonomy (Pava, 1983; Mumford, 2003). Above all, it is essential to focus the design of systems on the needs of users, founded on a rigorous understanding of their working practices. The case for user-centred design (UCD) has been cogently made in many design disciplines, including information systems and human-computer interaction (Norman, 1998). UCD is essential in order to gain reliable knowledge for designing new tools and processes. Failure to involve users in the development of systems inevitably engenders alienation, and there were unmistakable signs of practitioner disquiet (complaints of additional workload and excessive “bureaucratization”) in pilot studies of the ICS (Cleaver and Walker, 2004; Cleaver et al., 2008). It is regrettable, unconscionably-so, that such early warning signals apparently went unheeded, written off with oracular reasoning as “implementation issues” rather than more fundamental problems of design dogma. As a result, the strictures of the work regime imposed by ICS have not only produced unsafe practices but, as we have seen, are now provoking overt resistance from an increasingly frustrated and mutinous workforce (Unison, 2008).

We believe that new systems and technologies can be developed which both assist the users in their daily work and achieve desired organizational goals, but without an ethnographically-informed
understanding of human practice (such as this paper provides), this virtuous circle will not be achieved. Ethnographic studies have shown time and again that even work which seems highly routine is a skilled accomplishment (Gasser, 1986); its orderliness is a product of the artful worker, not determined by the imposition of a formal rule-base. It is noteworthy that some design methods explicitly call for ethnographic engagement in order to develop a valid evidence base for design, e.g. the SPRINT methodology which has been specifically developed for the public sector (Wastell et al., 2007). There is no final guarantee against chiasmus, but the deployment of such user-centred approaches certainly offers a less hubristic way forward.

We claimed in the Introduction that our findings have relevance beyond the domain of children’s services. Certainly, there appear to be parallel examples of similar problems in other large scale IT-enabled modernization projects, such as the gargantuan National Programme for Information Technology (NPfIT) in the UK health service. Eason (2007, p. 258) argues that NPfIT has generally followed a “push strategy, thrusting new technology into the healthcare practices of the NHS”, leaving little room for local design. Eason finds strikingly similar local adaptations (workarounds etc.) to those unmasked here, as well equally concerning symptoms of stress and “mis-use”. He goes on to argue a similar case for a flexible socio-technical approach fostering local diversity, based squarely on user needs. The command-and-control, performance management regime (combining “targets and terror”!) which we have seen in children’s services is pervasive across all UK public services, producing a common pattern of dysfunctional effects (Bevan and Hood, 2006). It is surely time to move away from such crude and self-defeating managerialism. Rather than pressing ever more urgently the cause of top-down centralization, salvation surely lies in reversing the direction of travel, reclaiming an older mode of “control” founded on common values, decision premises and assumptions, i.e. the culture deriving from the shared professional task. Public service agencies (schools, welfare, health etc.) are loosely-coupled organizations; systems such as the current incarnation of ICS, which attempt to over-screw this coupling, inevitably impair performance (Perrow, 1984). Only by loosening the electronic yoke and amplifying discretion will requisite variety, and therefore reliability, be augmented. On this point, it is fitting to end with another sagacious utterance from Karl Weick (1987, p.124):

[A] system in which both centralization and decentralization occur simultaneously is difficult to design. And this is where culture comes in. Either culture or standard operating procedures can impose order,. but only culture also adds in latitude for interpretation, improvisation, and unique action.

Abstract

This paper elaborates on the personal relation between the facilitator and the participants in Social Practice Design. It is argued that such processes can not just be managed, but have to fostered in relatively free way, so that results can transcend expectations and more closely approach the actual possibilities. This is explained by aspects of Rogers' theory on therapy.

The paper aims to be an interesting and strong example of the critical need for a good relationship in facilitating design. By itself, such a conclusion would not be surprising, but some of its constituent aspects are detailed: the paper elaborates on the relevance of deploying focus and effort on personal relation, in interventions for organisational innovation.

Supporting the establishment of sense making and trust with Social Practice Design (SPD) approaches is found to be of primary importance in an e-Government development project. Here regional employees user-design a computer-based aid for public tender editing – a tender configurator - with the support of facilitators. We address the structural problem with infra-structural measures including open conversations to promote shared understanding, and user design laboratories to promote concept emergence and learning, while practicing relation and trust building all along. Our constructivist approach renounces from the start to solve the governance problem within a narrow managerial perspective.

The paper offers a demonstration of the mission critical relevance of the relational component in SPD, intertwined with the customary functional component, in resuming governance towards project success. This experience is far from a complete experiment. But a wealth of indications and partial results have been harvested on needs, opportunities, and practices, for promoting shared understanding and trust in the project, and letting emerge idiosyncratic solutions.

We judge the quality of the SPD approach by three requirements (Baskerville and Myers 2004): a contribution to practice (the action), a contribution to research (the theory), the criteria by which to judge the research, and we show explicitly how the research in the case meets these criteria.

Keywords: participatory design, organizational change, social practice design, trust, sense making
1 INTRODUCTION

Governance in design projects of social informatics services is still problematic. User participation is essential for Participatory Design (PD) of sustainable IT use (Bodker, Kensing, and Simonsen 2004). However, often participation alone is not enough. Trying to define better requirements within a given conceptual and pragmatic sense-making frame appears not to be feasible. In these cases, design cannot be confined between requirements and solutions: even the given frame must be abandoned, and new rules of the game and goals co-produced by all stakeholders. This happens in particular when there are no shared concepts, motivations, goals, and even language, among the various actors: the establishment of relation and trust in the project is hindered by ambiguity. To overcome the stall, one has to abandon the given frame, trying to recover sufficient sense making and shared understanding (Jacucci and Martin 2008). If facilitated by management through appropriate infrastructural measures, like in co-production Social Practice Design (SPD) approaches, as soon as trust relations are re-established, a new frame emerges, co-constructed by relevant actors, along with brand new outcomes, solving the structural problem (Jacucci 2007; Jacucci, Tellioglu, and Wagner 2007, 2008; Cattani and Jacucci 2007). Also changing the meaning of the whole process, however, and heavily reshaping its governance beyond what intended, and suggesting new practices and a new deontology in facilitating participative design.

2 THEORY

2.1 Managing ambiguity, taking a second step back

Watzlawick (et al. 1967), in studies of the pragmatics of human communication, identifies content and relation as equally relevant. Bion (1961) in studies of the psychology of groups distinguishes between the task to be executed, and the equally important establishing of relation and trust in the group. Is there a dichotomy in our interventions for innovation in technical systems and organisational processes, between attempts to establish functional rationality through analysis of content and task, on the one hand (reducing uncertainty), and attempts to establish culture change through communication, relation and trust, facilitation and learning, on the other (managing ambiguity)? Posing this question corresponds in the words of Bourdieu (1992) to be taking a second step back. We have discovered in the last decade the need to re-balance focus and effort in current approaches between function and communication. (Cattani and Jacucci 2007; Jacucci and Martin 2008).

2.2 Nurturing trust with Carl Rogers’ qualities

Carl Rogers (1951), in his person centred approach studies of therapy, advocates the respect of three criteria, three qualities of the counsellor (non-judgemental unconditional acceptance, empathy, congruence), for establishing working communication and trust relation with the client. Trust is a pre-requisite for establishing a web of shared understanding. In alignment with criteria introduced by Carl Rogers in personal therapy, and extended already by himself to learning and company consulting (Rogers, 1969), non-judgemental respect, empathy, congruence, are needed here, to allow the establishment of trust. This calls for, on the other hand, introspection, self-awareness, clear and clean intentions, and control on the part of facilitators, as well as are their awareness and intentionality in conceiving, proposing, co-constructing with clients the appropriate path in that context towards the desired development; a path that is more important, if possible, that the very content and task objective.

2.3 Facilitating with SPD

Social Practice Design has recently emerged by urgency of praxis, as a ‘sand-box’ type approach, seeking to construct winning paths to ensure that the potential benefits of envisioned novel technologies can be realised. We consider SPD a methodological extension of PD to the
implementation phase of information systems, often intertwined with design, however. It is not to be regarded as rigorous method, or an apodictic truth, rather as the concocting by bricolage of useful responses to stringent needs. SPD entails aspects of research intervention and facilitation, in which facilitators elaborate with organisation personnel visions of solution, i.e., how to attain desirable change goals by leveraging on organisational assets and strong points, and/or how to cope with problem issues, possibly emerged through ethnographic observations and recognised and accepted in previous phases of the SPD work. In SPD, facilitators thus have a crucial counselling-type job, for the sake of which they must follow a holistic approach, performing an accompanying task from start to finish of the innovation path, and for the success of which the establishment of a good communication and of a good relation of trust is all important. Actions, communication, behaviour of the facilitator establish trust with, and support, the client – at all levels: individual, group, organisation – towards change, for promoting the conscious and proactive care taking and hospitality (Ciborra 2002) to the introduction of socio-technical solutions: a person centred approach, an intentional way to proceed, designed in all its passages.

2.4 Recursive intervention and introspection

This paper puts emphasis on the relevance in SPD of Rogers’ counselling-derived perspective, oriented towards trust gaining, learning, and the reduction of ambiguity. A recursive structure then characterizes SPD: it is a continuous coming and going between client and facilitator in a dialogic process in which the facilitator is capable of observing, performing ethnography, elaborating on the observations, constructing visions, but paradoxically also of forgetting them when coming back to the client (“being without memory and desire”, says the group theoretician (Bion 1961)), to reconstruct afresh visions with them, putting to practice in that instant her competences, especially in the communicative, relational domain (ability of managing a flexible and open communication: Schein (1987; 1999), Rogers (1980)), as well as competences on group dynamics. We underline the process of continuous interaction with the client, and the ability of the facilitator to work substantially on self, in order to acquire the necessary ability and ‘purity’ of approach that really renders her capable of helping the client find themselves the solutions to their own problems (Rogers 1951).

3 INTRODUCING THE CASE BY EXCERPTS

This paper elaborates on experiences of practicing SPD approaches in an e-Government development project, the ‘Online call-for-bids’, at the Regional Administration offices of ‘Celtia’, one of the regions in Northern Italy. Here regional employees are brought to user-design a computer-based aid for public tender editing – a tender Configurator -, with the support of facilitators employing Interactive Use Case (IUC) as a PD tool (Calzà, D’Andrea, Jacucci, and Baskin 2004). IUC is a pictorial and interactive tool positioned in between Use Cases and Mock-up. We call the IUC tool “Interactive Use Case”, underlining the importance of the interaction with users, where it can provide a common place for a dialogue between system developers and system users. The research intervention lasts about half-year. ‘Clients’ of the intervention are the manager, and the employees of the administration, as well as technology designers of the regional administration owned software company: Celtia Informatica, and employees of the RTI (Regional Training Institute).

3.1 Browsing case lab-notes

a) The manager, expert about the tender Configurator issue and capable himself, had built by technicians on his own instructions a non participatory-design prototype, to which personnel charged with tender design responded without enthusiasm, with very few comments. In a subsequent user workshop, proposed by us, it had become evident that the Configurator software employees a philosophy, a procedure for the design of the public tender, which is completely out of tune with respect to the real work practice: the fact always emerges, that software designers abstract, hence depart from reality.

b) A proper user design laboratory is then organised on our proposal, for best results and user appropriation. Although uncertain at the beginning about direct user participation to design, the
manager is struck that we now in-act a true, participatory design laboratory, not just consulting, not just training; a true design laboratory, requiring the construction of a real work team.
c) The manager, kept out of the user design laboratory – our request to avoid hierarchical self-censorship by personnel -, is furthermore struck by our live rendering of that experience, not a power point, not a word document, but live video reproduction of the work session, with access to people discourses and action, with results recorded, and directly usable, via the Interactive Use Case tool.
d) In the end, he is so touched by the content of the presentation, and the obvious success of the user design session, that his doubts vanish, and he now asks that users be invited to redesign the tool, entirely from scratch, without influence from his own prototype; technicians too, present at this rendering session, shared the manager’s inclination to take risk and opportunity and ask the group to redesign the Configurator from scratch.

3.2 Anticipating inferences we shall deal with in the case

i) SPD building trust with manager – Manager: Here we see the high level of trust reached by the manager towards facilitators, his staff, and his own leadership. Trust relation with the manager has been constructed along the way with attentions like: timely and detailed reports, video recording, documents made available online, periodic update meetings, communicative attentions, and so on. So that he has perceived to be taken into good account, both professionally and personally.

ii) SPD empowering users – Participants: Participants enjoyed working in a group, found themselves at ease, as tasks demanded of them were simple, not stressful, albeit serious. They liked the method of hands on, of group work, also of written individual reflections. The video camera disappears, fundamental for documenting the work, no more invasive. People at last talk among themselves, share their work practices, never happened before. All this is more important that the goal: the path as all important.

iii) SPD designing for user design – All: the magic of when somebody with practical knowledge of her own work, builds herself the technology instruments to support her work, and as she goes on building, also performs continuous checks that all knowledge is preserved, embedded in the artefact. If the knowledge in question is tacit, it cannot be transferred to the designer. In turn, when designers build a software application for own use, things invariably go well.

iv) SPD inheriting from counselling - We can see the importance of the facilitator and of her direction of the performance: importance of the events she calls clients to participate in. Importance of how the facilitator IS and BEHAVES in situation (see Rogers: work of facilitator on self, re-elaborating how he/she lived through the group work, must observe how things went – video -, must build the passages each time).

v) SPD facilitating sense making by care taking - Importance that participants work and share viewpoints among colleagues, the facilitator here is fundamental, as must accompany this awareness process on their own work and on the work practices it consists of. It is important to make people work not on theory and abstract concepts, but on what they know, and to make them do, use their hands. It is also important working with them at the meta-level of reasoning, as this promotes awareness. And a new, co-constructed solution emerges.

4 ILLUSTRATING CASE INVESTIGATION AND OUTCOME

We present our investigation, and its outcome, enriched by photographs and brief transcripts of recorded discussions. Links to session videos are also provided.

4.1 Case investigation

We carry out our research-intervention with the specific Action Research methodology of observation, interpretation, step taking, outcome evaluation, and learning. The process is iterative as usual, with a succession of interaction events with manager and users. (see: Baskerville and Myers 2004). We describe the process of applying SPD step moves in the building of relations, sense making, and trust. The use of the SPD approach is exhibited by moving through the various stages of the iterative process, and seeing the congruence between the objectives set, and the characteristics and focuses of
facilitation (e.g., the establishment of trust relationship with the manager, and his understanding of the process). We also hint to what the facilitation team does between meetings: strategizing, analysing previous step, planning next step, material preparation; but also analysing observations in videos, and dialogues: emotions, behaviours, state of mind, the things that went well, the things that went badly, SPD attentions, counselling-like activities, etc. Each step is dealt with individually, recounted, discussed, linked to the next step, albeit we warn the reader that some lesson learned in some steps seems not to be confined to that step, but produced by along the WHOLE pathway. Counselling like qualities (acceptance, empathy, congruence) are constantly emphasised along this pathway. In the reflexive reconstruction we show how things worked because these criteria were followed. Evaluation criteria for AR results will be the degree of satisfaction of company manager, personnel, and facilitators/researchers, respectively, for change produced and final results, for theory and practice.

4.2 Report of selected research-intervention steps (steps are listed in bold)

More specifically, we define a number of interaction steps in our intervention, and give them names. For each step we discuss objectives, observations, lessons learned, and decisions taken for the next step, highlighting attentions paid to counselling-like qualities. For space limitations, we choose to report here the details of selected research-intervention steps only.

1. Needs collection

(Briefing with client for the collection of information regarding expectations and connected problems).

2. Presentation to the client of the project as a laboratory

a. - The objectives of the activity and expected results: Make the manager understand the potential of Participatory Design of computerised systems, and that their problem could be dealt with using this approach. Explain the potential of laboratory-type activity, which involves the group in real tasks.

b. - SPD attention points: Consolidate the bases of trust, collaboration and the personal relationship between the facilitator – Diego - and the manager.

c. - How things went and results achieved: During this meeting Diego presented the PD approach, which is very different from what the client expected. It was presented with great emphasis on the relationship among expectations, complexity and method to deal with the problem. During the presentation the client also stated the results expected more specifically: analysis of the current Configurator, connections with work practices, vademecum on using the instrument, training for all the contract announcement designers in the Celtia Region. These requests the Diego assessed to be coherent and achievable with the method proposed.

d. - Learning: It was important that the presentation of the method be brief, but focused on showing that change can be planned/achieved with a participatory format, and that the new work instruments, and the change that they induce in work practices, must be defined with users. It was important to “really” listen to the client and his statement that his aim was to promote change in his organisation. The client was already aware that realisation of the technological instrument would be the means of change but that the true end was change itself. This legitimated our approach.

more b. - SPD attention points: This phase moment was fundamental for the relationship between Diego and client. The relational/communicative style used conditioned the entire path. It is therefore necessary to conceive and plan how to implement it in a congruent, empathetic and conscious manner.

3. Laboratory: sub-groups tasked with defining and describing the work practices used to design contract announcements (18 March)

a. - The objectives of the activity and expected results: Sharing of work practices among the tender editors, creating a fertile humus for awareness. Get them to examine their own practices, measure the differences between what they do to design tenders and what they are asked to do with the technology.

b. - SPD attention points: Make persons communicate in a protected context (that of exercises/training), enabling them to exit from the usual work setting, with its rules, restrictions, roles (assigned, perceived), consolidated (also in their “pathologies”) rituals and relational communicative
procedures. Unconditional positive acceptance; sense-making, artefacts to facilitate sharing (posters in sub-groups, conceptual maps on stimulus questions). Attention to individual empowerment.

c. - How things went and results achieved: Division into workgroups. First activity with use of post-it notes at a sub-group level on a stimulus question: what does working on a contract announcement involve? Initial brain storming within each group, simple but powerful instrument (post-it notes can be easily moved around on a poster for later categorisation and reorganisation). Afterwards, Diego held a plenary session for sharing results (summary of post-it notes) through co-building of a map. Diego used projector and the Freemind application to represent a summary of the work involving all present.

PHOTO 1: Post-it notes sub-group activity
PHOTO 2: Freemind map, sum of design activities

continues c. - How things went and results achieved: Explore the Freemind map, describing the work scenarios: who does what, how, when, why etc. Work again started from a stimulus question: what do you when you design a call for tender? Each sub-group worked alone. Complicated things: sense making on the concept of scenario (what we expected from them regarding the concept of scenario). No wide-ranging scenarios emerged, contrary to expectations. The final product did not seem very satisfactory to facilitators but it was fundamental the process: birth of a functioning workgroup.

more b. - SPD attention points: Diego demonstrated positive unconditional acceptance towards all the participants and intervened only to help them perform the work requested, responding only to questions about the method to follow; he was also an example of open behaviour, empathetic, welcoming; he supported the sense-making process enacted by the groups on their work practices.

d. - Learning: Ask answerable questions and model them with artefacts. It was this work that gave rise to the idea of organising a laboratory presenting the Configurator in situated form, that is, producing a call for tender from beginning to end. The manager asked for advice on how to present the Configurator and we in fact said: present it with a contextual example.

4. Workshop on the contract announcement Configurator (19 March)

(The manager presented his way, his practice, of creating a call for tender supported by Configurator and those present listened and gave feedback (they were immediately able to see differences, the distance). We are aware of the importance of this encounter between the manager, inventor of the Configurator and the users. The manager immediately realised that the participants had numerous observations, many modifications, and with competence and commitment. The next step – he group analysis of Configurator and its functionalities – was obligatory and natural even for the manager).

5. Laboratory: (a) sub-group analysis of the Configurator, and (b) sharing, managed by Diego who handed over to the various groups, which performed a screen-by-screen analysis. (7 May)

a. - The objectives of the activity and expected results: The stated objectives of the work session were: analyse work practices, measure the distance between the work practices of designing a call for tender in reality and the new practices imposed by the Configurator; construct an artefact.

b. - SPD attention points: Consolidate group’s work practice and sharing process by involving the group in practical tasks through the production of artefacts. Reinforce the participants in their
commitment and participation, creating further opportunities for them to demonstrate their competence, professionalism and commitment/motivation. Continue along the workgroup’s learning path of the laboratory; continue along the path of awareness towards ever greater intentionality.

c. - How things went and results achieved: The detailed analysis of the Configurator in sub-groups takes place in the following conditions: a suitable setting, the use of three artefacts: conceptual map of the first meeting (on ‘what you do when you write a contract announcement?’), printouts of the most important Configurator screens, given to each group, and a poster visible to all participants which depicts the map of the entire Configurator. The task assigned: for each screen define what you consider important, what is wrong, what you would add, what you don’t understand (interface accountability). For the “don’t understands” the designers were deliberately kept away so that they did not respond in place of the users. The facilitator was always present for the sub-group and he provided support on method if he saw that a group was in difficulties. The participants were very active, free to express themselves in-group and in the plenary session. Without censorship. Everybody participated.

PHOTO 3: Group analyses Configurator screens PHOTO 4: The group orienting with screens map
VIDEO 1: Screen analysis activity (video with faces: http://www.etour.tn.it/mcis2008/video1.html)

d. - Learning: The participants immersed themselves in the role of analysts of the user interface. Diego did not expect this and it came as a revelation to find that in this group there were also computer specialists, something that was not clear at first. It is therefore essential to verify, understand and make use of the competences present in the group and to enhance them through involvement in a task. This observation conditioned the next project.

more b. - SPD attention points: All of this is positive and unconditional acceptance. The route was marked out by participants, not by Diego. Empathy: continuous listening, no forcing, use of the participants’ point of view. The participants felt enriched in their professionality (and this will have future consequences, also in their mode of participating, of being involved and present). Importance of selecting the group so that it is truly a “special” group.

Stretches of dialogue, phrases, situations: The group already reveals the differences between the work methods envisaged by the software and the need for data comprised in real work practices.
Second group: We don’t understand why the document folder is called that, because we think it is the menu…. As for the label, we would call it “denomination” not “description”. The item “personal data” is no good in our opinion, because it brings to mind something different from what it is in reality. The software was produced by computer specialists, using the framework of the regional computer system, a framework which works on the concept of document (which is why there is an inappropriate/different use of the word “document”).

6. Presentation of the laboratory results to the client

a. - The objectives of the activity and expected results: To present the results of the laboratory and agree with the client on how to continue (the client did not participate, on request by Diego, so that the participants could work more freely; it is therefore important to provide very rich feedback).
b. - SPD attention points: Ensure that the client was aware that the restitution was transparent and accurate, without interpretation or manipulation by the facilitator. Keeping him linked to each step of the work, consolidating the relationship with him and his faith in the project, giving proof that his hierarchal role and functions have always been considered, as well as his states of mind (anxiety, fear, resistance).

c. - How things went and results achieved: Present at the meeting were Diego, client and several members of the work group especially chosen (assertive, authoritative persons highly motivated to change, with important roles within the agency for change itself), because these persons would be guaranteed a true and not interpreted restitution. Various video clips taken during the laboratory were also used. Diego presented the results of the laboratory using a wide range of multimedia documentation with photographs and videos on comments by the sub-groups on each interface.

VIDEO 2: A clip from the multimedia presentation used to present the results of the work (http://www.etour.tn.it/mcis2008/video2.html)

continues c. - How things went and results achieved: The comments are made by the representatives of the workgroup, with important statements about the differences between actual work practices in designing a contract announcement and how this work could be supported by a computerised system.

Stretches of dialogue, phrases, situations: Statements of the type: “We saw that the Configurator interface contains elements that are not very clear; furthermore the interface does not help those using it to understand how it is used. In some cases the Configurator imposes a work logic that is very different from reality. Analysing the displays it was not easy to understand the operational context of each screen, the type of function performed by the screen”.

more c. - How things went and results achieved: The client, having seen the work carried out by the group and being convinced of the potential of the group, requested the facilitator to organise another laboratory to redesign a new Configurator. For the first time we were given the task of designers.

d. - Learning: The surprising thing that happened was that the participants showed great willingness to involve themselves, to be the protagonists of change (something generally not common among civil servants). Communicating to the manager/client what was happening in the laboratories proved to be crucial. From the moment when the client no longer came to the classroom, Diego always sent him the minutes of meetings within 48 hours and put the videos online so that the client could download them. The client was very impressed by this method of communicating, so rich in materials gathered in the field. This legitimated the method that we had selected. The client “trusted” the group, the method and the facilitator, so much so that he proposed something that was absolutely revolutionary and delicate/risky for the organisation. The client’s words “redesign it” expressed his acceptance of a new challenge, which would lead him to agree with IT management to discard the work done thus far (months of work) and rebuild everything using a new logic.

PHOTO 5: Paper user interface with buttons, labels, navigation menu

PHOTO 6: Image shown during work presentation

Proceedings ECIS 2009
7. Laboratory: construction of the Configurator interface in sub-groups

a. - The objectives of the activity and expected results: Construct the Configurator user interface using an agile approach (paper models). The objective is to construct with the group a new work scenario with work practices respectful of the past but able to exploit the potential of the new instrument.

b. - SPD attention points: The map of work practices constructed March 18 was used, from the vision of the participants (positive and unconditional acceptance), to incorporate these practices in a new artefact (Configurator paper interface) which this group built by themselves. Consolidate within the group the conviction that they are truly taken into consideration, beyond simple demagogy.

c. - How things went and results achieved: Work in sub-groups on construction of the Configurator with paper models, passing through three stages. The first stage led to the construction of posters using post-it notes to imagine what the new system should give to and ask of its users, in terms of data.

VIDEO 3: Brief sequence of the design activity with post-its
(http://www.etour.tn.it/mcis2008/video3.html)

continues c. - How things went and results achieved: Second stage concentrated on the sequence in which interaction with the system takes place (that is, what comes first and what comes later). In the third phase they worked to transform these into user interface elements (buttons, labels, menus etc.).

VIDEO 4: Brief sequence of sharing by the sub-group work in an assembly
(http://www.etour.tn.it/mcis2008/video4.html)

more c. - How things went and results achieved: After the sharing they agreed to create a summary of the work by building a new artefact (a map with the stages of work and results achieved, each node of the map a video or an artefact with notes on what was learned). One of the richest summary phases, here the work practices of the first day were re-discussed and redefined within the new instrument.

more b. - SPD attention points: A great deal of sharing and mutual listening, respect for the interventions of others. They discussed work process and sense making of the technical.

more c. - How things went and results achieved: Each person made a great effort to accept the contributions of the others. At the end of the session the group produced a large poster identifying all the interface elements positioned in the order that they wanted. In a somewhat unstructured debate they mixed aspects of what and how needed to be done. The facilitator suggested shaping the discussion through the shared construction of a poster depicting the system with its inputs and outputs.

PHOTO 7: Poster with the final interface design
PHOTO 8: Nodes on map connects to videos
d. - Learning: Again the key role of artefact construction. The crucial role of a facilitator able to accompany the group understanding its needs (for autonomy, but also being directive when the work proceeded in a disorderly and time-wasting manner).

8. Presentation of the results (4 August) to the client and RTI (Regional Training Institute)

(Presentation of all the work carried out in the laboratory, the methodology adopted and the results achieved. Obtain the go-ahead to continue the relationship with new projects even of a different kind. There is a risk that after having activated participation, involvement, change, it may disintegrate and be lost, backfiring both against the client who gave his trust and against the facilitator).

6. LESSONS LEARNED/REFLECTIONS ABOUT THE WHOLE PATH

Section 5 shows how our method made it possible for the client group to go beyond the initial project conceived by the manager, and even, later, by the facilitator. ‘Go beyond’ in the sense that not only were the users of the system able to enrich the instrument with new functionalities derived from a more detailed analysis of the work to do in its various dimensions, levels, functions, but they were also able to find the right language to voice their need for an instrument with a different philosophy which then emerged from their work, and which therefore went beyond what the designers had thought, and brought to light new potential and logic for the instrument, which neither the designers nor manager had thought of: an entirely new goal and outcome, an experience of which they became fully aware, and that they also later engaged to divulgate and preach to others.

What we learn above all is that, to ensure that making the client fully aware of what PD can do, is an objective to be pursued during the whole path; it is a goal that requires experimentation of the method. The client must be enabled to create prudent conditions so that the method can be practised, and these prudent conditions create space for the pursuit of smaller, more pragmatic objectives without forcing the client’s hand, or pushing him to do things prematurely (respect Kairos, the appropriate time).

We should remember that the objectives stated at the outset were only to analyse the Configurator already designed by designers, obtain feedback from its future users, construct a vademecum, and plan a training course for a larger number of users. These objectives of course fall short of a fully ‘blossomed’ Participatory Design approach. In reality the possibility to undertake genuine participation – not an easy task (Bodker et al. 2002) - in the design of the Configurator, and with it to redefine the work practices, was understood and granted by the client and the workgroup during the ongoing work, on the basis of results achieved, and after continuous interaction/exchange of information and thoughts between the s, client, and group (a path of reciprocal learning, of awareness). The group legitimised itself by doing: it was not evident at the start that this would occur.

Let’s list relevant practices towards this important result:

• To GIVE SPACE, HEED, AND ROLES to all involved, not only the manager, but also users, technicians, other managers, etc., with their different/opposing points of view, needs and interests.
• Of LISTENING, OBSERVATION, AWARENESS, REFLECTION, ELICITATION by the facilitator of the needs of the client and the different actors involved. Needs not decided upon once and for all but continually reviewed, re-discussed, in a process of learning/awareness making the client and group ever more involved, increasingly active.
• Of the client’s FAITH in the facilitator, because this allows the client to trust the facilitator, to feel accepted and respected, as well as protected.
• Of the ‘s CONSISTENCY in his relationship with the client (be authentic, coherent between the verbal and the non verbal, be convincing, assertive).
• Of ’s TRUST in the client, this generates positive unconditional acceptance, empathy.

Here is perhaps the key to understanding the entire process according to the logic highlighted in our AR: the stakeholders involved here, all have different perspectives, and interests. Some are interested in the PD approach because of their desire to use it in other cases (the manager of one of the computer systems divisions), some are interested in technology tout court, some in defining new work scenarios.
The employees in our group are not simply application software users: they are stakeholders expert in the design of call for tenders and their redesign started from work practices. On the other hand, the Configurator was previously designed by technicians used to design starting from abstractions, working on the possibility of processing the data according to a computational logic, a logic different from that of routine work. In the last case (technical design): $\rightarrow$ABCDE (from abstraction to work practices). In the second case (redesign participants in laboratories) $\leftarrow$EDCBA (from work practices, with ramifications, to abstraction).

Our SPD approach was successful in managing ambiguity and establishing trust towards a new governance, where users could in fact redesign system and work practices according to their own user-strategies, with the consent of all involved, all recognising the improvement of this state of affairs.

We judge the quality of the SPD approach by three requirements (Baskerville and Myers 2004): a contribution to practice (the action), a contribution to research (the theory), the criteria by which to judge the research, and we show explicitly how the research in the case meets these criteria: Contribution to practice. In the ‘Online call for bids’ project, users not only to enriched the instrument with new functionalities, they were also able to voice their need for, and designed, an instrument with a different philosophy which went beyond what the designers had thought.

Contribution to theory. Confirmation of the usefulness of:
- recursive dialogic process for sense making and the involvement of company personnel
- person centred counselling-like facilitation qualities for trust building and empowerment

Evaluation criteria for AR results. Hi degree of satisfaction of company manager, personnel, and facilitators/researchers, respectively, for change produced and final results.

5 CONCLUSION

In conclusion, we have experimented with user design laboratories based on the Interactive Use Case technique of PD, and on open conversations and learning, as ways of practicing SPD facilitation towards co-construction in a regional administration setting. These activities clearly enabled and supported participation in engaging, in sense making and awareness, and in the acquisition of perspectives of others. People generally felt comfortable and not at risk of being judged. Participants expressed how important the experience of working creatively on solving “real problems” had been for them. We can understand this also as a result of the in-depth observation and intervention character of our SPD engagement with people in the project, which provided us with good knowledge about their work practices, potentials and problems on the one hand, and allowed trust building on the other.

In closing, let is recall the basic attention points anticipated all along, to close the circle.

5.1 The group of facilitators prepares with care the activities in the field, in order to practice SPD indications – especially those from Rogers - in a real, ethic, coherent, manner.

Before each meeting there is always a consultancy workgroup session during which the team analyses the materials collected in the previous meeting, the observations made, the exchanges and the dialogues, content aspects, relational aspects, cross referencing all with first-off impressions, the notes taken by the s in a “log book” during and after the meeting. The primary aim of these sessions is to analyse the work performed “on stage”, reprocessing it through analysis of the observation materials and discussion among the s (both those who went directly into the field and those who remained back stage), to assess what happened in the previous step, the situations experienced, the content and relational aspects, the initial impressions/emotions, the purpose being to design and define the next step in light of the path taken thus far, the results achieved and the lessons emerging from the analysis. Planning means: thinking flexibly about what will be done later, who will do it, with what aims, strategies, communicative/relational concerns etc. For each of these consultancy team meetings a log-book was kept, an internal workgroup document which was used to keep accurate track of these steps. It was from these notes taken in the field and during the consultancy team meetings that the points developed for each step were taken.
5.2 They closely attend SPD attention points during intervention steps, opening the way to success

Facilitators pay attention to the relation of the facilitator with all concerned (managers, employees).

- **Incipit**: at the beginning of the relation, dedicating time to gathering the needs of all concerned through SPD attentions, i.e., facilitating the development in of awareness in individuals and groups
- **Ruit**: in all crucial passages of the project, activating and mixing individual and group meetings
- **Exit**: in approaching conclusion, activating occasions for visible, tangible results, as feasible with that group, with those people, in that context, giving sense to and justifying the entire path.

This means communication attentions (language, non verbal aspects, setting), observation, listening, both in managing meeting with participants, and facilitating internal relations in the organisation.

This means consolidating the trust relation with the manager through open communication and choice of appropriate language, unconditional positive acceptance, empathy.

This means, in laboratory activities, attention to: whom to involve in the work activities (caring for roles, people, competences, skills) → key persons; whom should be, or not be, present w.r.t. hierarchy (e.g., manager causing self-censorship on others); subgroup composition; setting and climate (a true laboratory, protected, non judgemental); role of the facilitator (observation and coordinator); communication management in the group; choice of job assigned (starting from own work practice, describing and comparing them among peers: this helps involve and motivate people, reassures them on their abilities, makes them learn new things in a protected environment: a job, in sum, of designing something useful for real, close to participants needs).

Lab activities strengthened the group, favoured contributions by individuals, and favoured training of all. In this environment, SPD behaviour of facilitators were winning bets: empathy, acceptance, congruence. The group felt guided, protected, non pushed, respected in its time and way (kayros). Its work and commitment was valued, yielded outcome. No demagogy or exploitation, real involvement, true trust in the group and in its potential. All this consolidated trust in facilitators, and in the project, increasing motivation.

Abstract

This paper focuses on design criteria for public e-services. The paper challenges traditional lists of usability criteria supporting design and evaluation of IT-systems. Traditional criteria within the field of human-computer interaction are perceived as too limited and an expanded view of the communication and business process is proposed. Within this expanded view, existing usability criteria are considered as important but not sufficient. Based on this claim, criteria also supporting communication and business actions are proposed. The proposed criteria are generated from an empirical study concerning a development of an e-service. The aim of this e-service is to support the communication between companies and the municipality when companies are going to get permission for running business. Analysing the communication need in this context has been of particular interest in order to generate complementary criteria for design and evaluation. Examples of criteria generated are: good conditions for users to become knowledgeable (support for perception, comprehension and information), differentiate between informative and performative parts, provide meta information (purpose and content).

Keywords: Usability, human computer interaction, e-government, e-service
INTRODUCTION

In the e-government field there is a rapid growth in the development of e-services (Anca\-rini, 2005; Buckley 2003). Such an e-service is a public service mediated electronically through a user interface that is generally available. Public e-services can be used by citizens or company. These users can be inexperienced and infrequent users of the public e-service. If e-services are to be used, they must be easy to use and be beneficial to the user. Important questions are: How to create usable e-services and what properties are desirable for such IT-systems?

There exist several lists of usability design criteria. Examples of criteria lists are: 10 usability heuristics (Nielsen, 1993), Eight Golden Rules (Shneiderman, 1998), design guidelines for small screen devices (Kärkkäinen & Laarni, 2002), context-aware mobile applications (Häkkilä & Mäntyjärvi, 2006) and Participatory Heuristic Evaluation (Muller et al, 1998). These lists are explicitly not web oriented; however, Nielsen (1999) has presented criteria for designing web usability.

In our literature research we could not find any list belonging to the context of public e-services. The importance of identifying different contexts is acknowledged by Henninger et al. (1995). They claim that “If the potential of usability guidelines as an interface design technique is to be fully realized, they need to be augmented with context-specific guidelines and examples that synthesize isolated guidelines into domain-specific solutions to design problems”.

A reasonable question to ask is “why are not existing criteria good enough?”. Our answer to this question is that criteria are always derived from a specific theory or perspective. That, which means that the usage of criteria lists support a specific focus of the phenomenon studied. To set a focus on something also means that other aspects are de-emphasized. The identified criteria lists are constructed in the field of human-computer interaction and their aim is to focus on the aspect of the interaction between a human and a computer. Our hypothesis is that the existing usability criteria can be too limited for supporting design and evaluation of the context of e-government. The reason for this claim is that we view e-government as a communication intensive context. In this context there are citizens or companies that need to communicate with e.g. representatives of municipalities or other authorities. When citizens communicate with municipalities they are often instructed to use artefacts such as answering machines or the internet. It is not an exaggeration to say that communication via traditional face-to-face situations is successively replaced or complemented by communication via information technology (e-services). Based on this we claim that there is a need for a complementary perspective (and design criteria) focusing on the e-service mediated communication between humans instead of a more limited human-computer interaction (see section 3). Our hypothesis is supported by Hartson et al (2001) who claim that “Usability is seated in the interaction design”. Our hypothesis is also supported by findings in Cronholm & Bruno (2008). A result from this study is that “most of the existing usability criteria are predominantly supporting a human-computer interaction perspective”. Furthermore, Gould and Lewis (1985) claim that existing design guidelines are limited since they are not detailed enough. We are not saying that the criteria lists referred to above are unusable; on the contrary they seem to provide good support for analyzing human-computer interaction, but they are not mainly supporting design of IT-mediated communication between humans.

Many of the existing criteria lists seem to be constructed for usage in any situation (e.g. Nielsen, 1993; Shneiderman, 1998). The risk of using too general criteria is that these do not provide enough contextual support that is needed in a specific domain. They can be perceived as too superficial and thereby not usable enough.

The aim of this paper is to propose a set of design criteria primarily to be used to support professional designers and evaluators within an e-government context. In this paper we restrict the discussion of criteria to design criteria for public e-services. This is the context of our case study described below. From this context we have found the traditional design criteria not enough supportive for our design decisions concerning communication between the municipality and the companies using the e-service.
The proposal of criteria is based both on existing criteria lists (see section 4) and on new experiences from the case study (see section 5). The introductory section is followed by a description of the research method (section 2). Section 3 describes the theoretical basis used and in section 5 we present the design criteria used in the case study. Finally, in section 6 we present some conclusions.

2 RESEARCH APPROACH

This study is part of a research project for improving the conditions of commercial and industrial life in municipalities. The project is a joint project between four municipalities and some researchers. In order to develop design criteria for e-services we have used three different knowledge or data sources: a case study, existing usability criteria lists and theories of communication and business processes. In the case study we acted as both researchers and designers of an e-service. The research process can therefore be characterized as action research since we intervened in the process (e.g. Lewin, 1946; Avison et al, 2001; Baskerville, 2001).

The case study has functioned as a data source for inducing design criteria. The overarching questions asked were “How can companies and municipalities benefit from an e-service?”, “How can companies and municipalities communicate with each other through an e-service?” and “How can companies interact with an e-service?”. The study started with a broad process analysis discovering problems and goals concerning the interaction between the companies and the municipalities. Based on this investigation a decision was taken to start developing e-services and redesigning processes. A critical analysis of forms was conducted. It was important to critically examine existing forms, e.g. content, structure and terminology. This was done in order to avoid transferring bad existing paper forms into e-forms.

We have used existing usability criteria as a source of inspiration and have reused or refined relevant criteria. The design criteria generated were also explicit compared to three existing usability criteria lists. The reason for choosing two of them was that they are well known. These lists are: 10 heuristics (Nielsen, 1993) and Eight Golden Rules (Shneiderman, 1998). The third list is called Actability Principles (Cronholm & Goldkuhl 2002). This list was chosen since it is based on a communicative perspective. It is more comprehensive but is not as commercially used as the other two lists. Behind the idea of comparing the developed design criteria with the list of Actability Principles was to understand if and how criteria generated from a communication perspective could contribute to design criteria for the domain of e-services. Finally, the communicative and business perspective has also had an impact on the development of the design criteria. We have continuously refined the proposals of design criteria and the e-service, which means that there has been a shift between action and reflection/evaluation. Through this the design criteria have emerged in an iterative way.

3 THEORETICAL BASIS: A COMMUNICATIVE PERSPECTIVE

In this paper we apply communicative and business perspective in order to develop design criteria for e-service. The theoretical sources for viewing IT-system as communication and business systems are social action theory (e.g. Weber, 1978) and language action theory (e.g. Goldkuhl & Lyytinen, 1982; Habermas, 1985; Searle, 1969; Winograd & Flores, 1986). The main message in Weber’s (1978) theory of social action is that communication is intentional. Using a social action perspective means that it is not acceptable to view IT-systems as a black box with some social and organizational consequences (Dietz, 2001). IT-systems are instruments for business action.

Language action theory discusses communication as one type of action, and IT-systems are not considered as “containers of facts” or “instruments for information transmission” (Goldkuhl and Ågerfalk 2002). The language action perspective emphasizes that communication is to establish interpersonal relationships between the sender and the receiver (Searle 1969). The communicative perspective emphasizes a user communicating with other users through a user interface. It is a human-
via-computer-to-human communication; it is not a limited human-computer interaction. Thereby, the use of IT-system is viewed as a social process consisting of technology mediated business communication.

In order to present our view on interaction we use the Elementary InterAction Loop (EIAL). EIAL was originally introduced in Ågerfalk et al (1999) and revised in Goldkuhl et al (2004). EIAL consists of an interactive situation divided into four phases: informing, execution, IT-system reaction and interpretation (see figure 1). The informing phase means that a business actor interprets the action repertoire offered and possible messages from other business actors in order to reach a decision about what to do. The execution phase describes that the user is performing the action chosen. The IT-system reaction phase describes the IT-system’s response to the business actor’s action. Finally, the interpretation phase describes how the business actor interprets the result of the IT-system’s reaction.

In the middle of the EIAL a screen document is placed. A screen document is any designed interface with which the user interacts (e.g. a form on a web page). The screen document plays different roles in the different phases. Therefore the screen document is multifunctional. In the informing phase the screen document is used when the user is reading the screen to figure out what to do. It contains information about the action possibilities and other action conditions. In the next phase the screen document is used for execution. In this sense, the screen document functions as an action medium. For example, the user enters some data in a field and clicks on a button on the screen in order to perform an action. Finally, the phase of the IT-system reaction should be understood as a response to the user execution. The IT-system’s reaction can result in changes of the screen document (as a feedback to the user). In this sense, the screen document consists of action results and functions as a basis for interpretation.

"I did" (Execution)
"What can I do?" (Informing)
"What has happened?" (Interpretation)

Figure 1. Interaction: The Elementary InterAction Loop (based on Goldkuhl et al., 2004)

The central concepts of interaction, communication and business process discussed above are depicted as three sets or three levels (see figure 2). As pictured, an interaction is the interplay between a user and an IT-System. The communication takes place between two users, mediated by an IT-system. The arrows in the figure above symbolize the business; a business that produces something (a product or a service) for a client. The communication level is viewed as a subset of the business process level and the interaction level is viewed as a subset of the communication level. This means that if the IT-system is considered as providing good support for the business level it also provides good support for the lower communication level and interaction level. On the other hand, if an IT-system is evaluated at the interaction level no predictions can be made of the higher communication level and business process level.

The aim of figure 2 is to bring forward three important and related levels. We are not saying that criteria formulated on the interaction level are useless; ideally we would like to see criteria residing on all the three different levels and that they are coherent and complementary. The model is chosen since e-services are supposed to support a type of business that is highly communication intensive (see section 5.1).
In order to motivate our proposal of design criteria for e-services we have analyzed two familiar and popular usability criteria lists; the Ten Heuristics proposed by Nielsen (1993) and the Eight Golden Rules proposed by Shneiderman (1998). We have also analyzed a criteria list that is not equally well known, this list is called Actability Principles (Cronholm & Goldkuhl, 2002, 2005).

An overarching result from studying these criteria lists is that we have found them important to consider while designing IT-systems; but they are not sufficient. Analyzed from a communicative perspective they are viewed as too limited, i.e. they are supporting the interaction that is going on between a user and a computer. Our claim is that they do not fully support communication between humans and they are not formulated to support business processes. Examples of criteria representing this limited view are “Visibility of system Status”, (Nielsen, 1993), “Enable frequent users to use short cuts” (Shneiderman, 1999) and “Clear feedback” (Cronholm & Goldkuhl, 2002, 2005).

Another result from our analysis is that we find several criteria hard to understand. The problem of comprehensibility is often to do with that: 1) the criteria are not categorized 2) the label of the criterion does not correspond to the adjacent explanatory text and 3) the label and the description of one proposed criterion often consist of several criteria. The criteria proposed by Nielsen (1993), Shneiderman (1999) and Cronholm & Goldkuhl (2002, 2005) are presented as flat uncategorized lists; i.e. the criteria are considered as belonging to the same abstraction level. The advantage and role of a multilevel abstraction hierarchy is discussed in Rasmussen et al (1994). They compare a multilevel abstraction hierarchy with a means-end hierarchy and claims that a multilevel abstraction hierarchy is often used in practical problem-solving processes.

The second problem, the correspondence between the label and the adjacent explanatory text, is best illustrated by an example chosen from Shneiderman (1998). The label of the criteria reads: “Offer informative feedback”. The explanatory text reads: “For every operator action, there should be some system feedback. For frequent and minor actions, the response can be modest, while for infrequent and major actions, the response should be more substantial”. The keyword in the formulation of the label is “informative feedback”. The explanatory text is discussing when and how much feedback that should be provided. There is no explanation or recommendation of how to provide informative feedback.

Another example of the lack of correspondence between the label and the explanatory text can be found in the criterion “Flexibility and efficiency of use”, proposed by Nielsen (1993). In the explanatory text Nielsen (1993) mainly discusses accelerators. We conceive it to be a too large abstraction gap between “flexibility and efficiency of use” and “accelerators”. We did not expect to find a discussion about accelerators in order to define flexibility and efficiency of use.

The third problem, that the label and the description of one proposed criterion actually consists of several criteria, contributes to the confusion of what is going to be evaluated. Several formulations of labels refer to more than one criterion. To clarify our criticism we use the same example again:
5 PROPOSAL OF NEW DESIGN CRITERIA

5.1 Prerequisites for the case study

A company may need different permissions from the local authority to set up and run a business. Permissions are often necessary e.g. when selling food, use chemicals or building a factory. To get permission easily and quickly is important for the company since permission is a prerequisite for running a business in a legal way. We have identified five main phases in the permission process: 1) Search info about application [company] 2) Formulate and send application [company] 3) Assess application [municipality] 4) Decision [municipality] and 5) Send decision [municipality]. This process is easy to conceptualise but different problems may occur when companies are going to apply, e.g.:

- Companies do not have sufficient knowledge about: 1. The legal rules; e.g. what are we allowed to do and not to do, is permission needed or not for different kinds of businesses? 2. The process of application, assessment and decision organised by the municipality; e.g. who is the executing officer, is the application supported by a form, what aspects are assessed, what is the fee, when do we get a decision? 3. How to get answers to questions; who is the right person to contact, by telephone, e-mail or by visit, how to find understandable information about regulation and permission process and application forms?

- Executing officers at the municipality are overloaded with rather simple questions, they have to handle incomplete and difficult-to-read applications, and they need to contact the companies to get completed applications.

The companies regarded the municipality as too bureaucratic and not service-minded enough while the municipality regarded the companies as ignorant and unwilling to follow legal rules. The identified problems are all located in the communication process between the municipality and the companies and also have implications for the conditions in the business process. The consequences are both inefficient municipality processes and inefficient and delayed business processes.

The four studied municipalities all had existing web sites but these were not informative enough. The web sites did not seem primarily to be designed to support the companies’ application processes. Some municipality web sites had reading functionality and application forms in pdf-files but none had functionality for sending information, e.g. questions and applications. Many of the application forms were designed to support the case handlers’ assessment processes rather than the companies’ process to produce a complete application. There were no proper e-services within this domain.

To improve the communication between the case handlers and the companies we started a pilot study to design e-services for firms active in food business. The first step in the study was to support the communication in the first two phases of the permission process: companies searching information about food permission and then sending their application to the municipality.

5.2 Designing the e-service

The pilot study has resulted in a web-based IT prototype. In the design process we have actively used a prototyping approach (Vonk, 1990). The e-service prototype holds information relevant for the application process and companies going to apply, e.g. information about legal rules, municipality principles for handling applications and decision making, information about the subsequent municipality control of the company handling food in a proper way. The e-service also includes
different supporting functions for applying: 1) an application form to fill out by companies 2) guides with proper questions depending on type of food business 3) completion control of forms 4) function for sending an application. Some of the food case handlers participated in the design process together with the researchers. The aim of the e-service was to support both companies and case handlers. Besides making it easier for companies, the aim was to ensure that case handlers achieved correct and necessary information.

Knowledge from the workpractice was an important basis when we created the e-services prototype but also practical theory including usability criteria and actability principles was important. The aim was to create an e-service easy to use for experienced and inexperienced users and frequent and infrequent users, i.e. all companies trading in food. The prototype was refined in an iterative design process until we got a satisfied e-services prototype. In this refinement process the researchers and the case handlers reviewed the prototype based on their different views on “what is meant by useful”.

When we demonstrated the prototype, also case handlers from other permission areas were interested. We decided to transfer properties from the food prototype to a new e-service prototype for building permission. In order to detect characteristic and important properties we examined the prototype ex-post and also reconstructed our design decisions. We found several characteristics of importance for success when using the e-service in the permission process. Then, when we compared the detected attributes to the existing design criteria we found it difficult to relate each of our attributes to any particular criterion from the criteria lists. We had achieved an e-service which met the case handlers’ and researchers’ aims and expectations, but it was not because of the existing criteria. As mentioned above, we found the existing criteria important and valid but limited in terms of support to the designer.

5.3 Different aspects of an e-service

A public e-service is about two actors communicating. A company needs information from the municipality in order to make decisions about the business and the application, i.e. the company needs to be informed by the municipality and the municipality needs to inform the company. The company needs to send an application to the municipality to get a decision from the municipality; i.e. the company needs to inform the municipality and the municipality needs to be informed about the application from the company. The company is both a sender and a receiver and these are also the roles of the municipality in the communicating process.

A public e-service is also about two organisations conducting their respective tasks. One important task for a municipality is to give permission to firms doing business, and for the company it is important to get permission in order to produce results, e.g. selling food in a shop or in a restaurant. This means that the e-service developed is created to support the producing processes in two different types of workpractices, one producing food permissions (a municipality) and the other producing food to customers.

Of course, public e-service is also about a human actor interacting with a computer. Handling the computer in an efficient way is important and a prerequisite for achieving communication between actors via the computer. A good working communication between the sender and the receiver contributes to results in the workpractices. We have identified three levels of e-services (see figure 3) where the IT-system plays an important role. The three levels concern different aspects of the workpractice and also focus on different aspects of the IT-system. Thus, to get an e-service that is useful and supports producing results in workpractices we have to consider the three levels of IT when designing e-services. As mentioned above, we found the existing criteria in the lists mostly related to the interaction level. A public e-service is not only about human-computer interaction. It is also about human to human communication via computer and furthermore about humans (with IT support) producing results in favour of humans.
When designing e-services it is important to recognise all three levels of human and IT-system actions and the e-service must be designed to support these levels. Thus, when designing e-services for public municipalities we also need criteria related to these levels, not only to the interaction level.

![Figure 3. Three levels of e-services in organisations](image)

5.4 Criteria for usable e-services

Every item carrying information intended for the user, i.e. words, pictures and sounds, should also be **perceived** by the user. The user should quickly and easily be able to detect adequate information without risk to miss something. Important features for achieving this goal are e.g. colour, shape, size/volume and location. All these properties may have values which make them highly perceivable or not perceivable at all. The perception differs between people, e.g. different people perceive colours in different ways. It is also important to be careful with hidden and concealed functionality.

Every sign perceived should also be **comprehended** by the user. The user interprets the perceived signs to understand its meaning. The user should easily and quickly be able to understand the information without risk of misunderstanding. The key features are e.g. simplicity, recognition and consistency. - Simple but informative expressions and symbols. - Signs related to the task and the users’ knowledge and understanding. Important aspects are e.g. the language and vocabulary used, signs related to standards, local standard in the IT-system and global standard in other IT-systems, other well known artefacts and other objects. - Avoid homonyms and be careful with synonyms. To perceive information is a prerequisite for achieving the goal of comprehension. The different properties for perception (colour, shape, size/volume and location) also have functions with importance for achieving simplicity, recognition and consistency.

The user should not only be able to perceive and understand; the user should also be **informed** by the signs. The information perceived and comprehended should make a difference; the user should become **knowledgeable** and prepared for action. That the receiver is informed by the sender is an aim of communication via e-service. Important features contributing to knowledge when the user perceive and comprehend the information are: information related to the user and to the task, the action which the user is going to perform or has performed, the process in which the information is a part of. In this context, properties as structure, thematizing, level of detail (detail, aggregation and summary) and level of knowledge (elementary, advanced) are important.

Perception, comprehension and informing are all basic aspects of importance for the IT-system and its use. These aspects must be taken into account in the designing process, whether the information is about a subject like food permission, navigation in the IT-system, feedback information or error.
messages. In this way these basic aspects can be related to all three levels of e-services in organisations (in figure 3),

What is a user going to do with the acquired knowledge? When the user becomes knowledgeable and prepared, the action taken can be: a) within the IT-system, b) via the IT-system or c) outside the IT-system. To navigate to the next page in the web site is an action within the IT-system (a) on the interaction level. To read information initiated by the case handler about e.g. legal rules and permission is instead an action via the IT-system (b) on the communication level. To send a question to a case handler is also an action via the IT-system (b) on the communication level. It is important to recognize that when a user communicates with a case handler through e-service the user is at the same time interacting with the computer. Thus, this action is multifunctional. Action multifunctionality builds on and extends the concept of pragmatic duality (Sjöström & Goldkuhl, 2004). To send a complete application to the case handler is an action via the IT-system (b) but on the business process level. An action via an IT-system on the business process level always also includes both the interaction and the communication levels. To have obtained food permission through the e-service and then running a restaurant is also an action on the business process level but outside the IT-system (c). Actions outside the IT-system are separated from the IT-system and these actions are restricted to the business process level only. The three different levels (interaction, communication, business process) are related in a way that all the lower levels are prerequisites for all the higher levels (see figure 3). Lack of quality on a lower level affects the quality on higher levels.

Informing and performing are different e-service functions. In a user interface every object is information. But the information objects can have different functions: to be used to inform or to be used to perform. Through the informing function the user is being informed about something. Every object has some informing function. But some objects also have a performing function which allows the user to perform something and that means more than being informed. There is a big difference between the user only getting information about something, e.g. how to pay, and the user performing a payment. In an IT-system it is highly important to clearly differentiate between these two functions. The user has to be aware of what is going on. Only receiving information is often not associated with heavy consequences. However, to conduct by sending information (e.g. a payment, an application, an update or a deletion) can be more serious. In the e-service for food permission we clearly differentiated between informative e-services and performative e-services. By the informative e-services the user can get information about e.g. legal rules and the application process. By the performative e-service the user can perform the application process, i.e. parts of the process with filling out the form and sending the complete application to the municipality. The IT-system for food application permits every user to read information (an informative e-service) but only logged in users are permitted to perform an application (a performative e-service).

**Purpose and content;** i.e. meta information about the main topic. What is the user offered by the e-service? Who benefits from the use of the e-service? It is important that a user as soon as possible is able to get an overview of what the system can give; what information to receive and what information to send? The user should have a basis to decide, “is this a ‘right’ site for me or should I leave the web site or the current page?” The function of this information is also to stimulate interest among prospective users. For example, on top of the first page on the web site for food e-service there is an overview picture and a synoptic description of purpose and content and the expected type of user. The description of purpose and content continues on the top of all other pages, where the user can find a description or a title that indicates what the page is about.

Clearly expressed main topic; the informative and/or performative e-service on the communication and the business process level. This is the content in the communication between a sender and a receiver, and also the purpose of using the e-service. The structure and the context of presenting the main topic are very important. The information should be displayed from the users’ point of view and the purpose of using the e-service (Eliasson & Hedström, 2005). In the example from the food e-service we related to the application process and structured the information in 1) information about legal rules 2) information about the application and 3) information about permission process. This
information is displayed for the user in both an aggregate and a detailed way. The user is able to receive information about the application process but also to conduct the process via the e-service. Filling in the form is structured according to different generic themes (who, what, where, when) related to the business process. The application process begins with a clear starting point and ends with a clear ending point.

**Navigation.** Information about principles and functions for information access and also information that allows performing navigations. Where and how can the user find the information in the IT-system? The design of the navigation has consequences for accessing the informative and performative e-services. The navigation can be open or limited. Open is when the user has the option to choose among pages and functionalities. Limited is when the user does not have any choice but the IT-system chooses the path within the IT-system. A fully open navigation is hard to realise; various mixtures of open and limited are more realistic. In an open navigation the user has flexibility to perform different actions, but in a limited navigation the IT designer may choose a proper way according to the user and/or the task. In the food e-service we have chosen a design to make the user knowledgeable before conducting an application. The user will be guided to read information before performing an application. The user has also the possibility to navigate directly to pages for performing an application (aimed for more advanced users). The pages for filling out the form can be accessed in any order. The informative and performative e-services concerning the main topic are supported by functions as e.g. forward, feedback, redo and rectify.

**Indicate forward.** The user should be able to navigate and act in a confident way within and through the IT-system. The IT-system must contain clear information that indicates what result the user can expect by using the system. In the e-service for food permission all buttons have a descriptive sign, for instance.

**Feedback.** The system should give feedback to the user, information about what the user has done and what the IT-system has done. The IT-system can display the result, e.g. accessed information about rules for food permission, or describe the result, e.g. your application is sent to the municipality.

**Redo.** If possible, the IT-system should permit the user to change actions already done. Information about opportunities to change is imported. Sometimes changes are possible and sometimes not.

**Rectify.** Support for error handling. When and how it is possible to correct an error, (i.e. an undesirable result not changeable by redo).

When designing the e-service it is important to pay special attention to the main topic, the navigation function and the difference between the informing and performing functions. The functions of feedback, indicate forward, redo and rectify are relevant in all actions in the IT-systems. However, the most basic prerequisites when using the e-service is its support to the trajectory of perceiving, comprehending and becoming informed as a basis for action.

## 6 CONCLUSIONS

An IT-system is about information, information to be used for some purpose and with some expected effects. The purpose and effects of the e-service in our case study can be related to the different levels in the three levels model (see figure 3). We used the model as a basic approach when creating the e-service prototype and also when articulating and analysing the criteria. When a criterion was identified at one level, corresponding criteria residing on the other levels were searched for. In this way, the model has governed us to pay attention to formulations of criteria and to search for criteria residing at different levels.

The knowledge contribution of this paper consists of design criteria for e-services. We have generated new criteria, refined existing criteria and reused existing criteria. In this sense our approach can be characterized as a cumulative approach. The most important new criteria that we have identified are to create good conditions for users to become knowledgeable, differentiate between informative and
performative parts and provide meta information (purpose and content). Examples of reused criteria from the HCI-field are feedback, redo and rectify.

The special character of governmental services has influenced the evolution of these e-service criteria. A municipality’s role is both to exercise public authority and to provide service. The municipality needs to inform the companies and handle applications in a legal and proper way. Different legal rules need to be clarified and readily available. The company managers need to be knowledgeable before making an application. The municipality has regulated obligations toward companies but also the companies have regulated obligations towards the municipality. The companies are in some situations forced to get permission and then to turn to the municipality to get that permission. There are no alternative ways for the companies. These conditions have influenced the e-service criteria, e.g. knowledge support, thematized forms and division into informative and performative services.

One message in this paper is that criteria proposed by HCI scholars are important to consider, but they are not sufficient. Our claim is that they are too limited and that they are not formulated to support the communication process or the business processes. They are formulated to support one individual user interacting with one computer, just restricted to human-computer interaction.

Our view is that human-computer interaction is important, but we view IT-systems as media or instruments used to support communication between users and business actions that are performed in the business process (Goldkuhl 2005). Therefore, the use of an IT-system is only a means to achieve a higher goal: to support the communication between a sender and a receiver in order to successfully manage a business process that produces value for the client. This means that we propose a changed perspective on design or evaluation of public e-services: An expansion from a more limited human-computer interaction perspective to a human-to-human communication via computer perspective.

Abstract

This paper addresses the research question: How do digital backchannels, mediated by Real-Time Communications, facilitate the progress of conference calls? It is argued that whilst the fields of Distributed Work and Computer Supported Collaborative Work have been studied in depth, research into Real-Time Communications (RTC) and Instant Messaging (IM) is at an early stage. There is a paucity of research into the use of these technologies in distributed settings within organisations, especially from a perspective of generating social cohesion within teams. Furthermore, there is no known research into the use of instant messaging to mediate “hidden” interactions between individuals, through digital backchannels, within conference calls. Qualitative empirical evidence is obtained from two case studies of teams using an established corporate RTC product. Goffman's Interaction Order (1983) is presented a suitable lens through which to interpret this mediated form of interaction. Empirical evidence points to concurrent working and use of digital backchannels during meetings and conference calls. Dramaturgy (Goffman 1959) is used to identify and analyse three interaction styles of “bitching”, “bouncing” and “brawling”. It is found that interactions over digital backchannels fulfil criteria of Interaction Ritual (Goffman 1967) and may contribute to the creation of social cohesion.

Keywords: Digital Backchannels, Real-Time Communication, Instant Messaging, Distributed Teams, Interaction Order, Social Cohesion
INTRODUCTION

In their research report (2008) on a Delphi study of Real-Time Communications (RTC), Frößler et al. described it as an emergent technology, which has recently come to the attention of academics. RTC represents a group of products originating from the convergence of the telecommunications and groupware markets. It consists of two main components, presence, or availability status, and unified communications (UC). Presence provides contextual information regarding the availability status of group members for engaging in communication. By indicating their availability for communication and their preferred means of being reached, individuals are able to signal when they can be engaged in communication. UC unites access to communication tools such as voice, instant messaging (IM) and e-mail in one application. As a result, UC facilitates the management and coordination of a user’s communication. To date there has been little academic research into RTC (Frößler et al. 2007) and its uses.

Companies are also adopting flexible modes of working, where teams are geographically distributed across sites. Many users of RTC form part of distributed teams involved in dispersed communications activities (Olsen et al. 2000) and are impacted by strains that such an environment might impose (Hinds et al. 2005). A common genre of communication and coordination employed by these individuals is the conference call. It has been noted (Olsen et al. 2000) that such forms of interaction are limited in context, interpersonal signals and cues when compared with face to face meetings. This may impact upon interaction and cohesion amongst teams.

RTC tools allow concurrent communication channels to be set up, using IM, during an instance of voice interaction. These secondary, private and unofficial channels of communication between two or more parties are known as Digital Backchannels and are invisible to the wider group taking part in the primary interaction (Cogdill et al. 2001). The use of backchannels may occur, for example, in the scenario of two teams on a conference call. One team may use IM to surreptitiously debate a point made by the other team, such that they can respond in a coordinated and effective manner. It is of interest to understand how conference call participants find backchannels useful, to see how backchannels may add context within calls and how they may create cohesion within teams. This paper reports on the use of backchannels occurring within audio conference calls, within two companies using an established corporate RTC product.

Whilst there has been little research into the use of RTC in the organizational sphere, there have been studies of IM. This research is mainly concerned with increasing user adoption (e.g. Aducci 2008) or on local practices and user adoption (e.g. Cameron et al. 2005). Some papers (e.g. Kellogg et al. 2006) mention the use of IM mediated backchannels within the context of conference calls, but without providing examples or theoretical understanding of what is occurring. No research was found regarding the use of RTC or IM within dispersed teams and the subsequent development or maintenance of cohesion. There are few papers covering IM mediated backchannels in other contexts. Cogdill et al. (2001) cover the use of backchannels within Multi User Domains (MUDs), but do not describe the understanding or theory of use. McCarthy et al. (2005) investigate the experimental use of IM mediated backchannels amongst attendees during conference presentations. The paper categorises use, but does not attempt to describe how the taxonomy was derived. Their use of backchannels varies from those encountered in this research. In their setting, backchannels were visible and open to all, rather than being hidden. The authors conclude that “a number of issues warrant further study, such as the nature of the social bonding that takes place in collocated verses distributed groups”.

Within the fields of distributed work and computer supported collaborative work, there is coverage of the need for cohesion within distributed teams for work to take place effectively. Olsen et al. (2000), describe situations when distributed work can be effective. One factor that they describe is common ground, which is the need for teams to be able to establish a shared identity, level of context and trust before they are able to engage in successful collaboration at a distance. This is reflected by Hinds et al.
(2005), who indicate that shared identity, context and spontaneous communication can have a moderating effect on conflict arising within geographically distributed teams. Cohesion that has been developed or maintained by mediated interaction is covered by a number of scholars. Licoppe (2004) posits that frequent mediated and co-present interaction between groups is interwoven and increases cohesion. Ling (2008) examines how mobile telephony affects interactions and suggests its use strengthens social ties within the close circles of frequently called contacts.

1.1 Aims and Objectives

The objectives of the research, described within this paper are threefold. First, it aims to assess the practicability of the applying Goffman’s theories of Interaction Order to understand interactions between employees mediated by RTC during and within meetings. Second, it assesses whether the research method, is sufficient to answer the research question. Last, it ascertains whether knowledge of how RTC is used within organizations is advanced, and whether this is of practical benefit.

2 METHOD

The empirical data used in this research, and the method through which it was collected, was informed by a number of sub questions: How do employees communicate? What forms of communication do they use? In what working contexts do they communicate? And what ends do they achieve through communication? The unit of analysis that was applied in the research is that of “situated instances of interaction”.

The epistemological orientation of this research is that human interactions can have different meanings for different human subjects, as well as for the researcher investigating them (Lee 1994). There may be an element of subjectivity in individuals’ opinions of meaning. In addition these meanings are inter-subjective as they are socially constructed and agreed amongst individuals within a team or organization, as well as between subjects and researcher. This research is broadly based on social constructivism and interpretive epistemology. An interpretive understanding, at a micro sociological level, is applied as to how interviewees understand their interaction using backchannels.

Qualitative interviews were carried out at two companies to form two case studies. The interview questions concerned individuals’: work style and practices; use of communications; use of presence; process of contacting colleagues; tendency to switch between communications methods. The first case study considers AppsCo, an established provider of business software applications. The team at AppsCo were concerned with product management and marketing of corporate office solutions. The second case study considers TelCo, an established provider of telecommunications services to corporations. The team at TelCo were concerned with propositions management of corporate mobile solutions. Ten interviews were undertaken, six at AppsCo and four at TelCo. The interviews were typically ninety minutes long. Approximately 750 minutes of recordings, covering ten interviews, were transcribed into 280 pages of notes.

A first stage of coding “pre-processed” the corpus of data, to break it down into a set of situations of mediated interactions, according to the unit of analysis. A broad set of coding categories was used in order to do this. Category groupings included: communications behaviours; forms of communication; working contexts within which communication occurred; purposes of instances of communications. A second stage of coding assisted the analysis of interactions and meanings by labelling situations of interactions with concepts from Goffman’s theories concerning Dramaturgy and then Interaction Ritual. The results of this second stage of analysis are considered in this paper.
3 THEORY

When considering theories relevant to the research question, it is useful to refer to Fiske’s definition of communication (1990) as “social interaction through messages”, involving symbols and codes. He assumes that these symbols and codes are transmitted to others and that communication is central to the existence of society. Fiske divides theories of communication into the process and the semiotic school. The semiotic school understands communication as how messages interact with people to produce meaning. Whereas the process school sees social interaction as the process by which one person relates to another, the semiotic school considers social interaction as that which constitutes the individual as a member of society. Similarly, the process school considers a message as that which is transmitted by the communication process, and the semiotic school views messages as the contribution of symbols, which through interaction with the receiver, to produce meanings (Fiske 1990).

The need to understand the meaning of interaction over backchannels, places the research question in the semiotic school of communications theory. The understanding of meaning is highly dependent upon the context of the backchannel interaction, as “The appreciation of the various details that define context is a subtle mental process and provides the key for interpreting a situation and the meaningful elements that pertain to it” (Kallinikos 2001). The interaction that takes places within the “backchannel” is highly contextualized as it takes its meaning from the primary interaction that is taking place, namely from within the conference call or meeting. In a similar way, any discussion or secondary interaction within the “backchannel” may provide context to subsequent primary interaction within the conference call or meeting.

The framework of Interaction Order (Goffman 1983), provides a seam of logic and method through which to understand the meaning of face to face, and possibly, mediated interaction. Goffman argued that people construct meaning for their social world through language and interaction. Interaction socially constructs meaning, and through this he believed that the sense of self was constructed as a product of this social meaning. Furthermore he thought that this meaning can be accessed through the careful analysis of interaction behaviours. Goffman’s focus was on understanding meaning behind individual instances of face to face interaction, and his methodological approach was generally based on ethnographic observation of individuals and groups in their day to day settings. Goffman’s unit of analysis was the situation within which interaction was taking place.

Ling (2008) applies Goffman’s theories, through extensions of Goffman’s Interaction Ritual (1967), to interpret the meanings mobile phone users ascribe to their mediated interaction. In this research, two aspects of Goffman’s framework of Interaction Order (1983) and extensions of these theories (Collins 2005; Ling 2008) were used in order to provide a lens through which to interpret the meaning that subjects give to their interactions through backchannels within the context of the conference calls. In addition, Goffman’s theories give clues as to how these mediated backchannel interactions may contribute to a sense of cohesion amongst distributed teams.

3.1 Dramaturgy and its Application

Dramaturgy, which was put forward in Goffman’s book “Presentation of Self in Everyday Life” (1959), is the first theory that was applied. Dramaturgy is an approach to interpreting how the self manages impressions and what is conveyed based on interactions within groups of people. He used the metaphor of “life as theatre” as a lens through which to analyse interaction within life situations. He uses this lens in order to understand the tactics and techniques by which people use the ritual of theatre to construct the impressions that they give and that individuals take. The main premise in this analysis is that human interactions are dependent on contextual factors such as time, place and audience. The impressions that one human presents to another is based on cultural norms, values and expectations that are contextualized. Goffman uses the theatrical metaphor to provide terminology to describe how individuals go about organizing their performances. Goffman assumes that interactions are social
performances in which individuals are concerned with giving off and maintaining certain desired impressions of themselves to others with the aim of achieving their goals of interaction. The aim of this act of self presentation is to gain acceptance from other people ("the audience") through manipulation. If "the actor" succeeds then audiences perceive "the actor" as she would like.

There are a number of theatrical terms that Goffman introduces to illustrate the performance of impressions management. Goffman introduces the concepts of "front stage", where the self is visible to "the audience" and "back stage", where the self is invisible. When "the actor" is present on the "front stage" she is visible to "the audience" and must manage her impressions or "role" as part of the "performance". Her demeanour and the way she behaves may well be quite different "back stage" to what it is "front stage". When she is "front stage" she is in role and her impressions management need to convey this. As in theatre "boundaries" are required in order to prevent or restrict the movement of "the audience" sitting "front stage" from getting access "back stage", in order that the performance remains credible. The ways through which hidden "back stage" interactions using backchannels, facilitate the progress of meetings can be examined using the language of Dramaturgy.

3.2 Interaction Ritual and its Application

The second theory taken from Goffman's Interaction Order (1983), is that of Interaction Ritual (1967), which analyses the rules of conduct that bring actors together. In Interaction Ritual (1967), Goffman builds upon the concepts of ritual, with origins in Durkheim's "Elementary Forms of Religious Life" (2008). Durkheim was concerned with the dynamics of ritualistic events at a macro level in order to study the societal transitions from one state to another (Ling 2008). The ritualistic events, that he studied, were special occasions, such as weddings, and typically took place in a religious setting rather than everyday life. Durkheim was of the opinion that the context of group interaction in rituals generated solidarity through shared symbolism, and that it is ritual and ritualistic events that bind society together (Ling 2008). Goffman applied Durkheim's concept of ritual to every day interactions, moving the ritual taken within the perspective of the macro to the micro. Goffman believed that there was a sharing of mood and mutual recognition of a situation in mundane rituals (Ling 2008). Building on Durkheim's ideas he posited that interaction ritual provides rules of conduct that provide cohesion and bind actors together (Ling 2008).

Collins (2005) develops Interaction Ritual further in an attempt to connect Goffman and Durkheim in order to link the micro perspective of day to day ritual to the macro perspective of the reinforcement and stability of social structure. Collins (2005, p.48) extends the work of Durkheim and Goffman to define ritual interaction as "A mechanism of mutually focused emotion and attention producing a momentarily shared reality which thereby generates solidarity and symbols of group membership." Through the perspective of Interaction Ritual Chains (2005) individuals focus on the same ritualistic object or action. By (re)enacting these interactions individuals practice deference and demeanour (Goffman 1967) and they develop a common mood. The repetition of micro interactions leads to the significance of artefacts (jargon, symbols or totems) being revitalized and they become charged with emotional intensity (Collins 2005; Ling 2008). Collins claims that the effervescence (Ling 2008) of these events creates social cohesion, as there is a shared sense of energy amongst the participants. Finally, Collins posits that this process allows a sense of solidarity or allegiance to form and that this in turn bolsters institutional stability (Ling 2008).

Ling (2008) develops Collins ideas in order that they can be applied to interaction within communities mediated by the mobile phone. The concern that Ling faces with when attempting to make this connection is that the theories of ritual interaction put forward by Durkheim, Goffman and Collins are based on co-located rather than mediated interaction. Ling circumvents this issue in order that the ritual interaction chain can occur. He claims that once a bond has been formed through co-present means, mediated interaction is as effective in generating the intense emotion that is needed to develop and maintain cohesion. He cites Licoppe (2004) who provides evidence to support these claims.
It is proposed to further extend Collins’ work to the context of IM, using the same logic as Ling. Whilst the individuals interacting by IM may not be co-present they may have bonded as working colleagues on previous occasions. When participants interact over a backchannel they are focusing on the same set of rituals, namely the meeting and the purpose of the backchannel interaction. These ritualistic interactions in turn provide a common mood and a degree of emotional intensity by the fact that they feel the need to use a discrete backchannel. In turn the degree of shared energy caused by this interaction may be little different to that caused in the mobile mediated interactions that Ling observes, so that they may in turn lead to cohesion within in a distributed group. The lens of Dramaturgy is used to analyse the empirical data before applying the lens of Ritual Interaction. The insights Dramaturgy provide into the use of the backchannel bring out the drama in IM mediated interaction, and expose the shared energy which is needed for the generation of cohesion in the context of Ritual Interaction.

4 RESULTS

A large quantity of generalised communications usage data was obtained from interviews. Part of this data concerns the use of digital backchannels in the context of meetings and conference calls, and is considered in this paper. The remaining data concerning other form of communications usage and behaviour is considered elsewhere.

Backchannels in the context of conference calls are of interest as participants are physically remote from each other and the possibility of the use of physical notes, gestures and signals to communicate discretely is impossible. Furthermore interactions over the backchannel may be richer and more sophisticated than what can be achieved using signals and gestures. A selection of examples of backchannel usage that arose during interviews are illustrated in table 1.

<td>1. “And the XXXX guy was speaking about something and the XXXX will come on “this guy’s bullshitting” …. it’s like who’s IM-ing who about what. Got to watch what I say …”</td>
</tr>
<tr>
<td>2. “So our group manager, once a year she goes away to (headquarters for a review) … she can’t possibly remember everything. And you know the second that she’s in that meeting and she’s on because all the IMs start popping up … it’ll either be her or a person she sits next to … she obviously gets asked a question, and she’ll say “right you want to know what we’re doing for Product X next year and where we see the biggest opportunities”? Then the answer comes back, apparently the same happens with the big execs on the other end. Our side will say “yes, well we think - we’re only four percent market share”. And someone will go shwe-shwe in the big guy’s ear; you know whispers in his ear. And then they say “actually I know it’s 10 percent”.”</td>
</tr>
<tr>
<td>3. “It’s a great tool for asking questions amongst your little community. Having everyone in context, you can write “I didn’t understand that, did anyone else?, should we press for this, should we do this”. It allows you to then have … a much stronger positioning meeting because you can ask the questions you won’t normally do in a face-to-face like “you ask him, if I’ll ask this”. Get that pincer attack on closing down on the negotiation points.”</td>
</tr>
<tr>
<td>4. “You could argue “is there a moral ethical dilemma about that. No, not really because … you would’ve prepared for that meeting anyway, you would’ve assigned the roles of who’s going to be the negotiator. All you’re doing at this point is cementing and tackling the stuff that comes off the left field that you might not have thought about.”</td>
</tr>
<tr>
<td>5. “we’ve been discussing recently with a supplier about … various conditions that XXX enforces as part of it’s procurement and increasing the cash flow is becoming a major issue for companies. And XXX is seeking … to extend its payment terms too …. in this instance because of our systems we’ve haven’t paid this particular supplier on a number of occasions and we’ve actually made it onto their bad debtors list. The procurement guy wasn’t aware that this was the situation when were trying to renegotiate the contract. So I logged on, quickly got in touch with him and said “this is the situation” and that guy had to change his tack slightly and he didn’t push quite so hard to get it.”</td>

Three categories of backchannel use within the context of Conference Calls were identified. They have been given the descriptive titles “bitching”, “bouncing” and “brawling”. “Bitching” describes
interactions which do not contribute to the progression or success of the meeting. These interactions are typically much more “social” in nature and are typically used to “let off steam” in the form of sharing frustrations and the sharing of jokes. “Bouncing” describes interactions between two or more individuals in a conference call or meeting and two or more individuals outside of the meeting. Unlike other examples of IM mediated concurrent work that may occur during meetings, these IM exchanges are directly related to the progression and maintaining the success of the meeting. The principle use of “bouncing” involves the pulling in of information from outside, into the conference call or meeting, in order to facilitate “its momentum” and to prevent the meeting from “stagnating”. “Brawling” describes interactions which seek to clarify a point or to strategise over an issue occurring in the meeting, so that one or more of the backchannel party can then reengage in the conference call or meeting and tackle the issue effectively. These categories are listed against the examples of backchannel usage in table 1.

These interactions are now analysed in depth, firstly through the lens of dramaturgy and then through the lens of interaction ritual. They are illustrated with example “thick descriptions”.

4.1 Conference Calls as a Performance

In the context of Dramaturgy, conference calls and meetings take place within the context of “front stage” which is the meeting room for face to face meetings, or virtual space for conference calls. Without a backchannel, there is little opportunity for “back stage” interactions, so that all of the actions by the “actors” can be seen or heard by the “audience”. However, with the addition of laptops enabling IM, it becomes possible for the actors to engage in “back stage” interactions over a backchannel, whilst the meeting or “performance” is unfolding “front stage” at the same time. The “back stage” is invisible to the “audience” and “actors” can interact without their behaviour being seen or heard by the “audience”, e.g. “You can have conversations where you couldn’t have physical conversations at the same time”. The descriptions of backchannel usage that were identified from the interviews were analysed by applying dramaturgical concepts. Table 2 illustrates dramaturgical concepts occurring in the example quotations of table 1.

“Bitching” interactions are typically “social” and joking in nature, e.g. Quotation 1. This comment indicates the necessity to guard “boundaries” between “front stage” and “back stage” and to prevent the “audience” gaining access, otherwise the “performance” will no longer be credible. “Bitching” as a form of “back stage” interaction resembles an “actor” complaining that the “audience” is particularly flat that evening. These “asides” distinguish “Bitching” from the other two categories. The “audience” are not intended to see any of these “back stage” backchannel interactions; otherwise their impression of the “performance” might be ruined.

The principle form of “bouncing” involves the pulling in of information from outside, in order to keep up the momentum of the conference call or meeting, e.g. Quotation 2. The process of “bouncing” is similar to the “prompting” of actors when they forget their “lines” which is occasionally required to keep up the momentum of a “performance”. However, the level of “prompting” must be kept as subtle as possible, as in a play, in order to maintain the “appearance” and “front” of the “actor”, so that their
“role” remains credible and convincing. Ideally the “audience” won’t be aware of “prompting” and the backchannel is relative subtle for this purpose, as it remains “back stage” out of sight. It is “prompting” that makes “bouncing” unique amongst the categories.

There were examples of individuals on conference calls using the backchannel to clarify points within their “team of actors” “back stage” before “brawling” “front stage”. The advantage of being able to have these interactions “back stage” on the backchannel, whilst the “performance” or meeting is continuing “front stage”, is that the “audience” remains oblivious as to these discussions. As a consequence the “actors” are able to coordinate and manage the “performance” without having to interrupt it. The ability for “actors” to be able to have these “back stage” dialogues enables sophisticated strategies to be developed quickly and responsively to achieve the objectives of the meeting, e.g. Quotation 3. There was some debate as to the morality of strategising “back stage”, but it was considered ethical, as teams would typically prepare and “rehearse” before meetings, and the backchannel is used for dealing with the unexpected, e.g., Quotation 4. In this last quotation, the interviewee raises an additional point of interest regarding to be able to react to unforeseen circumstances. The ability to be able to have a dialogue “back stage” is that it enables the actors to “improvise” better. It is “improvisation” that sets the category of “brawling” apart from the others. The ability, that backchannel provides, to allow people to be “front stage” and “back stage” at the same time, without interrupting the “performance” provides an ability to fine tune, or “direct”, events whilst they are unfolding, e.g. Quotation 5.

4.2 Conference Calls as Ritual

There is logic in applying both the concepts of Dramaturgy and Ritual Interaction. First, they both form part of Goffman’s Interaction Order (Goffman 1983). Second, the two perspectives are linked so that themes from Dramaturgy inform Interaction Ritual, in terms of the study of human interaction, its methodological and epistemological approach, and in terms of the concepts and vocabulary used. Last, the initial Dramaturgic analysis helps identify the shared energy that is created in parties interacting, which then feeds the sense of social cohesion resulting from Interaction Ritual.

For ritual interaction to take place, Collins (2005, p.48) states the following conditions must be in place: Two or more physically assembled people; Boundaries to outside; A common focus of attention through which participants are mutually aware of each others’ focus of attention; Sharing of mood (including: Collective engrossment; Sense of emotional energy; Development and markers of shared relationship; Standards of morality (e.g. sense of rightness) associated with being part of the group and willingness to defend against transgressors). Ling (2008) develops Collins’ ideas further in order that they can be applied to interaction mediated by the mobile phone. The first condition becomes: Two or more physically assembled people or people who are connected via mediated communication. Table 3 illustrates how all these conditions are matched within each example of backchannel usage. The paragraphs that follow describe how this comes about for each example.

| Table 3. Chain of Evidence: Ritual Interaction Concepts occurring in Example Quotations |
|---------------------------------|---------------------------------|---------------------------------|---------------------------------|---------------------------------|---------------------------------|---------------------------------|
|                                | Two or more physically assembled people | Boundaries to outside | Common Focus of Attention | Sharing of Mood: Collective Engrossment | Sharing of Mood: Sense of Emotional Energy | Sharing of Mood: Development of Shared Relationship |
| Q1                              |                                |                                |                                |                                |                                |                                |
| Q2                              |                                |                                |                                |                                |                                |                                |
| Q3                              |                                |                                |                                |                                |                                |                                |
| Q4                              |                                |                                |                                |                                |                                |                                |
| Q5                              |                                |                                |                                |                                |                                |                                |
Since “bitching” interactions are typically much more “social” and joking in nature, they may transform a tense energy within a meeting into energy which is more agreeable, e.g. Quotation 1. Applying Collins’ framework to these interactions, it can be seen that “two or more people are connected via mediated communication” by the very fact that they are engaged in IM interaction. There are clearly “boundaries to outside” as there are other people within the primary context of the conference call / meeting, for whom the content of the “back stage” interaction is not intended. There is a “common focus of attention through which participants are mutually aware of each others’ focus of attention”, the act of “bitching” within the primary context of the conference call/meeting is the common focus, and the backchannel is the means through which the “actors” are mutually aware of each others’ focus of attention. With regards to the final aspect of Collin’s framework, “sharing of mood”, there is a sense of “collective engrossment” and “emotional energy” through the fact that the act of “bitching” is transforming one form of emotional energy (e.g. frustration at being bored) to another (e.g. relief that someone else might be feeling the same way). It can be claimed that the conspiratorial nature of sharing a joke about how the meeting may develop or maintain “markers of shared relationship” and may indicate that there are “standards of morality (e.g. sense of rightness) associated with being part of the group and willingness to defend against transgressors”.

The principle form of “bouncing” involves the pulling in of information from outside, into the conference call or meeting, e.g. Quotation 2. Once again, applying Collins’ framework to these interactions, it can be seen that “two or more people are connected via mediated communication” by the very fact that they are engaged in IM interaction. There are clearly “boundaries to outside” as there are other people within the primary context of the conference call / meeting, for whom the “back stage” interaction is not intended. There is a “common focus of attention through which participants are mutually aware of each others’ focus of attention”, the act of “bouncing” within the primary context of the conference call/meeting is the common focus, and the backchannel is the means through which the “actors” are mutually aware of each others’ focus of attention. With regards to the final aspect of Collin’s framework, “sharing of mood”, there is a sense of “collective engrossment” and “emotional energy” through the fact that the act of “bitching” is urgent and emotionally charged in nature. It can be claimed that the hidden nature of sharing information and co-operating together may develop or maintain “markers of shared relationship” and may indicate that there are “standards of morality (e.g. sense of rightness) associated with being part of the group and willingness to defend against transgressors”. The “actors” in these quotations are sharing information with their “audience” to defend their point of view, and there is a sense of “us and them”.

Examples of “brawling” are reported for two observed purposes. Each has its own role in interaction ritual. The first is to enable a group to discuss strategies improvise solutions, “back stage” whilst being “front stage” at the same time, in order to cope with unforeseen circumstances on a conference call, e.g. Quotation 3. The second use of “brawling” is to influence, or “direct”, the “performance” of another “actor” in order to maintain the success of the overall “performance” of the conference call. Again this is done “back stage” whilst being “front stage” at the same time, e.g. Quotation 5. Applying Collins’ framework to these interactions for the last time, it can be seen that “two or more people are connected via mediated communication” by the fact that they are engaged in IM interaction. There are clearly “boundaries to outside” as there are other people within the primary context of the conference call / meeting, for whom the content of the “back stage” interaction is not intended. There is a “common focus of attention through which participants are mutually aware of each others’ focus of attention”, the act of “brawling” within the primary context of the conference call/meeting is the common focus, and the backchannel is the means through which the “actors” are mutually aware of each others’ focus of attention. With regards to the final aspect of Collin’s framework, “sharing of mood”, there is a sense of “collective engrossment” and “emotional energy” through the fact that the act of “brawling” is inclusive of a group and requires their attention. In addition there is likely to be a common sense of charged energy as the “actors” plot to outwit their “audience”. It can be claimed that plotting together may develop or maintain “markers of shared relationship” as those who are involved are very much part of the “in group” in contrast to the “out group” against who they are scheming. The act of brawling, intended to defend the interests of the “actors” against those of the “audience”,
indicates that there are “standards of morality (e.g. sense of rightness) associated with being part of the group and willingness to defend against transgressors”.

5 DISCUSSION

The framework of dramaturgy can be usefully applied to understanding and interpreting interactions over backchannels in the context of conference calls and meetings. It would also appear that the extensions of Interaction Ritual (Collins 2005; Ling 2008) can be used to understand interactions mediated via IM through backchannels, and that meaningful interpretations can be drawn from this analysis. A number of insights emerge from these analyses, which can be assessed, in terms of relevant findings, contributions and failings, against the objectives of this research.

5.1 Theoretical Findings, Contributions and Failings

The research had the objective of assessing the practicability of applying aspects Goffman’s Interaction Order and derived theories to interpreting and understanding meanings attributed by users of IM mediated backchannels in the context of conference calls and meetings. To date there has been little research into use of RTC within organisations (Frößler & Klein 2007) and little research into the use of Digital Backchannels (Isaacs et al. 2002; Kellogg & Erickson 2006; Cogdill et al 2001; McCarthy & Boyd 2005). Application of Goffman’s theories allow the meanings of Backchannels to be interpreted and understood. Dramaturgical concepts (Goffman 1959) provide a useful means of interpreting the interactions that occur through backchannels within the context of conference calls and meetings. Interaction Ritual (Goffman 1967) and extensions (Collins 2005; Ling 2008) were applied to the empirical data in order to ascertain whether these interactions were indeed ritualistic after Collin’s and Ling’s definitions. Interactions through backchannels fit Collin’s criteria, adapted by Ling, satisfactorily, and these mediated interactions can be loosely termed Interaction Rituals. In this way, it can be claimed the theoretical objective is achieved, and that the study contributes to the literature. It demonstrates that Goffman’s Interaction Order can be successfully applied to interpret interactions through IM mediated backchannels in the context of conference calls. However, the study had set out to claim that use of backchannels generates or maintains social cohesion within groups (through interaction ritual). Unfortunately, it cannot be claimed that this is the case. The reasons for this are twofold. First, for social cohesion to be generated and maintained by interaction ritual, the ritual needs to be repeated frequently (Ling 2008), a concern which is confirmed by Licoppe’s research (2004) into “connected presence”, which shows that it is frequent mediated interaction that helps maintain social bonds. Whilst it is apparent that the average day is quite literally “littered” by conference calls for some interviewees in this research, there is insufficient evidence that they engage in “bitching”, “bouncing” and “brawling” frequently enough. This question was not asked, nor was the evidence volunteered. Second, for the same reason, interviewees did not mention the fact that they find interaction over the backchannel a socially cohesive act, either directly or indirectly. Nevertheless these practices fulfil the criteria of Interaction Ritual which consequently provides evidence that they may contribute social cohesion, especially in conjunction with other factors.

5.2 Methodological Findings, Contributions and Failings

This research had the objective of assessing whether the research method is sufficient to address the research question. The chosen research design was based on obtaining qualitative data from semi structured interviews from two organizations and to present them as two case studies. Sufficient empirical data was collected in order to address the research question regarding backchannels. However, there are shortcomings with the research design and method. The first concerns the fact that research in Goffman’s tradition is based ethnographic observation, rather than case study interviews. Ling (2008), upon which this research is based, used ethnographic observation in order to obtain empirical data for his research into social cohesion, based on Interaction Ritual, generated from use of
mobile telephony. It is debatable whether an ethnographic study would have yielded sufficient data, given the short period of time that was available for field work. A second criticism is that whilst sufficient evidence was acquired to address most of the research question using Goffman’s concepts, there was no independent evidence to back up the claim that Interaction Ritual within backchannels generates social cohesion amongst interviewees. Future research designs must be improved in order that a full contribution is provided.

5.3 Practical Findings, Contributions and Failings

The research had the practice objective of assessing whether the research advances knowledge of how RTC is used within organizations, and whether this is of practical benefit. The process of analysis identified the following four findings. Firstly, in the backdrop of meetings, IM mediated backchannels provides a group of individuals an environment where they can engage in sophisticated interaction, invisible to other meeting attendees. Secondly, backchannels provide a dynamic means for information to be invisibly brought into face to face meetings or conference calls from outside. Thirdly, backchannels allow real time coordination amongst groups within meetings, in a manner invisible to others, which allows them to improvise and react to unexpected events as they unfold. Lastly, mediated interaction through backchannels shows characteristics of Interaction Ritual, which generate an energy amongst those who participate, which may contribute to social cohesion within distributed teams. These findings may be of mixed benefits to organizations. On the one hand interviewees reported how backchannels were of benefit to the way they conducted conference calls. On the other they also reported how backchannels and other examples of concurrent working may be distracting in the context of conference calls and face to face meetings. Indeed some senior managers were introducing policies preventing the use of laptops in meetings, although this would be difficult to enforce in conference calls. Finally, the application of dramaturgy to mediated interactions such as IM interaction through backchannels provides an insightful means of understanding how employees are interacting and how technology is used. In this way this research has contributed to the body of literature within the domains of Distributed Work, CSCW and especially RTC and IM.

5.4 Potential for Future Research

Two areas for future research are immediately identifiable. One is to continue and improve research regarding the use of IM mediated backchannels, and the second is to extend analysis of mediated interactions to other contexts and communications technologies within the organizational sphere. With respect to further research into backchannel interactions mediated by IM, or other technologies, there is a need to correct the methodological failings of this current research. First, an ethnographic approach to collecting data would be more consistent with the methodological approach of Goffman. Second, more evidence is required in order to make claims regarding the creation or maintenance of social cohesion as a result of mediated interactions studied. Last, research into this phenomenon would be more complete if the enquiry extended beyond the act of interaction as agency and also investigated the institutional structural elements and the impact of artefacts, which mediate interaction.

6 CONCLUSION

This research contributes to the analysis of the use of digital backchannels in the context of conference calls and RTC in the areas of practice, methodology and theory.

In practice, it was observed that in the backdrop of meetings, IM mediated backchannels provides a group of individuals an environment where they can engage in sophisticated interaction, invisible to other meeting attendees. Secondly, backchannels provide a dynamic means for information to be invisibly brought into face to face meetings or conference calls from outside. Thirdly, backchannels allow real time coordination amongst groups within meetings, in a manner invisible to others, which
allows them to improvise and react to unexpected events as they unfold. Lastly, mediated interaction through backchannels shows characteristics of Interaction Ritual, which generate an energy amongst those who participate, which may contribute to social cohesion within distributed teams. These findings may be of mixed benefits to organizations. On the one hand interviewees reported how backchannels were of benefit to the way they conducted conference calls, but on the other they reported how it can cause distraction.

Whilst the research design provided sufficient empirical data upon which to analyse the use of backchannels and to identify evidence of social cohesion, it was based on case study interviews rather than on ethnographic observation. Changes to the research design, in order that data is collected through ethnographic observation, would make it more consistent with previous research (Goffman 1983; Ling 2008), upon which it is based.

The application of Goffman’s Interaction Order and derived theories appear to be an innovative lens to interpret and understand meanings attributed by users of IM mediated backchannels in the context of conference calls and meetings. These practices fulfil the criteria of Interaction Ritual, and there is evidence that they may contribute to social cohesion within teams.

Abstract

Many companies utilize employee portals to improve information exchange and communication between their employees as well as to better support business processes. Owing to limited IT budgets and the need to justify portal investments, assessing employee portal benefits is important. In this article, we propose a model for measuring employee portal success on the basis of the DeLone and McLean IS Success Model as well as an extensive review of employee portal success measurement literature. The resulting model is put forward as the foundation for future empirical work in this area. A card-sorting and item-ranking approach as well as a survey trial is conducted in order to validate the survey instrument. Methods of classical test theory are proposed for the further validation of the survey instrument and the assessment of the measurement model.

Keywords: Employee Portals, Business-to-Employee, IS Success, IS Effectiveness

1 INTRODUCTION

The ways employees handle information, communicate, as well as execute business processes have significantly changed with the emergence of web-based technologies and the subsequent emergence of employee portals. Over the past decade, company intranets transformed from collections of static web pages into highly integrated and interactive information systems (IS). Whereas the first-generation intranets only provided a single interface to information, today’s employee portals enable the integrated support of information, communication, applications, and business processes.

Technically speaking, an employee portal offers a browser-based user interface which provides access to personalized information, resources, and applications. In many cases, an employee portal is the primary tool through which employees do their work. Ideally, employee portals yield different benefits to both organizations and employees, such as reducing information overload, reducing organizational costs, improving corporate communication, and enhancing employee productivity (Tojib & Sugianto & Sendjaya 2006).

Today, many companies, especially large ones, offer their employees portals. A 2006 US study by Forrester Research, Inc. indicates that 46% of large companies offered an employee portal, and another quarter planned to establish one by 2008 (Forrester 2006). The use of employee portals has been growing steadily and, despite restricted IT budgets in many companies, investments in portal solutions are still growing (Remus 2006). Although IT departments and decision-makers have to justify portal investments, a significant number of companies do not assess the actual benefits of their portal implementations (Brown & Mines & Moore & Barnett 2007).

Companies which do assess their portal benefits have often used monetary indicators such as return on investment (ROI) or total cost of ownership (TCO) and other cost-benefit analysis methods (White 2003). These success-measurement approaches do not take into account intangible impacts and intervening environmental variables. Clearly, in order to be comprehensive, success measurement would need to consider both tangible and intangible effects in order to truly judge portal success, to detect potential improvements, and to justify present and future investments in portal solutions.

To date, only a few studies have scientifically investigated single aspects of employee portal success such as user satisfaction (bin Masrek 2007, Sugianto & Tojib & Burstein 2007) and service quality (Cheung & Lee 2005). None of the reviewed studies examined employee portal success comprehensively and in an integrated way. The dominant model for measuring IS success is the DeLone and McLean IS Success Model (DeLone IS Success Model) (DeLone & McLean 1992, DeLone & McLean 2003). It is considered a sound basis for measuring employee portal success, as it is a comprehensive evaluation framework with validated measures and associations; it has also been applied to several types of IS (Urbach & Smolnik & Riempp 2008).

In this paper, we report on our development of a conceptual model, based on the D&M IS Success Model, which considers the specific requirements of employee portals. Where possible, we employ existing measures that have been tested and proved. The following section 2 describes the theoretical foundations of employee portals and a literature review on measuring IS and portal success. In section 3, we explain how we developed our employee portal success model and discuss the characteristics of its success dimensions. Section 4 outlines our steps for validating the survey instrument applying a card-sorting and item-ranking approach as well as conducting a survey trial. The future validation of the survey instrument and the assessment of the measurement model are presented in section 5. To conclude, we summarize the paper’s contribution, refer to the limitations, and present suggestions for additional future research.
2 FOUNDATIONS

The starting point for developing the conceptual model for assessing employee portal success was studying the existing research in the field. We thus reviewed relevant literature on employee portals, information systems success, and existing approaches for evaluating portals.

2.1 Employee portals

Employee portals can be regarded a specific type of the broader concept of enterprise portals. The latter will therefore be discussed first. In this context, we use corporate portal, enterprise information portal, business portal, and enterprise portal interchangeably (Dias 2001).

An early definition of a portal in the corporate context appeared in a Merill Lynch report (Shilakes & Tylman 1998). In this report, an enterprise (information) portal is considered an application that primarily integrates the company’s information and provides users with a single interface to this corporate information. Subsequent definitions tend to include the integration of collaborative applications such as e-mail and calendars (Eckerson 1999). Current enterprise portals not only integrate information and simple tools, but also business applications and processes (Chan & Liu 2007, Daniel & Ward 2005). In summary, enterprise portals have evolved from low-end intranets into highly integrated IS. Today, such portals enable the integrated support of information, communication, applications, and business processes.

Enterprise portals can be classified in terms of their target user group as supplier, customer, and employee portals. Ideally, these three types have the same technical infrastructure. Thus, organizations effectively have one portal with different “windows,” that give each user group access to specific functions that are relevant to it (Riempp 2002).

Before portal technology was available, the web-based intranet was a popular tool for building work force commitment (Azzone & Bianchi 2000). Although it yielded benefits for organizations in this regard, these intranets lacked personalization, offered poor navigation, and did not provide centralized access to information, which often led to losses in productive employee time. To overcome these problems, organizations began to implement employee portals (Tojib et al. 2006).

An employee portal is a web-based interface to access personalized information, resources, applications, and e-commerce options. Employees can access a range of internal and external information from their computers through a network connection. They are provided with relevant proprietary information, displayed in a password-protected setting (Sugianto & Tojib 2006). In addition, business applications are increasingly integrated into employee portals. Thus, in many organizations, the role of the employee portal has become crucial, especially when an entire business process can be completed through the use of the portal. In some organizations, an employee portal is the primary tool through which employees do their work (Tojib et al. 2006).

Ideally, employee portals provide a number of benefits to organizations and employees. These include:
- structured access to enterprise information;
- common and personalized views as well as collections of portal elements;
- improvement of organizational information gathering as well as knowledge acquisition and management;
- improvement in employee productivity;
- improvement of corporate communication; and

Our literature review shows that employee portals have received some attention, but that there is a lack of empirical studies to confirm the assumed benefits of employee portal use.
2.2 Research on measuring IS success

The IS literature provides several definitions and measures of IS success. As DeLone and McLean (1992) state, there are nearly as many measures as there are studies. Obviously, there is no ultimate definition of IS success. Since there are different stakeholders who assess IS success in an organization (Grover & Jeong & Segars 1996), each group has a different definition. From a software developer perspective, a successful IS is completed on time and under budget, has a set of features that is consistent with the specifications, and functions correctly. Users may find an IS successful if it improves their work satisfaction or work performance. From an organizational perspective, a successful IS may contribute to the company’s profits or create a competitive advantage. Consequently, success is always assessed from a certain stakeholder’s point of view. Furthermore, IS success also depends on the type of system being evaluated (Seddon & Staples & Patnayakuni & Bowtell 1999).

In order to provide a more general and comprehensive definition of IS success, one that covers these different perspectives, DeLone and McLean (1992) reviewed existing definitions of IS success and their corresponding measures, and classified them into six major categories. They then created a multidimensional measuring model with interdependencies between the different success categories. The D&M IS Success Model received much attention from IS researchers. Since its publication, many researchers have treated IS success as a multidimensional construct and have measured it as such (Urbach et al. 2008).

Motivated by DeLone and McLean’s call for further development and validation of their model, many researchers have attempted to extend or respecify the original model. A number of researchers have claimed that the DeLone and McLean Model is incomplete; they either suggest that further dimensions should be included in the model, or they present alternative success models (Seddon 1997, Seddon & Kiew 1994). Other researchers have focused on the model’s application and validation (Rai & Lang & Welker 2002). Although some weaknesses have been revealed, the D&M IS Success Model has become a dominant model for measuring IS success (Hu 2003).

Ten years after the publication of their first model, and based on the evaluation of the many contributions to it, DeLone and McLean proposed an updated IS Success Model (DeLone & McLean 2003). The updated model consists of six interrelated dimensions of IS success: information, system and service quality, (intention to) use, user satisfaction, and net benefits. It can be interpreted as follows: A system can be evaluated in terms of information, system, and service quality; these characteristics affect subsequent use or intention to use and user satisfaction. As a result of using the system, certain benefits will be achieved. The net benefits will (positively or negatively) influence user satisfaction and further information system use.

The updated D&M IS Success Model appears to be a sound basis for measuring the success of employee portals because:

- it is a comprehensive evaluation framework;
- the proposed associations have been validated by a large number of empirical studies;
- there are many validated measures for the proposed success dimensions that can be reused;
- it has been applied to several types of information systems;
- web-based systems other than employee portals have been evaluated by applying this model; and
- it is the dominant evaluation framework in IS research (Urbach et al. 2008).

2.3 Research on portal success

Existing measurement approaches to assess portal success in practice usually utilize monetary indicators. Typical examples are return on investment (ROI), total cost of ownership (TCO), or other cost-benefit analysis methods (White 2003). Building business cases on the basis of such indicators is questionable because non-monetary impacts and intervening variables are not taken into account.
There is little documented research on employee portal success measurement. Some studies investigate single aspects of employee portal success, but none of the studies we reviewed took a comprehensive, integrated approach.

In order to measure user satisfaction with employee portals, Sugianto et al. (2007) proposed the model of the B2E Portal User Satisfaction (B2EPUS) on the basis of the End-User Computing Satisfaction measure (EUCS) developed by Doll and Torkzadeh (1988). Another approach for assessing user satisfaction with campus portals was proposed by Bin Masrek (2007) on the basis of an extract of the updated D&M IS Success Model (DeLone & McLean 2003). Focusing on the user-perceived service quality of web portals, Yang et al. developed and validated an instrument based on different conceptual models in the areas of IS and technology adoption (Yang & Cai & Zhou & Zhou 2005).

In our review of the IS success literature, we found no study specifically aimed at comprehensively examining the success of employee portals. Consequently, we built our measurement model for employee portal success on the above-mentioned focused studies. Secondly, we extended our literature review by analyzing studies focusing on the evaluation of web-based systems (WBS), which are similar to employee portals. Additionally, since employee portals have commonalities with web-based knowledge management (KM) systems, we reviewed empirical studies focusing on KM system success with the objective of adapting measures to our conceptual model.

3 CONCEPTUAL MODELING

Since employee portals are widespread, but there is no known comprehensive, integrated theoretical framework for measuring their success, we propose a conceptual model of employee portal success that is based on the D&M IS Success Model (DeLone & McLean 2003).

3.1 Success dimensions

We modified the dimension definitions of the D&M IS Success Model for application in the employee portal context. To this end, we examined the definitions of the original success dimensions, contrasted them with the specific characteristics of employee portals, and merged the different points of view into a revised classification scheme. Consequently, we propose a conceptual model for measuring employee portal success consisting of the following success dimensions:

- **System quality**, which consists of measures of the employee portal as a system in itself. It considers performance characteristics, functionality, and portal usability, among others.

- **Information quality**, which focuses on the quality of the employee portals’ output, (i.e., the quality of the information that the portal provides) and its usefulness for the user. Information quality has been shown to be a prominent success factor when investigating overall IS success, especially in the context of web-based systems (Schaupp & Fan & Belanger 2006).

- **Service quality**, which includes measures of the overall support delivered by the service provider. In the context of employee portals, this success dimension covers aspects such as responsiveness, reliability, empathy, competence, and the overall quality of the portal owner.

- **Portal use**, which measures the perceived use of the employee portal by a company’s staff. To assess use in this context, we propose to measure the perceived time of use of the different functionalities such as e-mail, searching for information, as well as the overall portal usage time. Since we assume that portal use is typically non-mandatory (Tojib & Sugianto & Sendjaya 2008), we believe that perceived use is a sufficient indicator. Thus, we omit measuring the intention of using the portal as a surrogate for portal use.

- **User satisfaction**, which is the affective attitude of the employee who interacts directly with the portal towards the portal (Doll & Torkzadeh 1988, Tojib et al. 2006). User satisfaction is considered one of the most important measures when investigating overall IS success. The
proposed construct evaluates adequacy, efficiency, effectiveness, and overall satisfaction with the portal.

- **Individual portal benefits**, which subsume measures of the perceived individual benefits gained by the employee through the use of the portal. These benefits cover aspects like task performance, job efficiency, improved use and exchange of knowledge, improved communication, and overall usefulness.

With this model, we focus on individual performance impacts as the final dependent variable of interest – instead of organizational performance. The difficulty of measuring the organizational impact of individual IS initiatives has been discussed and demonstrated by many researchers (e.g., Gelderman 1998, Goodhue & Thompson 1995). Thus, we do not consider the organizational impact in our model, although the impact of utilizing employee portals is very likely greater than the individual impact.

### 3.2 Conceptual model and hypotheses

Our research model for measuring employee portal success on the basis of the updated D&M IS Success Model is shown in figure 1. The proposed model assumes that system, information and service quality are linked to user satisfaction and to use an employee portal, and that these, in turn, influence the portal’s benefits for individuals. Furthermore, user satisfaction and portal use are interrelated. In addition, we propose knowledge intensity of tasks, the level of process standardization, and the organizational culture with respect to using the employee portal as control variables, since we expect that these factors may influence some of the constructs and relationships.

![The Conceptual Model](image-url)

*Figure 1. The Conceptual Model*
3.3 Constructs and measures

In order to operationalize the constructs of the conceptual model, we follow the recommendation by various authors (e.g., Bharati & Chaudhury 2004, DeLone & McLean 2003, Sugianto & Tojib 2006) to use tested and proven measures if possible. Thus, we adopted items identified in previous studies and modified them for use in the employee portal context. For measuring system, information, and service quality we used second-order multidimensional constructs as discussed by Petter et al. (2007). The sub-constructs are operationalized with reflective indicators, and the relationships between sub-constructs and constructs under study are formative. Portal use, user satisfaction, and individual portal benefits are measured as reflective first-order constructs.

After surveying the literature for existing instruments, initial item pools were created for each of the constructs. We added additional items where important aspects of the content domain of a construct have not been covered. In doing so, we followed suggested item writing principles found in the literature (e.g., Dillman 2008). All of the constructs used within the study except portal use should be measured using a seven-point Likert-type scale (1 = Strongly disagree, 7 = Strongly agree). Portal use should be measured in terms of actual daily use and the frequency of use. In table 1, we present an overview of the items we have used to operationalize the constructs.

Table 1. Measures of the Item Pool

This initial item pool will be revised and developed further in the validation phase of the research project. We will start with a larger item pool than we will use in the final questionnaire and successively reduce the number of items. A generally suggested minimum is three questions per construct (Kankanhalli & Tan & Wei 2005). Because of the relatively high number of constructs in our research model, we consider a number of three items per each of it as reasonable, since a larger number would result in a too long questionnaire that probably leads to low response rates.
VALIDATION OF THE SURVEY INSTRUMENT

Our development of the conceptual model on the basis of theoretical considerations is the first step of a long-term research project that seeks to present a reliable and valid instrument for measuring the success of employee portals. Before it can be applied in practice, it needs further development and validation. We apply methods of classical test theory to validate the survey instrument and assess the measurement model (Churchill Jr 1979). The first step to be taken prior to the field studies is the validation of the survey instrument.

4.1 Content and construct validity

The main focus of the first stage was to ensure content validity of the item pools, i.e. the degree to which the pools reflected all relevant facets of their underlying constructs. We therefore discussed the choice of items with a group of four IS experts. Based on the experts’ feedback both the choice of items as well as the wording has been refined. Finally, we chose four items for each of the sub-constructs and a larger set of items for the other constructs.

Our next step targeted the refinement of the items into scales with a high level of construct validity. We used a card-sorting and item-ranking approach similar to the one adopted by Davis (1989), Moore & Benbasat (1991), and Kankanhalli et al.(2005). In this approach, a group of IS researchers and practitioners, serving as judges, are given cards with the definition of a target construct, as well as cards with one of the items. Each judge is (independently) asked to assign each item card to one of the construct cards. Items that are sorted into the same category by more than half of the judges can be regarded to having face validity for that construct. If items are consistently assigned to one construct, they can also be considered to demonstrate convergent validity with their construct and discriminant validity with the other constructs. Items not meeting the validity criteria can be considered candidates for modification or deletion. In a second stage, each judge is asked to rank the items according to their representativeness in respect of the specific construct. Items considered to represent the construct weakly are also candidates for modification or deletion.

Instead of cardboard cards, we used a computer-based spreadsheet solution to support the sorting procedure. Eight experts (other than the experts that were consulted to develop the items) participated as judges, who were independently asked to assign each item to one of the constructs or an extra “Ambiguous/Unclear” category. Additional space was provided allowing for comments and suggestions on the items. The card-sorting and item-ranking approach was limited to the sub-constructs of system quality, information quality, and service quality for two reasons. Firstly, in contrast to the other constructs, existing items have been modified to a high degree and additional items have been created. Secondly, a sorting and ranking of all items of the initial pool was not acceptable to the judges.

To assess the consistency of the assignments, we used the item placement ratio (IPR), i.e. the percentage to which judges have assigned items to the intended target construct. In order to increase the construct validity and to shorten the questionnaire, we eliminated the one item of each sub-construct with the lowest IPR. In cases where this criterion was ambiguous, we drew on the results of the item-rankings and eliminated the item with the lowest average ranking. The results for both the initial and the revised item pools are reported in table 2. The overall IPR of .91 for the revised pool indicates satisfactory item placement consistency. However, the operationalization of the assurance sub-construct with an IPR of 42% appeared to be problematic, although we used well established items. Accordingly, we modified the wording of the items on the basis of the judges’ feedback.

Table 2. Item Placement Ratios

4.2 Test trial

In the next stage, we combined the initial item pool into a draft survey instrument for pre-testing. The questionnaire therefore had to be translated in the target language of the companies that will participate in the upcoming field surveys. The committee (or parallel) approach was used for this translation (Harkness & Schoua-Glusberg 1998). Three translators competent in the target language and in the skills required for survey work translated the questionnaire independently. At a reconciliation meeting, the translators compared the translations, reconciled discrepancies, and agreed on a final version that was considered the best of the independent translations.

In order to ensure the quality of the survey instrument design and presentation, we discussed the draft again with four IS experts and modified it according to their feedback. As a final pre-test prior to using the survey in the field, the draft instrument was trialed with a group of 20 information systems PhD students and faculty members serving as test users. The test users were asked to refer to their institute’s intranet application which acts as an employee portal when completing the questionnaire. One objective of this first field test was to confirm the results of the card-sorting and item-ranking approach as well as getting additional feedback from the respondents. The full model was estimated using Partial Least Squares (PLS) based on the sample data. Although the sample size of 20 is quite small, the model should possess sufficiently high statistical power to evaluate the reliability of the reflective indicators of the sub-constructs.

The indicator loadings of the items on their respective construct were trialed first to assess the quality of the scales. Items with a loading below .500 can be considered too unreliable (Straub 1989). Based on this criterion, we considered four of the items as candidates for deletion. Surprisingly, none of the four items were deletion candidates at the card-sorting and item ranking stage. In addition, the significance of the indicator loadings was tested using a bootstrapping procedure. Almost all of the loadings were significant at the .001 level. However, the loadings of all four items for ‘System Quality: Availability’ did not show significance on the commonly accepted .05 level. Thus, these items have to be modified for the final questionnaire.

Furthermore, we tested the model for convergent validity by analyzing average variance extracted (AVE), composite reliability (CR), and Cronbach’s alpha. AVE indicators above .500 suggested that
all of the factors possess adequate convergent validity. CR and alpha values for all scales were above the generally recommended level of .700 (Bruce & Gary & Terry Anthony 2005).

5 RESEARCH IN PROGRESS

Since the sample size of the first survey trial was very small, we will explore the survey instrument in a further field test. Data will be obtained from the employees of an international development organization through a web-based survey. The organization employs about 10,000 staff in more than 120 countries. In the first stage, the survey will be conducted at the head office, where around 1,000 people are employed. A non-probability convenience sampling method will be used. Even with the disadvantages inherent in a non-probability sample, it is deemed the most suitable method to achieve a response rate that is as high as possible.

Following the validation guidelines of Straub et al. (2004) and Lewis et al. (2005), we will test the measurement model for reliability, nomological validity, convergent validity, discriminant validity, and predictive validity. We will apply commonly employed decision rules. Given an adequate measurement model, the structural model will be analyzed to test the associations hypothesized in our research model. In order to further test and challenge the model, additional field studies will be conducted in several organizations in different countries. Furthermore, a benchmarking study will be conducted on the basis of the validated model.

6 SUMMARY AND CONCLUSIONS

In our review of the IS success literature, we found no study aiming to comprehensively evaluate employee portals. Based upon the D&M IS Success Model, we propose a model for measuring employee portal success. Furthermore, we present our steps for the development and validation of our survey instrument. Research methodology for further developing and validating the model is proposed.

Our research presented here is limited in that the proposed model is merely based on an extensive literature review, on our experiences, and on expert feedback. The results are the foundation for future empirical work in this area. First validation steps are presented in this paper. However, the model needs further development and validation before it can be applied in practice. Future research within this long-term research study will focus on empirically validating the conceptual model and on applying it in practice, as described in this article.

Having finished our research, we believe that our model together with the survey instrument will be valuable for practitioners who want to evaluate employee portals in their organizations. Furthermore, we hope to expand the IS success literature by presenting a complete validation of the updated D&M IS Success Model in the employee portal context.

Abstract

This paper presents an exploratory study into the use of real-time communication (RTC) systems to support distributed work. Motivated by the authors’ dissatisfaction with theories assuming individually rational actors, the paper suggests the idea of informed presence to capture phenomena emerging from employees’ increasingly computer-mediated engagement with their work environment. Four case vignettes are presented to illustrate different communicative strategies that develop in response to presence availability updates generated by RTC systems. Drawing from Goffman’s microsociological idea of interaction order and Zuboff’s seminal work on computer-mediated work, the findings indicate the limitations of approaches such as information richness theory in understanding real-time communication in organizational settings. More research is needed to elaborate the implications of informed presence on distributed work and coordination of knowledge workers.

Keywords: communicative strategy, distributed work, presence, real-time communication, RTC
1 INTRODUCTION

This paper presents an exploratory study into the use of real-time communication (RTC) systems to support distributed work. Real-time communication systems are a distinct type of computer-mediated communication tools emerging from the convergence of telecommunications and groupware systems. The applications typically combine a number of synchronous and asynchronous channels such as instant messaging, voice over IP calls, conferencing, and file transfers in addition to incorporating presence availability information (Frößler and Klein 2006). Systems such as Skype, IBM Lotus Sametime and Microsoft Office Communicator are already in use in numerous organizational settings and their proliferation is projected to continue in the coming years (Dewing 2008, Gantz et al. 2007, Gantz et al. 2008, Lyman and Varian 2003).

Previous studies on real-time communication in organizational settings have made several interesting findings regarding the function, content and style of communication. However, paid to understanding how these systems reframe the communicative arrangement employees find themselves at work. We argue that the material makeup of RTC tools differs from antecedent systems (such as email) to an extent that warrants re-examination. More specifically, the systems incorporate real-time presence information unlike any previous media. It is our contention that common approaches such as information richness theory (Daft and Lengel 1984) used to explain media choice are inadequate to understand these differences.

The paper puts forward an idea of informed presence as a way of capturing organizational phenomena revolving around shifts in the interactional arrangements. It also discusses emerging communicative strategies employees harness to cope with interaction in an increasingly digital working environment. We understand communicative strategies as the ways individuals choose a particular media and establish channels in order to communicate with others. The argument draws from the microsociological idea of interaction order (Goffman 1983, Knorr Cetina and Bruegger 2002) and the discussion on information as the substratum of organizing (Kallinikos 2006, Zuboff 1988). In order to substantiate our views we present four case vignettes representing distributed knowledge work, both in small and in large organizations in the information and communication technology industry.

Our contribution is primarily targeted for the study of distributed work and real-time communication in organizational settings, but we believe the findings could as well be useful in Computer-Supported Cooperative Work (CSCW) and Human-Computer Interaction (HCI) research. The reader should, however, be aware of the tentative nature of claims made in the paper. In other words, we do not claim to provide unquestionable evidence for our argument. The empirical data is drawn from two separate, ongoing PhD thesis projects that, nevertheless, have come to point to similar insights. This is at the same time promising but also introduces some methodological difficulties. Moreover, the authors’ shared dissatisfaction with media choice theories based on the assumption of individually rational behaviour was strengthened by our empirical observations and to that end we think it is useful to apply fresh ideas to the topic.

The paper is structured as follows. The next section provides a concise summary of existing literature surrounding real-time communication systems in organizational settings and outlines the idea of informed presence. The third section presents four case vignettes to illustrate emerging communicative strategies through which employees use technological information to be present to each other. The fourth section reviews observations on informed presence and elaborates the communicative strategies that the employees developed across the cases. Finally, we identify possible avenues for future work.
2 LITERATURE REVIEW

It might be assumed that developing communication genres such as instant messaging or voice over IP calls, loosely grouped together as real-time communication, make no significant difference vis-à-vis practices revolving around email. Work-related, interpersonal communication becomes quicker and possibly more efficient, but it is essentially more of the same. In this section we first briefly review extant literature on real-time communication and discuss presence information as a key affordance that sets RTC apart from email. Finally, we sketch informed presence as a perspective to capture organizational implications of real-time communications.

2.1 Literature on real-time communication

The current understanding of the use of RTC systems in organizational settings derives mainly from studies on instant messaging (Cameron and Webster 2005, Huang et al. 2007, Isaacs et al. 2002, Nardi et al. 2000, Quan-Haase et al. 2005). Instant messaging has been found to take place often in a polychronic situation in which the employee engages simultaneously in several different conversations. It can speed up the exchange of information and support new forms of collaboration, but instant messaging has not been found to eradicate social distance or status differences between people. Users typically perceive instant messaging to be more informal than email.

Studying individual communication channels in isolation tends, however, to provide an impoverished view on how technologies mediate social relationships (Licoppe 2004). In the age of internet, employees can choose from a diverse and expanding portfolio of tools and channels to get in touch with each other (Aducci et al. 2008). The variable geometry of work communication easily escapes studies focused narrowly on individual channels. The same employee can take care of equivalent tasks through different media and different employees can use the same media for a variety of different purposes. Most importantly, RTC systems overlay this diversity with situational metadata intended to support individuals in their attempts to instigate and make oneself available for mediated communication with others.

RTC systems provide a status indicator and a short mood message that are used to convey one’s immediate availability to other users. This sets RTC apart, for instance, from email (Quan-Haase et al. 2005). Even relatively simple RTC systems are known to generate awareness of remote colleagues ongoing activity in a number of ways (Riemer et al. 2007), and the sensation of mediated co-presence has been found to play an important role in distributed work (Frößler 2008, Schmidt 2002). Nardi et al. (2000) identified certain outeraction practices, in contrast to the content of the interaction, by which people reach out to others in order to manage their interactions. Outeraction encompasses negotiations about the availability and choice of appropriate media in order that individuals can communicate effectively. Mediated presence has been available in planned occasions using dedicated technologies such as videoconferencing systems. More recently, however, real-time presence information has become increasingly integrated into generic technologies, such as workstations and mobile devices, gradually turning it into a constantly active background condition. RTC applications are often configured to launch and set the user’s online status automatically.

2.2 Computer-mediated presence

Researchers in the field of Computer-Supported Cooperative Work (CSCW), Human-Computer Interaction (HCI) and virtual environments have studied presence awareness since the mid-1980s (Luczak 2002, Makropoulos et al. 2007). The concept refers to the phenomenon of employees effectively coordinating their work without making a cognitive effort to align their interdependent acts (Schmidt 2002). Under such circumstances people are able to take heed of each other’s unfolding activity while focussing on their individual tasks.
Several conceptual distinctions have been put forward to describe the phenomenon. *Presence* is the experience of being in and interacting with a place other than the one is physically located in, and *co-presence* refers to carrying out this process jointly with others (Schroeder 2006). *Connected presence* is the degree to which one’s relationships are mediated in environments in which presence and co-presence are experienced (Licoppe 2004). *Presence availability* refers to practices around the instruments such as the status indicator that are at actors’ disposal to signal their availability and eventually come together in the mediated setting (Frößler 2008).

It is, however, too limited to frame mediated presence merely as a question of efficient coordination. Whenever two or more people enter into each other’s presence they enact a distinctive social institution that microsociologist Goffman (1983) labelled *interaction order*. The basic sociability of humans entails that in order to cope with immediate availability to each other people has to enact a set of institutionalized rules how to co-produce an orderly encounter. Knorr Cetina and Bruegger (2002) observed a similar phenomenon in a technologically mediated, real-time environment of currency traders buying and selling currencies on financial markets. They found that market transactions were embedded in situations distributed across organizations, continents and timezones leading the authors to distinguish between the embodied *face-to-face presence* observed by Goffman and technologically mediated *response presence*. The awareness of other’s presence results in accountability of interaction, as participants are tied to a moral order knowing that everyone is aware of everyone else’s acts. Erickson and Kellogg (2000) describe systems that facilitate normative, immediate commitment to those who are present to us as socially translucent.

### 2.3 Media choice in the context of informated presence

Computer technology differs from most other machineries in that it does not simply automate tasks, but, crucially, renders organizational processes, events and objects visible in a way that opens up new avenues of acting upon them. Zuboff (1988) labelled the latter as informing in contradistinction to the former in her seminal study on computer-mediated work. Processed by complex and to degree unpredictable corporate information infrastructures, the importance of technological information in organizational matters is steadily growing (Ciborra et al. 2000, Kallinikos 2006). The widespread availability of RTC systems holds a promise of going beyond informated organizational processes and objects of work. In RTC systems the availability of employees, allowing them to engage with each other across space, is turned into technologically mediated information. Presence availability updates constitute “a difference which makes a difference” being thus potentially informative (Bateson 2000, Kallinikos 2006). This is what we call *informated presence*.

The ephemeral presence availability updates generated by RTC systems are not persistently stored and have very little semantic content. This may lead an observer to ignore them in favour of the content of interaction. For instance, information richness theory (Daft and Lengel 1984), which posits that some media are richer than others, and managers, by default, prefer richer media for communication, has serious difficulties analysing this type of informativeness. The theory understands the richness of a medium as a function of its capacity to transmit cues such as body language, voice tone, and inflection. Consequently, alternative theories have been put forward to explain media choice. Straub and Karahanna (1998) researched media choice based on actors’ prior knowledge of which media were available to the person being contacted. They suggested a theory based on task closure, so that individuals choose media that they know will likely result in completed communication sequences.

### 3 CASE VIGNETTES

In this section we present four case vignettes to illustrate our argument with communicative strategies employees deploy in the context of informated presence. In order to explore the topics outlined in the previous section we chose four organizational settings in the information and communication technology sector that had adopted real-time communication system for professional purposes. The
aim of the sampling was to generate rich data on practices revolving around organizational RTC while attributing less weight on the representativeness of our sample. We either knew each setting from our previous engagements or we carried out few days of participant observation to familiarize ourselves with them. The primary data corpus resulted from nineteen recorded and transcribed interviews, four to five in each setting, focusing on how employees get hold of each other and how they communicate in the context of distributed work. The nature of work in each case was essentially collaborative. Individuals had to actively coordinate their activities on an ongoing basis with remote others.

Two of the four case studies took place at multinationals, TelCo and AppsCo, both of which had deployed the same corporate RTC system. Since the companies employed tens of thousands of individuals, the interviews focussed on particular teams. IntStart, in contrast, relied by and large on freely available Internet applications. The employees used Skype as well as other RTC applications largely driven by their individual preferences resulting in a remarkably heterogeneous environment. PeriphCo employees had installed Skype on their workstations on the initiative of the company head. IntStart and PeriphCo organizations were radically co-located (Olson et al. 2002) so that their mediated communication was generally oriented outside the company while at TelCo and AppsCo a significant proportion of internal communication was mediated.

In descending order, the general perceived order of time spent on mediated communications activities in TelCo and AppsCo was email, followed by conference calls, instances of synchronous communication (voice calls and instant messaging) and then other modes of communications. All in all, there was within TelCo and AppsCo a significant variation in interviewees’ responses regarding whether they reported using instant messaging more than voice calls or vice versa. Whilst the employees of IntStart considered Skype as a necessary part of their communication toolbox, email and fixed and mobile calls were perceived to be their most important modes of communication. PeriphCo had adopted Skype as the primary communications system and made an ample use of its features including instant messaging, voice and conference calls, file transfers and text messages to mobile phones. Email and other modes of communication were still used in addition to RTC. Despite variation between the entire portfolio of tools and their relative importance between the cases, real-time communication was an integral part of communicative practices in each case.

3.1 Case TelCo

TelCo is a large, traditional telecommunications operator offering consumer and corporate services in several countries. The interviews took place in a team developing solutions for mobile work in large corporations. Informants were a mix of home and office workers whose work required keeping in touch with other sites and occasionally spending time with customers. There were lots of commonalities in the use of mediated communication between TelCo and AppsCo. Amongst those interviewed, email generally remains the primary mode of business communications. It was felt that the asynchronous nature of email suited busy people, because they could respond on their own terms. Email was also perceived to allow an audit trail and facilitate the management of self-expression. The fact that email hands control to the receiver in terms of response meant, however, that questions could be skirted around, misconstrued and manipulated.

In comparison with the other cases, hierarchical control culture came most clearly through in the TelCo interviews. For instance, the informants reported using fixed line communications whenever possible, as the use of mobile was monitored to control costs. Managerial control was also implicated on online status indicator in the corporate RTC system that was used to give the impression of being a good employee. The description of status indicator usage by a lower grade employee expressed a clear awareness of his relative position:

“I’ve never set my presence to ‘Do not disturb’. […] I do see people who have done that and generally it does put a bold message up to say ‘I cannot be contacted’. But I don’t like to do that. I think its fear in a way. I don’t really want my assignment managers or senior
people looking at it and saying ‘Why doesn’t he want to be disturbed, what’s so important that he doesn’t?’ [...] I guess sometimes I have logged out of [RTC application] instead of having it as do not disturb.”

Calls were thought of being more persuasive and suitable for debate and asking someone to get something done than email. Often misunderstandings and ambiguity that occurred through email had to be cleared up by a phone call. The dialogue enabled by a voice call was perceived to provide more control over ambiguity compared to other modes of communication. Calls were typically made from deskphones instead of the RTC application that was used mainly for simple instant messaging exchanges. Instant messaging was often perceived to be best suited for exchanging short bits of time critical information. It was also treated as urgent when received, which generally accorded a quick response. A time-pressed project manager described his use of instant messaging:

“I probably use it maybe at least a few times a day with various different people. It does depend on what work you’re doing at the time. IM tends to be used at the early stages of projects as well and subsequent meetings. Because you’ve got lots of unknowns and you’ve got lots of questions that you have to ask. To save time [...] maybe send out a quick IM [...] It’s very quick, maybe focused questions, but then as the project progresses and the maturity of understanding increases, you probably tend not to have those IM conversations until later on, when things are getting a bit close to completing then you might want to just double-check, you’re finalising what you’re doing at work people are, the wrap up type of stuff.”

Informants noted, however, that busy people avoided taking calls, as it was felt that asynchronous modes such as email gave them more control as to when they responded to instances of communication. The majority of employees had incoming calls routed via their virtual number and few advertised their mobile numbers as their preferred point of contact. The fixed number for contact at home was only given to a select few. The preference for voice calls coupled with the sporadic availability of people to take up calls produced, interestingly, a specific practice around RTC application.

“I quite often, as behaviour, might look on IM to see – track down where somebody is, before I decide whether I ring them or not.”

Despite the more limited use of RTC for the actual interaction at TelCo, it was useful as an outreaction device for assessing and negotiating recipient’s availability in other channels. Individuals were clearly conscious of the availability status they displayed and they said to respect the status of others. In other words, even in the setting in which RTC was used in such a limited manner, being in the system demanded attention to the presentation of self and the others through presence availability information. This was the case both with light and heavy users of RTC.

3.2 Case AppsCo

AppsCo is one of the world’s leading software development companies producing a range of office productivity applications. The interviews took place within the team concerned with the product management and marketing of these applications within the UK. Whilst the majority of interviewees were based in the same office, projects within the company often drew together people from various domestic and international sites. In contrast to TelCo, the company is less hierarchically controlled and encourages flexible working, so many employees often spend a day or two a week working from home. The widespread use of RTC system was implicated in many telecommuting practices. The system was perceived to engage employees with the work environment to a significant degree as is illustrated by the following comment by an administrator within AppsCo:

“If I do take my laptop home, it’s normally because I need – you know I’m waiting for something - a call. So then I’ll just check it a period in the evening. [...] But I do try and switch [RTC application] off because it’s just too tempting for other people to contact you.

Although sometimes you get contacted and it’ll be by somebody saying “what are you doing working at this hour?”
Since AppsCo was a multinational with employees working in different time zones around the globe, there was a realisation that switching on the computer in the evening and becoming present on the corporate RTC resulted easily in being drawn into work with colleagues in other settings. Instigating calls was much less popular at AppsCo than in TelCo as many employees preferred instant messaging over voice calls that were viewed as the least effective means of communication within the company. Interestingly, while people were often simply too busy to pick up the call, email was considered by some too slow. Online presence had a clear impact on media choice as in the TelCo case, but with quite different outcomes.

“If they’re online, in fact, invariably if somebody is online, I won’t send them an email I’ll IM them. I’ll just click on the globe and instead of sending them email, I’ll IM them instead, generally.”

Voice calls were said to be made most often when away from the desk, contacting a person for the first time or reaching people external to the company - especially when handling a sensitive issue. Much like TelCo case, it was felt that voice calls, along with instant messaging, had the advantage of more control, the feedback from intonation and other contextual clues help cut through the confusion that can occur when an email veers off track. There was a sort perception of information richness related to voice calls, but this was not always an advantage. Employees often preferred instant messaging because they found conversations over this medium more succinct avoiding the pfaff of having to waste time going through social grooming in a channel saturated with unnecessary contextual information. The synchronous nature of instant messaging nevertheless provided more control over the course of communication.

“Before, there was a lot of email so my emails have reduced and my instant messaging traffic has gone up. [...] There are probably slightly more [transactions] because they are shorter and probably because you would break up one - would’ve been one traditional email thread, be it perhaps many smaller interactions. The topics, maybe a number of things that you’ve discussed, might be constant. [...] It’s chopped up into smaller, more nimble interactions that we try to communicate with bigger single transactions on email. So the fidelity improves because you get more chances to correct the direction of your conversation rather than once a day, or how often you respond to email.”

The shift from email to instant messaging was perceived to divide communication into ever-smaller segments. This enabled to tap into smaller and smaller in-betweens in the busy managers schedules – often facilitated by presence availability updates. A consensus appeared to be an emerging in terms of which communications mode should be used based on the availability status of the recipient. For instance, when the availability status of a correspondent was set to “In a meeting”, a common strategy was to approach them with an instant messaging. The awareness that that a person is going to a meeting by underground without network coverage in London enabled to send SMS message to be delivered within those few free minutes when the person appears overground and walks to the meeting. This kind of communication needs to be made of very concise messages in order not to overwhelm the recipient. Tapping into such bits and pieces of information may not seem relevant, but, for the following informant, it was precisely what he needed to keep things rolling.

“A lot of the projects I do have lots of dependencies on other people. But the dependencies are quite small. If I just need an answer that’s ‘yes/no’, ‘it’s £27’, ‘here’s a code’, ‘speak to this person’, waiting for everyone to answer that in their own email schedule really can divert your day. And you can wait two or three days for someone to reply to an email saying ‘I’m not the right person to speak to’.”

The bulk of email processing was generally done in the company first thing in the morning and late in the working day. The responses were often received at the end of the business day and it was felt that it was easier to ignore email than other modes of communication such as instant messaging. Waiting all day for a reply from a colleague, whose presence availability you could observe, felt too long. There was also a view amongst some interviewees that an instant messaging dialogue was less intrusive than calling or emailing someone, as it did not require one hundred percent attention. In
TelCo and AppsCo where many people sat in the meetings most of the day it enabled concurrent working in environments such as meetings and conference calls and, as in special cases, backchannel chats between subsets of people engaged in a meeting. In contrast to TelCo, the team interviewed at AppsCo represents corporate heavy users of RTC. Resulting from the different organizational setting the practices revolving around RTC were different, but they equally drew from the affordance generated by presence information.

3.3 Case IntStart

IntStart is a social enterprise founded in 2006 by five co-founders (the informants) with a mission to introduce a radical innovation in the educational sector while aiming to be financially profitable at the same time. The company develops and operates an internet-based platform to facilitate informal learning by matching individuals who are interested in teaching and learning various skills. In a stark contrast to corporations like TelCo and AppsCo, people were relatively free to use whatever tools available in Internet to get their work done at IntStart – including using Facebook and a range of consumer instant messaging systems for work-related communication. While the informants reported a number of idiosyncratic communication patterns and tools, email, both fixed and mobile phone, and Skype were used by everybody.

“It [Skype] is a sort of necessity rather than hey this is a really good idea, let’s get on and do it. It is kind of I need to, I have to, I have no choice.”

Having originally worked from various locations around the UK without a physical office space, the employees valued highly physical presence afforded by the newly acquired office. Resulting from this the importance of mediated communications in running the daily operations had diminished. Great deal of the daily activities revolved around the two big tables the company occupied in an open-plan office hosting several other organizations as well. In terms of advancing their common endeavour, being radically co-located at the same physical space was seen crucial. In order to enable the team to come physically together, the company relied, however, on distributed forms of work and RTC tools.

The informants reported having used real-time communication extensively before they had acquired the office space. Nowadays, RTC was still being used whenever the team members were working remotely or were travelling to meet different stakeholders. Status indicator was then used to signal availability between the remote team member and the core team at the office providing a sense of social cohesion. Long RTC conversations could emerge when distant team members were working simultaneously on the same software development issue or document. Questions about status indicator triggered elaborate accounts on how the informants interpreted each other’s presence information.

“A lot of people don’t respect other people’s business [status indicator state] very much. I like to think I do, but I think that it means that then you ask someone if they can talk, and they don’t have to reply if they don’t want to.”

Individual employees had different habits with respect to how they set their online presence. These ranged from some of the employees being virtually always online whenever their computer was turned on to others preferring to hide their presence availability status. The very possibility of broadcasting and having others observe one’s online presence was, nevertheless, something that employees had to relate to. Staying out from the digital work environment was difficult and, as in other cases, employees felt ambivalent towards the demands computer-mediated presence availability in the local setting.

“Now, partly because [colleague name] is at home, the others maybe not around, and we are using Skype a bit more internally for a sort of pinging documents, doing things like that. I just kind of leave it on. But I hate it because what immediately happens is that I then go off to have a meeting other side of the desk and hour later I found someone tried to Skype me because I forgot to change my status.”

Finally, the nature of start-up organization introduced an interesting twist to use of RTC and computer-mediated presence. The co-founders of IntStart had been and to some degree still are
simultaneously involved in other organizations. Real-time communication has enabled them to share their individual contributions – while sitting together at the office – across several organizations providing vital personal income before the company secured funding. In the case, presence information penetrates into the work of radically co-located team.

3.4 Case PeriphCo

PeriphCo develops computer peripherals such as headsets and webcams, and sells them to distributors throughout the world. The company is a subsidiary of an Asian manufacturing company that has its factory in Mainland China. Located in Northern Spain, PeriphCo office employs 7 people in a relaxed atmosphere. The informants included a product development manager, IT manager and the head of the company. In the fast-moving, highly competitive industry, everyday operations require coordinating projects with product designers, distributors and the main factory across the continents.

At PeriphCo Skype had become the preferred tool for many daily tasks. Employees used instant messaging, voice calls, file transfers and conference calls as part of their everyday tasks to interact with partners in Asia, Europe and North America. Email and mobile phones were still used, but the office had given up desk phones and all the calls were made using Skype. Informants also reported using Skype at the office to talk to a person next room. Voice calls and instant messaging were often used simultaneously, for instance, to clarify details, overcome language barriers and to leave a trail of what was said. The employees used the status indicator in Skype, but just like in the other cases they were ambivalent about it’s meaning because people did not respect it consistently. Mediated presence availability was felt to change the environment in which business was being done. In addition, the value of the system was perceived to increase as more partners adopted it. The head of the company explained how the RTC system intensified certain business relationships.

“I think the most interesting change I find about Skype as a business tool is that you find that when you become a Skype adopter you gravitate towards other people that use Skype. So that business I do, is more intense with other people that use Skype.”

PeriphCo had been evangelizing Skype for its partners as a preferred way of keeping in touch and took some pride in making others to use the system. Given the small number of employees, most of the people in the contact lists were from outside the company. In addition and in contrast to TelCo and AppsCo, employees did not perceive significant differences in how they used RTC with people from inside and outside the company. The fact that mediated presence gave information concerning the availability of others remote from the company offices, sometimes led to local matters taking second place to those at a distance. People had to occasionally disconnect from the system in order to focus on the local task at hand.

“The thing that I did not expect from Skype was that it is another level of ownership I did not expect. Even more so you become owned by the people you work with every day. So [partner name] owns me a little bit more because he knows when I am online.”

Whilst presence availability updates were open to interpretive flexibility, the interpretations had a common orientation: the current situation of an omnipresent other. Like IntStart employees, the informants sometimes reported using RTC to approach others even if they did not seem to be online, as they knew that some people had the tendency to hide their presence when online. Despite the interpretive dance around presence information, people seemed to have no choice but to dance.

“Getting to a buyer through a telephone is quite offensive, it is in English called a cold call. But send them a message over a Skype. You see they are online. They know that you know that they are online so they generally have to respond to it, but they can respond ‘I am busy now can I call you back later’, but at least you get a response.”

In the last excerpt, the head of the company describes, almost word-by-word the accountability mechanism discussed by Erickson and Kellogg (2000). Awareness of the other introduced an obligation, that, in turn, could be harnessed to elicit at least minimal response. Much like in TelCo and
AppsCo, the employees of PeriphCo felt generally that RTC offered more flexibility in terms of choosing and negotiating the right time and channel for interaction, both in terms of the task content and in terms of the situation of receiver.

4 SUMMARY OF FINDINGS AND DISCUSSION

The minuscule digital events informing who is online, in a meeting, at the airport and so forth, both frame employees' attempts to get hold of each other and make their engagement in the work environment visible in a new way. In all of the cases, real-time presence information mediated the engagement of employees with their work environment resulting in different performances depending on, for instance, management culture, spatial arrangements and the type of work. The event of becoming available, change in user’s online status, could perhaps be perceived as a question: "Should I contact this person now when he is available?" Knorr Cetina and Bruegger (2002) argue that the flow of real-time information from the currency traders’ environment was not merely a resource for traders’ decision making, but a self-perpetuating mechanism exciting the market itself. While the empirical evidence does not lend itself to generalizations, the case vignettes provide some insights in respect to study of RTC in organizational settings.

4.1 From media choice to co-configuration of channels

The case vignettes illustrate how different channels were co-configured and switched within broader patterns of mediated communication. Even in the case of TelCo with most limited RTC use, the application was used as an outeraction device to harness other channels appropriately. When instigating mediated interaction, different channels such as instant messaging was often used to negotiate the most appropriate time, for instance, for a call. There was no simple choice between clearly separate channels. Our study adds to the body of literature (e.g. Lee 1994, Markus 1994, Ngwenyama and Lee 1997) presenting contrary evidence to information richness theory that seems inadequate for understanding media choice in the context of real-time communication. Individuals perceived some media occasionally richer than others, but this seemed to have little to do with their choices between different channels.

Employees managed their communications in order to maintain control, maximize the likelihood of achieving their communications objectives and to behave appropriately. Whilst many media choices appear to be consistent with the goal of task closure as posited by Straub and Karahanna (1998), there was also evidence that this is not always the case. For example, it was reported by interviewees that email communication is sometimes favoured as a means of response as issues can be skirted around, misconstrued and manipulated. Rather than focussing on task closure, it would appear that mediated communications may sometimes have other communications objectives, such as task obfuscation. In a similar manner with Knorr Cetina and Bruegger (2002) the order of interaction we observed in the context of mediated presence was not fully amenable to strategic action.

4.2 Obligation to observe the other’s situation

The employees observed each other’s presence and were aware that their own status indicator was being observed. The information was used to figure out what distant others were doing and to save time trying to get hold of someone. If a potential correspondent was freely available, then it was felt that the initiator of communication has a free choice as to which mode of communications to use. There was also evidence that it provided a sense of social cohesion. Presence information was not, however, just a resource for decision-making regarding media choice. It generated a moral obligation between people who shared their online presence to acknowledge each other at some minimum level.

Synchronous communication was perceived to provide the instigator with more control as long as they connect with their destination and, given the awareness of each other’s presence, to impose an
obligation to reciprocate on the side of a recipient. Asynchronous communication was perceived to hand control to the receiver so that they could choose when to get back and how to interpret the message. In terms of receiving communication, interviewees were concerned with being communicated with on their own terms. They often preferred to be communicated with using asynchronous forms that are easier to filter and manage and could be responded to when it was convenient. The appropriateness of handing over or retaining control over the interaction is necessarily a complex issues that transcends any particular communication technology.

5 THE WAY FORWARD

This paper put forward the idea of informated presence as a means to understand organizational implications of real-time communication. Using this lens we analysed four cases and found strategic approaches such as information richness theory and task closure too simplistic in their underlying assumptions to understand mediated situations in which participants enact a form of interaction order through computer-mediated presence information. Employees were not just using presence availability information, but were, to some extent, overwhelmed by it.

Informated presence could be defined as reactions, reflections and orderings that develop out of presence availability updates in organizational settings. In all of the cases it appeared to affect the way interviewees went about their mediated communications. Informated presence forced increasing reflexivity in respect to the recipient’s ongoing situation. Theoretically, the concept is an attempt to synthesize Zuboff’s concept of informing with Goffman’s interaction order. Although this is by no means a modest task, we hope that by describing some of the communicative strategies emerging in the context of informated presence the current study has illustrated the potential of such synthesis.

The limitations of the research design and the scope of study mean that a lot more work remains to be done. It is, for instance, interesting how the findings, so far, resonate with the observations made by Knorr Cetina and Bruegger (2002) on global microstructures. This suggests that further work studying the interplay between real-time communication and emerging coordination mechanisms underpinning distributed work environments could help to elaborate the underdeveloped role of technology in contemporary organization theory (Orlikowski and Scott 2008, Zammuto et al. 2007). Chunking work-related, interpersonal communication into smaller and smaller instances that are punched opportunistically into every possible in-between in employees’ schedules may, at the same time, solve certain coordination problems while making it increasingly difficult to lay out work as a temporally planned succession of activities.

MITIGATING RESPONSE DISTORTION IN IS ETHICS RESEARCH

Abstract

Response distortion attributable to a variety of human motivations has long been a recognized problem for behavioral research relying on self reports by individuals. Researchers studying unethical IS behaviors usually need to solicit self reports because of the secrecy of such behaviors. Unfortunately, the unethical nature of those behaviors often subject self reports to various response distortions such as socially desirable responding. This paper discusses the method of psychometric adjustment for response distortion and empirically examines response distortion due to socially desirable responding in a software piracy research. The boundary conditions of psychometric adjustment are then discussed in depth and the use of randomized response technique, an alternative to mitigate response distortion, in IS ethics research is highlighted.

Keywords: response distortion, socially desirable responding, software piracy.
1 INTRODUCTION

With the rapid development and proliferation of information and communication technology, we are witnessing a growing impact of information system (IS) on our daily lives and social behaviors. More and more concerns pertaining to the ethical uses of IS have come to light. Two decades ago, Mason (1986) identified privacy, accuracy, ownership and accessibility of information as four ethical issues of the information age. These issues are more relevant today than twenty years ago and touch on a wide spectrum of behaviors regarding the ethical (or unethical) uses of IS. With the widespread use of the Internet, many issues such as inappropriate use of IS (e.g., “cyberslacking”) and illicit behaviors enabled by the Internet (e.g., on-line gambling or pornography) are emerging.

Conceivably, individuals who engage in unethical IS behaviors may seek to conceal their behaviors as much as possible because such behaviors may be embarrassing or even subject to legal sanctions in certain cases. Unfortunately, behavioral researchers may sometimes have to solicit self reports of such behaviors from individuals in order to investigate these behaviors in greater depths. Ironically, the trustworthiness of such self reports can often be challenged and this has impeded the scientific investigation of many unethical IS behaviors.

In fact, the general problem of response distortion has long been recognized among behavioral researchers (Himmelfarb 1993). Namely, response distortion occurs when the answer provided by a respondent does not accurately reflect his/her genuine opinion, belief, feeling, intention or behavior. Apparently, such distortion would be more serious when a respondent finds the question embarrassing or when the response might incur legal liability (Locander et al 1976), as are the cases of many unethical IS behaviors.

The existence of response distortion poses serious threats to behavioral research on at least two dimensions. First, researchers are forced to study less relevant proxy variables because the variables of primary interest may be extremely sensitive and are especially inclined to elicit response distortion. Such difficulty has resulted in a general lack of research in areas where objective investigations are most needed. Second, response distortion threatens the conclusion validity of the findings. Substantive conclusions could be biased if response distortion is not taken into consideration.

For example, consider behavioral research on software piracy. Software piracy is an unethical IS behavior estimated to cost the industry over $31 billion a year (BSA 2005). Over the past 20 years, it has attracted a continuous interest among the community of IS researchers. Due to the secret nature of the piracy behavior, many researchers studies the topic using self-reported data solicited from individuals. It is not uncommon for researchers to acknowledge response distortion as a limitation of their empirical findings (e.g. Christensen and Eining 1991; Taylor and Shim 1993; Sims et al. 1996; Cheng et al. 1997; Seale 2002; Limayem et al. 2004; Moores and Chang 2006). However, little effort has been expended to resolve this problem.

The current study uses an empirical study on software piracy to explore the existence of response distortion in IS research on unethical behavior. We outline a methodological approach based on psychometric adjustment in order to cope with response distortion. We will examine the extent to which research conclusions may be misguided if response distortion is not properly accounted for. Furthermore, the boundary conditions of psychometric adjustment will also be discussed in the hope that such approach can be adequately applied in future IS research on ethical or sensitive issues.

---

1 Cyberslacking refers to the practice of employees using the Internet for leisure during work hours.
2 RESPONSE DISTORTION DUE TO SOCIALLY DESIRABLE RESPONDING

The motivations behind response distortion are multifaceted. According to Himmelfarb (1993), people hide their true responses “to protect their privacy, to avoid legal prosecution, to gain economic advantage, to obtain social approval and avoid social disapproval, and to project or protect particular identities” (p. 72).

Among the many forms of response distortion, socially desirable responding has received much attention in research on response distortion in self-reported data (Kline et al. 2000). Socially desirable responding is defined as “responding to items more as a result of their social acceptability than their true feelings” (Podsakoff et al. 2003 p. 882). Ganster et al. (1983) considered socially desirable responding as “a tendency for an individual to present him or herself, in test-taking situations, in a way that makes the person look positive with regard to culturally derived norms and standards” (p. 322).

More specifically, respondents are likely to underreport socially unacceptable opinions, attitudes, and behaviors while they over-report socially acceptable ones. Socially desirable responding is mainly driven by the need for social approval (Crowne and Marlowe 1964), which belongs to one of the motivations of response distortion as discussed by Himmelfarb (1993). In the context of IS ethics research, socially desirable responding may lead the respondent to over-report ethical IS behaviors (e.g. observing the acceptable IS use policy of the company) while underreport unethical IS behaviors (e.g. breaking privacy regulation of the company). As such, it is reasonable to expect that socially desirable responding is an important source of response distortion in IS ethics research.

2.1 Psychometric Measurement of Socially Desirable Responding

Personality psychology researchers have been studying socially desirable responding since the seminal work of Hartshorne and May (1928). Based on the Minnesota Multiphasic Personality Inventory (MMPI), Edwards (1957) provided strong empirical evidence that respondents had a high tendency to admit self-descriptions they regarded as desirable, suggesting that the MMPI score was likely to be contaminated by socially desirable responses. Crowne and Marlowe (1964) further proposed that socially desirable responding is driven by “the need for social approval and acceptance and the belief that it can be attained by means of culturally acceptable and appropriate behaviors”. (p. 109) The authors managed to assemble a collection of 33 behaviors that are either “desirable but uncommon” or “undesirable but common”. These behaviors constitute the M-C SD Scale, a psychometric instrument aiming at measuring a respondent’s propensity for socially desirable responding.

Paulhus (1984) argued that there are in fact two dimensions of socially desirable responding: self-deception and impression management (also known as other-deception). The former refers to the unconscious tendency for one to see oneself favorably while the latter refers to a conscious presentation of a false image, for the purpose of pleasing others. Paulhus (1984, 1991) developed another 40-item psychometric measurement scale for socially desirable responding, called the Balanced Inventory of Desirable Responding (BIDR), which clearly separates the self-deception dimension from the impression management dimension.

The sixth version of the BIDR scale (aka BIDR-6) published by Paulhus in 1991 is shown in the Appendix. BIDR-6 consists of a total of 40 items, with 20 of them measuring the self-deception dimension and the remaining 20 measuring the impression management dimension. All the items are on the possession of a variety of “unlikely virtues” such as “never cover up mistakes” or “always

---

2 The development of the “lie scale” by Hartshorne and May (1928) can be regarded as one of the early attempts to assess socially desirable responding among school children.
appreciate criticism”. The summated score of these items indicates the extent a respondent claims to possess these virtues. Since these virtues are desirable but unlikely, the score indicates the propensity of a respondent to engage in socially desirable responding. The summated score of BIDR-6 was found to correlate highly with the more traditional M-C SD Scale and had very stable test-retest reliability (Paulhus 1991).

2.2 Psychometric Adjustment for Socially Desirable Responding

The psychometric perspective on socially desirable responding posits that respondents differ in their propensities for socially desirable responding and these idiosyncratic propensities can be measured psychometrically. Measurement of idiosyncratic socially desirable responding is usually administered together with measurement of substantive variables of interest. This serves two main purposes. First, researchers can detect if socially desirable responding does exist in self-reported data by checking if there is a significant correlation between the socially desirable responding score and the variable of interest (e.g., Paulhus 1991). Second, if socially desirable responding is indeed detected, researchers may correct or adjust for it using various statistical techniques (Fisher and Katz 2000; Podsakoff et al. 2003).

A commonly known approach of psychometric adjustment applies to the correlation between two variables that are believed to be contaminated by socially desirable responding. The simplest form of adjustment can be accomplished by using the partial correlation controlling for socially desirable responding in place of the zero-order correlation between the substantive variables. A more sophisticated adjustment can be performed by adopting a measurement model that is confounded with measures of socially desirable responding. Podsakoff et al. (2003) provided an excellent summary on such methods.

Apart from adjustment on the correlation between two variables, it is also possible to adjust for socially desirable responding in individual variables. This can be accomplished by regressing the substantive variable of interest on the measurement of socially desirable responding. The resulting intercept term represents the mean estimate of the substantive variable with effect of socially desirable responding removed (Fisher and Katz 2000).

In the following, we will examine psychometric adjustment in an empirical study on software piracy.

3 Psychometric Adjustment for Socially Desirable Responding in Software Piracy Research

To illustrate socially desirable responding, we make reference to the work by Cheng et al. (1997). The authors attempted to identify factors that motivate people to use pirated software through a survey of 340 university students. Students were asked to score their perceived importance of nine commonly considered motivations of software piracy. Their results are shown in Table 1 (ratings range from 1 to 9 with a smaller value indicating higher importance).

Cheng et al. (1997) were careful to employ the indirect questioning method (Robertson and Joselyn 1974; Anderson 1978) in their study. Specifically, respondents were asked to rank the reasons that motivate “people”, not necessarily themselves, to use pirated software. Fisher (1993) provided empirical evidence that indirect questioning helps to reduce socially desirable responding. Also, Simon and Simon (1975) reported that responses solicited from indirect questioning are not totally objective. To a large extent, the responses include the respondent’s own thinking.

<table>
<thead>
<tr>
<th>Reason to Pirate Software</th>
<th>Rating of Importance</th>
</tr>
</thead>
</table>

Proceedings ECIS 2009
Table 1. Ranking of Reasons for Piracy (Cheng et al. 1997)

As shown in Table 1, some of the listed reasons appear to be more socially desirable than do others. Thus, it is plausible that socially desirable responding was not completely eliminated. For example, the reasons “software too expensive” and “can’t afford the software” appear to be more socially acceptable than “little chance of being caught.” Therefore, the tendency for the respondents to overrate the first two reasons and underrate the third reason cannot be ruled out. In fact, the relatively low importance of “little chance of being caught” is surprising and contradicts the findings from other research (e.g., Peace et al. 2003). It is possible that respondents with high propensities for socially desirable responding might have underreported the importance of the chance of being caught.

3.1 Methods

To probe further into the existence of response distortion, we conducted a survey similar to that of Cheng et al. (1997). A total of 612 university students (289 male and 323 female) from a major university in Hong Kong were recruited to participate in the study. Respondents were unaware of the topic of study at the time of recruitment so that bias due to sample selection was minimized. All respondents were requested to answer a set of questions anonymously.

Respondents were first asked to complete the 40-item BIDR-6 (see Appendix). The BIDR items were measured using a 7-point scale ranging from “Strongly Disagree” (1) to “Strongly Agree” (7). The summated score of the 40 BIDR items was used to indicate an individual’s propensity of socially desirable responding as it was found to correlate highly with the more traditional M-C SD Scale and had very stable test-retest reliability (Paulhus 1991).

Then, they were asked to rate the importance of the nine reasons for people to pirate software, as listed in Table 1. The reasons for pirating were rated with a range from 1 to 9 with a smaller value indicating higher importance.

3.2 Detection of Socially Desirable Responding

We detected traces of socially desirable responding in the correlation between respondent’s socially desirable responding (SDR) score and the corresponding ratings of piracy reasons as shown in Table 2.
Our results show that the socially desirable responding score does not have significant correlation with the rating of all reasons except Reason 7 (i.e., “little chance of being caught”) and Reason 8 (i.e., “most people I know copy software”). In both cases, the correlation is positive, suggesting that respondents with higher propensities for socially desirable responding indeed reported a higher rating (and thus lower importance) for these two reasons. Although the correlations (0.13 and 0.127) for Reasons 7 and 8 are only moderate, they are significant (p < 0.01) and may have an impact on the relative ranking of the listed reasons.

### 3.3 Adjustment of Socially Desirable Responding

To illustrate the sensitivity of the findings to socially desirable responding, the nine reasons were ranked again after adjusting for socially desirable responding based on the BIDR instrument. This is accomplished by regressing each rating score on the socially desirable responding score. The resulting intercept term represents the mean estimate of the rating with the effects of socially desirable responding removed (Fisher and Katz 2000).

An assumption behind this technique is that socially desirable responding is unrelated to the factors leading to one’s genuine judgment of a reason’s importance. Technically speaking, the simple regression of the importance score on the socially desirable responding score is subject to the problem of omitted independent variables (see Cohen et al. 2003 pp. 127). However, as we assume that socially desirable responding is orthogonal to the underlying factors affecting a person’s evaluation of the importance of a pirating reason, the estimate of intercept term is still unbiased (Greene 2003) by the assumption of orthogonality.

Table 3 shows the mean estimates and the 90% confidence intervals of the nine reasons before and after the psychometric adjustment. It can be seen that the ranking is quite different after adjustment for socially desirable responding. While Reason 1 (“software too expensive”) still maintains the top rank on the list, Reason 7 (“little chance of being caught”) rises to become the second most important reason for software piracy. Also, Reason 8 (“most people I know copy software”) advances to the fourth place after adjustment. The revised ordering is consistent with our expectation that respondents do not reveal their true responses.

This study serves to demonstrate how socially desirable responding affects any substantive conclusions of software piracy studies based on self-reported data. It is observed that the slim likelihood of being caught is an important motivation to engage in software piracy behavior. However, our respondents did not directly admit to this behavior. A plausible explanation is that university students, being the more educated and elite class in the society, may feel embarrassed to admit that deterrence is an important consideration of whether to pirate.

The implementation of any anti-piracy strategy or policy is likely to incur substantial business, social and political costs. In order to formulate the most effective countermeasures against software piracy, an in-depth understanding of the importance of motivating factors behind piracy behavior is essential. For instance, the software industry has been calling for more stringent law enforcement whereas critics maintain that reduction in price may be more effective. Understanding whether people would be dissuaded from piracy by a reduction in software price or by more stringent law enforcement would provide valuable insights for reaching broad consensus among different stakeholders. Our results suggest that both price cutting and law enforcement would be effective and important countermeasures to combat piracy. Had we ignored the response distortion in our studies, we would have missed out an important motivation behind piracy and an effective countermeasure to the problem.

4 DISCUSSIONS

Our empirical study is based on a sample of university students in Hong Kong and thus the substantive findings should only be interpreted within this confine. Nevertheless, we highlight the methodological implications of ignoring response distortion in similar empirical studies. In the following, we further consider the boundary conditions of the approach used.

First, we assume that the propensity for socially desirable responding is unrelated to the underlying substantive variables of interest. It follows that the correlation between socially desirable responding and the variables of interest can be attributed to socially desirable responding alone, and thus can be safely removed. Otherwise, adjustment is unwarranted and will reduce the content validity and predictive power of the measured variable (Zerbe and Paulhus 1987). Paulhus (2002) commented on the importance of distinguishing measurements of socially desirable responding that focus on the “style” of the response (i.e., response style) from measurements that tap on the “content” of the response (i.e., relevant components of the variable in concern). Adjustment is not necessary in the latter case.

For instance, Fisher and Katz (2000) argued against adjustment for socially desirable responding on self-reported personal values because of a conceptual overlap between the “need for social approval”, the motivation of socially desirable responding, and the intrinsic values of a person. In our study, we were cautious about the existence of such a conceptual overlap when responses on personal involvement (e.g., evaluative variables such as attitude toward piracy) are solicited through direct questioning. For instance, if respondents feel that purchasing licensed software would make them
appear stupid before their peers (i.e., social disapproval), such a sentiment may also be reflected in their self-reported attitude toward software piracy. Adjustment on the self-reported attitude for socially desirable responding scores would therefore be redundant and would distort the true attitude held by the respondent.

Second, psychometric adjustment for socially desirable responding is not applicable in cases when respondents feel threatened (e.g., due to risk of prosecution) even though social sanctioning does not exist or is largely absent. Such situations are best exemplified by discrepancies between law and social norms. Nederhof (1985) pointed out that norms, instead of laws, are the most important determinants of socially desirable behaviors. His example to illustrate this point was gang members who admitted to more violations of the law than actually committed in order to impress others. In the context of software piracy, using pirated software may not be judged as undesirable in certain social groups. In this case, underreporting of piracy intention (or behavior) would not be motivated by socially desirable responding. Instead, it is triggered by the fear of legal sanctions.

In summary, response distortion in self-reports of software piracy behavior may not be entirely attributed to socially desirable responding alone and therefore psychometric adjustment may not always be effective.

4.1 Confidentiality Assurance to Respondents

In view of the limitations of psychometric adjustment, it would obviously be more desirable if motivations behind untruthful responding can be eliminated as much as possible rather than being adjusted for after the fact. Conceivably it serves as a more fundamental cure to response distortion than psychometric adjustment.

Traditionally, researchers soliciting self-reports on sensitive topics would provide confidentiality assurance to respondents so as to encourage truthful responding. Usually this is accomplished by convincing the respondents that a survey is completely anonymous or confidential. Over the years a number of good survey practices (e.g. physical separation of respondents, promises of confidentiality, emphasis on truthful responding rather than a “right” answer, etc.) has been identified for different types of survey administrations (see Paulhus 1991). Confidentiality assurance is a very powerful strategy in the sense that, if successful, should naturally eliminate most of the motivations behind response distortion (including socially desirable responding). The success of this strategy hinges on whether the assurance does look convincing to the respondent. When questions are considered threatening, credibility of such confidentiality assurance would be of prime importance as respondents may demand a more convincing assurance.

4.2 Randomized Response Technique and Research on Unethical IS Behaviors

Randomized response technique (RRT) is a questioning method that incorporates respondent confidentiality by design, and was developed to encourage truthful responding on sensitive topics. First invented by Warner (1965), various forms of RRT have been designed (Warner 1965; Greenberg et al 1969; Greenberg et al 1971; Himmelfarb and Lickteig 1982; Fox and Tracy 1986) to date for soliciting truthful responses to evasive or embarrassing questions. The core idea of RRT is to assure complete confidentiality of a participant’s response by contaminating it with a random “noise” value with known statistical properties.

For instance, in the unrelated-question randomized response model (Greenberg et al 1969), participants are instructed to choose among a set of questions to answer according to a randomizing device controlled by them privately (e.g. as simple as flipping a coin). Each sensitive question is paired with another unrelated and innocuous (i.e. non-sensitive) question such that the participants would answer either one of them depending on the outcome of the privately performed randomization procedure. As the researcher has no way to know exactly which question was answered, complete
confidentiality can be assured and this should in turn help eliminate any possible stigma or embarrassment caused by the sensitive question, resulting in more truthful responses. On the other hand, as the probabilistic property of the randomization procedure is known, useful aggregate properties of the answer to the sensitive question can be estimated using statistical methods. For instance, if coin-flipping was used as the randomization procedure, researchers would know that about half of the respondents should have actually answered the sensitive question and may derive useful research conclusions.

Originally, RRT was limited to two-choice questions only. It was later extended to cover multiple-choice questions as well as quantitative answers. As the majority of literature on RRT focuses on univariate analysis (e.g. proportion of people committing a certain criminal behavior, mean value of a certain sensitive characteristic, etc.), there is a common misunderstanding that RRT is limited to univariate analysis. This is in principle not true although more sophisticated statistical estimators would be required for multivariate analysis.

In particular, Kwan, So and Tam (forthcoming) demonstrated an innovative method to deploy RRT for correlational studies. By representing randomized responses in a mathematical model consisting of indicator variables, estimators for the mean, variance and covariance of randomized responses can be derived based on the method of moments. The method has been empirically tested using two empirical studies on software piracy using online survey data. The applicability and usefulness of RRT for studying unethical IS behaviors have been clearly demonstrated.

Comparative studies have shown that RRT leads to higher admission of sensitive characteristics. Validation studies deploying participants whose sensitive characteristics were known in advance have also revealed that RRT does outperform other techniques in soliciting valid responses to sensitive questions (Umesh & Peterson 1991; Scheers 1992; Hosseini & Armacost 1993).

However, there are a number of issues with RRT that must be noted. First, there is an additional sampling error due to the randomization procedure. This would inevitably reduce the overall measurement reliability and a larger sample size would normally be needed. As the loss of statistical power would depend on (i.e. decrease with) the probability of respondents answering the sensitive question, researchers have to trade off between a higher perceived confidentiality protection and a higher data collection efficiency (Fox & Tracy 1986). Hosseini & Armacost (1993) thus concluded that RRT should only be used for questions of sensitive nature. We believe that questions pertaining to unethical IS behaviors should belong to this category.

Second, the complexity due to randomization procedure may not be completely understood by respondents, especially those less educated ones, resulting in incorrect responses or missing data. Those respondents who do not understand the procedure well may not be convinced of the confidentiality protection that is built into the method, further undermining the benefit of RRT. In most research studies on unethical IS behaviors, it should be reasonable to assume the target population (i.e. IS users) should belong to the more educated class. We thus believe this should be an appropriate context to apply RRT.

Third, it should be noted that RRT is a procedural improvement (Podsakoff et al 2003) on increasing the credibility of response confidentiality. Even if RRT is successfully applied in a survey, there may still be untruthful responding although it is reasonable to assume the amount of distortion should be much less than that when direct self-reports are solicited. In fact, a recent RRT validation study conducted by van der Heijden et al (2000) compared the proportions of respondents admitting income fraud when surveyed using different questioning methods. The study revealed that RRT could help boost the percentage of truthful response to 43%, up from 25% with face-to-face direct questioning and 19% with computer-assisted self interview. Although it is not a complete cure to the problem of response distortion, this clearly represents a significant improvement.
5 CONCLUSION

We have empirically examined response distortion in self-reports based on an empirical study on software piracy. Despite the use of an indirect questioning technique to minimize socially desirable responding in our study, we still observed evidence of response distortion. Our findings substantiate the worries of many previous researchers about response distortion in software piracy research.

We demonstrated how substantively different conclusions about the motivating factors behind software piracy can be reached with or without psychometric adjustment for socially desirable responding. In particular, we found that the slim possibility of being caught committing piracy could be an important reason for piracy behavior although respondents would not admit this directly. Our findings demonstrate how response distortion could mislead researchers into erroneous conclusions.

We also discussed the limitations of psychometric adjustment for socially desirable responding. First, if the substantive variables of interest are actually related to socially desirable responding in theory, psychometric adjustment would be inappropriate because it would reduce the content validity of the measured constructs. Second, psychometric adjustment would be irrelevant when the anticipated distortion is not attributable to socially desirable responding. Lastly, we highlighted the use of randomized response technique for assuring confidentiality and mitigating response distortion when psychometric adjustment is inappropriate.

In conclusion, we find response distortion to be a real threat to research that relies on self-reports of unethical IS behaviors. Although our empirical study was conducted in the domain of software piracy, we believe the problem is also threatening research in ethical or unethical IS behaviors such as data privacy, cyberslacking, system hacking, online gambling and pornography viewing. Psychometric adjustment for socially desirable responding should help alleviate the problem in certain contexts but may not be useful in many others. We encourage researchers to employ RRT as a more fundamental remedy for tackling response distortion in research related to sensitive topics.

IDENTITY IN ORGANIZATIONS: A REVIEW OF INFORMATION SYSTEMS RESEARCH

Gal, Uri, Aarhus School of Business, University of Aarhus, Fuglesangs Allé 4, DK-8210 Aarhus V, Denmark, urig@asb.dk
Kjærgaard, Annemette, Copenhagen Business School, Howitzvej 60, DK-2000 Frederiksberg, Denmark, amk@cbs.dk

Abstract

Research into the role of identity in organizations has become increasingly popular in recent years. Scholars from different organizational and management disciplines have applied the concept to address a wide variety of issues. In light of the concept’s broad applicability, we conduct a review of six prominent IS journals to examine the extent of the concept’s use in our field. Our review reveals that the concept is scantly employed by IS researchers, which, we believe, constitutes a missed opportunity. In light of this finding, we outline possible directions and opportunities for using the identity concept in IS research with the aim of enriching and diversifying the conceptual discourse in our field.

Keywords: Organizational Identity, Information Systems, Literature Review.
1 INTRODUCTION

Research into the role of identity in organizations has become increasingly popular in recent years (Albert et al. 2000; Corley et al. 2006; Cornelissen et al. 2007; Gioia et al. 2000; Haslam and Ellemers 2005). The interest in identity is quite diverse, reflecting perspectives that originate in the fields of organization studies, corporate communications, social and organizational psychology, personnel and human resources, and strategy and marketing (Cornelissen et al. 2007). Furthermore, theoretical and empirical research has explored identity and identification processes as well as their organizational outcomes at various analytical levels from personal to social to organizational (Ibid.).

The growing interest in identity issues reflects the concept’s centrality to the way scholars from different disciplines understand and theorize about organizations. In addition it underscores the importance and practical relevance of the concept to a variety of organizational areas including strategy (Dutton 1997), management and leadership (Gioia and Chittipeddi 1991; Pratt and Foreman 2000), inter-organizational collaboration (Beech and Huxham 2004), and corporate communication (Cheney and Christensen 2001; Schultz et al. 2000).

In light of the broad applicability and use of the concept in general management and organizational studies, its scant utilization in IS literature stands out. Accounts of the relationship between IS and identity in organizations have been sparse (e.g., Barrett and Walsham 1999; Lamb and Davidson 2005; Walsham 1998). This is surprising given the significance of identity to a variety of issues that have received considerable attention from IS researchers such as group and organizational sense-making (Weick 1995), the shaping of organizational practices and change (Corley and Gioia 2004; Gioia et al. 2000), organizational learning (Corley and Gioia 2003), and knowledge work (Nag et al. 2007).

Although identity research in management studies does not focus on technology in general or IS in particular, we believe that focusing on identity issues in organizations can help IS scholars to produce thoughtful and meaningful insights into individual and collective self-constructions in organizations and into the interactions between the implementation and use of IS, and organizational processes and outcomes. Motivated by this premise, we set out to review and characterize the use of the concept of identity in organizational settings in existing IS literature.

Based on this review we aim to point at possible directions for employing the concept in future studies and indicate how it can contribute to explanations of the organizational implications of and reactions to IS, as well as the interaction between IS and users of systems in organizational contexts.

Next we present the concept of identity, in particular with respect to its application in organizational settings. In section three we present the research methodology which is followed by the findings from the review of the use of the identity concept in IS literature. We continue by outlining possible avenues for future IS research employing the concept of identity, and conclude by emphasizing the versatility of the concept and encouraging researchers to make use of it in their future work.

2 THE CONCEPT OF IDENTITY IN ORGANIZATIONS

The increase in theoretical and empirical identity research in organizational settings can be attributed to the richness of the concept and the opportunity that it provides to explore a wealth of issues that are of interest to scholars from multiple fields. In the organizational domain, this research spans several levels of analysis, ranging from individual or personal to organizational.

Personal identity typically refers to unique individual attributes that are assumed not to be shared with other people and which do not indicate or derive from group membership (Alvesson et al. 2008). Different from personal identity, social identity refers to an individual’s perception of him or herself, resulting from his or her membership in a social group (Tajfel and Turner 1979). Moving up the
analytical scale, organizational identity is generally understood to be the members of an organization’s collective understanding of the features that are presumed to be central, distinctive, and relatively permanent about the organization (Albert and Whetten 1985; Dutton et al. 1994). Common to most theoretical and empirical accounts of organizational identity is the view that identity is rooted in a deep cultural level of the organization (Gioia et al. 2000), residing in interpretive schemes that organizational members collectively construct to provide meaning to their shared history, experiences, and activities (Gioia 1998; Ravasi and Schultz 2006).

Despite the apparent distinctions separating the different levels of analysis, several scholars have emphasized their similarities and called for a more holistic understanding of identities in organizational contexts. For example, Alvesson et al. (2008) maintained that “despite the appeal of persistent distinctions between personal and social identities… we also wish to resist the often arbitrary clarity of such divisions. Instead… we develop a sharper eye for the diverse and fine-tuned ways in which the personal-social relation might be configured in identity research” (p. 10). The authors observe the role that personal and social identities play in each other’s construction. On the one hand, “personal identities necessarily draw on available social discourses or narratives about who one can be and how one should act” (p.11). Furthermore, self conceptions emerge and develop in reference to a range of associations, roles, and behaviors that tie the individual to his or her social surroundings. On the other hand, social identities cannot be formed without individuals that engage in action and interaction that are informed by some notions of the self. Thus, the two forms of identity are intimately intertwined in a way that makes it hard to examine or understand one in complete separation from the other.

In accordance with this line of argumentation, several researchers have attempted to highlight the common features that personal, social and organizational identities share. Some have done this by stressing the relational aspects of identity. As pointed out by symbolic interactionists, personal identity is inherently relational (Sluss and Ashforth 2007); one’s self-conception as a powerful leader is difficult to achieve without the presence of followers. Social identity is similarly relational; it is through ongoing relationships, interactions, and comparisons with various out-groups that the in-group becomes a salient locus for individual identification and attachment. Organizational identities are also relational as they are constructed not only against a backdrop of members’ shared histories and experiences but also in the context of multiple interactions in which the organization is involved with a variety of outsiders such as costumers, competitors, and suppliers (Ashforth and Mael 1996; Gioia et al. 2000).

Another characteristic of identity in organizations is its fluidity. Although much of the literature has played up and focused on the seemingly stable and permanent features of identity, acknowledgement of its potentially changing character can be found in recent research on the topic (Gioia et al. 2000). For instance, personal identity is seen as a social construction deriving from changing interactions with others. As Weick puts it, “identities are constituted out of the process of interaction. To shift among interactions is to shift among definitions of the self” (Weick 1995, p.20). Social identity is also flexible; an individual’s representation of in-groups and out-groups is likely to change as features of the comparative and normative context undergo transformations (Cornelissen et al. 2007). Flexibility is also characteristic of organizational identity. Changes in the organization’s environment and relationships with other organizations are likely to require modifications to the way members interpret what is central and distinctive about their organization. That is, organizational changes will require members to actively reinterpret and develop new representations to symbolically characterize their organization (Fiol 1991).

Two additional qualities that characterize identities in organizational contexts are the role that they play in informing individual and collective action and their embeddedness in social discourse and communication. Firstly, individual actions are performed by actors with certain dispositions and preferences that derive from their self-conception. Likewise, social identity orientates the behaviors of individuals based on inter-group comparisons and relationships and the construal of social information. Organizational action is informed by organizational identity that provides a basis for
sense-making and renders a particular repertoire of behaviors appropriate; a “green” organization is likely to take certain actions to reduce operational costs and be associated with relevant industry and environmental groups to justify its green identity.

Secondly, most researchers agree that identity in organizational settings is produced and reproduced through ongoing communicative activities that take place within and across people and organizations. For example, social construction theorists maintain that personal identities are created, negotiated, and changed through ongoing interactions among multiple actors (Alvesson et al. 2008). Organizational identity is also a product of social communication; organizational members negotiate, through continuous interactions, a shared symbolic representation of their organization that gives a sense of meaning to the organization’s actions, objectives, and existence, and that distinguishes the organization from other social entities in its environment (Gioia 1998; Gioia et al. 2000).

To sum, identity issues are experienced by social actors embedded in organizational settings. The concept of identity provides a lens for studying how organizational members give meaning to their experiences as a basis for individual and collective action. Therefore, it offers an opportunity to explore the interrelationships between the symbolic and the concrete organizational domains, as well as to examine the reciprocity of micro activities and macro phenomena. The recognition that identity is a foundational notion that is essential to understand multiple organizational processes and experiences is evident in the wealth and diversity of research that has employed the concept. In what follows, we examine the utilization of the identity concept in IS research and characterize its application.

3 RESEARCH METHODOLOGY

3.1 Defining the Scope of the Review and Searching the Journals

To examine the use of the identity concept in IS research we conducted a review of some of the primary journals in the field: MIS Quarterly (MISQ), Information Systems Research (ISR), Journal of the Association of Information Systems (JAIS), Information Systems Journal (ISJ), European Journal of Information Systems (EJIS) and Journal of Management Studies (JMIS).

In selecting journals for review we wanted to include top ranked, North American journals (MISQ, ISR, and JAIS), top ranked European journals (EJIS and ISJ), and a journal which we thought is likely to publish identity research (JMIS). As we focus the on use of the identity concept in academic research, we did not include practitioner-oriented journals in our sample.

3.2 Selecting and Examining the Articles

Our search of the databases produced a sample of 395 articles, which matched our keyword. These articles constitute our Sample A. Next, both authors read the abstracts and keywords of the papers in Sample A to determine whether the concept of identity was employed theoretically and/or to interpret empirical data. After going through a portion of the articles in the sample we compared our analyses to align our sorting criteria and establish inter-rater reliability. The result of the sorting was a reduced
Sample B of 27 articles. We then read the articles carefully to assess each article’s use of the identity concept. In reviewing the articles, we examined two issues: first, whether the articles’ use of the identity concept was substantial and; second, whether they addressed the topic of identity in organizational settings, which is the focus of our study. In this process, we excluded articles that did not use the concept of identity in a theoretically-informed way. For example, articles that only mentioned identity in the introduction but not in other parts of the paper, or articles that used the concept as a peripheral idea. Furthermore, we excluded articles that used the word identity in a completely different connotation from our research interest of studying identity in organizations. This produced a (surprisingly) small sample of 11 articles, which we refer to as Sample C (a list of articles excluded is provided in Appendix A).

4 FINDINGS: IDENTITY IN ORGANIZATIONAL SETTINGS IN IS RESEARCH

The remaining 11 articles were read carefully with the aim of constructing categories based on their use of identity. Using techniques from grounded theory (Glaser and Strauss 1967; Strauss and Corbin 1998), we constructed categories of the use of the identity concept based on a process of naming and comparing. We constantly alternated between reading the articles and naming first order concepts that were then compared to the text and finally combined into second order categories which formed the categories of use.

Five of the articles address the interrelationship of technology and identity in the context of IS implementation. Van Akkeren and Rowlands (2007) examined the assimilation of a new ICT in a radiologist practice and drew on social actor theory to analyze the relationships among the radiology practitioners, the technology, and the context. Findings from the case study showed that user-identity can both inhibit and enable IS assimilation. Gal et al. (2008) studied the implementation of 3D technologies into the architecture industry. They proposed a model to outline the relationship among IS, information infrastructures, and organizational identities and suggested that IS help to form organizational identities and enable cross-organizational change. Similar to Gal et al, Alvarez (2008) also emphasized the co-construction of identity and IS and argued that technology, structure, and identity are mutually constitutive. Critically examining the implementation of an enterprise system, Alvarez discussed users’ power relations, experienced loss of autonomy, isolation, and fragmentation during the implementation process. Barrett and Walsham (1999) studied the implementation of an electronic trading system in the London Insurance Market and drew on work by Giddens to examine its impact on users’ self-identity. Finally, Barrett and Scott (2004) also utilized Giddens’ concept of

---

1 Most articles in Sample A used the word “identity” without actually engaging the concept as, for instance, in exploring identity-matching for crime-solving.
self-identity and examined how reflexive self-identity is impacted by increased globalization and ICT during the adoption of an e-trading system.

Articles in the second category examined the influence of the presentation and perception of identity on online behavior. Winter et al. (2003) conceptualized identity as the way an organization is perceived externally by its customers and discussed how managing a website as a symbolic representation of a company influences the customers’ perception of the company and thereby their purchasing behavior. Related to this is a paper by Forman et al. (2008) about online-shopping and consumers’ identity. Drawing on theories of information processing and partly based on social identity theory, the paper suggests that self-disclosure of consumers’ identity affects the behavior of other shoppers and is positively related to sales. Finally, Ma and Agarwal (2007) studied the impact of community infrastructure design and identity verification in computer-mediated communication. Their findings suggested that identity verification is positively impacted by IT artifacts, and leads to satisfaction and knowledge contribution in online communities.

The third category focuses on the role of identity in enabling collaboration and coordination across groups and organizations. Sarker and Sahay (2003) propose a theoretical model that relates the concepts of communication, virtual team development, and collaboration to understand how virtual teams develop over time. They suggest that the development of an ‘integrative identity’ across teams is an enabler of successful collaboration. The second paper in this category by Dickey et al. (2007) is a study of how customers and customer service representatives build a shared context in chat communication. Identity is viewed as the interpretations that customers have of the company representatives’ appearance in the chat session. The paper describes how improvements in peoples’ articulation of intention and creation of a shared frame of reference may be valuable in enabling coordination between customers and customer service representatives.

The fourth and final category is represented by a single paper by Merali (2002) that examined the role of organizational identity in enabling organizations to survive. Looking at inter-organizational relationships in managing organizational transformation, Merali views identity as the abstract characterization of the organization that persists over time. It is the embodiment of this identity through action that impacts the world and influences boundary management between organizations. The paper draws on Maturana and Varela’s concept of autopoietic unity as a metaphor and provides a framework for exploring issues of organizational identity and integrity, focusing on boundary phenomena to explain organizational knowledge processes.

5 INCORPORATING IDENTITY INTO IS RESEARCH: POTENTIAL DIRECTIONS AND OPPORTUNITIES

Our review of the leading IS journals revealed that the concept of identity work in organizations is seldom used by researchers in the field. When it is employed, it is mostly done without theoretically engaging the concept or leveraging the insights that could be yielded from its application. This finding stands in stark contrast to the overall trend in other management disciplines. As noted, the concept of identity has become increasingly popular in recent years and been used to investigate a wide array of organizational and managerial issues such as workers’ motivation, organizational strategic behavior, group functioning, power relations and politics, entrepreneurship, loyalty, and emotions at the workplace (Alvesson et al. 2008).

In light of the broad applicability of the concept, we believe that the lack of attention to the importance of identity in organizational settings constitutes a missed opportunity. Bringing identity issues into the fore can help develop novel theoretical accounts and produce rich empirical analyses that capture the complexity of organizational life and of the interactions between people and technology in organizational settings. In what follows we outline possible avenues for using the concept of identity in IS research.
Organizational research on identity has been previously classified according to three philosophical orientations (Alvesson et al. 2008): functional, interpretivist, and critical. We build on this classification to describe different theoretical areas in which the identity concept can be utilized to inform IS research and identify research opportunities that characterize each area.

**Functional**

Research in this area typically aims to find causal relationships between different organizational phenomena in order to enhance control over organizational processes and increase organizational functioning and efficiency. Identity is treated as a tangible construct that can be gauged, assessed, and intentionally manipulated through management interventions with real organizational consequences. For example, some research argues that members’ level of identification with their organization impacts decision-making processes, group cohesion (Ashforth and Mael 1989), and commitment (Sass and Canaray 1991). Other research maintains that the emergence of a collective identity influences the way members interpret and react to issues facing the organization (Dutton and Dukerich 1991; Gioia and Thomas 1996) by influencing the importance that members assign to them.

The theoretical framework most often associated with the functional approach is social identity theory (Tajfel and Turner 1979). The theory’s main contention is that people’s identity derives from the groups to which they believe they belong. Because people strive to maintain a positive self-identity, they will tend to favorably compare their in-group to external out-groups along valued dimensions. Applying these ideas to the organizational domain, it has been argued that organizational identity is merely a form of social identity, one that is associated with perceived membership to an organization (Haslam 2001). Therefore, one’s degree of identification with the organization provides the basis for a range of organizational behaviors such as leadership, group motivation, and the willingness to take on organizational roles and exercise collective power (Turner 2005).

Opportunities for IS researchers in this approach are varied. For example, one could look at the role of technology in facilitating the creation and maintenance of organizational identification among group members. As identification with the organization is assumed to have a decisive influence on a range of organizational actions, being able to control and manipulate the identification process becomes an important managerial issue. Therefore, research that looks at the way technology can assist in accomplishing this in different organizational situations, such as geographically distributed or virtual teams, can be particularly valuable (these ideas are reminiscent of those explored in papers in the third category we identified above). Another research possibility lies in examining the impact of members’ identification levels on their willingness to accept new technologies. Technology acceptance research is one of the most substantiated in the IS field. This area can be considerably enhanced by examining how the emergence and strength of social identities influence the propensity of users to adopt and use a new technology.

**Interpretivist**

Whereas functional research aims to target and utilize identity to produce effective organizational behavior, interpretivist researchers are primarily interested in understanding human experience in organizational settings. Rather than directly serving organizational interests, researchers in the interpretivist tradition look to gain in-depth insights into people’s subjective reflections on who they are and what they do (Alvesson et al. 2008). Interpretivist approaches focus on how people weave organizational narratives with personal experiences to construct identities that provide a sense of meaning and continuity over time and across geographical locations (Ravasi and Schultz 2006). This construction process is often referred to as ‘identity work’, a term that is meant to emphasize the continual and dynamic nature of identities in organizational settings and their capacity to change and adapt to accommodate transformations that take place within or outside the organization.

This idea is demonstrated in a number of studies such as Fiol’s examination of an organization named Tech-Co. During the 1970’s and 1980’s Tech-Co had a stable organizational identity as an engineering-driven data storage company. However, during the 1990’s, the computer storage industry
as a whole was undergoing significant changes from a primary hardware, engineering mindset to mindset of information management and storage solutions. Fiol followed the transformation in Tech-Co’s identity as the company attempted to adapt to the changes in its environment (Fiol 2002).

Some IS research that used the concept of identity has been interpretive in nature. For instance, Lamb and Davidson (2005) described the transformations in the professional identities of groups of scientists associated with the introduction of new IT. Similarly, Gal et al. (2008) studied the transformations in the identity of an organization as it adopted new IS. Walsham (1998) and Barrett and Walsham (1999) explored the links between the introduction of new IT and changes in the identities of groups of professionals in the London insurance market.

Thus, interpretivist IS research can enrich our understanding of how individuals, groups, and organizations incorporate technology-enabled changes in their environment into ongoing identity work; how new technologies get interpreted and fed into the way people perceive themselves and their organizations; how ongoing enactments of organizational interactions, practices, and identities are influenced by the introduction of new technologies; and what role existing identities play in sense-making processes of new technologies.

**Critical**

The critical approach focuses on power relations and repressive discourses that exist within and across organizations. These relations and discourses impose certain normative demands, behavioral scripts, and cognitive frames that shape individual, group, and organizational identities, both explicitly and implicitly. A critical perspective challenges some of the basic assumptions that characterize the functional and interpretivist approaches, most importantly, that individuals and groups freely construct their identities and (challenging the functional approach) that these identities will have beneficial outcomes both for the individuals involved and the organization (Alvesson et al. 2008).

A prominent theme in critical identity research is managerial interest in controlling employees through the regulation of their identities. Efforts to establish a rigid organizational environment that funnels identity construction in specific ways are given prime consideration. Attention shifts to the role that organizational elites play in generating discursive regimes and material arrangements that pose strict limitations on identity construction in ways that are deemed congruent with broad managerial objectives. For example, discourses of quality management, service management, and knowledge management provide a rich vocabulary and conceptualize the organization and its relationship with its members in ways that form and define certain identities, such as ‘the knowledge worker’. Identities can also be constituted by reference to their location within a broader organizational or inter-organizational scheme and in terms of their relationships to others. For instance, in a study of an advertising agency, Alvesson found that reference to other agencies as amateurish and insincere tended to be interpreted as communicating professionalism and honesty as desirable attributes to be possessed by members of the researched agency (Alvesson 1994).

IS identity research that adopts a critical stance can build on existing work in the field that has examined the repressive impact of IS on people’s privacy (Zuboff 1988), capacity to exercise their agency (Kallinikos 2004), and on the way organizational action and discourse are induced through the implementation of new technologies (Doolin 2002; Doolin 2003). Future research can examine how IS are used to impose certain discourses that facilitate the construction of particular identities; the role that IS play in the distribution of material and symbolic resources within and between organizations and the way these resources are used to construct different identities; and the mechanisms through which IS structure communicative activities within and between organizations and how these communicative activities (that may be power-laden, asymmetrical, or exploitive) are incorporated into identity construction processes.
6 CONCLUSION

Our review of the use of the identity concept in IS research has shown that term ‘identity’ has been cited substantively in the dominating IS journals to date (395 times, to be exact). At face value, this would seem to indicate a significant level of interest in the concept in the IS field and point to the existence of a high number of IS researchers seeking to engage seriously and constructively with the identity concept.

From an IS perspective, it would seem that the notion of identity work in organizations offers a number of distinctive concepts and perspectives that are appealing to researchers in the field. Among these are the possibility of using IS to develop members’ collective identities and enhance organizational performance; and developing an identity-based view of organizations which can open a conceptual platform to address IS implementation challenges, IS-induced organizational change processes, and the ongoing adaptation of IS to users’ practices.

While 395 articles in the sampled journals used the term ‘identity’, only 11 of them had examined the concept in organizational settings to develop or expand theoretical insights, interpret empirical data, or both. The vast majority of IS researchers have adopted the identity concept in a non-theoretical fashion. Nonetheless, the IS researchers that used the identity concept substantively, have done so in a wide variety of ways, demonstrating its broad applicability. A number of them focused on the relationship between technology and identity and examined how this relationship plays out during the implementation of IS. Another group of researchers have investigated the formulation, perception, and presentation of identity to enrich current understandings of online behavior. Others have looked at the role of identity in facilitating collaboration and coordination within or across organizational boundaries.

In light of the concept’s versatility, we would encourage future IS identity-researchers to follow suit and seek to explore the full scope of identity theory by borrowing from other disciplines rather than restricting themselves to building on the limited understanding of the concept that is apparently most directly applicable to their work. Based on Alvesson et al.’s classification, we outlined possible directions for such research, which fall into the functional, interpretivist, or the critical perspectives.

From a functional standpoint, identity is a tangible mechanism that can be utilized and leveraged to solve organizational problems, impact a range of organizational behaviors, and promote organizational effectiveness, e.g., through the timely implementation and adoption of technology. An interpretivist understanding of identity in IS research views IS users as social actors whose actions are underlined by their self and group conceptions. Therefore, in order to understand how and why people respond to and interact with technology in certain ways, we necessarily need to understand their identities. An in-depth examination of the communicative and symbolic activities that underscore identity construction can therefore provide a better understanding of a range of organizational events, e.g., why a particular technology is rejected by its intended users, or why users have difficulties integrating a technology into their everyday practice. From a critical point of view, the understanding of identity can produce important insights into the power structures and opposing interests often involved in the interaction between technology, social institutions, and actors in organizations.

Finally, the IS field has a lot of catching up to do with other management disciplines in terms of addressing identity work in organizations. As we noted in the beginning of the paper, in recent years identity research has flourished in most management disciplines to address numerous issues and enrich the discourse around a variety of managerial and organizational topics. IS researchers, for the most part, have yet to capitalize on this opportunity to further develop and diversify their conceptual playing field. This paper is meant to provide an initial exploration into some of the opportunities and possibilities for carrying this out.

A SITUATED KNOWLEDGE WORK CONTEXT PERSPECTIVE
ON KNOWLEDGE MANAGEMENT
SOFTWARE-ORGANISATION MISALIGNMENTS

Abstract

Underpinned by the work of Schultze and Boland (2000) on situated knowledge work context, and using Bourdieu’s (1990) theory of practice, this paper draws attention to potential sources of likely misalignment between Knowledge Management (KM) software and the implementing organisation. Using the case of a global IT-Management consultancy firm, the paper elucidates KM software-organisation misalignments as the consequence of differences between organisational and KM technology developer’s ‘situated’ knowledge work contexts with due consideration of the case organisation’s large and diverse user base. Such contextual differences reflect the differing ‘situated’ knowledge work structures that KM technology developers and adopting organisations deliberately acquire and evolve over time. Theoretically, by giving a more comprehensive account of how knowledge work structures were emergent and then embedded into the organisation that either develops or implements the technology, we wish to provide readers with insights into the sources of misalignment, thereby enriching theory of KM technology implementation. Practically, studies of this nature would help make organisations more aware of the factors that can influence KM software package implementation, particularly in the case of large firms that are characterised by high-value, text-based knowledge for decision-making, such as consultancies, R&D, healthcare or legal organisations.

Keywords: Knowledge Management, software package, theory of practice, knowledge work context, global IT-Management consultancy firm.

1 INTRODUCTION

An increasing number of knowledge management (KM) projects have not achieved the expected benefits from the technology and even worse, suffered critical failures (Malhotra, 2005). As Roell (2004: 1) argues: “tools that have been developed in KM focused on information management and do not support many of the key knowledge work processes”. Hence, if KM technology is not appropriately aligned with organisational and people ways of working, then even with state-of-the-art technology, organisations would not be able to provide the ‘right knowledge’ to the ‘right people’ at the ‘right time’. Our reading of the literature highlights that such low success rates were in part attributable to misfits arising from the different situational contexts of the adopting environment and the software developer. In other words, poor understanding of situated work practices often lies at the heart of failed KM implementation projects (e.g. Grudin, 1994; Suchman, 1995). More specifically, vendors and adopters alike should create solutions that are consistent with the situated knowledge work practices of the intended user communities (Schultze and Boland, 2000). This requires them to follow a practice-oriented approach, which, as Townley (1993: 235) argues, should focus not only on what people ‘actually’ do, but also on ‘what doing it does’. Suchman (1995) suggests that this approach is particularly suitable for KM because system developers do not have accepted models for the largely invisible and complex nature of knowledge work.

Although the concepts of situated knowledge work context and practice have been central in the writings of Orlikowski (1996), Majchrzak et al. (2000), Schultze and Boland (2000) and Orlikowski (2002), little is known of the sources of misalignments in terms of such situated context as well as how emergent knowledge work structures are surfaced on a large-scale. Notably, of the four studies, only Schultze and Boland opted for Bourdieu’s theory of practice (1990 and 1998) whilst the remaining employed Gidden’s (1984) structuration theory. We find that while both theories emphasise knowledge work practice as an on-going accomplishment, constituted and re-constituted in daily practice (Orlikowski, 2002), Bourdieu’s articulation of elements such as field (structures), habitus and practice in his theory helpfully reflects the nature of knowledge work practices as we observed it in our research setting to elaborate on the nature of misalignment. Further, Schultze and Boland’ study also exposes some limitations. Their study focused only on a small group of knowledge workers, and particularly a specific practice named ‘gate-keeping’, which we argue does not reflect a sufficiently diversified range of knowledge works. Their research setting – a large building material manufacturing firm – may also not truly represent a ‘knowledge-intensive firm’ consisting of communities of practice (Alvesson, 1993). Most importantly, the technology implementation project ‘did not move beyond its initial pilot stage’ (Schultze and Boland, 2000: 197), raising questions in our minds as to unexplored potential misalignments occurring in actual implementation.

Specifically, in this paper, our objective is to understand the sources of misalignment between KM technologies and organisations. To do so, we use a case study of an IT-management consulting company ranked among the world’s top 20 companies and whose offices are located throughout the world. Our discussion proceeds as follows. Section 2 uses Bourdieu’s theory to review the misalignments between the context of KM software and that of the adopting organisation. Section 3 introduces our research methodology and the framework. Section 4 introduces briefly the case company and then presents data analysis and findings. The last section discusses the key issues arising from the findings and presents some conclusions and suggestions for future research.

2 UNDERSTANDING THE MISALIGNMENT OF SITUATED KNOWLEDGE WORK CONTEXT

For this study, understanding the ‘situated’ nature of knowledge work practices is of paramount importance to help analyze sources of misalignment between KM technology and the adopting
organisation on the following grounds. First, users are usually unaware of developers’ context and the embedded assumptions and rules of the surrounding world (Orlikowski, 1992; Latour, 1992). Indeed, the context of knowledge work, along with their assumptions and rules as well as knowledge attributes such as its “sticky” and contextualised nature (Szulanski, 1996), is the factor that makes knowledge work practices different from other work practices (Schultze, 2000). In this context, a mere understanding of what ‘people do’ is often not adequate in helping organisations to anticipate the long-term impacts of technology, both intended and unintended (Schultze and Boland, 2000).

Second, knowledge, be it object, cognition or capability, must be enacted from people’s practices and reside in a particular work context (Orlikowski 2002). In this regard, to understand KM problems, analyzing what experts do in situ is crucial for studying how their practices are embedded in and shaped by work contexts (Hsiao et al, 2006). In other words, people and their practices can not be separated from the embedded work contexts (Lam, 1997; Tyre and von Hippel, 1997). Neither is it possible to analyze KM problems without considering the contexts where these practices were acquired (Lave and Wenger 1991; Orlikowski 2002). An ignorance of how practices are shaped within work contexts also induces operational problems of KM initiatives and results in difficulties with regard to technology adoption.

Third, different expert groups may employ different types of knowledge under different work contexts (Bogenrieder and Nooteboom, 2004). Alternatively, to acquire a ‘situated’ knowledge for a particular project, experts must participate in different working situations (Lave and Wenger, 1991; Tyre and von Hippel, 1997). Under different work contexts, knowledge can reside in physical processes, social communities and industrial contexts (Lam, 1997; Tyre and von Hippel, 1997). Therefore, detached from work contexts, the analysis of misalignment will only show ‘how information is managed’ without elaborating on why one group can employ technology to collaborate, share, and reuse knowledge effectively whilst another group struggles with the same technology (e.g. Huber, 2001). Hence, unattached to practices, transferring knowledge as object from one place to another or sharing it as individual cognition is out of the question (Hsiao et al, 2006). Transferring knowledge as a capability initiates a learning and evolving mechanism within individuals to enact ‘doable practices’ in any particular context (Orlikowski, 2002).

Our growing awareness of situated knowledge work context implies that anticipating the impact of KM technology on both organisation and individuals alike would require us to understand the various processes and relationships through which work practices enact and re-enact the ‘objectified social structures and the conditions’ where they occur (Schultze and Boland, 2000: 195; See also Orlikowski, 2002). We employ Bourdieu’s theory of practice as we believe it fits the analysis of ‘situated’ knowledge work practices in our research setting.

For instance, elements such as field (structures), habitus and practice described in Bourdieu’s theory of practice (1990 and 1998; Bourdieu and Wacquant, 1992) are very much relevant to knowledge work practices in any organisation (See figure 1 in section 3). To illustrate, within a particular field, knowledge workers struggle for power to obtain the intellectual capital. These multiple fields then define the (social) knowledge structures characterising a ‘context’. Such (social) knowledge structures are then internalised into knowledge workers’ minds and bodies as habitus acting as a symbolic template for their conduct, thoughts and judgments. These dimensions of habitus, underpinned by their own cognitive and motivating principles and shaped by their own collective experiences (Bourdieu, 1990), then decide their repeated and patterned knowledge behaviours and practices. Notably, understanding two important qualities of habitus is significant to know why there may be existing differences between the knowledge work practices between two individuals or two organisations. One is the habitus’ durability that explains why people adhere to certain knowledge work practices regardless of the working conditions. The other is the transposable quality that facilitates the knowledge worker’s ability to cope with ever-changing situations and to innovate in the face of unforeseen circumstances. Such an improvisation in practice is critical for organisational learning, innovation and change (Barrett, 1998). Deducing from Bourdieu’s theory, if a KM technology is developed in a context where people, for some reason (e.g. history, culture, experience, etc.) become
familiar with a particular ‘style’ of knowledge work practice that favours resistance to change practices, then this particular KM technology may not be appropriate for a wider market where requirements for technology customisation is mandatory. Alternatively, in a context such as that of a global management consultancy firm, knowledge workers, in some cases, may need to adapt to certain types of knowledge work practice in order to be able to work with international clients. Such ‘situated’ knowledge work practices may inevitably be different from what was assumed and inscribed by the KM technology developer. In sum, since habitus is a concept resembling culture (Harker, 1990) and ‘socialised subjectivity’ (Bourdieu and Wacquant, 1992: 126), we believe that country-level as well as industry-level differences are among pivotal factors in designing, developing, adopting and implementing KM technology.

As a result of a dialectical relationship between a specific circumstance in a field and habitus, knowledge work practices are effectively improvisational actions enacted by dynamically combining past experience, the present situation, and the implicit anticipation of the future consequences of these very practices (Bourdieu, 1973). The combination of all three elements varies from one organisation to another. Although two organisations may have the same assumptions and visions for their current contexts of knowledge work together with the implicit prediction of the outcomes of such practices, differences in their past experiences (i.e. behaviours, feeling and judgement, success or failure) may eventually result in somewhat differing situated practices performed by each organisation. For instance, Lam’s (1997) study exploring knowledge transfer between British and Japanese engineers found that British engineers worked quite independently in their social network and relied on explicitly codified practices (i.e. electronic repository) for disseminating knowledge. In contrast, as the Japanese engineers collaborated in a close-knit social network, knowledge transfer was mostly dependent on their intensive socialisation, which cannot be easily made explicit unlike formally codified rules. In this example, we contend that the difference in habitus, where British engineers work individually whilst Japanese engineers work collectively, eventually leads to the difference in knowledge work practice where Japanese engineers rely more heavily on their team-mates for solutions. We would therefore argue that a specific KM software package, if produced by developers in the UK and sold to the Japanese market, should additionally reflect such unique knowledge work practices to boost collaboration and capture necessary knowledge for re-use. The differing ‘situated’ knowledge work contexts can be also reflected via industry-level differences. Consider the pace of innovation activities for example. In the context of an innovative but stable industry, the development of a new product often follows a continuous technological roadmap (e.g. microprocessors). However, in the context of fast-moving industries such as biotechnology, aerospace, nano or computing, the ever-increasing competition in the marketplace may activate a rapid, discontinuous innovation in product and process (Hsiao et al, 2006). Eventually, lessons learned must be updated frequently, rendering it increasingly difficult for experts to spend sufficient time submitting their reflections and experiences (Hsiao et al., 2006). The differing nature of the two industry contexts reflected by the propensities (habitus) towards producing products, suggest that the resultant practices would require organisations to acquire differing knowledge work structures. Hence, employing the same technology to support knowledge works in two completely differing ‘situated’ contexts could be problematic. We would expect for example a KM software package employed in the context of fast-moving industries to incorporate special structures to enable experts to capture, classify and extract contents for re-use more efficiently and in a more timely fashion than in slower moving industries. Pentland (1995) for instance reported in his research that the decision-support system designed to share energy-audit engineers’ practices was significantly limited because the software algorithms became quickly outmoded due to the increasingly diversified energy-audit regulations in the US and the consequent changes to the audit processes.

3 THE RESEARCH FRAMEWORK AND METHODOLOGY

Our literature review has suggested that the misalignments of knowledge work context between KM software and organisations can be conceptualised as in figure 1. Additionally we use Markus and
Tanis’s (2000) four-phase view of the enterprise system experience cycle to explore misalignments. Markus and Tanis’s phase view helps us to clarify the business or operational context where misalignments arose. Such a context is also essential to understanding how KM practices occur throughout the technology lifecycle. Based on our case firm’s actual software implementation, we focus on the first three phases. Phase I, the chattering phase, involves gathering and defining the business case and solution constraints. Phase II, the project phase, involves getting system and end-users ‘up and running’. Phase III, the shakedown phase, involves getting the system and users to be in normal operation after the system’s roll-out. Each of these phases occurs sequentially with no time lags in between the phases.

We adopted a case study strategy (Yin, 1994) to investigate the likely misalignments between KM software package and the implementing organisation. This is a well-accepted approach to study the complex phenomena of IT implementation in an organisational setting (Orlikowski and Baroudi, 1991; Yin, 1994). We analysed the Change Request Forms (CRFs) submitted by the case study organisation from phase I to III to identify instances of misalignments during the course of a KM portal implementation project. A misalignment was defined as any instance where the KM group identified an organisational requirement that they felt was not being addressed by the KM software package. To exclude minor or trivial misalignments only those reviewed and accepted by the KM team and recorded in the standardised CRFs were analysed. The KM group and IS professional discussed with each other to decide whether to accept, put on hold or reject the request, and then with vendor’s consultants to decide whether to adapt to or customise the portal. Following this analysis, semistructured interviews were used to confirm and further clarify the contexts and rationale of identified and potential misalignments. The field work (lasting about 9 months) comprised of familiarising ourselves of the company’s business processes, reviewing the KM system and documentation (e.g. the technology, company’s documentation, contracts, project files, meeting minutes, requirements analysis, issues logs and video recordings of the negotiation between the KM group and vendor’s consultants), and interviewing 19 key internal stakeholders to gain insights from many different perspectives including all members of the KM group, i.e. KM programme manager, KM roll-out project managers, content managers, IS professionals, and especially two consultants representing the vendor. Additionally, informal meetings formed further sources of data gathering. Care was taken to consider all pertinent case evidence to reduce the risk of research bias. Contextual data that further explain the observations made were taken into account (Klein and Myers, 1999). Each interview lasted about an hour and was then transcribed and checked with interviewees for accuracy. The interviews were analysed to identify the sources of misalignments. The conceptual framework is used to examine the data, and to consider some ‘what if’ questions arising from problems reported by the interviewees or anticipated during the case. Findings were also discussed with two industry experts with rich experience of KM implementation. In all, 83 distinct instances of misalignments were
identified. However, since the focus of this paper is on misalignments of situated knowledge work context, we therefore analysed only 43 instances that are related to this issue. Our analysis was conducted as an iterative loop to uncover the factors underlying each instance. We found that of 43 instances, 32 surfaced during phase III. This means that the majority of misalignments only surfaced during actual interaction with the business or operational context. The remaining instances submitted during phase II were requested because of the consultants’ experiences.

4 CASE STUDY ANALYSIS

4.1 Case company’s profile

*KLN (pseudonym)*, headquartered in Europe and currently ranked within the world’s top 20 companies in terms of revenues, is a global IT-Management consultancy firm and employs tens of thousands of people in over 35 countries. KLN provides business consulting, systems integration and IT and business process outsourcing services across diverse markets including telecoms and media (T&M), financial services (FS), energy and utilities (E&U), industry, distribution and transport (IDT), space and defence (S&D) and the public sector. The company formally launched its KM initiative in 2005 although it had used portal technology from mid 2003. From late 2006, the company decided to migrate onto the latest version of the portal technologies with many enhanced features and a new design. The company’s portal is divided into three environments, namely *My Information*¹, *Workspaces*² and *Our Knowledge*³. This organisation was chosen based on a combination of accessibility and representativeness: KLN is a global consulting firm which is commonly discussed as the archetype of knowledge-intensive firms consisting of multiple communities of practice (Alvesson, 1993); KLN has implemented its KM initiative, including its portal, in a substantial way; KLN has a large-scale technology infrastructure in terms of its user base; KLN’s global operational context could present some interesting challenges affecting its technology implementation.

4.2 Data analysis

As far as the ‘situated’ knowledge work context misalignments are concerned, we have identified and classified them into six main themes of misalignment in accordance with our conceptual framework. The themes are related to access control for external workspaces, assistance for working with smart documents, enhancing the report function in *Our Knowledge* environment, searching and grouping results according to content types, capturing organisational metadata, and re-using workspace’s default components.

The first misalignment theme was about strengthening the access control mechanism. One of the key objectives of this case company’s KM initiative is to enable its clients to access workspaces outside the company conveniently. Since clients can only access ‘external workspaces’, which are similar to the ‘actual’ workspaces inside the company, it is important to effectively control clients’ access to these external workspaces. Upon reviewing the current protection and authentication method, some consultants found that the controlling mechanism must be strengthened to ensure the integrity of the organisation’s intellectual assets. For example, the current authentication method requires only a username and password check to fully access the system. However, the requesters were attempting to implement a more secure access control process that required the verification of a client’s identity and

---

¹ *My Information* provides private and shared information relating to each staff. It features a personal storage space for shared and private documents and allows for the management of an individual’s company profile.

² *Workspaces* are web-based environments that enable teams to share and collaborate on information.

³ *Our Knowledge* is a central store of publications, shared with all company staff. The information is stored in knowledge areas by subjects, such as sales and marketing and market intelligence.
purpose of access, in order to facilitate a more differentiated approach to access levels for various
clients. To progress between levels, clients must interact with a series of prompting questions on their
understanding of the projects, i.e. their roles and status. All these practices are monitored by the local
workspace’s manager in real-time. Viewed from Bourdieu’s theory of practice, this ‘situated’
knowledge work practice led to a misalignment that can be explained as follows. First, for the position
in field (structures), the primary concern of this global consultancy firm, in general and the KM group
in particular, is dealing with risks of breaching information security, ensuring knowledge integrity and
protecting intellectual assets. Specifically, the risk of breaching information security is higher than
ever because of KLN’s global operational context. The problem is getting more acute since KLN has
pursued an acquisition strategy in recent years, and thus experienced an expanding pool of
international projects. In this context, the fact that ever more clients have access to external
workspaces further threatens the integrity of KLN’s intellectual asset. These facts resulted in the
habitus that led the KM group to apply a more restrictive access control mechanism. Thus, by
suggesting the above-mentioned practices to verify and authorise the clients’ access level, consultants
believed organisational knowledge would be better controlled. Misalignment arose as the portal was
not intended to support this sophisticated mechanism.

The second misalignment theme was related to assisting content managers and experts in classifying
documents more efficiently. Specifically, what the requestors suggested doing was to equip the portal
with structures to easily capture contextual organisational metadata from produced or received
contents. For example, regarding the E&U industry, many projects and requirements from
international clients have produced a very high volume of documents, prompting the need to classify
these contents more efficiently. According to the KM Co-ordinator in Holland: “Tim [consultant
based in Holland] told me a couple of times that the [current] metadata could not help classify the
documents effectively. [Here is] an example. Tim is the author of two documents on Intelligent
Transport Systems (ITS) in Holland and Singapore. There are certainly many common attributes
within [these documents]. However, the context [between them] is slightly different. I mean, users
need to know how, what and why behind the work [of ITS] is being undertaken in those countries or
[they] need to know for each work’s context, what decisions were made in the first place that our
company can begin and continue, to learn”.

One way to deal with the above problem is to capture more ‘information in context’ for the meta-data.
This kind of ‘information in context’, which seems to be unique or situational, is normally defined and
reviewed in a meeting held every month for leading experts in each industry sector to find out what
have been the prominent or newly-emerging issues to be included. Then, such ‘information in context’
would be cross-checked by other industry sectors to remove duplication or confusion and to increase
transparency. Eventually the portal should be able to detect certain keywords which appear in
frequencies defined by this ‘contextual information’. Viewed from Bourdieu’s theory of practice, this
’situated’ knowledge work practice led to a misalignment that can be explained as follows. First, for
the position in the field (structures), being empowered by portal technology, content managers must be
able to classify an increasing volume of contents accurately. However, what is worth mentioning is the
fast expanding pool of international clients and projects that causes difficulties and complexities for
classifying the contents effectively and quickly. Given this context, content managers are prone to
(habitus) capturing more valuable data describing the projects’ circumstances, thereby continually
updating the metadata and taxonomy. Adopting the above-mentioned practice can strengthen content
managers’ positions in the field. Misalignment arose since the portal was not assumed to have the
capability of capturing such ‘situational’ data.

The third misalignment theme touched upon enhancing the reporting function in the organisational
repository. Because lack of reporting (i.e. on pushing and pulling knowledge items to and from Our
Knowledge environment) led to resistance in terms of KM implementation in some parts of the
business, content managers in Bangalore (India) and UK suggested upgrading the reporting function.
On the one hand, this upgrading is crucial for content life-cycle management to ensure the
effectiveness, quality and reliability of the content for users. On the other hand, upgrading the
reporting function could provide content managers with competent tools to encourage users’ participation in contributing knowledge to a particular area such as sales and marketing. Content managers could also measure the level of contribution from different users or establish the most visited or frequently downloaded documents in a particular country, business unit or service sector. This information could also be useful for the HR department as part of the KM performance indicator (KPI). This context was clarified by a KM programme manager: “One of the key things is to provide them [with] the feedback in terms of what is actually happening. If we ask the Marketing department in a country to do something, then we need to show them what they have actually achieved so far and give them some targets, for example and allow them to compare how they are doing with another company in other parts of business...So, we will know how much content is being provided by each part of the business and what the usage level is like...In other words, there are two sides. One is [that] we want to have reporting on what is in there [Our Knowledge]. The other is [that] we want to have reporting on what has been taken out. That means we have the publication side and the usage side”.

This misalignment reveals a difference in ‘situated’ knowledge work context. In accordance with Bourdieu’s theory, for position (structure) in the field, to support the overall KM initiative, content managers need to assess how users across the company pull and push knowledge from and to Our Knowledge environment. Their roles to support the knowledge contribution and use then lead to their tendency (habitus) to measure the number of documents to be downloaded and uploaded in each business unit or sector. The portal was not designed to assist content managers in capturing and reporting data on knowledge use in Our Knowledge environment. Therefore, by adopting the above suggested practices, content managers believe their positions in the field could be strengthened.

The fourth misalignment theme regarded to enabling the project teams to work more productively. From a knowledge-based perspective, assisting knowledge workers in creating contents is a good way to increase responses to fast changing business environment (Nonaka et al., 2000). There could be certain ways to automatically provide staff with data, information and reports for analyses. One way was to request to adopt a process whereby consultants are able to work with smart documents in workspaces. Specifically, by trying to embed a special tool into the portal, consultants could start a new project based on time-lines. Each of the project’s time-lines links with appropriate templates for documents and analyses that need to be created at each point of the project life-cycle. To do the analysis, topic or context-related reports for each of the project’s time-line are supplied by an automated procedure that collects data from Business Intelligence (BI) software. This kind of procedure is based on profiles defined by consultants before and during their project. Such knowledge works are particularly useful in the FS, T&M and E&U sectors. According to a senior consultant in IDT and FS in Germany: “Because of our recent acquisition, within six months, the number of projects and clients has increased remarkably. The deals are getting more complex and uncertain. To ensure our powerful delivery capability, we must be able to cope with abrupt changes and complexities...Internally, part of our competitive advantages is a strong BI [Business Intelligence] system continually providing us with quality and reliable data about our competitors and the [global] market. Our approach is to connect the output of BI with each of the project’s time-lines. That means [that] we are trying to make things [reports and templates] ready for them [consultants] to analyse throughout their projects. They would no longer spend too much time reading and manually importing things from BI [system]”.

Viewed from Bourdieu’s theory of practice, this misalignment can be explained as follows. First, for the position in the field (structures), there are several unforeseen or fast-changing circumstances occurring in sectors such as FS, T&M or E&U. To survive in the field, team members need to equip themselves with tools and data to cope with such situations. To tackle these situations, team members tend to look for (habitus) appropriate ready-for-use templates and automatically imported reports to support analysis in a timely fashion. By adopting the above mentioned practices, consultants could cope better with the fast-moving business environment. Misalignment arose because the portal was not assumed to support such an organisation-specific approach.
The fifth misalignment theme was related to organisation’s processes of extracting and viewing knowledge items. Given the nature of the work, many users favour searching and grouping results by content type (i.e. brochure, project summaries and references) and languages in Our Knowledge environment as they believe content type is important for refining what they are looking for. For example, the KM roll-out project manager argued that the retrieval process would be more productive and accurate when items are grouped and displayed according to content type. This misalignment could be understood by using Bourdieu’s theory. Indeed, at each point of time during the project, consultants would have a special need for knowledge items because of their positions in the field. If they are related to customer service, what they need to find is customer reference. From a Knowledge-Based View, this practice is related to the speed of pulling the knowledge items for knowledge workers. For instance, a staff working on a Customer Relationship Management project for clients of public transportation in France would need to know about sales of tickets, brochure or case studies on their roles thus lead to their disposition (habitus) to find only things having the appropriate properties and metadata. Hence, the suggested practices may assist consultants in searching for the right items in less time. Misalignment arose because the portal was not assumed to address this organisational-specific need of extracting and view contents.

The sixth misalignment theme was about automatising more the mechanism of creating bidding workspaces. To win bids over competitors, one of the critical tasks is creating bid projects, and thus developing the necessary bidding workspaces in less time. To do so, it is important to be able to ‘reuse’ templates as well as default components of existing workspaces. The context was clarified by the KM programme manager as follows: “Here is an example of UK financial services. OK, I want to create bid workspaces. It may be that I’ve got some local business processes which applied for that particular business unit. So this means [that] all bids must have certain checklists [of what-to-do actions as described by the local business processes] to be followed. In that situation, it’s more convenient for me to set up workspaces with default lists or web-parts or whatever for all bid workspaces which are owned by UK financial services. That is to say, I want to have the ability to save the template for [new bid] workspaces, and to feed that [the templates] into [the local business] processes so one can use that template by default”.

Simply put, such a requested approach could be seen as a way of standardising bid workspaces, which was supposed to be changed in the old version of the portal. Now with the portal’s new version, it is possible for the KM group to do things like default web-parts and default checklists so that the workspace’s configuration can be captured and stored. By employing Bourdieu’s theory, this misalignment can be explained as follows. First, for the position in the field (structures), in some core service sectors of KLN such as FS, IDT and E&U, the pressure for winning bid projects is gradually rising. A fast expanding pool of projects and an ever-increasing demand from clients create pressure on consultants to respond to bids rapidly. Given this context, consultants could quickly create (habitus) bid workspaces using templates without having to manually re-create every aspect of the workspace or default checklists. Such evolving structures would help teams save cost and time, thereby reducing the cost of the bid. Misalignment arose because the portal was not assumed to support consultants to create workspaces in this way.

5 DISCUSSION & CONCLUSION

Misalignment instances found in this case study have shown differences in situated knowledge work context between technology and the organisation. Such misalignments have also illustrated the complexities of the on-going interaction between consultants using the portal and both the immediate
and broader contexts in which these technologies are situated. Specifically, underpinned by Suchman’s (1987) account, we contend that such complexities reflected by the requirements and justifications for changing existing knowledge work structures or embedding emergent ones are contingent upon the immediate and broader contexts rather than the mere intention of the consultants for better knowledge work performance per se. We then argue that it is the intensity of such complexities that may be attributable to the extent, whether it should be superficial or deep, to which consultants wish to change existing knowledge structures or embed emergent ones. Additionally, we believe that the nuances of such complexities may also have certain impact on the consultants’ attitude towards changing or embedding the structures. We have shown how this occurred in the case using Bourdieu’s theory to analyse the surfaced misalignments. For instance, in relation to the misalignment in terms of external workspace access control, the ongoing interaction between consultants and both the immediate context where the clients were operating, and the broader context represented by the company’s global operational environment, created new levels of complexity that in turn opened up the potential for information security breaches. This complexity became more severe in terms of intensity, and more acute in terms of nuance because of the less secure global context and an expanding user (including international clients) base. Under these circumstances, the fact that more and more clients access the external workspaces further threatened the integrity of the company’s knowledge asset. This explains the reasons why some consultants suggested adopting a more subtle controlling mechanism, and why some consultants’ attitudes were rated ‘emergency’ in order to ‘deeply’ embed certain knowledge work structures into the portal with maximum effort and resources. Another illustration is the misalignment related to assisting experts to easily capture contextual organisational metadata. The complexity here had to do with increasing time pressures on consultants causing difficulties for classifying the contents effectively and quickly. This ever-growing pressure was due to the fast expanding pool of international clients and projects which resulted in an increasing volume of contents. Consequently, since this complexity is severe in terms of intensity and nuance, some consultants requested a ‘deep’ change by embedding emergent structures into the portal. Such ongoing interactions between consultants and both the immediate and broader contexts will continually create new complexities because the KM technology in this case study has opened up a new network of relationships across boundaries which eventually make uncertainties and instability become more prevalent (King and Star, 1990). Alternatively, in accordance with Orlikowski’s (2002) account that ‘knowing-in-practice’ is necessarily provisional, not something as ‘given and static’ as people draw upon their physical presence in a social setting, on their cultural background and experience, and on sentient and sensory information (Blackler, 1995; Tyre and von Hippel, 1997), we believe that misalignments of this type will keep arising. More particularly, knowledge work practice does not exist independent of social interaction, and its content does not necessarily mean the same value to all the people getting involved in the designing, developing and adoption processes (Dougherty, 2004). This differentiates KM software packages from the other enterprise systems such as ERP/CRM in that the misalignments relating to KM are perpetual throughout the system life-cycle.

The contributions of this study are threefold. In discussing a number of misalignments, our study strengthens Schultze and Borland’s (2000) account that exploring as well as understanding the unique knowledge work context is critical for the successful adoption and implementation of KM software packages. Besides, in addressing the weaknesses of their work, our results could be useful in terms of understanding the sources of misalignment and further presenting a more diversified, nuanced picture of misalignment in a global operational context comprising a large user base, thereby enriching theory of KM technology adoption and implementation. From an organisational perspective, such an understanding is highly salient as the issues of technology adoption “profoundly affect the manner, quality, and outcomes of organisational realities” (Orlikowski and Scott, 2008: 5). Practically, studies of this nature should assist organisations toward understanding the factors inherent within a successful KM technology implementation project in large or global firms, particularly those rich in high-value

---

4 KLN’s KM group defines four levels of priority to tackle misalignments: emergency, high, medium and low.
text-based knowledge for making decisions like consultancies, healthcare, R&D, defence, financial services and legal organisations.

Results of this study must be interpreted in the context of its limitations. First, given Markus and Tannis’s (2000) four-phase enterprise system lifecycle and the actual implementation, this single case study has only explored the first three phases. Misalignments arising from the onward and upward phase, which continues from normal operation until the system is replaced by an upgrade or a different system, remain undetected. This latter phase is essential for a complete assessment of the misalignments between the technology and this global firm. Second, due to limited organisational resources, we could not interview more users in different countries to gain a better view of situated knowledge work structures, both current and emergent. Future research should look into misalignments identified from a more highly regulated domain such as legal or health-care services, or how such misalignments have influenced organisational responses via organisational adaptation or technology customisation, or the process through which organisational staff arrive at a resolution for the misalignment (e.g. how users identify emergent situated knowledge work structures and then persuade the KM group to accept their requests). Such findings could have some valuable implications for knowledge based structures for innovation (See e.g. Anand et al, 2007).

SUCCESS FACTOR VALIDATION FOR GLOBAL ERP PROGRAMMES

Seidel, Gunter, Institute of Information Management, University of St. Gallen, Müller-Friedberg-Strasse 8, CH-9000 St. Gallen, Switzerland, gunter@gunter-seidel.de
Back, Andrea, Institute of Information Management, University of St. Gallen, Müller-Friedberg-Strasse 8, CH-9000 St. Gallen, Switzerland, Andrea.Back@unisg.ch

The success of current global enterprise resource planning (ERP) programmes depends on a wider range of factors than encountered in previous ERP efforts. Therefore, a better understanding of how these factors contribute to the effectiveness of ERP will aid programme development. To this end, the validity of twelve success factors with two to seven associated management actions derived by prior research was verified by a survey evaluated with structural equation modelling (SEM) based on the partial least squares (PLS) algorithm. This study was able to verify all twelve success factors and more than 80% of the associated management actions. The results form a predictive model of success probability of global ERP programmes.

Keywords: CSF, ERP, global, SEM, PLS, predictive model, success factors.
1 INTRODUCTION

The number of companies operating globally is constantly increasing. This expansion applies to large corporations as well as small and medium-size enterprises. In order for these companies to operate globally, they require a global view of processes and their implementation in global enterprise resource planning (ERP) systems. These ERP systems allow to integrate an organization’s information sources and to harmonize its processes across multiple sites and countries. Most ERP systems are based on software packages from companies like SAP or Oracle. ERP implementations are generally cost intensive and have a duration of many months or years.

But, not all global ERP programmes are successfully implemented. Some implementation projects fail in terms of classical project tracking, e.g. slippage of roll-out dates, budget overruns or missed scope objectives, while others fail more severely in their business impact, e.g. intended business benefits are not achieved including process standardization, process automation and asset carrying cost reduction.

A report on ERP implementations in companies with more than $500 million in revenues indicated an average schedule overrun of 230%, an average budget overrun of 178% and an average slide of functional improvements of 59% (Buckhout et al., 1999, p. 61).

To reduce the number of failed ERP programs, their general success factors have been investigated but reports of these are not sufficiently comprehensive for global programmes as multi-national operations generate aspects that need to be addressed for success. To generate a better understanding of how these success factors contribute to the efficiency and effectiveness of ERP and to aid programme development the validity of twelve success factors with two to seven associated management actions derived by prior research was verified by a survey evaluated with structural equation modelling (SEM) based on the partial least squares (PLS) algorithm.

This study was able to verify all twelve success factors and more than 80% of the associated management actions. The results form a predictive model of success probability of global ERP programmes. Use of this model may aid companies in developing effective global ERP programmes.

2 BACKGROUND

Many companies of various sizes must decide the extent and means by which to support worldwide activities through globally-harmonized processes and systems. An example of a typical global ERP implementation based on a case study is extensively described in the literature by Sankar & Rau (2006). A detailed review of whether to implement an ERP system, categorization of the types of benefits to be expected and the guidelines in selection of ERP consultants, software and hardware vendors can be found in Davenport (2000).

One way to face this decision is to use a technical approach based on templates; this approach was defined about a decade ago. Huber et al. (2000) defined a template as "concepts or models for the standardization of processes, functions, and data that could be implemented in a physical (ERP) system (Huber et al., 2000, p. 4)" and further defines a concept for standardization of company-wide ERP systems.

Necessary requirements to implement global ERP systems are investigated in Davidenkoff & Werner (2008). In particular the legal requirements, customs and user requests, but as well challenges in languages, address versions and time zones are reviewed (Davidenkoff & Werner, 2008, p. 37ff).

In general, Critical Success Factors (CSF) for implementing ERP programmes have been broadly analysed in the literature. Early investigation of CSF as Holland & Light (2003) were based on general case studies. Later Nah et al. (2001), Somers & Nelson (2001) and Al-Mashari et al. (2003)
investigated CSF for the different phases of ERP programmes. While recent studies investigated CSF for specific settings as e.g. industry and size (Soja & Put, 2007), no comprehensive investigation of CSF for global ERP programmes was identified from literature.

Aspects of change management are always part of ERP implementations and have been investigated repeatedly. For example, Hossain et al. (2002) propagates the use of the "myth of integration", i.e. the vision of an integrated enterprise as the driver for change (Hossain et al., 2002, p. 17ff). While the CSF list in the literature is extensive, it generally does not consider multi-national aspects of ERP implementation. However, a few papers have been dedicated to this subject. Huang & Palvia (2001) introduce a research framework to compare ERP deployment in developed and developing countries (Huang & Palvia, 2001). Multi-national ERP implementation practices were shown to be affected by national differences, identified as culture and language, government/corporate politics, management style, government regulations, time zone and labour skills (Sheu et al., 2003). The relationship between ERP implementation and a firm’s competitive strategy has also been investigated and national culture and government/corporate policies, in particular, were found to have a significant impact on ERP deployment (Yen & Sheu, 2004).

3 HYPOTHESIS

A series of expert interviews conducted in prior research and an extensive review of CSF literature has led to a definition of success of global ERP programmes and a number of common and site specific success factors (Seidel, 2009). In total 13 interviews were conducted with CIOs and project managers of multi-national ERP programmes defined as covering more than one language area. Content validity was ensured by using a theory based interview guide and inclusion of CSF only if cited without contradiction by multiple interviewees. These success factors and associated management actions and their impact on success as defined below are the hypothesis to be verified in this research.

3.1 Definitions of Success

Success of a global ERP programme is two-fold. On one hand the impact of the resulting Information System on the organisation is of interest. On the other hand the execution of the global ERP programme is of interest as a measure of efficiency. The former is named 'Programme Objectives', the latter 'Project Objectives' in this research.

The programme objectives are either clearly quantifiable 'Savings' in terms of IT costs, process costs or directly associated reductions to specific business expenditures such as stock-carrying costs. On the other hand, a number of indirectly quantifiable long-term business benefits are possible benefits such as risk reduction, auditability, adherence to standards and improved competitiveness. These are company-specific and are grouped under the heading 'Business Improvements'. Therefore the variable 'Programme Objectives' is hypothesized to be defined by 'Business Improvements' and 'Savings'.

The importance of the project objectives varies from programme to programme. Generally an on-time introduction is considered important, as it is highly visible in the organization and directly drives costs. On the other hand, the traditional trade-off between scope and time is always imminent. While in-budget programme completion is desirable, many programmes have multiple budget revisions due to the long timeframe of implementation and the constantly changing conditions during the roll-outs. While in-scope has many company-specific definitions, one common theme was the avoidance of business interruptions during go-live, and functioning maintenance and support. Therefore the variable 'Project Objectives' is defined by 'On-Time', 'In-Budget' and 'In-Scope'.
3.2 Common Success and Endangerment Factors

A number of success and endangerment factors are common to all ERP programmes and influence the programme outcomes of each site. Each factor has a number of management actions associated which drive the respective success factor. All of these success factors and management actions were verified by expert interviews in prior research. The list of these indicators to be verified in this research can be found in Table 1.

3.3 Site-specific Success and Endangerment Factors

A number of success and endangerment factors are site-specific. These influence the programme outcomes for each site individually and must be aggregated over all sites to estimate their impact on the overall programme. Each factor has a number of management actions or indicators associated which drive the respective success factor. All of these success factors and management actions /
indicators were verified by expert interviews in prior research. Table 2 summarizes the site-specific factors to be verified in this research.

4 RESEARCH APPROACH

The research conducted prior has led to the generation of twelve success factors for global ERP programmes. These factors were derived from the opinions of experts captured in interviews. For each success factor a number of management actions to drive each success factor were identified.

The current research step described here now brings the success factors to another level of certainty and operationalisation. It proves the validity of the success factors as valid drivers of overall ERP programme success as defined in the preceding section based on the actual outcome of a statistically relevant number of ERP programmes, focussing on outcomes rather than opinions. In addition it generates relative weighting of the success factors and the management actions driving them. This will enable a forecast of the ERP programme success based on the implementation of the relevant management actions in early set-up and blueprint phases of global ERP programmes.

4.1 Research Method

The structure to be verified with SEM was generated from the results of the qualitative research conducted prior. This is an acceptable approach according to Skrondal & Rabe-Hesketh (2004): "Instead of defining hypothetical constructs on theoretical grounds, they are sometimes 'derived' from an exploratory analysis (Skrondal & Rabe-Hesketh, 2004, p.5)". Albers (2007) states that "selecting the relevant factors [...] should be done on the basis of expert interviews and a thorough literature review (Albers, 2007, p.9)". While the analysis which has lead to the model is based on expert opinions, this research step focusses on the situation of actual programme outcomes and therefore verifies the model beyond the distortion of opinions.

There will be a number of variables which cannot be directly observed or measured – so called hypothetical constructs of latent variables. This is either because the variable is unobservable by nature (one example is 'Unwillingness to Change' as a collective attitude, which cannot be measured directly) or has not reached the final state which the model intends to predict (one example is 'Programme Objectives' which eventually can be measured but shall be predicted in early stages of the ERP programme). For these latent variables a measurement model has to be specified which defines "the relationship between latent variables and suitable indicators, which allow to measure the latent variables indirectly (Backhaus, 2006, p. 11, translation of the author)".
While the factors related to 'Programme Objective' and 'Project Objectives' are elements which describe the underlying latent variables, the causal relationship is different for the critical success factors. By the design of capturing these factors they are described as elements which can be used to change (i.e. to cause) the latent variables of the twelve success factors. This is often the case in success factor research as was pointed out by Albers & Hildebrandt (2006). Therefore the success factors are formative indicators and the ERP programme outcomes are reflective indicators. This assertion was verified by a list of criteria stipulated by Fassott (2006).

In Herrmann et al. (2006) variance and covariance based SEM approaches are contrasted. While the covariance based approaches result in a model structure to minimize covariance error terms, the variance based approaches aim for an optimal reproduction of the real data structure, i.e. the indicator values. As one of the goals of the SEM based verification is to generate a quantifiable prediction, a variance based approach was chosen in this research.

Based on the software review by Temme et al. (2006) the software SmartPLS version 2.0.M3 (Ringle et al. 2005) was chosen to conduct the analysis. The software is platform independent and without license fees. It supports graphical modelling, the bootstrapping procedure to generate significance measures, and different handling approaches for missing data.

4.2 Data Gathering

The development of the questionnaire was directly based upon the qualitative research conducted in prior research. In particular for each success and endangerment factor a number of management actions driving them were defined (see Table 1 and Table 2) which were asked individually in the questionnaire grouped by the respective success factor. The questionnaire can be found under http://www.gunter-seidel.de/phd/questionnaire_DSAG.pdf. Design guidelines to avoid common method bias as outlined in Podsakoff et al. (2003) were considered in the questionnaire design, but practical limitations of survey administration as 5 point likert scale, anonymous data collection, and non-availability of secondary sources limited their applicability. In particular the anonymity of respondents did not allow to assess whether they possess a complete picture of the EPR programme they assessed. Instrument validation as demanded by Straub (1989) was partially ensured by the development of the questionnaire based on expert interview guides and peer review, but no multitrait-multimethod comparison (comparing multiple measures of the same research subject gathered by different methods) nor pilots of the survey were conducted.

The chosen Likert scale interval data do generally violate the normality assumption. The degree of impact under different estimation methods was investigated by Muthén & Kaplan (1985) with the conclusion that “it is therefore reassuring to find that these normal theory estimators perform quite well even with ordered categorical and moderately skewed/kurtotic variables (Muthén & Kaplan, 1985 p. 187)”. In particular PLS is very robust against non-normal data.

For the sample size the recommendation for PLS based analysis as indicated by Ringle (2004) is the highest number of paths leading to any latent variable times ten (Ringle, 2004, p. 16) – in case of the final model this implies 80 data points. As PLS is considered robust against small sample size (Chin & Newsted, 1999) a number below the theoretical optimum stipulated was deemed acceptable.

The target for the survey was the DSAG (Deutschsprachige SAP Anwender Gruppe), an organisation with 2000 member companies of which more that 400 are subscribed to the globalization group. The survey was administered in a period of three months with multiple reiterations to address potential participants. It resulted in 67 admissible data sets (data sets with incomplete outcome indicators and two test data sets entered by the researcher were excluded). Although the intended sample size had not been reached, the analysis was conducted with the available data in full understanding of the limitations of applicability resulting hereof.

There are a number of missing observations for success indicators in the data set. A visual inspection of the data set resulted in the assertion of data missing at random (MAR). Therefore a number of
approaches could be used to handle the missing data set (Byrne, 2001, p. 289ff) as casewise or listwise deletion or imputation of the missing data via means, regression or pattern matching. The approach of mean replacement was eventually chosen as a method supported by the analysis tool which does not decimate the number of cases further.

The data was analysed regarding *kurtosis and skewness* with the help of SPSS 16. The kurtosis of the indicators is between -1 and +3 with an average of 0; skewness is between -2 and +.5 with an average of -.6. These values are generally not considered extreme skewness or kurtosis, nonetheless it would have distorted the covariance based SEM approach which relies on normal distribution – fortunately the same does not apply for the chosen PLS approach.

*Non-response bias* was analysed by comparing the responses received until one week before end of the initial response period, and further responses received thereafter including based on reiterated requests and extended periods. In particular the design choices of the programmes as centralization, process standardization and adherence to package standards as being the closest to demographic data were compared for these groups. Deviations between both groups were within single digit percentages indicating limited non-response bias. Due to the limited sample size a full PLS model comparison of both groups were not conducted as results were deemed not statistically relevant.

The extent of *common method bias* was assessed using Harman's single-factor test according to Podsakoff *et al.* (2003). All variables of the study were loaded into a principal component factor analysis and the unrotated factor solution examined. Although one factor accounted for 28% of the total variance, it was not concluded that neither "(a) a single factor [did] emerge from the factor analysis [n]or (b) one general factor [did] account for the majority of the covariance among the measures (Podsakoff *et al.*, 2003, p. 889)". Therefore no significant common method bias was corrected for in the remainder of the analysis.

## 5 RESULTS

Henseler *et al.* (2008) provides a general structure for validity analysis. It recommends to check for reflective and formative measurement portions according to different procedures and subsequently for the validity of the structural portion. PLS based analyses does not generate any overall goodness-of-fit measures similar to covariance based SEM outlined in Hu & Bentler (1999).

For the reflective measurement models of the endogenous variables 'Programme Objectives' and 'Project Objectives' the size of the load is one criteria to be used to assess *indicator reliability*. According to Hulland (1999) "items with loadings of 0.7 or more, which implies that there is more shared variance between the construct and its measure than error variance (Hulland, 1999, p.198)" should be accepted. Given the factor loads in the range of 0.708 to 0.921 for the reflective measurement variables the model fulfils this requirement.

*Composite Reliability* (for the reflective measurement models) can be assessed with Dillon-Goldsteins Rho with a suggested value of higher than 0.7 as benchmark for modest composite reliability. It replaces Cronbach's alpha used in regression as "in comparison to Cronbach's alpha, this measure does not assume tau-equivalency among the measure with its assumption that all indicators are equally weighted (Chin, 1998, p. 320)". Both 'Project Objectives' and 'Programme Objectives' do fulfil the requirement with a value of 0.910 and 0.803 respectively.

*Convergence validity* (for the reflective measurement models) can be assessed by a value of the Average Variance Extracted (AVE), which should be higher than 0.5 (Fornell-Larcker-Criteria). Again, 'Project Objectives' and 'Programme Objectives' do fulfil the requirement with a value of 0.772 and 0.675 respectively.
Discriminant validity (for the reflective measurement models) can be shown when the root of Average Variance Extracted (AVE) is larger than the correlation to any other latent variable. In case of the reflective measurement models 'Project Objectives' and 'Programme Objectives' this can be confirmed as indicated in Table 3. On the diagonal of the matrix the square root of AVE for the reflective measurement models are shown, below the diagonal are the correlations. The square root of AVE is larger than the correlation in the respective column and row for both 'Project Objectives' and 'Programme Objectives'.

Table 3. Root of AVE larger than correlation

Table 4. Cross loadings – row with formative indicators were excluded due to space constrains as measure for discriminant validity is only applicable for reflective indicators

Another measure for discriminant validity is the cross loading of indicators assigned to the reflective measurement model variable against any other latent variable. For the indicators 'Business
Improvement' (BI) and 'Savings' (S) as well as for the indicators 'On-Time' (OT), 'In-Scope' (IS), and 'In-Budget' (IB) the highest load is on 'Programme Objectives' and 'Project Objectives' respectively as can be seen in Table 4.

For the formative measurement portion of the success factors the "examinations of correlations or internal consistency have been argued as inappropriate and illogical (Chin, 1998, p. 306)". To rely on the path estimates it is recommended to analyse the data regarding multicollinearity indicated by the variance inflation factor (VIF). As Albers (2007) indicates that "intercorrelated factors do not imply indicators reflecting a construct but are rather the result of applying certain holistic strategies in practice (Albers, 2007, p. 10)". Therefore they are not due to be removed for unidimensionality reasons, but rather as they generate unstable results in the signs and size of the weights. With the help of SPSS 16 a multiple regression was run for each group of indicators belonging to a formative measurement against an arbitrarily chosen indicator of an endogenous variable. The analysis resulted in VIF generally below 2, which does not give raise to serious concerns regarding multicollinearity as level of concerns are stipulated to be above 10 (Henseler et al., 2008, p. 25).

No review of absolute size of loads and t-test were conducted, as these elements were confirmed in the prior qualitative research and only the load onto the objectives were of interest. Albers & Hildebrandt (2006) strongly objects to model changes based on pure statistical criteria, as the causal relationship was established prior and remains even in case of small quantifications. Only loads which signs were in contradiction to the prior established direction of causality were excluded.

Having established the validity of the measures scales the validity of the structural portion to explain the success is of interest next. As for the PLS algorithm no model improvement process is established similar to covariance based SEM the review based on path coefficients was proposed by Henseler et al. (2008): "Structural paths, whose sign is in keeping with a priori postulated algebraic signs, provide

Figure 1. Revised critical success factor model
a partial empirical validation of the theoretically assumed relationships between latent variables. Paths that possess an algebraic sign contrary to expectations do not support the a priori formed hypotheses (Henseler et al., 2008, p. 26f). Therefore from an initial n:m (many-to-many) relationship relating all success factors to both success variables 'Project Objectives' and 'Programme Objectives' all paths with a negative loading were removed to come to the final model outlined in Figure 1. The reported values are the weights for the formative measurement, the loadings for the reflective measurements, and the path coefficients for the inner model.

The measurements to be reviewed follow the logic of multiple regression. First the degree to which the model is able to explain the data set is defined by the $R^2$ value. The value of 0.503 and 0.410 for 'Project Objectives' and 'Programme Objectives' respectively define that about half of the success can be explained by the model, while the other half is driven by factors not captured in the defined success factors. Chin (1998) describes an $R^2$ of .67 as "substantial", and $R^2$ of .35 as "moderate", and an $R^2$ of .19 as "weak" (Chin, 1998, p. 323). Others define an $R^2$ of at least 50% as desirable, as it explains more than it does not explain. While a better $R^2$ would clearly be desirable, already a moderate explanation of the success of global ERP programmes can be considered an addition to the understanding of these programmes.

All prior tests were focussed on the model itself in regard to the data sample. To ensure that the model represents the population requires to assess confidence levels of the relationships. As PLS does not rely on distributional assumptions as covariance based SEM does, no implications can be made based on it. Therefore a distribution has to be generated based on the bootstrap procedure. This procedure generates a number of random samples of same size drawn from the main sample with replacement and calculates the model. The distribution of each path loading can be assessed by the students t-test. According to Albers (2007) "the result of a significance test heavily depends on the number of investigated cases or other non-controlled effects. Therefore, we get richer information if we determine the level of impact that different drivers have on business performance. Insofar we advocate that not significance testing is the main purpose of success factor studies but the determination of the parameter levels (Albers, 2007, p.15)". Therefore the significance levels have been added to Figure 1.

While the figure shows that all indicators to the reflective measurement model are of a confidence of above 99%, some of the indicators to the formative measurements are even below the 85% confidence. Nonetheless as stated by Henseler et al. (2008) "the researcher should keep both significant and insignificant formative indicators in the measurement model as long as this is conceptually justified (Henseler et al., 2008, p. 25)". Given the source of the success factors (expert interviews) none of the factors were removed due to confidence considerations. On the other hand for the paths with lower confidence a substantial relationship remains to be verified. Therefore a review based on a larger data set would be desirable.

In addition based on the weights in Figure 1 a relative impact of each management action to the success factor and a relative impact of each success factor to either 'Project Objectives' or 'Programme Objectives' or both was established. The results can be used for predictive purposes when the implementation or intention of a management action can be gathered. To apply the weights on unstandardised raw scores the effect of standardisation must be reversed. SmartPLS offers the output of index values for the measurement model which are unstandardised and sum to 1 for each CSF (personal communication via SmartPLS forum, Diógenes de Souza Bido, Universidade Presbiteriana Mackenzie, Sao Paulo, Brasil). Building a sum of each index value multiplied by the path coefficient to 'Project Objective' or 'Programme Objectives' leads to an overall impact factor for each management action.

### 6 CONCLUSIONS AND DIRECTIONS FOR FUTURE RESEARCH

While the model derived from this research fits the data reasonable well, it should always be noted that any "model - regardless of how well it fits the data - remains only one possible means of its [the data's]
description and explanation (Raykov & Penev, 2001 p. 298). A replicated analysis therefore should always start again with a full many-to-many relationship of all success factors to both 'Programme Objectives' and 'Project Objectives'.

The data set gathered allowed to verify a positive impact of 34 of the initially gathered 41 management actions to drive success of the global ERP programmes (which does not imply the other must be rejected, rather that the limited sample does not allow to verify them). The positive impact of each of the twelve success factors to either 'Project Objectives' or 'Programme Objectives' or both could be verified, although not always generalized to the whole population due to insufficient significance levels. These factors jointly allow to explain about half of the success of global ERP programmes.

Future research to improve the extent of success prediction could take into consideration the lifecycle of the ERP programme, design choices of the programme as mediating factors, a more detailed analysis of the dependent variable of success, or a replication of the survey in a different national culture to compare the impact of management cultures.

To allow prediction of success of global ERP programmes the individual contribution of each management action to either 'Programme Objectives' or 'Project Objectives' or both was established. This will allow to forecast the success probability of a global ERP programme once the implementation of the respective management actions has been decided in an early set-up or blueprint phase of the programme.

Abstract:

Most of empirical research about users’ resistance toward IT has been conducted after IT been implemented in organizations surveyed. Few longitudinal research have been done about the way individual and group resistances emerge and evolve during prior stages of projects. This focus on pre-implementation phases is all the more important that IS managers need to anticipate potential conflicts and users’ resistances likely to involve project failure. This article delivers the results a two year longitudinal research conducted at Netia corp. (a worldwide leader in video and audio broadcasting) during preliminary phases of its ERP implementation project. As main findings, while conflicts toward IT implemented are often considered as having negative effects and requiring to be actively managed by the hierarchy, the case study delivers an alternative observation: it describes how an affective oriented conflict has been solved while managers adopted an “avoiding management style”. Our observations differ from several prior studies about conflict management styles and support that an avoiding management style can drive team’s members to cope efficiently with conflict situations during IT pre-implantation phase. In conclusion, the article presents research perspectives associated to these results.

Keywords: IT implementation, ERP, user’s resistance, conflict situations.
1 Introduction

Understanding key factors contributing to IT adoption in organisations is a central concern in information system research. Among key factors associated to IT project failures, users' resistance is one of the most salient because related to human resistance to change (Jiang, Muhanna et coll. 2000). Existing literature on IT resistance provides practical knowledge about underlying conflicts types and conflict management styles' performance (Cramton 2001, Montoya-Weiss et coll. 2001, Barki & Hartwick 2001, Markus et coll. 2000, Miranda & Bostrom 1993). However, most of these researches has been empirically conducted after IT been implemented in organizations surveyed and can be considered as observations made on downstream results of upstream resistance process. As a consequence, a large part of resistances are observed as task oriented and related to the non appropriateness of IT users have to cope with. Little empirical investigations were done about the way individual and group resistances emerge and evolve during prior stages of projects (Lapointe & Rivard 2005) while negotiations about IT to implement can raise affective oriented resistances if users perceive threats about their values or power relationships because of organisational changes expected. A focus on pre-implementation phases is all the more important that IS managers need to anticipate potential conflicts and users' resistances likely to involve project failure (Marakas & Hornik 1996, Joshi & Lauer 1998, Robey et coll. 2002, McAfee 2007).

Because enterprise systems are considered as ones of most impacting IT on future actions (Jiunn Chieh Lee & Myers 2004) because of their cross-functional perspective (Markus et coll. 2000) and readiness to change (Kwahk & Jae-Nam Lee 2008), we decided to report resistance evolution toward ERP adoption project during pre-implementation phase. To contribute to this issue, the article is structured as follow. The literature analysis reviews conceptual foundations of resistance, conflict and conflict management styles associated to IT implementation. The case study analysis delivers the results a two year longitudinal research conducted at Netia corp. (a worldwide leader in video and audio broadcasting for TV and Radio channels). Firstly, our observations revealed that task oriented conflicts expressed by users actually hid an affective oriented conflict. These resistances required the abortion of the ERP initially considered for a less impacting application on some specific process changes and on underlying power redistribution across group of employees. Secondly, we observed how this conflict between developers and administration employees switched to a solving solution while managers adopted an avoiding management style. Whereas conflicts toward IT are often considered as requiring to be actively managed by the CEO (Markus et coll. 2000, Barki et coll. 2001), the case study delivers an alternative observation. In conclusion, the article considers users' resistance toward IT as not a systematic negative behaviours aiming project abortion, and invites researchers to explore how task oriented and affective oriented conflicts can turns out to be key processes embedded in information system design.

2 Literature review

In management and organisation theories, the political school of thought developed by famous authors like Mintzberg (1998, 2002) or Crozier (1977), considers strategy formation and implementation shaped by power and political plies. As a consequence, strategical project usually involves shifting coalitions of dominant actors of parochial interests (Jiunn Chieh Lee et coll. 2004). Even if lot of research in IS proposed understanding IT user’s resistance toward a deeper approach (Joshi 1990, Krovi 1993, Joshi et coll. 1998) it seems marginal compared to articles published on the subject. Lapointe & Rivard (2005 p.462) revealed among 43 articles published during last 20 year period about user’s resistance toward IT, only 4 did not settle for considering resistance as a factual characteristic of the context. The majority of these studies treated users’ resistance as a component of an organisational system at individual and group level (Markus et coll. 2000) and only a minor part of these studies were devoted to study the causal conflicts (Jiang, Klein et coll. 2000). While literature stress on “resistance” or “conflict” without making clear differences between both concepts, our analysis, both based on psychology and sociology theories, incites to consider resistance as the behavioural dimension of conflict.

Resistance literature background

User’s resistance is defined as a subjective process psychologically based at individual level (Jermier et coll. 1994). It corresponds to behaviours in reaction to a present or ongoing situation perceived as negative (Ang & Pavri 1994), as inequitable (Joshi 1991), as a threat or as a stressing feeling (Marakas et coll. 1996). According to Joshi (1991) resistance appears when user perceives changes involved by an “unfair” project in regard to his/her personal work or in regard to the group he/she belongs to.
Users can express resistance toward IT with an active form (visible and relatively easy to detect) or in a passive form (hard to detect and difficult to deal with) (Tetlock 1999, Tetlock 2000, Jiang, Klein et coll. 2000). Empirical studies shown that resistance is higher at group level than at individual and organisational levels (Lapointe et coll. 2005). In other words, group of persons (depending on their professional category, professional competencies, age, gender, etc.) represents the more likely unit to develop high resistance toward IT. Indeed, at group level, users’ resistance is often socio-political whereas at the individual level it is more psychological (Markus 1983). Coetsee (1999) identified 4 types of resistance expressions:

- **apathy** corresponds to attitude of disinterest and inaction of a person toward the situation;
- **passive resistance**: a person adopts some behaviours aiming for slowing down changes and keeping the previous system (examples: voluntary delays in task to do, argumentation in favour of so-called advantages of existing rules and processes);
- **active resistance** is considered as a “constructive form” (examples: expression of different points of views, negotiation about a consensus, accommodation);
- **aggressive resistance**: users can resort to threats, blackmails, boycotts and all other actions whom objective is blocking the situation.

According to the author, these forms are not exclusive and should be considered as part of a continuum encompassing on the other extreme user acceptance and involvement.

**Conflict types**

Conflict is defined as a disagreement of persons or groups of persons considering a situation as inconsistent with their own interests (Boulding 1963, Robbins 1974, Putnam & Wilson 1982, Hocker & Wilmot 1985). A conflict can oppose somebody to himself or herself (internal conflict), to other persons, groups of persons or to institutions (Thomas 1992). Several definitions synthesis made in organization theories (Putman & Poole 1987), psychology (Thomas 1992) or information systems (Barki et coll. 2001) considers three properties of interpersonal conflicts: interdependence, interference and disagreement. By itself, each property can not be considered as a sufficient condition. Interpersonal conflicts are more dependant of their overlapping.

- **Interdependence** exists when each party reaches a specific goal, at least because of the actions of the other party. In essence, interdependence is a structural condition for conflicts in a professional context because of respective consequences of the way the other party acts.
- **Interference** is a behavioural condition for conflict and occurs when one or several parties opposes the other party's attainment of its interests, objectives, or goals. Interference thus represents the central behavioural node of any conflict (Barki et coll. 2001 p.198).
- **Disagreement** is a cognitive condition for conflict and correspond to divergence of interpretations toward values, objectives, needs, methods, etc. Disagreement refers to disputant behaviours and is considered as the central process associated to conflict (Wall & Callister 1995).

While first and second properties sounds like relational configuration associated to conflict, the last one deals with upward causes. In professional contexts, these causes can be task (or process) oriented versus affective (or relational) oriented (Deutsch 1969, Pinkley 1990, Jehn 1995, Jehn & Bendersky 2003). Conflicts about tasks are issue oriented and arising from differences between professional missions to be performed, whereas affective conflicts refer to personalized disagreements or individual disaffections. The first ones can be considered as differences of points of view rarely assorted of negative emotions while the second ones can raise frictions and tensions which can affect team performance (Jehn & Mannix 2001). We distinguished 4 different conflict types drawn from task and affective orientations (see Table 1).

Conflicts about task definition and execution are caused by the way organisational processes have to be adapted or transformed to fit with IT process requirements (for examples: how invoices and orders must be established, new data codification, signature validation process). These conflicts can be “internally initiated” when users compare the way they achieve their tasks and perceive organisational inconsistencies (Besson 1999). They can also be “externally initiated” because of the process constraints imposed by information technology to be implemented. For instance, ERP standard modules represents one of the most well known conflict driver because of new “best practices” imposed to employees without too much consideration of organisation specificities (Davenport 1998, Markus et coll. 2000, Lim et coll. 2005). This type of misalignment with organisation processes (Hsiao-Lan et coll. 2005) is all the more important that problems in MIS are more about the ability of users to understand how they must carry out their new tasks than ability of the firm to manage change (Robey et coll. 2002).

Conflicts about new professional skills deal with competences users must develop in order to be qualified to job transformations involved by IT (Markus et coll. 2000, Besson & Rowe 2001). Accountancy is one of the most salient professional illustrations: before ERP implementation during 90's, an important part of daily work of these employees consisted of collecting, aggregating and synthesising a huge quantity of financial data. Enterprise applications change dramatically their assignments: being no more the ones who collect financial data, they are asked to interpret these information’s ex-post, to make sense and recommendations to top managers (Bernard et coll. 2004).

Value conflicts are psychologically based. They refer to ideology by which some people share beliefs and make sense of their worlds (Trice & Beyer 1993). Firm subunits may have their own subculture varying in their ideological content (Stewart & Gosain 2006). In IS, value conflicts may arise on inconsistency between cultural principles of users or group of users and the perceived underlying strategic objectives assigned to IT implementation (Leidner & Kayworth 2006). Several empirical researches (Besson 1999, Kohli & Kettinger 2004, Ménard & Bernier 2004, Bhattacherjee & Hikmet 2007) revealed how these conflicts raised in the hospital sector. For example in his study, Besson (1999) observed that financial control allowed by the ERP over all the hospital activities was perceived by medical employees as an attempt of a market based activity inconsistent with fundamental principles of health public services. The empirical analysis of Wagner & Newell (2004) revealed complementary observations according to which ERP can be problematic for organisation sub-cultures because mandating one epistemological position through the software design based on “best practices”.

Power conflicts concern the way individual autonomies and capabilities of influence are likely to be redistributed among employees after IT implementation. Research in IS challenged understanding of IT development and implementation deviations by pointing out intricacies due to power influence exerted by actors (Markus 1983, Davis et coll. 1984, Markus & Bjorn-Andersen 1987, Jasperson et coll. 2002, Avgerou & McGrath 2007). On one side, IT can give more power to key users by allowing them to use real time data access functionalities (Davenport 1998). On the other side, IT can reduce the autonomy of employees (Markus 1983). Despite hierarchical monitoring supported by IT, power loses for employees may be caused by more interdependencies with colleagues. For instance, in civil
engineering project management, ERP implementations changed the way main actors (project supervisors, architects, electricians, plumbers, etc.) collaborate (Gilbert & Leclair 2004). Formerly, they did not have to communicate to their colleague the details and calculations on which their analysis and conclusion were based. The integration of processes associated to IT looks like a management of interdependencies (Rockart & Short 1995) by which actor become prescriber of conditions and means of his colleagues. As a consequence the political perspective in terms of power distribution misfit appears to be primarily applicable for cross-functional IS (Markus 1983).

Actually users' resistance forms are not exclusive and can occur simultaneously. However, emotional conflicts are considered as highly contagious (Hatfield et coll. 1993) and likely to overshadow or dominate congruous task oriented conflict (J. Ford et coll. 2008 p.369). Actually, MIS literature based on the interaction theory (Joshi 1992) considered that the fundamental reasons of resistance toward IT systems are not the ones expressed about the system nor persons characteristics, but users' perceived values and social content gain or loss before/after system implementation (Jiang, Klein et coll. 2000, Kendall 1997). Indeed, advocating system inconsistencies or organisational misalignment is probably a more comfortable resistance strategy than the one consisting to express underlying individual socio-political challenges. In this research we assume that users having affective oriented conflicts related to IT project are likely to use a bypassing strategy and to express their resistance only with task oriented conflicts. Following this reasoning, we formulate the following research proposition:

Proposition 1: expressed task oriented conflicts toward IT to be implemented may hidden affective oriented conflict.

Resistance management styles
IT projects can rarely be properly completed without any implication of the CEO. Often, top management ought to appear as “sponsor” of the projects in order to promote their credibility toward employees (Davenport 1998, Markus et coll. 2000). CEO should be able to balance the choice that must be made between satisfaction of individual expectations and the general objectives of IT projects in order to manage efficiently conflict resolutions. There are three common conflict resolution approaches: integrative (solving the problem through collaboration), distributive (solving the problem through assertion), and avoidance (ignoring the problem) (Sillars 1980). The integrative approach aims to identify and achieve outcomes perceived as satisfactory to all team members. These approaches support also previous studies that demonstrated the preference of IT users toward participative resistance management methods in opposition to direct management methods imposed by managers (Robey & Taggart 1981, Ives & Olson 1984). The distributive approach yields outcomes that favour some team members but not others. The avoidance approach consist for managers not intervening in the conflict and relying on the team capability to self resolve the conflict.

Within the conflict domain, many studies have been done to examine the management and resolution of conflicts, identifying a number of conflict management styles and their role in achieving satisfactory outcomes (Barki et coll. 2001, Kankanhalli et coll. 2006). We identified five different management styles using the common conflict resolution approaches: problem-solving, compromising, asserting, accommodating and avoiding (see Table 2).

<table>
<thead>
<tr>
<th>Integrative approaches</th>

situation to resolve by itself. Avoiding occurs when managers refuse to act and to participate in conflict situations.

<table>
<thead>
<tr>
<th>Table 2: Management styles of IT resistances</th>
</tr>
</thead>
</table>

According to Montoya-Weiss et al. (2001) integrative and distributive approaches appear to facilitate team performance whereas the avoidance approach seems to hinder. In their empirical analysis conducted on IS staffs and future users of 162 IS projects, Barki and Hartwick (2001 p.218) observed asserting mode and avoiding management as associated to negative results in terms of interpersonal conflict solving. In others words, the two most opposed styles were considered as inefficient techniques. In the same time, authors considered that negative emotions involved by interpersonal conflicts are not only negative experience, but negatively affect IS project outcome and remain pervasive even when properly resolved (op. p. 220). However, resistance management styles can not be considered as exclusive. MIS literature shows that, depending the project budget, the delays, the evolution of employee perspectives, etc., project managers are likely to change their style several times during the project duration. For instance, Gibson (2004) describes how during an ERP implementation project at Dow Corning corporation, resistance management style evolved from an “improvisation approach” to “big bang” assertions. Then, for a large part, information systems literature incites managers to not remain passive (Leidner et coll. 2006 p.381) and to solve users’ resistance by identifying conflict situations in order to prevent a project or an on going situation to evolve negatively toward IT implementation. On an other side, some empirical studies showed that conflict situations managed by team members were linked to conflict reduction (Kankanhilli et coll. 2006) or team performance improvement (Jehn et coll. 2001). In other words there would have no evidence that depending the context a management style relying on teams self ability to resolve resistance can not not be suitable. However, these observations have been only done on task oriented conflicts and do not permit to expand the corresponding assumption to affective oriented conflicts.

Proposition 2: avoiding management style is not associated to positive results in the case of affective oriented conflict.

This literature review on conflict situations, user’s resistances and management styles toward IT implementation, represents the theoretical background we used to analyze Netia case study. The longitudinal research conducted explores user resistance causes and conflict situations lying behind preliminary phase of ERP implementation while managers decided not to intervene.

3 Case analysis

In general, conflicts in organisations evolve over time which justify the higher adequacy of longitudinal research methodology than the one of static analysis (Jehn et coll. 2001 p.239). This method is often used in IT implementation studies (Molla & Licker 2001) and recommended for Small and Medium Enterprises’ analysis (Chetty 1996). There is also an interest for using a single case study which delivers illustrative stories (Benbasat et coll. 1987). So, we adopted a longitudinal research methodology for Netia from the beginning of 2005 until the end of 2006 using standard techniques of case studies analysis (Miles & Huberman 1984, Eisenhardt 1989, Yin 1994).

Case description

Netia corporation (located near Montpellier, France) is one of the worldwide leaders in broadcasting (40 countries covered). Its customers are TV channels and radios like, BBC, ABC, Rai uno, Canal+, France Télévision, etc. Created in 1993, the company employs an hundred of persons spread over two sites in France and subsidiaries abroad (Amsterdam, Liège, Rome and New York). The firm is an IT service agency dealing with development of audio and video data digital solutions. Besides IT development, Netia offers implementation management services (consulting, process analyses, engineering, training, maintenance and evolution of audio and video data digital solutions.). The information system of Netia has been developed progressively by ad-hoc initiatives. These isolated and independent developments have been involving a lack of data coherence as well as an excessive growth of applications. Consequently, a large part of employees’ tasks was dedicated to re-entering data in order to feed all of the redundant applications implemented to respond to local needs. For example, the management control service developed a set of Excel macros to partially deal with a divided utilisation of SAGE accountancy software. Each process (order forms, delivery forms, etc.) corresponds to a data entry for one or more shared Excel files (on the server there is a file for the order forms, another for the clients, another for prospects, etc.). The information system was structured
around a huge quantity of office files from which data were manually extracted and aggregated into other files to produce performance indicators required by managers.

Thus, a loss in productivity raised because of repeated data entries and redundant procedures. The lack of IS integration was also highlighted by data access problems. For example, the project coordinator did not know the status of the client order in progress; he had to contact directly the logistic service which browsed the SAGE application. Given that, transaction histories were dispersed throughout several isolated applications and purchases' tracking was hazardous to carry out. Customer invoices were not automatically triggered by a delivery note; the logistic staff had to type corresponding informations in a shared Excel file with the account number in order to edit the invoice. Due to these inconsistencies, administrative employees asked for the implementation of an integrated information system to ensure a more coherent and efficient management of the daily tasks.

Our research has been articulated with two phases aiming to identify explicit and tacit causes lying behind the ERP adoption abortion and, later, the implementation of the Genesys software.

**Research design**

To reach an appropriate degree of internal validity, we used the same three sources of evidence as the ones used in multilevel analysis of resistance to IT (Lapointe et coll. 2005): interviews (during the first step); direct observation (during the second step); document analysis, informal discussions and records of events (all along the project). These several data sources allowed us to achieve triangulation in order to ensure satisfactory information interpretations (Yin, 1994).

The aim of the first step analysis (from January 2005 to November 2005) was to identify explicit and tacit causes explaining why the firm had failed at the ERP implementation preliminary phase. This approach was explorative and consistent with thematic analysis (Boyatzis 1998) where codes must be constructed inductively. To carry out the analysis, 8 semi-directive interviews were conducted over 4 months. Even if the overall activity of the firm was highly technological, an understanding of different levels of culture was important to study IT implementation (Leidner et coll. 2006 p.358). It was relevant to analyse how the co-existence of subcultures had influenced conflict situations which involved the IT project abortion. Interviews were realised with key employees of firm departments (see Table 4 in appendix). The interview grid used had been conceived with reference to the risk factor lists of Markus et al. (2000), Akkermans & Van Helden (2002), Besson et al. (1999). The interviews were realised in a one-to-one interaction with an anonymous format response gathering. During the first part, the employees interviewed were asked to select on the grid the factors he/she considered as explaining the rejection of the ERP implementation. In a second part, we asked him/her to explain the causes he perceived as associated to ERP implementation project. Interviews lasted around 90 minutes approximately and were audio-tape recorded in order to avoid potential biases of only one interviewer interpretation. We completed this first step analysis by several formal and informal meetings with key actors of Netia in order to perceive users’ resistances and conflict situations toward the preliminary phases of the ERP implementation.

A second step of analysis (from March 2006 to October 2006) was conducted when, after several invitations to bid, a package editor (Genesys corp.) was asked to present its software. The presentation has been done in front of the Netia employees concerned by the IS implementation (see Table 5 in appendix). We took the advantage of being invited to this meeting to analyse the direct reactions of employees. To avoid any suspicions about our presence, Netia managers presented us as academic researchers interested by IT solutions for firms without any role to play concerning the project. The passive observation method we used was consistent with Yin (1994) who considers this technique like an additional source of data useful to understand the social context of the firm. To control the risk of instrumental biases involved by observational methods (Weick 1968), both authors attended the meeting and aggregated, latter, data collected. The meeting lasted 3 hours and took the form of a presentation and discussion about the software functionalities. Seeing directly on the screen the usability of the product, participants were able to ask questions all along the presentation. This type of interactions allowed us to note verbal and non verbal users’ behaviours.

**4 Results**

**Step 1**

During the first step analysis, computer department employees expressed an aggressive resistance toward the ERP implementation project which was considered as inappropriate to the needs of the organisation. This conflict situation between computer department employees and administration employees was consistent with prior studies which showed that cultural differences within organisations tend to influence contrasted interpretations of IT to be developed (Dubé 1998,
Programmers represent a key competence asset for Netia. In fact, the broadcast software applications developed by the company are in no way standard package applications that can be bought on the market. Consisting of solutions billed for several thousand of euros, these programs ensure storage, management and broadcasting of audio and video programs for TV and radio channels. Therefore, very specific skills are required regarding sound, image, storage (on servers of several terabytes), and data diffusion by hertzian, satellite or GPRS transmissions. The programmers in the company represent a rare workforce on the professional market and this gives them a strong negotiation power towards the hierarchy. Thus, they have gained overtime strong independence in the way they organize their job. “I decide my own objectives!” declared a program coordinator. An administration coordinator described for us the example of holiday management: “The programmers are used to freely organize their work depending on the tasks and on the assignments to be completed. They do not really respect the process for taking holidays. Instead of filling out the holiday sheet and having it validated by managers, the requests (when they are made) usually take the form of an informal conversation”. The implementation of the ERP was perceived by programmers as inconsistent with their ad hoc processes and their autonomy. Considered as a “spy eye”, such ERP system was considered as a threat for their own autonomy.

The top managers avoided any risky decision - in the sense of Cyert and March (1963) - and adopted a passive management – in the sense of Cooke and Lafferty (1987). CEO never interfered in the conflict situations and did not decide to impose this unpopular solution to programmers and preferred to let all employees finding a compromising solution by themselves. An administration coordinator stated: “If we really wanted to impose a standard solution, we could. However, this would mean interfering with the programmers. But they are the makers of the programs sold, so...” Because there has been no concrete or major prejudice due to the unreliability of the existing applications used, managers were not particularly motivated to settle this situation and to take a decision likely to disturb the social climate. “Regarding the successful implementation, the management favours the programmers, only the programmers... The rest, such as improving the organization, is not considered as crucial”. These observations illustrate that IT employees are mainly rewarded for delivering technically sound systems on time and to budget and are not really encouraged to consider organizational issues in IT systems (Hornby et coll. 1992 p.165).

Step 2

Because of the programmers disagreement about the ERP implementation project and the passive attitude of top managers to solve the conflict situation, administrative employees decided to look for less impacting software’s from an organisational point of view.

Among the commercial propositions received, administrative employees of accounting service considered Genesys application as an interesting alternative. Its functionalities covered most salient needs of administration employees: customer and potential customer management, sales and procurement management (quotations, order and invoice tracking), treasury, after-sales management, etc. Then, the application was focused on process management of administration employees without implying cross-functional processes. In other words, the software could not be considered as an integrated information system forcing programmers to cope with badly perceived tasks like reporting their daily work or filling out electronic forms to have holiday demands validated by the managers. Moreover, it was interoperable with SAGE application and was not requiring data migration from the existing database.

During the presentation meeting we attended to, both computer and administration representatives found this new solution satisfactory towards the needs previously expressed (during step 1). The application was supposed to be used only by administration employees. Computer department representatives only made remarks and asked questions about technical specificities of the software. Some allusions to the previous recalcitrant behaviours of developers about the ERP solution were expressed with irony and the general laugh reaction allowed us to observe an alleviation of the initial conflict between administration and computer employees.

Despite the general positive impression about the application, an active form of resistance appeared few minutes later when conversations converged on the required task reconfigurations. For example, because of his frequent travels abroad, the Asia commercial agent of Netia mentioned some practical problems not treated by Genesys functionalities. This employee was used to type a text file within
which he added complementary information and comments about potential customers. Then, he uploaded the file on Netia server in order to make it available to other employees. But the customer management function of Genesys software did not allow joining complementary files like that. So, he firstly considered this as an annoying limit of the application toward his daily activity. Then, the discussion moved on how to overcome this problem until one programmer noted that it was more related to the task definition than the software appropriateness to user needs. Actually, Netia employees were used to include in “transaction” concept all upstream processes to the order (quotations, bargaining, etc.) whereas in Genesys application those tasks were included in an other functionality than the one talked about. Actually resistances expressed during this step were essentially because of ambiguity in professional jargon between Netia and Genesys corporations.

Few minutes later, another active resistance raised while Genesys engineers were presenting the treasury management function. The Finance Director was reluctant to use this function because she explained that it only satisfied a minor part of the activity. According to Netia practices she revealed that on-going payments of invoices sent to customers were included in treasury while not yet cashed. If this practice may sound as inconsistent with accounting classical rules, it sounded consistent with Netia business practices. Indeed, the recovery rate of customer debts is always 100% and paid immediately when the invoice is received. So, any invoice sent to customer are considered as existing cash. However, at the end of the meeting, all employees agreed on the global adequacy of Genesys ERP for Netia needs, only task-related oppositions remained and were resolved. As a result, at the end of 2006, the decision was made to implement Genesys solution and the software was bought. Table 3 presents the evolution that has known the user’s resistance, conflict types, and conflict management styles toward the IT implementation project.

5 Discussion

Our research puts the emphasis on longitudinal research, versus cross-sectional data collection, to analyse the dynamic nature of conflict and user’s resistance during project steps prior to the IT implementation. We believe that researchers should consider these “upstream resistances” like additional influencing factors of IT adoption to explore in order to expand existing theoretical models.

We use this French corporation case study to observe how user’s resistances and conflict situations associated to an IT implementation project evolved over time. Therefore we can not pretend the same generalisation of the result as if we had used several case studies and quantitative analysis. During the first step of analysis, data were mainly collected through interviews which likely induce some interpretative biases on the feelings expressed by interviewees. However, we tried to reduce these biases by interviewing several employees of each department, using a grid to help respondent to identify and formalize the factors he/she considered as explaining the resistance to the ERP implementation, comparing the data collected, adding informal meetings, etc. During the second step of analysis, data were mainly collected through observation techniques during the Genesys presentation to Netia employees. Our presence might have influenced the way persons behaved and participated during the meeting even if we had been presented as having no role to play on the decision process of the IT project. Moreover, one inherent limit of longitudinal research is that the processes observed continue to evolve after the end of the research investigation (Volkoff et coll. 2004 p.302). Further research should be done in order to study other findings in other cultural, structural (large firms), professional and organisational contexts to give a deeper understanding of user’s resistance and conflict situations during a longer longitudinal research which would cover all the IT project life-cycle.
Nevertheless, by exploring conflict evolution during pre-implementation project phase, our results offer additional contributions to IT users’ resistance research. Firstly, task oriented conflict expressed during step 1 hindered affective oriented conflict related to the autonomy treat perceived by developers (our proposition 1 is confirmed). This observation is consistent with previous studies done on value and power conflicts associated to IT implementation (Markus 1983, Hart & C. Saunders 1997, Jasperson et coll. 2002, Kohli et coll. 2004, Leidner et coll. 2006) and is in line with recent investigations of Ford et al. (2008) who observed that emotional conflicts can dominate task conflicts in organisations.

Secondly, resistances moved from an aggressive form (observed during step 1) to a constructive form (observed during step 2) which led to the implementation of an alternative IT solution. The evolution showed that conflicts are not fixed and our results are in line with observations of Jiang et al. (2000 p.32) who observed causes of users’ resistance differed according the IT type to be implemented. Our investigation illustrates how an affective oriented conflict related to IT has been solved during these preliminary phases while top managers adopted an avoiding management style (our proposition 2 is rejected). Netia case study do not support the conclusion of Barki and Hartwick (2001) who observed avoiding management style as associated to negative results in terms of conflict solving.

Because our longitudinal observations delivers the story of one conflict management style we can not assume the effects other conflict management styles would have provided and we can not consider any intrinsic superiority of the avoiding style on other styles. However, our results are in line with the attribution theory (Cramton 2001) and some empirical studies which showed that conflict situations managed by team members were linked to conflict reduction (Kankanhalli et coll. 2006) or team performance improvement (Jehn et coll. 2001). However, these studies have been mainly realised on task oriented conflicts whereas our observations extend the results to affective oriented conflicts which are considered as more difficult situations that managers prefer to avoid to be engaged with (Edmondson & Smith 2006 p.25).

Concerning MIS literature, the article expands the empirical researches which observed the lack of “organizational fit” as a failure cause of ERP implementation (Hong & Kim 2002, Hsiao-Lan et coll. 2005). We could consider our results as a possible extension of these results in the sense we observed the “fit”not limited to the adequacy of IT to business but covering also underlying organisational change consistency with value principles of firm sub-culture units. Indeed, when an organization is composed of several sub-cultures, the use ERP can be problematic because mandating one epistemological position through the software design based on “best practices” (Wagner et coll. 2004).

For IS practitioners, our study suggests a greater attention to issues relating to power, autonomy and professional sub-cultures when implementing IT. The main practical implication of this paper for managers is inciting them not considering task oriented conflicts expressed by users, as sufficient informations to understand whole resistance causes related to IT projects. Discovering and understanding potential underlying affective conflicts about users’ values or power losses turns out to be necessary before deciding the IT to implement.

6 Conclusion

The underlying message of this article is being out of considering users' resistance toward IT as a negative behaviour toward the organisation effectiveness. By considering resistance as dysfunctional conflict, IT project managers can disregard its potential contribution to the change and implementation. In organisations with absolutely no resistances, employees would accept all change projects including those detrimental to the organization effectiveness (J. Ford et coll. 2008). Affective oriented conflicts are not necessarily about present change involved by the project but can be related to unresolved issues form previous changes (Reichers et coll. 1997). So they can be interpreted as appeals for some managerial rectifications, like restoring trust or professional recognition of employees, which should be taken into account in the design the IT to implement. As a consequence, decisions made about the implementation without consensus are likely to involve systems’ usages very different from the ones expected by managers (Soh & Kien Sia 2004). As future investigations, we incite researchers to explore how both task oriented and affective oriented conflicts should be considered as consistent with inscription theory (Orlikowski 1992) and assumed as key processes embedded into IT choices and information system design.

Abstract

Since the 1990’s integrated information systems, better known as Enterprise Resource Planning, really started to take off as a potential solution for the integration of all core business areas in the organizations, allowing more visibility by consolidating all the information in one shared database, in real time. On the other hand, implementing a ERP system causes profound changes in the way employees perform their tasks. Research of the concerning literature suggests that ERP systems increase visibility and control within the company, the better access to information contributes to the empowerment of the employees, in the same way that the procedures of the ERP systems engage employees in self discipline and reflection on work practices. The literature review addresses concepts such as Foucault’s view of disciplinary power, organizational control and empowerment. The study adopted a quantitative methodology through a survey conducted in a multinational organization with 213 respondents, revealed that the visibility offered by the ERP system fosters autonomy making empowerment easier and that the respondents do not feel more controlled by their superiors or peers. In contrast to previous research, which relates reflection to improve working practices, the present study relates reflection with commitment to performing the system’s standardized tasks.

KEY WORDS: Information Technology, ERP Systems (Usage), Control, Empowerment
1. INTRODUCTION

This study seeks to test constructs of the specialized literature and analyze aspects of organizational behavior related to the use of ERP (Enterprise Resource Planning) systems through issues such as empowerment, control, reflection on practice, and conformity with rules. Our primary intent is to consolidate prior knowledge – and add information – on the visibility provided by ERP systems. Our study presumes that multiple, profound organizational changes have arisen in the post-implementation phase of the ERP system life cycle, and presumes that they have a considerable potential to generate employee control and empowerment. Our main points of reference were the concepts of Panoptic Empowerment and Reflective Conformity, proposed by Elmes et al (2005), and Panoptic Control, proposed by Sia et al (2002), in light of Foucault’s concept of disciplinary power and Bentham’s Panopticon.

In recent years, employee empowerment has emerged in parallel with the traditional function of employee control (Drucker, 1988). The post-ERP implementation environment has revealed the considerable impact of these systems on user behavior, both among managers and among their subordinates. This seeming dichotomy has been reinforced by the literature, with authors such as Hanseth et al (2001) claiming that ERP systems are the ideal managerial control technology and Elmes et al (2005) showing that ERP systems are simultaneously able to provide management with ample visibility (and, consequently, greater control) and contribute to employee empowerment by providing access to information. Placing emphasis on the paradoxical view presented in the literature, in which a control technology such as ERP simultaneously facilitates control and fosters empowerment when such control may impose restrictions, and using as a reference the work of Elmes et al (2005), which introduces another, distinct contradictory concept of reflection and conformity, this study seeks to contribute with a greater understanding of these effects on organizational behavior, providing the necessary subsidies for organizations to effectively manage these impacts, with the organizational culture of different countries as its background.

Our study was conducted in a multinational organization in the post-implementation stage of the ERP system life cycle by quantitative field survey. Respondents from eight countries in which ERP had been in use for at least two years were chosen, for a total sample size of 213. The next section provides a theoretical background which represents the most relevant and related studies up to its completion date and presents the proposed research model, hypothesis and the underlying construct. Section three outlines the methodology and the data collection process. The analysis of results is presented in section four and the final section of this paper concludes with the final considerations and the study limitations.

2. THEORETICAL BACKGROUND AND RESEARCH MODEL

In the 1990s, new approaches to management appeared to keep up with the increasingly competitive environment of the corporate world. These new approaches were followed by new technologies, such as ERP systems, considered one of the most important instruments available capable of providing organizations with a competitive edge. ERP tools imposed themselves as a means of maximizing operational efficacy, cutting costs, integrating business processes, and consolidating information into a single database. In addition, there is the ERP system benefit of enabling a transformation from inefficient business processes toward accepted best of practice processes (Gattiker and Goodhue, 2004).

In implementing an ERP system, organizations envision – in addition to intended cost-reduction benefits – an ideal of control over and visibility of their business, which is emphasized by standardized and integrated processes. An integrated system highlights governance capacity, achieved through the integration of data generated by and used in distinct parts of the organization (Hanseth et al, 2001). On the other hand, the implementation of ERP entails profound changes in the manner in which employees carry out their duties, not least because most ERP implementation processes involve
reengineering of business processes, which leads to radical organizational restructuring and changes them, seeking gains from extraction of novel information.

Several studies have sought to investigate individuals’ perceptions on the manner in which work practices have unfolded post-implementation of an ERP system. One such study has found how individual performance can be affected by ERP use, when system users are empowered in high-pressure contexts (sometimes characterized by an overload of work and information) or, conversely, by insufficient provision of relevant information by the system (Elie-Dit-Cosaque et al, 2006).

Some studies have focused on the relation between control and empowerment in the context of ERP system use. An empirical investigation conducted by Psinos et al (2000) suggested that while information systems (including ERP systems) may contribute to empowerment by providing access to information, they can also restrict employees’ freedoms by limiting actions through inflexible processes and increasing performance expectations. Control and empowerment must therefore, be carefully balanced to ensure that the former does not hamper the latter. Hanseth et al (2001) also note that a global organization that implements ERP seeking to strengthen control may in fact obtain the opposite result, that is, less control than it had before.

Our study recognizes the potential of ERP systems to generate control and empowerment, and, particularly, on two prior studies conducted in light of Foucault’s perspective of power and Jeremy Bentham’s *Panopticon*. These concepts are presented in greater detail below:

1) Sia et al (2002) argue that ERP systems create an *information panopticon* through the visibility of information they provide, giving employees decision-making power while simultaneously making them visible to management, thereby leading to employee empowerment; ERP systems thus make both control and empowerment viable. Sia et al call this duality *panoptic control*. Despite finding evidence of its potential in their study, the authors report that management at the studied hospital tended to keep hierarchical structures in place, leading to greater reinforcement of managerial authority than employee empowerment and, consequently, an unbalanced distribution of power with a high level of control and low empowerment. A qualitative methodology was adopted, followed by a quantitative survey whose data collection instrument was validated in a series of interviews.

2) Elmes et al (2005) define empowerment as any increase in employee power, be it through greater formal authority or through maximization of access to useful information, enabling workers – and, consequently, the organization – to achieve institutional objectives with maximum efficiency and efficacy. Like Sia et al (2002), Elmes et al suggest that employees are empowered mainly because they have greater visibility of information, giving them greater control over the factors affecting the manner in which they carry out their functions. From Foucault’s standpoint (1979), they suggest that an organization can empower its workforce without actually transferring power to employees, by considering power to be the “property” of the entire system. The authors call this combined concept of empowerment and multidirectional visibility *panoptic empowerment*, and add to the study the concept of *reflective conformity*. In this concept, they suggest that the rules and procedures of organizational processes in an ERP system lead to greater discipline and induce greater reflection of work and of how the ERP system itself works, making both more effective. The results of the study showed a simultaneous increase in control and empowerment, and also found greater conformity and reflection in business processes. They used an interpretive perspective with “Grounded Theory” methods, using the Glaser (1978) approach, and conducted data collection through observation, formal interviews, and informal conversations in a multinational industrial corporation.

Seeking to answer a series of questions regarding behavioral aspects of the use of ERP systems in global organizations, such as user empowerment, control, reflection on work practices, and conformity with rules – to which this study intends to contribute, be it by consolidating prior knowledge or by obtaining new information – the figure 1 below suggests a structured model built around a few research hypotheses. The research model considers a structure in which the integrated nature of ERP Systems (Davenport, 1998; Al- Mudimigh et al, 2001; Al-Mashari, 2003; Souza and Zwicker, 2003; Volkoff et al, 2005) determines: (a) ample visibility of information, (b) conforming to the rules of ERP
systems embodied in unrestricted way and (c) visibility of employee activities. This causal structure is well discussed in previous literature (Davenport, 1998; Dillard et al., 2005; Elmes et al., 2005; Sia et al., 2002).

The Visibility of Information enhances power of users allowing them to make their job more effectively (empowerment) (O’Leary, 2000; Psinos et al., 2000; Sia et al., 2002; Elmes et al., 2005; Elie-Dit-Cosaque et al., 2006), as well as the integrated business processes of organization embodied in the ERP Systems enable the autonomy improving the group decision making (Saccol et al, 2003). Within the context of a positivist paradigm, we may then formulate and test the following hypotheses: “H1- The Visibility of Information provided by the ERP system fosters empowerment of system user employees” and “H2-The Visibility of Information provided by the ERP system leads to autonomy of user employees”.

The control is enhanced because workers’ performance can be better monitored given the systematic tracking of transaction details and the real time (Sia et al, 2002). Standardized and accessible information makes visible any deviation from the norm (O’Leary, 2000), and as Sia et al. (2002) suggest this knowledge of being visible extends the exercise of self-discipline at the individual level. Thus, we propose the following: “H3- The Visibility of Employee Activities provided by the ERP system makes it easier for the organization to exercise control over user employees”.

Besides the results of Elmes et al’s study (2005) that showed a simultaneous increase in control and empowerment, Saeed et al. (2006) attempted to demonstrate that empowerment and control are intrinsic to each other in the same manner that empowerment supports control on present organizational environment, effective control relies on the empowered employee. So, based on the literature review, we propose the following hypothesis: “H4- Employee control is positively related with empowerment of user employees”.

Dillard et al (2005, p.115) remark that ERP systems are the expression of instrumental rationality revealed in administrative expertise, and “As an instrument of control and domination imposes a mode of organizing and changing social relationships”. Kallinikos (2004, p.10) reinforces this discussion when he observes that “…ERP systems have profound effects on the structuring of work and the forms of human action they enable or constraint.” Eventually, in researches conducted by Saccol et al (2003) in organizations could be noted that the workers with more knowledge on ERP system were more valued by the organization. However, aspects as creativity and innovation in work practices were not used as much they should due to procedures routines. On the other hand, as previously mentioned Elmes et al (2005) suggest that the rules and procedures of organizational processes in an ERP system lead to greater discipline and induce greater reflection of work and of how the ERP system itself works, making them both more effective. Finally, we formulate: “H5- The disciplinary nature of conforming to the rules of ERP systems is positively related with reflection on work practices”.

3. METHODOLOGY

Our study was divided into two phases. The first, exploratory, phase consisted of a review of existing literature on the theme for increasing our understanding of the constructs above. We used several sources, as literature review, interviews, and documents on ERP implementation in the subject organization. Secondly, a quantitative field survey was made with a structured questionnaire as the data collection instrument, seeking to test and verify the inferences and conclusions of the previous authors.
Our subject organization, “Alpha”, is a Belgium-based multinational in the food sector, with 88 offices in 57 countries, 54 production facilities in 40 countries, and with a population of ERP users about 700 employees. The organization adopted the Baan ERP system in 1997, when it had 79 branches. The organization is in the post-implementation phase of the life cycle; the system has been in place at least two years in most branches. It was implemented for two main reasons: software standardization – the company used 19 different software packages at the time – and preparation of 38 branches for the Y2K bug. Analysis of the specific literature shows that most case studies of ERP implementation have focused on SAP systems; few studies of organizations with Baan systems have been conducted.

In light of the difficulties in contacting respondents in all the countries with the implemented Baan system, our criteria for sample definition was to select those countries in which the system was used by 20 or more employees. This narrowed our sample locations to Belgium, Spain, Portugal, Romania, England, Canada, the U.S., and Greece. This type of nonprobability sample, that is, a sample in which the probability of individuals to be chosen for the sample is not known to be equal (Malhotra, 2006) is done at the researcher’s convenience, and is therefore known as a convenience sample. Based on variables found in the literature (Sia et al, 2002; Elmes et al, 2005), we developed a questionnaire to measure the constructs required for hypothesis testing. In order to ensure that items corresponded to theoretical constructs, and, consequently, validate our data collection instrument, we conducted a pilot test (Sprangers and Hoogstraten, 1989) with 14 respondents (managers and non-managerial employees) using the Baan system in a production plant in Athens, Greece.

We used a structured, formal questionnaire with closed-ended questions in pre-established order (Malhotra, 2006). Notably, the questionnaire was self-filling, without respondent’ identification. Marconi and Lakatos (2000) note the advantages of self-filling questionnaires: they allow greater freedom in answering thanks to anonymity and dampen the risk of answer distortion, as there is no researcher influence whatsoever. We used a multiple-item Likert-type scale of one to five, with one (1) being complete disagreement and five (5) being complete agreement. We were concerned that respondents might not fully understand the questions due to the complex nature of the subject and therefore, devised three versions of the questionnaire: one in Portuguese, one in English, and one in Spanish. Questionnaires returned with only one of their two parts filled in were excluded from the sample.

The questionnaire comprised two parts, each of which was saved as a worksheet in an Excel workbook. Part 1 was composed of multiple-choice questions for the following variables: Country, Gender, Age, Department, Organizational Level, Position, Academic Background, and Years of Service. For the second part of the survey, we devised 20 statements based on inferences from Elmes et al (2005) and on the data collection instrument used by Sia et al (2002). These statements were distributed according to certain aspects described in the study hypotheses.

Access to the Baan user population was provided by the company’s Intranet and valid corporate email addresses. Due to security reasons, the company’s IT department would not allow employees access to an electronic form made available in a regular website. Our data collection strategy consisted of making employees aware of the survey through email messages, highlighting the importance of the study and its scholarly nature and purpose. Before mailing these messages, we contacted the company’s general management in each sample country, by telephone, in order to provide clarification on the study’s objectives and foster cooperation to ensure maximum, satisfactory results.

Data collection began on March 30, 2008, and concluded on May 30, 2008. Over the course of these two months, we received 240 responses; 213 of these questionnaires were considered valid (response rate, 89%). The 27 remaining questionnaires (11% of total) were excluded from the sample due to inconsistencies in data or incomplete response (one of the two parts of the questionnaire missing). Response was considered incomplete if less than 90% of the second part of the questionnaire had been filled out.

4. ANALYSIS OF RESULTS
4.1. Data Analysis Procedures and Sample Characteristics

Data analysis was carried out with the Microsoft Excel for Windows spreadsheet software and the SPSS for Windows statistical package. We sought to describe respondents’ demographic characteristics and compare their responses to analyze any possible patterns: high levels of agreement or disagreement with certain statements and grouping of statements related to empowerment, control, self-discipline/conformity and reflection on practice factors. Data were analyzed through univariate and multivariate procedures (Hair et al, 2005). To validate our research model, we used descriptive sample analysis, factor analysis, Pearson correlation analysis, and univariate analysis of variance (ANOVA). We verified three hypotheses through descriptive analysis, by measuring mean agreement with the questionnaire’s statements. We then tested two factor association measurement hypotheses through Pearson’s correlation coefficient, seeking to measure the degree and magnitude of the relationship. ANOVA was used to detect any statistically significant differences between the perceptions of different groups, as defined by respondents’ demographic data and average factor scores. For both ANOVA and correlation analysis, we created a score for each construct to be tested, determined by averaging the construct’s component items.

The sample was distributed as follows: 81 respondents in Belgium, 29 in Spain, 28 in Romania, 26 in the United States, 18 in Greece, 14 in Portugal, and 11 in the United Kingdom. The majority of respondents (54.1%) were male. Respondents were concentrated (38.2%) in the 30–39 age bracket; 50% of respondents were 40 years old or older and 51.4% were college graduates or had a graduate education. As for organizational aspects, 58.7% of employees were non-managers; interestingly, 55.6% of managers who responded were stationed at the company’s headquarters in Belgium. Allocation of respondents was broken down as follows: 27.3% worked in the Sales areas and 28.3% in Operations/Production.

4.2. Analysis of Respondent Perceptions

Descriptive statistics and the number of valid cases (n) were calculated for each variable (see Table below), as well as percentage agreement rates (PAR), calculated by the formula \((\text{mean} - 1)/4 * 100\), showing responsibility, commitment, reflection on practices translating into good work, and interest in obtaining greater knowledge of the ERP system. Low levels of agreement were found with the following statements: 4, with a PAR of 41.86% and a 2.67 average; 9 with a PAR of 44.81% and a 2.79 average; 12, with a PAR of 45.42% and a 2.82 average; and 20, with a PAR of 43.66% and a 2.75 average. The first two statements concern employee control through peer and supervisor visualization. For both ANOVA and correlation analysis, we created a score for each construct to be tested.
4.3. Factor Analysis

Tests showed that factor analysis could be an appropriate method for analysis of correlation matrices, by means of the Kaiser-Meyer-Olkin measure of sampling adequacy (KMO 0.846) and Bartlett’s test of sphericity. Factors are determined by their factor loadings, which must be significant; their values are obtained by rotating the loading matrix with Varimax rotation, a method that seeks to minimize the number of variables with large loadings, simplifying interpretation (Malhotra, 2006). Measurement scales are analyzed through communalities and Cronbach’s alpha coefficient, based on the tenet that, if all items in a measure are drawn from the domain of a single construct, responses to these items should be highly correlated (Churchill, 1999). The lowest acceptable threshold for Cronbach’s alpha coefficient is usually set between 0.6 and 0.7 (Hair et al. 2005). The measure of communalities, which refers to the variance shared by the original variable and all other variables, was included in the analysis.

Validation of the constructs mentioned in prior studies was carried out through factor analysis, in which factor loadings showed the significance of responses, which are able to express the behavioral impacts of the research model as perceived by individuals in the sample, with loadings distributed among the variables of four factors which we found and named Empowerment, Control, Reflection, and Conformity to Rules (see Table 2 bellow). We had total explained variance of approximately 60% (within acceptable limits) and an eigenvalue criteria of >1, as recommended for definition of factors. We considered the values closest to 1 (in modulo), which indicate strong correlation between the statement and the factor it is supposed to represent. We did so also with the Conformity to Rules construct, which did not show satisfactory reliability as measured by Cronbach’s alpha, but it showed high communality (>0.50) and we therefore decided to keep it.

#### 4.3. Factor Analysis

Tests showed that factor analysis could be an appropriate method for analysis of correlation matrices, by means of the Kaiser-Meyer-Olkin measure of sampling adequacy (KMO 0.846) and Bartlett’s test of sphericity. Factors are determined by their factor loadings, which must be significant; their values are obtained by rotating the loading matrix with Varimax rotation, a method that seeks to minimize the number of variables with large loadings, simplifying interpretation (Malhotra, 2006). Measurement scales are analyzed through communalities and Cronbach’s alpha coefficient, based on the tenet that, if all items in a measure are drawn from the domain of a single construct, responses to these items should be highly correlated (Churchill, 1999). The lowest acceptable threshold for Cronbach’s alpha coefficient is usually set between 0.6 and 0.7 (Hair et al. 2005). The measure of communalities, which refers to the variance shared by the original variable and all other variables, was included in the analysis.

Validation of the constructs mentioned in prior studies was carried out through factor analysis, in which factor loadings showed the significance of responses, which are able to express the behavioral impacts of the research model as perceived by individuals in the sample, with loadings distributed among the variables of four factors which we found and named Empowerment, Control, Reflection, and Conformity to Rules (see Table 2 bellow). We had total explained variance of approximately 60% (within acceptable limits) and an eigenvalue criteria of >1, as recommended for definition of factors. We considered the values closest to 1 (in modulo), which indicate strong correlation between the statement and the factor it is supposed to represent. We did so also with the Conformity to Rules construct, which did not show satisfactory reliability as measured by Cronbach’s alpha, but it showed high communality (>0.50) and we therefore decided to keep it.

### 4.4. Univariate Analysis of Variance (ANOVA)

Seeking a more in-depth analysis of the factors that mirror impact on behavior in the organizational environment, we used sample segmentation, analyzing possible relationships between perceptions and...
the demographic variables that make up the first part of the questionnaire. We employed one-way univariate analysis of variance (ANOVA), a statistical test used to compare means in two or more populations; in this particular case, it was used to detect whether there were any statistically significant differences between the perceptions of different populations. The null hypothesis is that samples arise from populations with equal means for a dependent variable (Hair et al, 2005).

ANOVA uses the F-test to prove significant variance between mean group scores. In this case, groups may be countries, age brackets, or departments within the organization. However, according to Glass and Hopkins (1996, p. 405 apud Vidal, Zwicker & Souza, 2003), when used to compare groups with different variances, ANOVA may not produce accurate results. In such cases, one may use the Brown-Forsythe test, which does not presume homogeneity of variance and corrects the results of the F-test ($F^*$). Although univariate ANOVA allows us to reject the null hypothesis that group means are equal, it does not pinpoint the location of significant differences. In-depth investigation of a specific group means that may be of interest requires post hoc tests such as Tukey's honestly significant difference (HSD) (Hair et al, 2005).

ANOVA revealed no significant differences between countries in the Empowerment and Reflection factors, whose mean values ranged from 3 to 4. There were significant differences in the Control factor between Belgium and Romania, between Romania and Greece, and between Romania and the UK (see Table). Belgium data (81 respondents, 2.51 mean) suggests significant disagreement regarding control issues addressed by the visibility provided by ERP systems, while Greece and Romania show higher agreement (means 3.26 and 3.52 respectively) and a smaller number of respondents. Likewise, Romanian respondents (mean agreement, 3.52) disagreed markedly with those in the UK (mean, 2.36).

Our analysis of Organizational Level groups found no statistical differences between them in the Empowerment, Reflection, and Conformity to Rules factors, while there was a significant difference in the Control factor, as shown by a striking difference in mean agreement: the mean agreement (or, rather, disagreement) of managers was 2.44, while that of respondents in non-managerial positions (the majority of the sample) reached 3.12. There was a total of 125 respondents in the sample. Post-hoc testing with Tukey’s honestly significant difference could not be performed, as there were less than three groups to compare.

Among Level of Education groups, ANOVA found no statisticant difference in the Empowerment, Reflection, and Conformity to Rules factors. Significant differences were found in the Control factor between respondents with secondary-level education and those holding master’s degrees, and between those with secondary-level education and those holding doctorates (see Table). The mean agreement of respondents with a secondary-level education (3.07) – respondents who usually hold non-managerial positions and make up the majority of the sample – corroborates the notion that respondents without a graduate education feel that ERP increases the control their superiors hold over them. Respondents with master’s or doctorate degrees showed significantly lower mean agreement with this statement (2.55 and 1.44 respectively), meaning they do not feel controlled, watched, or monitored; this leads us to infer that graduate-level respondents hold managerial positions.

Table 3 Factor ANOVA, sample broken down by country and Level of Education
ANOVA of the Control factor again showed significant inter-group differences when respondents were divided into groups according to the department in which they worked, while, once more, there were no significant differences regarding agreement with the Empowerment, Reflection, and Conformity to Rules factors (see Tables below). Disagreement with the Control statements was most pronounced among employees of the company’s Lab and R&D Department (2.07), compared to the Financial (3.3), Sales (5.7), Accounting (1.5), and Operations/Production (6.2) departments, which showed mean agreement values of 3.18, 2.98, 3.58, and 2.81 respectively. This may be explained by the fact that use of the ERP system is more widespread in these departments, which may lead to increased recognition of the activity and performance visibility afforded by ERP among the employees of these departments. The difference in agreement may also be explained by the nature of each department; the Marketing department (mean agreement, 2.38, 8 respondents), for instance, differs markedly from the Accounting department (mean, 3.58, 15 respondents), whose activities feature a high level of monitoring and control. The difference between Accounting and IT (mean agreement, 2.50, 10 respondents) is likely because the IT department does not use the ERP system and therefore does not recognize the monitoring and vigilance imposed by it.

4.5. Hypothesis Testing

After the reliability of scales has been assessed, the next stage is hypothesis testing. We will test hypotheses H1, H2, and H3 by using the mean scores of significantly loaded explanatory variables, and in hypotheses H4 and H5, we will analyze the intensity of association between factor variables with Pearson’s correlation coefficient. To carry out this test, we created a score for each construct from the mean of its component items.

Hypotheses one and two, “H1 – The Visibility of Information provided by the ERP system fosters empowerment of system user employees” and “H2 – The Visibility of Information provided by the ERP system leads to autonomy of user employees”, concerning the visibility of information provided by the ERP system and its role in facilitating empowerment and fostering autonomy, were proven by verifying mean respondent agreement with questionnaire statements that explain the Empowerment factor. Respondents agreed somewhat (average agreement 3.6) with the assertion that ERP provides visibility of information, thereby fostering autonomy and facilitating a decision making. With access to a greater volume of information comes increased employee power, as employee decisions are now supported by a more secure and reliable information base. According to an interviewee in the company’s Greece branch, adoption of the ERP system was followed by delegation of greater responsibility and autonomy to operational areas, which then showed greater and more significant changes. Prior to ERP implementation, all transactions were performed by employees in the Financial department; according to the interviewee, the ERP system encouraged the (logical) conclusion that each department should carry out its own transactions. ANOVA revealed significant differences in the average agreement with factors related to these hypotheses between age brackets: respondents aged 50–59 or >60 expressed greater perceived recognition of the Empowerment factor than did employees in the 30–39 age range.

The third hypothesis, “H3 – The Visibility of Employee Activities provided by the ERP system makes it easier for the organization to exercise control over user employees”, verifies whether the visibility of actions provided by the ERP system makes it easier for the organization to exercise control over employees who use the system. Respondents disagreed slightly (average agreement, 2.7) with the assertions that express the visibility of actions provided by the ERP system to employees’ peers and superiors. We were unable to confirm the effects of this concept as presented in the studies of authors mentioned previously in this article. Agreement with the two component variables of the Control factor with greater explanatory power (0.812 and 0.859) ranged from neutrality to disagreement, (41.86% and 44.81%, averages 2.67 and 2.79 respectively), that is, respondents did not express recognition of increased control over their work performance, whether exercised by their superiors or by their peers. Respondents were neutral to the assertion that ERP makes it easier for superiors to spot errors (mean agreement, 3.03). From these results, we may infer that, although ERP systems make employees’ actions more visible to their superiors and peers, employees did not feel more controlled,
monitored, or watched, as Sia et al (2002)’s Panoptic Control proposed they would. H3 is therefore not supported.

ANOVA revealed significant differences in the mean agreement of respondents with the Control factor. Managers and respondents holding master’s and doctoral degrees disagreed more with the Control statements than did respondents with a secondary-level education; respondents working in Belgium disagreed more than did respondents in Romania and Greece, who showed the highest levels of agreement with the Control assertions; likewise, respondents in the UK disagreed more with these assertions than did those in Romania. Respondents in the Lab/R&D department disagreed most with the Control factor, as in comparison to those in the Financial, Sales, Accounting, and Operations/Production departments. These figures may be explained by the fact that ERP use in the Lab/R&D department is less prevalent than in other departments, which suggests that R&D employees underrecognize the visibility of actions and performance provided by the ERP system.

Although there was no express recognition that the increased visibility of actions provided by the ERP system facilitates control, our fourth hypothesis, “H4 – Employee control is positively related with empowerment of user employees”, verifies whether employee control is positively correlated with empowerment of user employees. Our finding of a positive correlation between control and empowerment corroborates the Panoptic Empowerment concept defined by Elmes et al (2005), that is, the association of these two constructs arises with the visibility of information provided by the ERP system, which leads to greater autonomy and decision-making power for employees in operational positions, consequently giving them a greater sense of responsibility and fostering a concern with their actions within the ERP system. Pearson’s coefficient was found to be 0.374 at a significance level of 0.01.

Our final hypothesis, “H5 – The disciplinary nature of conforming to the rules of ERP systems is positively related with reflection on work practices” tests whether the disciplinary nature of conforming with ERP rules is positively correlated with reflection on work practices. The concept of Reflective Conformity identified by Elmes et al (2005) emerged in our hypothesis testing, revealing a correlation between Reflection and Conformity to Rules – however, the correlation was negative. H5 is thus rejected. This may be explained by the fact that the Conformity to Rules construct sought to measure conformity that does not derive from hierarchical power, but rather from the inherent disciplinary power of ERP system procedures. Conformity was measured by two variables: one referred to the use of parallel resources in addition to the ERP system in order to perform tasks more efficiently, that is, non-conformity, and the other stressed conformity as performance of activities in accordance with the system’s demands, without questioning its procedures. Our analysis revealed that respondents do not conform to the rules. Agreement with the statement that referred to the use of parallel resources was above average (PAR, 63.85%; mean agreement, 3.55), while agreement with “not questioning the system’s procedures” ranged from neutrality to disagreement (mean agreement, 2.75; PAR, 43.66%). This shows a latent concern with doing a good job, even if it means not using the ERP system.

Regarding Reflection, Elmes et al (2005) captured this concept as being allied with conformity to the inherent rules and procedures of the ERP system, that is, the limits imposed by ERP systems are explained by Elmes et al (2005) from the standpoint of Foucault’s “regime of truth” – the power of discourse that values disciplinary action. According to Elmes et al (2005), increased reflection on practices arises from the search for solutions to problems related to the use of ERP systems, or rather, the restrictions imposed by ERP systems would trigger reflection on how to improve one’s practices at work. This Reflection construct featured the highest levels of agreement, as shown by the following variables: recognition that the respondent’s actions may have an impact on other areas of the company had the highest PAR overall (76.17%) and a mean agreement of 4.05; user commitment to performing well within the system, PAR 74.41% and mean agreement 3.98; and interest in learning more about the ERP system in order to perfect work practices, PAR 72.65% and mean agreement 3.91. When asked whether ERP increased their reflection on how to improve work practices. However, respondents were neutral (PAR, 51.53%; mean agreement, 3.06).
This result showed that ERP system users are greatly concerned with their responsibilities and their commitment, and their Reflection on work practices is translated into a concern with doing a good job; however, their vision strayed from that proposed by Elmes et al (2005), according to which the ERP system would foster reflection on improving one’s work practices in addition to promoting conformity to the system’s rules. According to our results, it would be more realistic to characterize the Reflection construct as fostering increased user responsibility, so that users may correctly perform activities that were made highly standardized by the implementation of ERP.

5. FINAL CONSIDERATIONS AND LIMITATIONS

Interpretation of the results of our field survey led to the following conclusions:

- Although ERP provides greater visibility of employees’ actions, respondents did not report feeling more tightly controlled or monitored by their superiors or peers. This contrasts with the results reported by Sia et al (2002), who recorded the Panoptic Control mechanism, and Elmes et al (2005), who claimed that employees know they are being watched and that access recorded by the ERP system correlates with disciplinary power, in accordance with Foucault’s perspective. We must note that ANOVA showed significant differences in the average perceptions of manager-level respondents, with greater disagreement regarding the Control factor; this finding is coherent with the fact that employees in managerial positions do not feel the effects of vertically exercised disciplinary power.

- As for Panoptic Empowerment, verified by Elmes et al (2005) but not corroborated by Sia et al (2002), our results showed that the real-time, multidirectional visibility of information provided by the ERP system within Foucault’s perspective fosters autonomy and increased decision-making power. This helps empowerment, regardless of the manner in which hierarchical power is transferred. None the less, the concept of Panoptic Empowerment – which Elmes et al (2005) stress is a contradiction, as it productively correlates high levels of control with high levels of empowerment – was not corroborated by high levels of control as reported by our respondents.

- The Reflective Conformity concept identified by Elmes et al (2005) correlates Conformity to Rules – brought about not by hierarchical control, but rather by the inherent disciplinary power of ERP procedures – with increased Reflection on work practices; that is, the limits imposed by these systems are explained by Elmes et al (2005) in light of Foucault’s “regime of truth” – the power of discourse that values disciplinary action. According to Elmes et al (2005), increased reflection stems from the search to solve problems related to use of the ERP system, or rather, the restrictions of ERP systems would lead employees to reflect on their work practices. Our results, however, showed a negative correlation. The present study has shown that users of an ERP system show great concern for their responsibilities and commitment, and their Reflection on their practices translates into a concern for doing a good job. Our view strays somewhat from that of Elmes et al (2005), however, according to which ERP systems would promote reflection on work practices in addition to obedience to the rules of the system. A more appropriate characterization of this construct would be that reflection fosters increased user responsibility, to ensure that users carry out their activities (which become highly standardized upon implementation of ERP) correctly.

Some limitations should be considered in this study. First, our results do not permit a generalization of findings for the user population of systems ERP, getting restricted to the sample. The second limitation is concerning the problems of scale of Conformity to Rules. The reliability of Cronbach’s alpha coefficient indicates that subsequent analysis should be seen with some reservations. The results of this factor suggest the need for improvement in the scale, probably through a search of the theoretical framework for new items that would assist in adequately explaining its meaning. The impossibility of identifying a relation between cause and effect by correlation analysis is the third limitation. However, as the literature points to the existence of such variables, the final analysis considers this relation as proposed in the literature. Future research can go deeper into behavioral...
aspects, especially the control factor, taking into account the findings identified here as well as cultural dimensions of the countries.

Abstract

Aligning information technology (IT) strategy with business strategy has been one of the top concerns of practitioners and scholars for decades. Despite the documented positive effects of strategic alignment on organizational success, only a few organizations consider themselves in alignment. Although numerous studies exist about how to accomplish IT-business alignment, empirical studies based on strong theories have been rare in the literature. This study attempts to fulfill this gap by proposing and empirically validating a comprehensive strategic alignment model. Drawing on prior literature, we identified five antecedents of alignment: centralization, formalization, shared domain knowledge, successful IT history and relationship management. We further hypothesized that the effects of these antecedents are mediated by two drivers of alignment, which are conceptualized as the level of connection of IT and business planning and the level of communication between IT and business managers. Using survey data and structural equation modeling methodology, we show that both drivers had significant effects on alignment, and the effect of connection is about twice that of communications. Our findings also confirm the effects of all antecedents except centralization. Overall, the main contribution of this study is the development and empirical validation of a comprehensive strategic alignment model, providing a more ample prescriptive insight for managing IT-business strategic alignment.

Keywords: IT-business alignment, strategic alignment, antecedents of alignment, drivers of alignment
1 INTRODUCTION

Aligning information technology (IT) strategy with business strategy enables an organization to maximize the impact of its IT investments, achieve harmony between IT and business (Byrd et al. 2006, Henderson & Venkatraman 1993, Nelson & Cooprider 1996, Tan & Gallupe 2006), and increase the organization’s competitive advantage, profit margins, and growth (Alter 2005, Byrd et al. 2006, Pearlman & Baker 2005). During the past two decades, executives have consistently identified achieving alignment as one of the top key issues in IS management (Brancheau & Wetherbe 1987, Luftman et al. 2006, Niederman et al. 1991, Rosa 1998). Alignment between business and IT has been an enduring subject for IS scholars as well (Chan et al. 1997, Henderson & Venkatraman 1993, Reich & Benbasat 1996, Sabherwal & Chan 2001). In fact, IT-business alignment is one of the early research streams in the IS literature (King 1978, McLean & Soden 1977), yet it is gaining even more attention in recent years as organizations rely more on information technology for competitiveness and survival in the global economy (Chan et al. 2006, Hu & Huang 2006, Luftman et al. 2006).

However, given the importance and potential benefits of alignment, the number of organizations that successfully align their IT strategy with business strategy is shown to be considerably low. A study by Rosa (1998) has revealed that only eight percent of IT and business managers viewed themselves very effective in aligning IS and corporate goals. Similarly, Luftman et al. (1999) noted that only half of more than one thousand executives that participated in their survey reported that their organizations have achieved some degree of alignment. Naturally, questions like “why haven’t we mastered alignment?” have been raised by scholars (Chan 2002).

One of the strategies to improve alignment suggested in the literature is to identify what managerial practices improve the probability of alignment (Chan 2002). Finding these factors has captured the attention of many scholars. These scholars conceptually agreed upon a number of antecedents, yet empirical validation and support for the arguments raised in these studies are lacking, and the few quantitative studies have mixed results (Chan et al. 2006, Reich & Benbasat 2000, Sabherwal & Kirs 1994). Thus, our knowledge regarding the process that leads to alignment is largely limited at conceptual and intuitive level. There is a clear need for both theory and practice for a comprehensive empirical study based on the recent advances in the alignment knowledge and statistical techniques. This study attempts to fulfill this need. The main objective of this study is to integrate and extend the literature by investigating and statistically testing a theoretical IT-business strategic alignment model.

2 LITERATURE REVIEW

Achieving IT-business strategic alignment within the organization has been considered as one of the key issues in IS management for the past decades (Brancheau & Wetherbe 1987, Henderson & Venkatraman 1993, King 1978, Niederman et al. 1991). Aligning IT and business strategies enables organizations to use their IT resources to support their business strategy, thus leading to higher levels of organizational success. Several studies in the IS literature have focused on this performance effect of IT-business strategic alignment. This body of literature has argued conceptually and found limited empirical support for the enhancing effect of alignment on organizational performance (Chan et al. 1997, Chan et al. 2006, Henderson & Venkatraman 1993, Kearns & Sabherwal 2007, Palmer & Marcus 2000, Sabherwal & Chan 2001, Sabherwal & Kirs 1994, Teo & King 1999).

Another stream of research has investigated the antecedents of IT-business alignment to understand the alignment process, and also to provide prescriptive guidance on how to achieve alignment. Recent literature has in general found that the most important antecedents of strategic alignment are shared domain knowledge of business and IT managers, previous success of IT units, connections of business and IT planning, and communications between IT and business executives (Chan et al. 2006, Hu & Huang 2006, Reich & Benbasat 1996, Reich & Benbasat 2000, Sabherwal & Kirs 1994). Although
studies have conceptually agreed on these antecedents, they are largely at conceptual or qualitative level. The number of empirical studies on strategic alignment is limited and the findings across the studies are inconsistent and have three main shortcomings. First, the data for most of the empirical studies were collected in the mid 1990s (e.g., Chan et al. 1997, Chan et al. 2006, Sabherwal & Kirs, 1994). The role of IT in today’s organizations is considerably different, and therefore, their values in providing insights to the strategic IT-business alignment process in today’s business environment are limited. Second, only a few studies have utilized the benefits of sophisticated statistical methodologies, such as structural equation modeling (SEM), to test the proposed research models. The extant empirical studies mostly utilized multiple regression, ANOVA, and t-tests, which could severely limit their ability to uncover complex interactive relationships among the key alignment constructs. Finally, no empirical studies as we know of have tested the comprehensive models that integrate alignment constructs proposed in multiple studies.

In summary, the current state of the strategic alignment literature calls for a comprehensive empirical study based on the recent advances in the alignment theory and statistical techniques. In the next section we present our research model and develop our hypotheses based on the extant literature.

3 RESEARCH MODEL AND DEVELOPMENT OF HYPOTHESES

After integrating the studies in the literature, we included IT unit structure, shared domain knowledge, successful IT history and relationship management into the model as the most significant antecedents of alignment. We defined strategic alignment as the fit between IS strategy and business strategy of organizations. Thus, when organizations achieve high degrees of strategic alignment, their IS strategy (e.g., IT for efficiency) would support their business strategy (e.g., operating efficiency). Parallel to Reich and Benbasat (2000), we hypothesized that the immediate drivers of strategic alignment are the current business practices and they mediate the effects of antecedents of alignment (Figure 1).

![Figure 1. Proposed research model for IT-business strategic alignment.](image-url)

**Connection:** Connection captures the level of integration of IS planning and business planning. When IT units do not refer to business objectives, their contribution to the organization can be limited (Pearlman & Baker 2005). Higher levels of integration provide an effective way for chief information officers (CIO) to identify top management objectives (Lederer & Mendelow 1987) and leads to better understanding of the role of the IS function, more contribution of IS to the organization, less output and process related problems, and consequently to a better organizational performance (Pearlman & Baker 2005, Teo & King 1996, Teo & King 1999). Parallel to that, Teo and King (1997) reported that managers choose to increase the level of planning integration when their organizations need to use IS to support business strategy and to align IS objectives with business objectives, as well as when they realize the importance of IT for their organization.

Although there is qualitative support for the positive effect of planning integration on strategic alignment (Hu & Huang 2006, Reich & Benbasat 2000), the empirical support is somewhat mixed with studies reporting insignificant (Chan et al. 2006, Sabherwal & Kirs 1994) as well as significant (Newkirk & Lederer 2006a, 2006b) effect of planning integration on strategic alignment. Overall, literature seems to suggest that successful strategic planning leads to alignment of business and IS strategies, better analyses of internal operations, more cooperation between organizational groups and
IS group, improvement in capabilities of IS planning process, and achieving competitive advantage (Earl 1993, Segars & Grover 1998). Building on these theoretical arguments, we posit that;

Hypothesis 1: The level of connection between IT and business planning processes will positively influence the level of strategic alignment.

Communication: Communication process involves sharing and exchanging information between parties for the purpose of coordination and mutual understanding (Bacharach & Aiken 1977, Johnson & Lederer 2005). When business executives meet with IS managers frequently and discuss where the business is heading or how to resolve some of the emerging issues, it is more likely for them to converge on how IT can help the organization to achieve its goals (Johnson & Lederer 2005, Pearlman & Baker 2005). This convergence leads to mutual understanding of the organization’s business and IT functions and the strategic role of IT in the organization, resulting in collective actions to use IT for competitive advantage (Johnson & Lederer 2005). Overall, communication between IT and business executives is considered as an important enabler for strategic alignment (Alter 2005, Earl & Feeny 1994, Hu & Huang 2006, Johnson & Lederer 2005, Reich & Benbasat 2000, Tan & Gallupe, 2006). Thus, we posit that;

Hypothesis 2: The level of communication between IT and business managers will positively influence the level of strategic alignment.

IT Unit Structure: The structure of organizations has a significant influence on the information flow and human interactions through channeling collaboration, specifying modes of coordination, and prescribing levels of formality (Miller 1987). Considering its potential effect on alignment, the IT unit structure aims to capture the degree of centralization of IT decision making and formalization of IT activities.

Centralization: Centralization represents “the degree to which the right to make decisions and evaluate activities is concentrated” (Fredrickson 1986, p.282). In centralized governance modes, IT activities are coordinated at the corporate level (Sambamurthy & Zmud 1999), and therefore, organizations may require less effort for alignment (Chan et al. 2006). In contrast, in decentralized modes, divisional managers assume authority (Sambamurthy & Zmud, 1999), and they are more likely to focus on their own objectives rather than the central objective. When organizations aim to leverage their IT for a more strategic role or when they are dissatisfied with the level of alignment, one of the first tasks executives undertake is to centralize the decision making (Brown & Magill 1994, Rothfeder 2005).

Centralization has an influence on the communication levels as well. Although centralized mode does not foster interactive and participative decision making across hierarchical levels in organizations (Ranganathan & Sethi 2002), this does not necessarily affect the communication level within the top management. Hage et al. (1971) argued that power and status between job occupants are important inhibitors of communication. As the social status increases in organizations, free flow of information decreases (Barnard 1964). However, since in centralized structure there is less power and status discrepancies among decision makers (e.g., top management team, all C-level executives, etc.), centralization enables better communication among decision makers. Overall, the literature suggests that centralized IT governance is indeed an enabler of IT-business strategic alignment. However, we posit that the positive effects of centralization are mediated by the drivers of alignment. Thus,

Hypothesis 3.1a: The level of IS centralization will positively influence the level of connection between IT and business planning.

Hypothesis 3.1b: The level of IS centralization will positively influence the level of communication between IT and business managers.

Formalization: Formalization indicates “the extent to which an organization uses rules and procedures to prescribe behavior” (Fredrickson 1986, p.283). It facilitates planning process (Miller 1987) and use of formal planning procedures in organizations (Pyburn 1991). Especially in complex organizations, formalization enables the clarification of business objectives, thus increase the effectiveness of IS
planning process in terms of reaching to a consensus on the role of IT (Earl 1993, Lederer & Sethi 1988, Pyburn 1991). Formalized IS planning also ensures that overall IS goals are consistent with business goals of the organization (Lederer & Mendelow 1986).

Top management views identifying corporate strategic direction and business plans as one of the most difficult aspects of strategic IS planning (Lederer & Mendelow 1986). Lack of formal organizational strategic plans creates difficulties for CIOs to identify business objectives as well (Lederer & Mendelow 1987). Therefore, the absence of formal business planning could severely damage the IS planning process (Lederer & Mendelow 1989, Lederer & Sethi 1988, McLean & Soden 1977). Overall, formalization promotes better task coordination through frequent communication and integration of planning, and in turn, increases the quality of strategic IS planning and enhances the IT management and decision making process (Bai & Lee 2003, Ranganathan & Sethi 2002). Thus, we posit:

**Hypothesis 3.2a:** The level of IS formalization will positively influence the level of connection between IT and business planning.

**Hypothesis 3.2b:** The level of IS formalization will positively influence the level of communication between IT and business managers.

**Shared Domain Knowledge:** Shared domain knowledge captures the IT knowledge of business managers and the business knowledge of IT managers (Ranganathan & Sethi 2002). The lack of shared domain knowledge is considered as an inhibitor of communication and strategic IS planning (Lederer & Mendelow 1987, Feeny et al. 1992) since it increases the information asymmetry and results in inaccurate interpretation of messages, ultimately leading to intergroup conflict (Nelson & Cooprider 1996). CIO’s business knowledge enhances formal and informal interactions of CIO with top management and increases the assimilation of IT in organizations (Armstrong & Sambamurthy 1999). Moreover, business competency of IS managers has a significant effect on determining the extent of IT-business planning integration (Teo & King 1997). Kears and Sabherwal (2007) also argued that when top managers possess knowledge of IT, the opportunities are created for business and IT managers to participate in each other’s planning process.

Shared domain knowledge is considered as an important component of strategic alignment (Reich & Benbasat 1996, Tan & Gallupe 2006, Teo & Ang 1999). In their respective case studies, both Reich and Benbasat (2000) and Hu and Huang (2006) reported the positive influence of shared domain knowledge on the communications between IT and business executives and connections between IT and business plans. Overall, the literature converges on the positive effects of shared domain knowledge on IT-business alignment through enhancing current business practices. Thus, we posit:

**Hypothesis 4a:** The level of shared domain knowledge of IS and business managers will positively influence the level of connection between IT and business planning.

**Hypothesis 4b:** The level of shared domain knowledge of IS and business managers will positively influence their level of communication.

**Successful IT History:** Successful history of an IT unit gives credibility to the IT unit and creates favorable perceptions of IT in top management (Chan et al. 2006, Earl & Feeny 1994, Hu & Huang 2006, Reich & Benbasat 2000, Rockart et al. 1996). Also, it is an important determinant of the participation of business managers in the planning process (Pearlman & Baker 2005, Teo & Ang 1999). The confidence of top management in the IT department and IT department’s efficient and reliable services are found to be important critical success factors for aligning IS plans with business plans (Teo & Ang 1999, Luftman et al. 1999). Teo and Ang (1999) postulated that confidence of top management in IT increases their commitment to the strategic use of IT, making them more likely to allocate appropriate resource for planning and development of IT applications. On the other hand, lack of IS management credibility discourages top executives from communicating their needs and problems (Pearlman & Baker 2005), and more importantly, from communicating their goals, objectives and plans (Lederer & Mendelow 1989), thus inhibiting strategic alignment (Luftman &
Brier 1999). Clearly, successful IT history itself won’t impact IT-business alignment directly. However, the increased confidence of top management and the higher credibility of the IT unit are likely to enable IT unit to participate effectively in the strategic planning process and communicate effectively with business managers. Based on these arguments, we posit that:

**Hypothesis 5a:** The level of successful IT history will positively influence the level of connection between IT and business planning.

**Hypothesis 5b:** The level of successful IT history will positively influence the level of communication between IT and business managers.

**Relationship Management:** Relationship management captures the extent to which IS and business managers invest time and effort in managing relationship between each other. A close relationship between IS and business managers enables them to work together to understand business and technological requirements (Jones et al. 1995, Rockart et al. 1996, Watson 1990). Ongoing personal relationships facilitate the parties to engage in knowledge creation and their availability for knowledge exchange (Hatzakis et al. 2005, Nahapiet & Ghoshal 1998). Having a good relationship between CIO and CEO is considered as an enabler of IS-business planning integration (Feeny et al. 1992). Bai and Lee (2003) noted that the CEO/CIO relationship can be crucial for the alignment and the quality of strategic IS planning. This relationship, in turn, enhances the ability of IT to add value to the organization (Earl & Feeny 1994) and ensures the successful integration of business and IT strategies (Rockart et al. 1996).

Moreover, several scholars suggested that stronger relationship between business and IT managers would improve their communication level (Coughlan et al. 2005, Hu & Huang 2006). Rockart et al. (1996) noted that only through the established relationship between IT personnel and line managers can the necessary communication occur. The informal relationship networks are also an important component of alignment (Chan 2002). The development of relationships makes the alignment concept more tangible through the understanding of existing communication channels and networked relations in organizations (Coughlan et al. 2005). Overall, IT/business relationship is considered as an important enabler of strategic alignment (Luftman & Brier 1999, Tan & Gallupe 2006). Thus, we posit that the active relationship management by IT and business managers enhances the connections between IT and business planning, and improves their communications, or;

**Hypothesis 6a:** The level of relationship management will positively influence the level of connection between IT and business planning.

**Hypothesis 6b:** The level of relationship management will positively influence the level of communication between IT and business managers.

### 4 RESEARCH DESIGN

Based on the theoretical alignment model and a thorough review of the literature, we developed a survey instrument to collect data for validating the constructs in the model and testing the research hypotheses (Table 1). A seven-point Likert scale was used for all the measurement items in the survey.

<table>
<thead>
<tr>
<th>Construct</th>
<th>Sample Questionnaire Item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strategic</td>
<td>The IT plan contains detailed action plans/strategies that support organization’s business</td>
</tr>
<tr>
<td>Alignment</td>
<td>objectives and strategies.</td>
</tr>
<tr>
<td>Connection</td>
<td>Business and IT executives both participate in the strategic planning process.</td>
</tr>
<tr>
<td>Communication</td>
<td>Business and IT executives have frequent, direct, formal communications.</td>
</tr>
<tr>
<td>Centralization</td>
<td>Issues related to major IT investments have to be referred to business executives at the top</td>
</tr>
<tr>
<td></td>
<td>management.</td>
</tr>
<tr>
<td>Formalization</td>
<td>Operating rules/procedures play important roles in how issues are handled in the IT unit.</td>
</tr>
</tbody>
</table>
IT executives have a good understanding of the organization’s business environment.

The IT unit has been considered as credible.

Business and IT executives make an effort to maintain a better relationship with each other.

Table 1. Constructs and Sample Measurement Items Used in the Survey

Following a pilot test with EMBA students enrolled in a large public university to validate the survey instrument, we collected the data from organizations in Turkey primarily because of one of the authors’ connection to the Turkish industry organizations. The survey instrument was translated into Turkish and then back-translated for discrepancies with the original instrument in English. Considering that constructs such as strategy, technology and structural characteristics are considered as having low cultural dependency and are invariant in different cultural setting (Samiee & Athanassiou 1998), with respect to this study, we believe that potential threats to conceptual equivalence was minimal.

An invitation for participation to the survey website was distributed through e-mail to 440 organizations in the directories provided by Istanbul Chamber of Industry. Also, one of the authors personally contacted the executives and business managers of 120 organizations. A total of 560 invitations were distributed. The target population included business administrators with complete knowledge of IT and business strategizing processes. At the end of the process, there were 169 usable questionnaires. The average revenue of the firms in the sample was about $1.3 billion. Manufacturing firms represents one third of the sample. This is followed by Wholesale/Retail firms (20%) and Technology/Telecommunication (10%) firms.

We used partial least square (PLS) analysis to analyze the survey data and test the research hypotheses. After verifying that the missing data were not systematic, multiple regression method was used for data imputation. Item loadings and average variance extracted (AVE) values were examined to assess convergent validity. Item loadings range between 0.68-0.91 (p < 0.01), and AVE scores range between 0.61 and 0.78. These results showed that the constructs demonstrate convergent validity. We assessed discriminant validity by examining the AVE scores and the cross-loadings of the items. The loadings demonstrated that the items loaded higher for their corresponding constructs than for other constructs, and the items loaded higher for their corresponding construct than other items, thus providing adequate statistical support for discriminant validity. The Cronbach alpha values of the constructs range between 0.79 and .93, suggesting adequate level of construct reliability (Table 2). Lastly, we utilized Harman’s one-factor test and common method latent variable test to measure the common method bias, and found that the effect of this bias is insignificant.

Table 2. Descriptive Statistics and Psychometric Characteristics of the Constructs

Notes: (1) ** p< 0.01; (2) Diagonal elements are square root of AVE; (3) α: Cronbach’s alpha
5 HYPOTHESIS TESTING AND RESULTS

SmartPLS software (Ringle et al. 2005) was used to conduct PLS analysis (Figure 2). Initially, organizational size was included in the structural model as a control variable, however, considering its insignificant effect, we excluded it from the model for parsimony. The results of the analysis provided support for the positive effect of connection ($b = 0.50, p < 0.01$) (H1) and communication ($b = 0.24, p < 0.01$) (H2) on alignment. The $R^2$ value of .46 demonstrates that the model explains a considerable amount of variance in strategic alignment.

We found partial support for H3. On one hand, the effect of centralization on connection and communication was insignificant. On the other hand, formalization had significant positive effect on both connection ($b = 0.20, p < 0.01$) and communication ($b = 0.13, p < 0.05$). The results also provided support for the positive effect of shared domain knowledge of IT and business executives on connection ($b = 0.28, p < 0.01$) and communication ($b = 0.18, p < 0.01$) (H4). Similarly, we found support for our arguments that when both business and IT executives foster good relationship, this, in turn, increases the connection of IT and business planning ($b = 0.20, p < 0.01$) as well as the communication between IT and business executives ($b = 0.19; p < 0.01$) (H6). Lastly, prior success of IT unit had significant effect only on the communication of the executives ($b = 0.26, p < 0.01$), thus providing partial support for H5. Both connection and communication have $R^2$ value of .31, indicating that the antecedents explain a good amount of variance in the drivers of alignment.

![Figure 2. Results of the PLS analysis](image)

Overall, we found strong support for our arguments regarding the positive effect of drivers of alignment on strategic alignment. Also, most of the antecedents had significant positive effect on the drivers of alignment as expected.

6 DISCUSSION

Studies in the IS planning and strategic alignment literature underline the importance of IT and business planning connection and communications between IT and business executives (Hu & Huang 2006, Reich & Benbasat 2000, Teo & King 1996). Building on these arguments, we hypothesized that the effects of antecedents are mediated by these current business practices. The statistically significant positive associations provided empirical support for these arguments. When the effects of these drivers are compared, the results indicate that the positive effect of connection is about the twice that of communication. This suggests that integrating the planning process is more essential than the level of communication between the executives in terms of achieving and sustaining strategic alignment. This finding is important in a sense that although previous studies postulated the effects of connection and communication, due to the qualitative nature of these studies, a comparison of their effects on alignment was not possible. This empirical study not only provides support for the qualitative studies, but also extends our understanding of how the underlying mechanisms of strategic alignment work. One possible explanation of this finding is that planning process is more formal and results in written
documentation, thus, enforcing a stronger form of alignment compared to communication which is bound to individuals and embedded in relationships. However, this finding does not in any means diminish the importance of communication between IT and business managers.

We identified five antecedents of strategic alignment based on literature review and validated their roles in alignment based on the data. First, we examined two characteristics of unit structure; centralization and formalization. In centralized structures, IT activities are supposedly coordinated at the corporate level, requiring less effort for alignment. Our results unexpectedly showed insignificant effects of centralization on drivers of alignment. Although studies in the alignment literature found similar results (Chan et al. 2006), more research is needed to fully understand the underlying reasons of this insignificant effect. On the other hand, the results provided support for positive effect of formalization as expected. Highly formalized organizations have clearly defined job descriptions and standardized policies and procedures, and they make use of task forces and committees more often. These characteristics are beneficiary for IT executives since unclear business goals and objectives present challenges to them. It is considerably easier and more effective for IT executives to integrate IT strategy into business strategy when the business strategy is formally outlined in the organization. Similarly, as a result of formalization, it is likely that executives would participate in more committees or task forces which would increase direct interactions and information sharing, which, in turn, would increase the level of communications and the number of channels used for communications.

Shared domain knowledge is one of the widely studied antecedents of strategic alignment. It refers to business and IT executives’ knowledge and understanding of each other’s environments. This understanding also brings the appreciation to each other’s accomplishments. If executives do not have shared domain knowledge, communications among them will be ineffective, and this will consequently inhibit the level of communications. In other words, without shared domain knowledge, effective communications shouldn’t be expected. On the other hand, when executives have shared domain knowledge, this creates more opportunities to achieve integration during the strategic planning process. Our results clearly support these argument by indicating that an increase in shared domain knowledge leads to better integration of IT and business plans and more frequent communication between IT and business executives.

Similar to shared domain knowledge, successful IT unit history is another commonly recognized antecedent. When IT units are reliable, credible, and deliver their commitments on time, this creates a positive impression on business executives. Our findings showed that successful IT history has a positive effect on the communications between IT and business managers. This outcome is only logical because business executives would like to consult some of their ideas with or query certain solutions from IT executives only if they consider the IT unit as credible, reliable, and successful. In an organization where the IT unit cannot deliver its promises, business executives wouldn’t take the time and effort to communicate with IT executives and the role of IT would certainly be marginalized.

Our findings also show that the significant effect of relationship management on both drivers of alignment is approximately the same, lending empirical support to the largely qualitative arguments in the literature. Having good relations between CEO and CIO is considered crucial for the quality of IS planning (Bai & Lee 2003) and it is also identified as an important enabler of strategic alignment (Feeny et al. 1992). When IT and business executives invest their time and give effort to have a good relation, this in turn would increase the level of communications between them. Furthermore, they would value more each other’s inputs during the planning process, and consider each other’s priorities, goals, and objectives as their own, resulting in higher levels of planning integration.

7 CONCLUSION AND CONTRIBUTIONS

Strategic alignment between IT and business has been one of the top concerns of practitioners and scholars. However, despite its documented positive effects on organizational success, only few organizations consider themselves in alignment (Luftman et al. 1999, Rosa 1998). We attempted to
fulfill the need for a comprehensive alignment model that not only integrates and extends the alignment literature, but also provides prescriptive insights to practitioners. Given the limited empirical findings in the literature, our first aim was to provide a more comprehensive framework that is empirically tested with survey data, and find support to the largely qualitative framework of IT-business alignment theory. Moreover, we chose to use SEM to test the proposed model to overcome the limitations of previously utilized techniques (i.e., ANOVA, t-tests). Also, by collecting the data from Turkey, we added a different dimension to the alignment literature, which mostly utilized data from US and Canada. Another contribution to the literature is the direct measurement of centralization in organizations. In the literature, organizational size was used as a proxy to centralization, assuming that small organizations are centralized and large organizations are decentralized.

The findings of this study present a more complete view of the strategic alignment process, thus providing a finer prescriptive guidance to executives for achieving and sustaining the alignment. First, with regards to communication and connection, business managers may reconsider their strategizing process and keep planning integration as one of their primary goals and seek opportunities to increase their communication level with IT managers. Second, given the positive effect of formalization on strategic alignment, executives can choose to increase the level of formalization in their organizations through different strategies including clearly outlining the responsibilities of IT and business units in terms of integration and implementing policies and procedures regarding decision making processes. Third, considering the importance of shared domain knowledge, business and IT executives should seek opportunities to increase their knowledge in each other’s domains by attending internal and external trainings and seminars. Forth, they should invest in time and effort to maintain a good relationship amongst each other. Lastly, IT executives should be more proactive in terms of increasing the visibility of their unit’s success and making sure that they deliver on their promises.

There are some notable limitations in this study that deserve attention. For example, although we based the causalities in our research model on the findings of the strategic alignment literature, this does not preclude potential recursive relations between some of the constructs. In addition, due to the characteristics of the data collection process, we weren’t able to calculate the non-response bias. One venue for future research is to investigate the proposed model with regards to the type of business strategies an organization is pursuing. Such an investigation would reveal how the effects of antecedents vary by strategy type. Also, this study was built on the common proposition that IT strategy should support business strategy. However, other schools of thought (e.g., synchronization or convergence of IT and business strategies) are also suggested in the literature (Sambamurthy 2008). Future research can investigate the model with respect to these considerably new approaches to strategic alignment.

Abstract

The ‘SISP community’ is an evolving environment, which generally learns from the past. However, the lesson that top management commitment is a key determinant of SISP success has not been learnt. Regardless of the industry type or size, a lack of real commitment from senior management is still the main reason for the SISP formulation and implementation failure. The study introduces the SISP Stakeholders’ Designation construct to analyze commitment and participation of the available SISP resources in the light of maximizing success of SISP. Also the association between organisational learning and management commitment to SISP is examined. A postal survey of top management from 260 Australian companies revealed that obtaining high-level stakeholder engagement is critical to SISP success. The study presents optimal roles and level of engagement for the SISP Stakeholders’ Designation. It was found that if every managerial stakeholder’s designation is committed to SISP in all its phases it may result in wasting of valuable time and resources. The findings point to SISP learning reviews as a significant antecedent for managerial commitment to SISP.

Keywords: SISP success, top management commitment and participation, organisational learning.

1 INTRODUCTION

Organisations respond towards the pronounced need for strategic planning of IT/IS resources when they are critically dependent on IT/IS (Palvia & Palvia 2003). The need for Strategic Information Systems Planning (SISP) is present in small and large organisations (Porter 1998). It is nearly impossible to find an IS strategist who did not raise management commitment to SISP as an issue. The most general lesson to be learned from the more successful SISP cases is that when SISP has management commitment, success is almost guaranteed (Kearns 2006). Despite that, there is equal evidence that a top management support for SISP process in many firms is only declarative, and hence that is one of the reasons for SISP failure (Hartono 2003). Not believing in SISP ability to create a competitive advantage, drive revenue and innovation, could be a reason for top management lacking of real action. Or perhaps, excessive organizational commitment to SISP is detrimental (Basu et al. 2002). In any case, at present, business profitability is noticeably in decline, and accountability is a major requirement for SISP practitioners (Pisello 2001). The successful CIO can be a strategic business partner rather than an infrastructure provider and if the CIO holds strategic responsibilities he/she may significantly contribute to the organisation’s expansion and growth (Dearstyne 2004). Otherwise, IT practitioners could be the obstacles to implementing business solutions.

Little empirical research exists that examines involvement and commitment of SISP stakeholder’s like top managers, senior business, IT and user managers, IT computing personnel and users. In addition, because of very conceptual nature of the SISP studies, the relations among SISP stakeholders remains hidden on the variable level. Previous research (Basu et al. 2002) suggested further investigation in
this area, in particular, senior management involvement and the impact of additional matters like organizational learning on SISP success. This study is an empirical work conducted in that direction using data obtained from a large scale survey of 2000 Australian companies. Thus, close examination of the role of SISP stakeholders can provide valuable insights not available elsewhere.

The purpose of this paper is: (1) to confirm that traditionally the lack of commitment from top management (Lederer & Sethi 1988, Ward & Griffiths 1998, Teo & Ang 2001) is still the main reason for SISP failure (2) to examine the relationships between SISP stakeholder’s participation/commitment and SISP (3) to examine the association between learning reviews experience and top management commitment to SISP.

This paper proceeds as follows. After an overview of SISP problems, some key stands from SISP literature are presented to be able to form hypotheses and a context within which the survey results may be interpreted. The methodology section follows to explain the collection and analysis of data. Finally, a summary of the survey results and the possibilities for further research is presented.

2 THEORETICAL BACKGROUND

SISP is needed to produce a strategic plan that addresses the future needs for IT/IS in accordance with the business objectives in formal or less formal ways (Hackos 1997). However, over half of SISP plans formulated are never implemented, or fail to achieve their goals and objectives (Flavel & Williams 1996). The reasons for SISP failure remain fairly constant over the years. A summary of SISP problems (Yeo 2002, Cerpa & Verner 1998, Lederer & Sethi 1992, Ward & Griffiths 1998, Wilcocks 2000) has been compiled in Table 1 (problems are not ranked). The reasons for SISP failure very well correspond to the top five management concerns: IT and business alignment, attracting, developing, and retaining IT professionals, security and privacy, IT strategic planning, business process reengineering (Luftman 2006).

Table 1. The Key SISP Barriers.

It is not only difficult to convince management to implement SISP, but is also difficult to convince them even to fund the initial SISP study (Lederer & Sethy 1999). The reason may be that top management may not understand the plan or they are not confident in IT’s ability to carry out SISP. Higher levels of managerial IT knowledge have positively influenced the extent of IT use, but top managers do not view information as a business resource to be managed for long-term benefit (Ward et al. 1998). They only appreciate it critically, when they cannot get what they need. As a result, the work is often delegated to ‘experts’ and thus managers are increasing the risk of losing control over IT applications. The applications turn out to be independent of the strategic context of the organization as a whole. Localized justification of investments can produce benefits that are actually counterproductive when overall business goals are considered (Ward et al. 1998). If control is lost, in particular, if the control of IS/IT investments is left to individuals or departments often striving to achieve incompatible objectives through IS/IT, the outcome can be disastrous (Broadbent & Weill 1997). Thus, top management involvement in IS/IT planning is crucial.

When the CEO and other top managers understand the value and potential of IS/IT assets for competitive advantage they provide support for SISP as allocation of quality resources. Commitment of the CEO to SISP would provide better knowledge about organisational objectives and can lead to a greater alignment between IS and organisational strategies (Kearns 2006) and consequently to greater
SISP success. While this alignment is necessary, it may not be sufficient to support the ‘simple’ explanation that the real planning or implementation problems are usually due to a lack of executive commitment. The reason is because it has been suggested that excessive top management commitment to SISP impedes SISP as it promotes excessive planning and provoke excessive bureaucracy (Basu et al. 2002). Therefore, these conflicting results are a great deal of confusion and the reason worth investigation of the optimal levels of top management commitment to SISP. This study acknowledges that SISP, as a highly political process, has complex interrelations between stakeholders of which a detailed investigation is a study per se. The aim of this research is to assess the stakeholders’ phenomena that are open to direct observation. Management commitment is one of them and the study in the light of overall SISP success tests the following hypothesis:

H1 SISP is more successful if: a) the CIO is committed to SISP from start to finish; b) the CEO is committed to SISP only at the start; c) the senior business management is committed to SISP from start to finish; d) the middle business management is committed to SISP from start to finish; e) the IS management is committed to SISP at implementation phase

In the terms of taking responsibilities for setting up the IT strategic directions, top management involvement is seen as unavoidable (Basu et al. 2002). However, IT professionals and business managers find it difficult to communicate and focus on improving their communications often caused more problems than it addressed (Luftman 2005). Very often they have a very different perspective on organisational values and how best to implement SISP. Implementation of SISP is not a trivial process and letting IT managers lead the SISP projects is seen as a potential obstacle to successful SISP implementation. The importance of the managerial role of IT managers is not in question, but IT has no ability to address the policy, procedures and organizational issues critical for successful business (Brown 1992). On the other hand, IT professionals are the only ones who really understand the IT process analysis. Thus, the question of what would be appropriate role of SISP participants can be raised. This study investigates the current stakeholders’ roles in Australian SISP practice and tests the following conclusions:

H2 SISP is more successful if: a) the CIO has a champion role; b) the CEO has a sponsor role; c) senior business management have a supporting role; d) IS management have an active leadership role

Successful SISP seems to require users and managers working in partnership with the IS function (Luftman 2005). Integration of inputs from all stakeholders should be an ongoing activity as their creative energy can help in generating more innovative strategies. Therefore, a participative SISP should enrich the SISP content (Ismail et al. 1996) and consequently will have a positive effect on overall SISP success. However, Ismail et al. (1996) also pointed to potential obstacles to stakeholders’ involvement. Many participants may slow down the planning process or have some other negative influence. Also, an obstacle to a participative SISP can be a managerial misalignment. A typical organisation has many types of managers who are suppose to collaborate but they often compete with each other (Goranson 2003). When they collaborate, i.e. if SISP is initiated by top management and IS management coalition, it would significantly add value to the SISP process (Spremic & Strugar 2002). In addition, when top management rather than IS management initiates the SISP study, more environmental assessment is done (Chi et al. 2005). Spremic et al. (2002) found that the main initiators of SISP in Croatian organisations are IS management (33%) and top management (27.5%). They relate the high rate of SISP failure due to the lack of line management initiating SISP. Flynn et al. (1993) found that more often SISP was initiated by the IT department than management (22% against 55%). Full integration or ‘partnership’ (Luftman 2005) of IS and business is seen as an imperative to avoid the barriers of a managerial misalignment, therefore it is hypothesised that:

H3 If SISP is initiated by business management and IS management coalition, it will be more successful.

The quality of people (intellectual capital) involved in the SISP process in terms of the ability to think innovatively, having adequate skills, knowledge, and experience is a key contributor to SISP. Appropriate business management knowledge of IT is significant for ensuring their commitment to
IT/IS projects (Kearns & Lederer 2000) and vice versa, IT management need to possess business acumen to improve strategic IT alignment with business (Teo & King 1997b). Learning from past experience and sharing knowledge is an important method of directing future SISP activities. Regular change reviews and learning reviews will enable better communication, knowledge sharing and improve likelihood of SISP success (Pai 2006). This discussion provides the basis for:

H4 Learning reviews positively influence management commitments towards SISP.

3 SISP SUCCESS (THE LACK OF FAILURE) AND CONCEPT OF SISP STAKEHOLDERS’ DESIGNATION

Multi-dimensional, multi-item measures of SISP success were proposed in the SISP literature. However, these dimensions of SISP success were examined and it was found that two dimensions: improvements in SISP capability and fulfilment of SISP objectives were not fully supported because of an overlap of these two concepts, suggesting the use of either of these dimensions (Warr 2006). As organisations do not have a single predominant SISP objective, SISP success as a composite of related perceptual items would rely on their average value and should be treated with caution. Thus, Basu et al. (2002) suggested the use of a single item measure for dependent variables. This study measured SISP success explicitly and operationalised it as a single item which measured the respondent’s perception of the overall SISP success. It is acknowledged that this measure can be biased, but some other researches (Pyburn 1983, Hartono et al. 2003) also used single items. SISP success is measured by directly asking the executives (business 31%, IT 69%) questions about their perception of SISP achieving its objectives. Other studies confirmed an insignificant error between the use of a single overall measure of success from the respondent and a multi-item measure (Warr 2006).

The extent to which powerful organisational actors are involved and committed to SISP will increase the success of SISP. Many studies (Ismail et al. 1996, Ruohonen 1991) categorise and characterise stakeholder groups for SISP. Generally, organisational stakeholders include business owners, data owners, developers and technical operational staff. SISP participants can be broadly characterised as managerial, IT non-managerial and other stakeholders like vendors and users. This study identifies managerial SISP stakeholders’ designations as: CEO, CIO, senior business management, middle business management and IS management group. Also, stakeholders’ designation is assessed through participation of other available resources, such as consultant, systems analysts, vendors, users and computer operations personnel. Participants are differentiated by the roles they have in the SISP process. For example, managerial members involved in SISP can have different roles, but top executives are supposed to have a champion role (Basu et al. 2002). Other roles are identified as supporting (assisting in all SISP activities), sponsorship (committing capital, personal time as well as resources for SISP, and making decisions with or without approval from higher-levels), and active leadership (guidance and empowering SISP team to higher levels of performance).

4 RESEARCH METHOD

This study uses only subset of data collected from an Australian-wide survey for a large study on SISP assessment and measurement. Data collection was completed by the end of 2003. The use of older data to mirror the current happenings ‘is not uncommon in SISP research because they tend to be relatively time invariable even though IT changes rapidly’ (Newkirk & Lederer 2006). To ensure generalizability of our findings, the questionnaires were administered to CIOs and senior IT executives in various industry sectors. Targeted key informants were IT executives, as they are usually the most involved in SISP (Segars & Grover 1998). To assess the validity of the answers, questions regarding respondent’s SISP involvement and experience in SISP were asked. A pilot survey was used to test the data collection method. The content of the questionnaire was discussed and refined through consultation with three prominent SISP practitioners being IT managers from three different industry types of organisations. A pilot survey
was completed with five organisations. The targeted companies were from government and private sectors, and they were small, medium and large in size. From a population of 2000 questionnaires sent, a reasonable number of questionnaires (260) with complete data were received. 86 surveys were received from companies that do not perform SISP but they supplied valuable data which is used to analyse the characteristics of organisations that do not perform SISP. This response rate (17.3%) is considered high as the chosen method of collecting data usually has a low response rate (Kress 1988).

Different statistical techniques were used to analyze the data. To calculate the strength of a relationship, Spearman's correlation coefficient, rho (\( r \)) was used for ordinal variables (Cavana et al. 2001) where data were not normally distributed. By convention, values of 0.15 or higher for rho are accepted as an indication of the strong relationships. Structural Equation Modelling (SEM) was used to confirm theoretical constructs that cannot be observed directly by explaining how the measured and latent variables are related to one another. Fit indexes, recommended by Byrne (2001), are reported but not discussed here as they are widely described in the statistical literature. Reliability of scales was checked for inter-correlation among their items using principal component factor analysis (PCA). The results of reliability tests are reported in Appendix A (Table 0.1).

5 DATA ANALYSIS AND DISCUSSION

Received responses indicated that about 24% of Australian organisations do not perform SISP at all. This study found that organisations that attempt IS planning in Australia in about 17% cases perform SISP regularly, 15% of them were developing SISP at the time the survey was conducted, 38% have irregular SISP, while about 31% of organisations have some form of IS planning.

Having 92.0% of respondents as active contributors to SISP, with 81.6% of them having more than 11 years of industrial experience, 89.6% having more than 6 years experience in the IS area, gave full credibility and confidence to the survey answers. The majority of respondents came from the manufacturing (18.4%), followed by public administration (11.5%), and banking (financial) services (9.2%). Industry types are grouped according to the size of the company: small (annual turnover < $10 million), medium (turnover between $10 and $500 million) and large for turnover of more than $500 million. Thus, respondents were: 5.7% from small, 62.1% from medium and 32.2% from large companies. About half of the surveyed companies have 100 to 1000 employees and 43.7% of companies have less than 10 IS employees. Only 36.8% of companies have more than 50 IS employees where about half of these companies employ more than 200 IS employees. The literature review revealed that SISP increases directly with the total number of employees (Groznik & Kovacic 2000, Teo et al. 1997a). The existence of relationships (Chi-Square=31.722, df=6, \( p<0.05 \)) was found in the case of the regular SISP planning. Thus, organisation size in terms of number of employees is a significant antecedent for conducting SISP.

Participants positions were: CEO (4.60%), CIO (33.33%), Information Systems Manager (35.63%), Divisional Manager (3.45%), Accounting Manager (3.45%), Financial Controller (4.60%) and General manager finance & administration (4.94%).

5.1 Key Reasons for SISP Formulation and Implementation Failure in Australia

The key reasons for the failure of SISP in Australian organizations are shown in Table 2. The rank position was calculated by ordering the mean values obtained as responses to the questionnaire in regard to the importance of the reason for SISP formulation and implementation failure (from (1) no importance to (5) crucial). The reasons for the SISP implementation and formulation do not differ significantly. The main reason for the SISP formulation and implementation failure in Australian organizations is the lack of commitment from senior management and the third and fourth failure reasons are also related to management (the ‘lack of senior management involvement’ and ‘IS
management is not part of the corporate planning process’). This is very much in line with the recent SISP literature (Palvia et al. 2003).

Budget limitation, as the second key reason for SISP formulation failure, at first was somewhat unexpected, but after finding that responses of business executives on their thoughts about IS/IT adding value to the business were only 32% positive, this became more clear. Misalignment with business objectives is the number one ranked management concerns (Luftman 2006) but this study found it to be the fifth reason for SISP formulation failure and as the second reason for SISP implementation failure. This may sound unexpected but on the contrary, when the common rationale for failures is known and widely publicized as IT - business misalignment, SISP actors focused their activities to avoid those barriers, which led to the reduction of SISP failures caused by misalignment at least in the plan formulation phase.

Table 2 Key Reasons for the SISP Formulation and Implementation Failure.

Also, ‘problem with resources’, a highly ranked management concern is not highly ranked as a reason for SISP formulation failure – it occupies the ninth position. A possible explanation is that the normal SISP evolution process added to the knowledge and experience of those involved and the popularity of IT attracted many students over last decades. These are now manifesting in terms of higher availability of IT resources. These factors elevated the problem, but the lack of adequate expertise is still considered as one of the ten most important reasons for SISP failure.

The study tested the relationship between the reason for SISP failure and the company size and found no relationship (r <0.15, p>0.05). SISP failures occur in any size of organization. This finding reinforces the result of the study of Flynn and Goleniewska (1993).

5.2 SISP Stakeholders’ Designation

The SISP Stakeholders’ Designation construct is assessed through the analysis of participation and commitment of the available SISP resources in the light of enhancing SISP success. The survey results suggest that managerial commitment in Australian SISP practice is not so pronounced. About 35% of organizational management has no commitment towards SISP, about 63% is committed only at the...
start of the SISP process, and about 13.3% of management is committed only during the implementation phase. As an average, 46.7% of the managerial structure is committed from start to finish of the SISP process. The highest percentage is related to the commitment of CIOs. They are dedicated to SISP from start to finish in 65.52% of cases. Also, the survey results showed that IT required skills are generally available at an average rate of 82%.

The Stakeholder’s Designation construct is operationalised by four latent factors (Figure 1). The PCA demonstrates that the original segregation between SISP participation and commitment is not fully supported. There is some overlapping between those two factors. Generally, management participation is considered as a commitment to SISP; while for stakeholders, such as users, vendors, consultants, etc., participation is distinguished from commitment. Certainly, the participation of users cannot be taken as their commitment to SISP. It is important to point out that CEOs’ contribution to SISP emerged as a latent factor on its own, indicating the importance of CEO involvement in SISP. The structural path analysis confirms that the most important factor to SISP is the commitment of organizational management and the least important factor is who the SISP initiator is. Using SEM, the goodness-of-fit statistics shown in Table 3 confirm that this model fits the data well.

Table 3  SISP Stakeholder’s Designation Model Fit Summary

Figure 1  Stakeholder’s Designation: Measurement and Structural Model.

5.3 Commitment to SISP

Hypothesis H1 is tested in two steps. First, a nonparametric correlation test is used to generally confirm the existence of the relationships between top management commitment and SISP success. Secondly, the mean values are compared to discover SISP maximums for various levels of commitment. Correlation statistics ($r=0.55$, $p<0.001$) generally support H1. The SISP success means for various levels of commitment are graphically presented in Figure 2. H1 (a), (d), (e) are fully supported. If senior business management is committed to SISP from start to finish, the success of SISP may not be greater than if their commitment is only at the implementation of SISP, hence H1 (c) is not supported. Figure 2 also shows that CEO’s commitment is more important in the implementation phase than at the start of the SISP process, thus H1 (b) is not supported. Hypothesis H1 can be interpreted that while top management commitment to SISP is generally positively related to SISP, it could be wasting of time and resources if every managerial shareholder’s designation is
committed to SISP in all its phases. Also, obtaining a management support in the implementation phase is more important than at the start of SISP.

Gottschalk (1999) found a relatively lack of importance of management support for the implementation of SISP, which is quite the opposite of the findings in this study. This study can offer several explanations for the present results. Firstly, there is no guarantee that a good plan will be adequately translated into action plans (Hartono et al. 2003, Teo & Ang, 2001). Furthermore, high SISP failure rates and the promoted importance of SISP success may influence greater support from management during implementation to ensure success of SISP. Finally, only implemented SISP can be (more or less) successful, but non-implemented SISP plan (regardless of its quality) is 100% failure.

![Figure 2: SISP Success and Managerial Commitment Relationships (categorical)](image)

Basu et al. (2002) found that organisational commitment predicted SISP success in an inverted-U relationship, i.e. as organisational commitment increases, SISP success increases until it reaches a maximum; as organisational commitment continues to increase, success decreases. A close lookup of the variables in a quadratic regression model (the square of independent variables used) revealed that in this study only senior business management commitment predict SISP success with an inverted-U shape relationship (Table 4). This could be because they increase the level of bureaucracy, which impede SISP. Therefore, strong devotion from the CIO and CEO does not impede SISP. Maximum SISP success is achieved if the CIO is committed from start to finish of SISP.

* Correlation is significant at the 0.01 level (2-tailed).

Table 4: Regressions between SISP Success and Managerial Commitment.

Managerial commitment increases as the size of the company increases. This relation is statistically significant (r=.34, p<0.01). When this relationship is inspected at an item level it was found to be a non significant coefficient for the CEOs. This is possibly because this designation does not commonly exist in small and medium organisations. There is no similar study to compare this result as the SISP literature mainly investigates the SISP phenomenon in large companies.

5.4 SISP Participation

The survey data shows that the highest SISP participants are CIOs (mean 3.14, std. dev. 1.49) and IS managers (mean 2.95, std. dev. 1.32), which is widely supported in the SISP literature (Teo et al.
Champion, sponsor and active leadership roles are the most pronounced roles for CIOs. The CEO has mainly more a sponsor and than a champion role. The data shows that other IS managers mostly have a champion or an active leadership role while senior business managers have a sponsor and an active leadership role most of the time.

It was found that only management participation is significantly correlated to SISP success ($r = .55$, $p < 0.01$). The influence of IT personnel as systems analysts, developers, programmers and other computer operations personnel on SISP success is not support. Consultants did not influence SISP success; perhaps they had not carried the significant SISP roles. This scale was assessed at an item level and a weak but significant relationship for users participation ($r = .183$, $p < 0.05$) was found. This is in agreement with the findings which suggested the involvement of users in SISP (Palanisamy 2005), and that computer experts should not handle SISP (Lederer et al. 1999). Still other stakeholders, not explicitly targeted by the study, could be influencing SISP success ($r = .18$, $p < 0.05$). Finding that SISP participants are mainly from senior management does not diminish the findings of Ismail et al. (1996), it simply could mean that wider SISP participation needs to be promoted in Australia. Also, the highest SISP success mean value is associated with the CIOs and IS managers’ participation in SISP.

The correlation statistics generally support H2 ($r = .55$, $p < 0.01$). The mean values depicted graphically (Figure 3) partially support H2: H2(a) and H2(b) are supported as the highest mean for SISP success is achieved if the CIO and CEO have a champion and a sponsor role respectively. H2(c) is rejected as the highest mean for SISP success is achieved if a champion is selected from senior business management. H2(d) is also rejected on a ground that IS management is more successful in a sponsorship role rather than in an active leadership role. These results are somewhat unexpected. They show that if the champion is elected from IS management, SISP may not be so successful, which could not be said for senior business management. On the contrary, if the champion is elected either from senior business management or if that role is fulfilled by the CIO, the SISP success rate may be equal.

![Figure 3](image-url)  

**Figure 3**  
**SISP Success & Main SISP Participants and their Roles (means.)**

SISP management participation is statistically significantly correlated ($r = .25$, $p < 0.05$) with company size. Large organisations are more associated with SISP success in comparison with small or medium sized companies. As SISP success is influenced by participation, small and medium sized companies should promote more participative SISP.

**5.5 SISP Initiators**

This study found that top management initiates SISP in 41.81% of cases (CIO - 28.25% and CEO - 13.56%). Senior business management more often initiated SISP than IS management and in their coalition, SISP was initiated only in 8.47% cases. The result that senior business management more
often initiated SISP (18.1%) than IS management (15.8%) is not consistent with the earlier findings of similar studies. IS management is expected to play a leading role in SISP, as confirmed by the survey results of Teo et al. (1997a). Perhaps, a high percentage of SISP initiation by CIOs’ is a compensation for the somewhat lower than expected percentage of SISP initiation by IS management. This research fails to support hypothesis H3 i.e. SISP is more successful if it is initiated by a senior business manager and an IS management coalition. The correlation shows positive and significant relationships only between the CIOs (rho =0.22, p<.005) and CEOs (rho =.28, p<.001) as initiators and SISP success. The underlying data show that SISP success can be as much as doubled if it is initiated by CIOs (mean .57 std. err. 0.038) rather than CEOs (mean 0.28, std. err. 0.034).

5.6 Organisational Learning

The sharing of experience and knowledge from SISP learning reviews is positively and strongly correlated (r=.79, p<.01) with commitments of management designations and consequently has an impact on SISP success. This statistic confirmed H4. Thus, when attendees of reviews have an opportunity to share learning about SISP they become more compelled to the process they better understand and they are capable to influence. Possibly, their communication and cooperation improve which reaffirm their commitment.

The scale mean value (2.62 on a 1 to 5 point Likert scale, std. dev. 1.43) shows that Australian organisations do not perform the learning meetings a great deal. Only about 36% of the population positively answered the question on the learning review. This could be probably one of the main reasons for the lack of managerial commitment to SISP. Consequently, if an organisation pays more attention to organisational learning, in particular to the sharing of experience on SISP, more commitment from managerial structure could be expected. Therefore, this study adds further validation to the work of Pai (2006), where the relationship between knowledge sharing and SISP in Taiwan was investigated.

6 CONCLUSION AND FURTHER RESEARCH

This study confirmed that the lack of managerial commitment and involvement are still the main reason for SISP failures. To make SISP deep and far reaching, the planning modules such as a commitment plan should be part of the SISP study. In a time of limited resources, eliminating unnecessary duplication of efforts and delegating clearly defined and most suitable roles to SISP stakeholder’s will lead to more successful SISP. While top management commitment to SISP is necessary in all SISP phases, obtaining their support in the implementation phase is more important than at the start of SISP. Practitioners may find it of interest that SISP success can be as much as doubled if it is initiated by CIOs rather than CEOs. In that case, CIOs would most likely have a champion role, they would more actively participate in business planning, gain better understanding of business needs and more successfully promote strategic aspects of SISP. The findings also point to lack of SISP learning reviews which are a significant antecedent for managerial commitment to SISP.

Future research may involve multiple respondents from the same organization to ascertain top management’s perception of SISP. This study used general description of SISP variables. Perhaps, the use of more specific scales could reveal different results. If future research is associated with specific types of organisations, their results could be extended into fine granularity and greater comprehensiveness. SISP is one of the processes within the overall IT governance and understanding influence and causality of other factors on managerial commitment to SISP would lessen the barriers to SISP success.

Abstract

Information Systems (IS) have come to play a larger role in how organizations function, including consideration in strategic planning. Responding to competitive change or enacting a new strategy often requires modifying or enhancing an organization’s IS. In this paper, the authors develop a process model of evolutionary change to address the role that IS plays in organizational strategy. The model is based in part on Miles’ strategic typology of Defenders, Prospectors and Analyzers. The model examines how strategic approaches influence attention to environmental change, investments in IS capabilities, and evolution of information systems.

The behavior observed in the simulations corresponds with the theoretical hypothesis developed from the model. The conservative defender organization experienced few discontinuous changes in the simulated 20 years. The innovative prospector organization exhibited extensive change, while the balanced approach of the analyzer organization fell between the two extremes. This study has taken steps to create simulations that approximate the behaviors predicted by a theoretical process model. The success of the simulation modeling in this study builds a foundation for future research.

Keywords: Strategy, IS Strategy, Organizational Change, Simulation.
1. INTRODUCTION

Responding to changes in the competitive environment, be it to take advantage of new opportunities or to respond to competitive threats, remains an important concern for organizations and the management of their information systems (IS). Such environmental changes may necessitate modifications or enhancements to an organization’s IS in order to facilitate changes to products, services and the work processes that support them. Possessing or lacking the IS capacity and capabilities to undertake such changes may hold important implications for an organization’s performance.

The occurrences of change in the environment are not completely independent events. To an organization, change events may will hold greater or lesser relevance depending on the importance that the events and adaptability hold for an organization’s strategy. Understanding the implications of different strategies, the occurrence of environmental change and how those events effect the evolution of systems can provide important contributions to theory and practice. Yet, little research has explored the connections and interrelations of organizational strategy, environmental volatility and the evolution of IS.

This research explores these relationships by examining how opportunities and demands for change in organizations affect the evolution of information systems. Our approach is to model patterns of environmental change and the evolution of IS capabilities in organizations by conducting controlled experiments with a computer simulation, an approach identified as one that can aid in the study of IS strategy (Sabherwal et al. 2001). We believe this theoretical model and simulation establishes a foundation for continued research in this area.

2. THEORETICAL FOUNDATIONS AND RESEARCH MODEL

A fundamental concern in strategic management is the relationship an organization has with its environment. In approaching the evolution of an organization and the interaction between strategy, environment and information systems, we subscribe to the strategic choice perspective as outlined by Miles, et al (1978). As stated, “organizational behavior is only partially preordained by environmental conditions”. Management determines target customers and markets, in conjunction with investments in technical and administrative functions (Miles, et al. 1978).

Management also makes choices about investments in resources. From a resource-based view, Grant conceptualizes strategy as “the match an organization makes between its internal sources and skills…and the opportunities and risks created by its external environment” (Grant 1991, p. 114). Investments in capabilities play a role in how organizations perceive their ability to respond to opportunities and demands. As a result, there is an interrelationship between the occurrence of environmental change, and the evolving design of products and services and the perceived need to undertake incremental or discontinuous changes in an IS.

2.1 Strategic Choice and Adaptation

Undertaking an evolutionary perspective, we are interested in what Miles, et al called the “adaptive cycle”. In this cycle, organizations seek to solve several interrelated problems; entrepreneurial, engineering and administrative. entrepreneurial activity is realized through the enactment of an organization’s market position and product and service designs (Venkatraman 1994). The engineering problem is realized in their enactment of technology, such as information systems. The administrative problem has two conflicting issues; how to create structures and processes that enable the current strategy, while also enabling future innovation. We approach the administrative choices as realized investments in the ability to deliver both current and future capabilities.

The challenge for organizations is in “not allowing the systems to become so ingrained that future
innovation activities are jeopardized” (Miles, et al. 1978). We view IS as a key strategic resource for organizations trying to enact changes in product, service and market approach. However, the structures and processes of an IS designed to serve today’s environment can enable, but sometimes constrain future capacity and capabilities for future innovation. Miles et al. asked how do organization’s move through this adaptive cycle? We ask how do information systems evolve as these adaptive cycles unfold?

Miles et al. (1978) proposed a typology of three strategic types that characterize organizational approaches to dealing with environmental change, uncertainty and adaptation—defender, prospector, and analyzer. Defenders are concerned with maintaining stability and efficiency in the design of their products and services, systems, processes and technologies that support them. On the other end of the continuum is the prospector strategy, in which flexibility and change are the driving forces. Prospectors explore new markets, product and services continually, much the same as the innovating firms explored in the work of Nelson and Winter (1982). This typology was applied to IS strategy by Sabherwal and Chan (2001), as well as others who have built on their research.

Lying between these two are analyzers, who try to undertake the difficult balance of maintaining flexibility while being efficient. Analyzers behave in similar ways as imitating firms conceptualized in the work of Nelson and Winter (1982). Analyzers wish to reap the benefits of both Defenders and Prospectors by remaining adaptable and controlling costs. A fourth possibility is the Reactor. The reactor is characterized by Miles et al. as a non-strategy and will therefore not be included in this study (see also, Sabherwal and Chan 2001).

These three approaches to strategy influence how organizations respond to environmental change. For this paper, we define environmental change events by their frequency, amplitude and instability, as defined by Wholey and Brittain (1989). We draw on work by Child (1972) and Hannan and Freeman (1977) to develop these constructs. Frequency is of course the number of environmental changes identified over a set period of time. Amplitude is the magnitude or size of changes experienced by organizations. Instability is the randomness resulting from uncertainty and inability to predict future environmental events.

2.2 Information Systems and Strategic Adaptation

Advances in information technology increasingly offer organizations the opportunity to adopt or create new innovative products, work processes and market strategies (Sambamurthy and Zmud 2000). An evolving information system allows organizations to extend their processing capacity and the capabilities to support business processes. By extending and enhancing their existing information system, organizations can expand the system’s range and reach (Keen 1991), while also developing new capabilities (Copeland and McKenney 1988).

Effectively leveraging information technologies can enable organizations to sense and respond to opportunities and demands in their competitive environments (Sambamurthy, et al. 2003). These IS capabilities are formulated in both technologies and human resources and provide the ability to employ resources in ways that enable delivery of new products and services (Bharadwaj 2000).

This approach to strategy is supported by the resource-based view of the firm (Penrose 1959, Grant 1991, and Bharadwaj 2000). Bharadwaj (2000) discusses the role of IT infrastructure and IT human resources. In this paper, capacity is defined as the resources, technology and man-power that allow organizations to cope with change. Bharadwaj (2000) also discusses the intangible IT resources that a firm holds, which are collectively grouped as capabilities in this study. These assets can include processes, routines, and regular and predictable behavior patterns of a firm (Nelson and Winter 1982). These assets are improved over time through organizational learning and experience (Cohen and Levinthal 1990).

At the heart of Miles’ et al. work is the importance of innovation. Innovations are viewed in this study as realized changes to the design of products or services that take advantage of opportunities or respond to
competitive demands in the organization’s environment. IS can enhance an organization’s ability to respond to these demands, adapting its product and service offerings by, for example, altering their product scope and market reach.

The scope of the organization’s product is defined for this study as the number of components in the product. If the components are closely interrelated, then any change in the design of one component will require corresponding design changes to others. This association increases the rate of change in a system, as adoption of one innovation creates ripple effects throughout the overall IS design. Reach is the number of markets in which a firm competes. Reach is determined, for example, by geographic or channel expansion. Extending reach, an organization encounters a greater number and variation in competitors, regulations, and customer needs.

The dynamics of the adaptive cycle and turbulence in the environment increases with the growth of scope and reach. So relevant changes are expected to occur more frequently, especially those having a greater amplitude and instability when moving along the continuum from defender to prospector. As the number of changes increases, it raises the demands placed on an organization’s IS department. Thus, the organization’s choices when solving “engineering” and “administrative” problems hold implications for its ability to adapt an IS in a way that enables it to realize its chosen strategy.

2.3 Operationalizing Change in Information Systems

In the management of IS, maintaining or developing flexibility relies on the development of certain technical and organizational capabilities. Capacity is supported in information system design through the concept of scalability, which allows for growth in the number of users and the volume of data processed, but also to expand the type and volume of data collected and stored. For human resources, capacity is concerned with the presence of slack resources, which facilitate the ability to undertake change and provides adequate time for planning, monitoring and learning from experience. Adequate levels of staffing in the organization influence the ability to support the adoption of innovations.

Important to the development of capabilities is organizational learning. Learning is realized and accumulated over time and influences the organization’s tendencies toward remaining innovative and maintaining its ability to implement change (Copeland and McKeeney 1988). Capabilities for change are enhanced as the organization experiences events, especially those offering greater development of experiences and knowledge (Cohen and Leventhal 1990).

Alternatively, inertia constrains an organization’s capacity and capabilities for change. Inertia builds through a series of design decisions (Gersick 1991), escalating commitment to decisions over time (Huff and Huff 2000), and exploiting current knowledge and capabilities (March 1990). Depending on various factors regarding an information system, such as its age (Swanson 1994) and design (Broadbent, et al., 1999), technology may enable or constrain the implementation of change in information systems.

The inability of an organization to respond to desirable opportunities or competitive threats in the environment due to inertial constraints will increase stress in the organization. Stress is realized in the desire for new approaches to resolving existing problems (Huff and Huff 1991). This often translates into a radical break from existing structures and practices (Tushman and Romanelli 1985).

Inertia and stress are not mirror images of the same concept, but complimentary (Huff and Huff 1991). As inertia rises in a system, stress also rises, but the rate at which stress increases is also dictated by the demands placed on the capacity and capabilities of IT to implement change. If stress exceeds the organization’s threshold of acceptability, then the organization will begin to look beyond existing solutions and begin searching for alternatives (Tushman and Romanelli 1985). Until the tolerance for stress is surpassed, then the cumulative effects of inertia will continue to constrain the organization’s ability to implement change, potentially stifling innovation (Huff and Huff 2000).
Outcomes that result from the tension between inertia and stress are patterns of incremental and radical change that punctuate long periods of equilibrium with short periods of radical change (Huff and Huff 2000). Such patterns are consistent across theories of scientific advancement, organizational change and information systems (Kuhn 1996, Tushman and Romanelli 1985, Gersick 1991, Orlikowski 1993). Changes in this study are classified as small adaptations that amount to the continuation of the status quo; enhancements to the system that extend its reach and range and discontinuities that reengineer or replace significant parts of the system.

2.4 An Evolutionary Process Theory of IT Innovation

Simulations were constructed based on the research model proposed below in Figure 1. The model includes relationships found in the literature review above. The behavior of the model also simulates the findings of historical case studies conducted in the U.S. property and casualty insurance industry (Gallagher 2008, Gallagher and Worrell 2008, Gallagher 2002). The studies documented the occurrence of discontinuous changes in these organizations over a thirty years period. The organization’s strategy and attention to changes in the competitive environment resulted in varying occurrences of discontinuous change events, i.e. the reengineering or replacement of IS.

The model is based on the theoretical relationships among organizational strategies (defender, analyzer, prospector), their implications for managing the competitive environment (product scope, market reach), and occurrence and characteristics of change events (frequency, amplitude, instability). The ability to implement change is dependent on an organization’s IS capacity and capabilities. When the ability to respond to change is constrained by increasing levels of inertia, the organization’s stress will rise. Ultimately, the inability to respond to the environment leads to occurrences of discontinuous change.

In the research model, changes in the environment are encountered as opportunities and demands for change that ultimately result in the evolution of the system. The outcomes of these events are either a continuation of the status quo (no change adopted) or the enactment of change events. The events are adopted as either incremental or discontinuous changes, based on the events and the current state of the organization.
system. The incremental or discontinuous nature of the change affects the evolutionary patterns of change in a system.

The organization’s strategy (using Miles, et al. 1978 Defender, Analyzer, or Prospector) acts as the directional forces in the model that influence the trajectory of events. Of specific importance are the strategy’s influence on scope and reach of the organization’s products and services and the resulting demands for change in an IS.

3. GENERAL SIMULATION MODEL

The simulation experiments conducted in this study were discrete and event-based. Four simulation experiments were conducted. Each simulation model in the experiment ran for 20 years (after an initialization period of two years). Arena simulation software was used to create the models. Since the models presented here are intended as a baseline for future studies, other simulation approaches maybe consider as model complexity increases.

As the simulated organizations encounter opportunities and demands for change in the competitive environment, characterized by their frequency, amplitude, and instability, the model describes how these variables influence the evolution of an IS and ultimately an organizations ability to implement change. The ability to change is enabled by having both sufficient capacity and capabilities. Over time, as existing processes are stabilized through status quo changes (i.e., changes within the capacity and capabilities of the organization) and adopted incremental changes (i.e., changes within either the capacity or capabilities of the organization, but not both). Thus, each event has the ability to increase the level of inertia in an IS due to the passage of time, increased size and complexity. The challenge is to then alleviate the stress that builds as the ability respond to environmental changes decreases. For example, lacking adequate capacity for adopting an incremental change, a major enhancement to the system may be necessary, requiring a discontinuous change.

The first variable associated with a change is frequency, which represents the stability or turbulence of the competitive, regulatory and/or technical environment in which the organization competes. Frequency is influenced by strategy and determines the number of changes that ultimately enter the simulation. As changes enter the simulation, they are assigned, amplitude and instability values. Based on these values, a change will be considered as a potential enhancement for the IS. If a change enters the system, it is then evaluated, based on the amplitude, which represents the time, effort and talent required to implement a change into the existing systems. Amplitude is compared with organizational capability to handle the change. The other variable that is considered is the instability of a change, representing the difference from the existing information system’s technology, the capabilities of the IT personnel and the design of the products and services it supports. The consideration of these variables is to determine if there is enough capacity and capability to handle the change. For each simulation, inertia acts as a multiplier of amplitude and instability when comparing these values with capability and capacity, respectively. When the current capacity and the capability are sufficient, the change is made and inertia increases based on a portion of the amplitude associated with the change. In this situation, only half of the amplitude is added to the current level of inertia for status quo changes.

When technical capacity are inadequate at the time a change is encountered, but there is enough knowledge capability to handle the change, an incremental change occurs increasing inertia at the full amplitude associated with that change. The logic behind this process is indicative of a situation where excess capacity is not available, yet the acquisition of additional resources can supplement the adoption of the intended change. Capacity and capability are both fixed at 0.75 for the purpose of our simulations. Future studies will examine varying capacity and capabilities. The function for the increase of inertia with regard to capacity and capability is shown in Equation 1.
The implementation of status quo and incremental changes will increase the levels of inertia in a system as enhancements to the design increases the size and complexity of the system. The inability to respond to changes as a result of constraints on knowledge capabilities or a combination of inadequate capacity and capabilities creates stress in the organization. Stress is realized in the desire for new and innovative approaches to the resolution of problems and cumulatively contributes to the organization’s consideration of radical change. In this case, radical changes translate into the redesign or replacement of some or all of the existing system. Once a new system is implemented and the organization’s capacity for change and the capabilities to adopt future changes are available, stress is reduced. As inertia builds in the simulation due to status quo and incremental changes, stress begins to build with each change that is not within the capabilities of the organization at a rate of half the amplitude associated with a change. If both capacity and capability are inadequate to deal with a change, stress increases by the full amplitude associated with the change. When discontinuities occur the stress variable is reset. Stress increases under these conditions, as shown in Equation 2:

\[
G(S) = \begin{cases} 
\frac{S + A}{2}, & \text{if } I \times A \leq Cp \text{ and } I \times Is \leq Cb \\
S + A, & \text{if } I \times A > Cp \text{ and } I \times Is > Cb \\
0, & \text{otherwise}
\end{cases}
\]

Equation 2: The Growth of Stress

Each simulation experiment builds on this simplified model. Three levels of complexity are added to provide a higher-level organizational realism. Each experiment is outlined below. First, the implementation of strategy in the simulation is discussed. Next scope and reach are added to the strategy models. In the third set, capacity and capability are added to the model. Finally, all variables are combined into an integrated model that includes strategy, scope, reach, capacity, and capability.

3.1 Experiment 1: Strategy and the Environmental Conditions

Strategy determines how the organization sets performance objectives and the demands placed on its systems to adopt changes over time. First, goals may focus on growth, stability or both. As a result, demand for change differs across organizations or within any one organization over time. For instance, growth may expand the geographic reach of the firm, resulting in increased opportunities and demands for innovation as more customers, competitors and regulators must be considered. This places increasing demands on the capacity and capabilities for change in the IS. Stability on the other hand, represents a focus on using IS to increase efficiency, which in turn leads to increased profitability in the short run.

Three simulations were conducted—one for each proactive strategy as outlined in the typology offered by Miles et al. (1978). The Defender approaches environmental conditions with the goal to minimize the impact of frequency so that fewer discontinuous changes occur. The Prospector, on the other hand, encounters change events of larger size having a much higher frequency, amplitude, and instability associated with change than the Defender. The Analyzers try to balance efficiency with opportunity in
evolving the system, falling somewhere between Defenders and Prospectors. In the first simulation, change events occur with a probability of 25% for Defenders, 50% for Analyzers, and 75% for Prospectors.

Within the first set of experiments, the organization’s IS capability and capacity for change are fixed at the same predetermined level for each strategy. Prospectors carry a lower level of inertia, due to the desire for rapid change increasing. Defenders carry the highest levels of inertia because stability is valued in the quest for efficiency. In contrast, Prospectors have a much lower threshold for stress than Defenders due to the perceived need for change. Again, Analyzers fall somewhere in between trying to integrate both the Defenders and Prospectors goals. The threshold for each strategy was set to allow for adequate variation between strategies based on pilot studies. The first experiment tests the following hypothesis:

**H1:** Prospectors will experience a greater number of discontinuities than Analyzers, which in turn will experience a greater number of discontinuities than Defenders.

### 3.2 Experiment 2: Strategy, Scope and Reach

The second set of simulations introduces the effect of scope and reach associated with changes in product and service designs. Reach defines the size of the geographic market, while scope deals with the range of customers served in a market. Scope and reach will increase the frequency, magnitude and instability of the demands for change. Specifically, scope of the product will increase the frequency and magnitude of these events as it extends the number of potential customers within a population by expanding the range of possible contingencies necessary to compete across customer segments. Conversely, reach increases the frequency and instability of changes entering the system. For example, if a new set of features are added to an existing set of product dimensions, it increases the complexity of the overall design. Within the simulation, the set of environmental conditions (frequency, amplitude, and instability) increase over time as scope and reach is increased, resulting in more frequent and varied change events entering the system.

In this experiment, the Defender will focus on stability and efficiency, minimizing the scope of products offered and the reach into different markets, thus having a narrower scope to its products and more limited in changes to market reach. The Prospector on the other end of the continuum will always be scanning for new markets to enter and products to offer, so it will experience greater frequency of change events. The Analyzer balances scope and reach to achieve efficiencies, without passing up profitable opportunities. The effect of scope and reach are hypothesized as follows, based on an organizations strategy:

**H2:** Increases in scope and reach of products will result in more discontinuous enhancements to the system for all strategies when compared to Experiment 1.

### 3.3 Experiment 3: Strategy, Capacity and Capability

Until now capacity and capability have been held constant across strategy. However, it is unrealistic to expect organizations not to invest in capacity or develop greater capabilities as they learn from their experiences in adopting change. Investments and system feedback, therefore, are incorporated in our model. Each strategy is assumed to improve both capacity and capability, but each strategy increases at a rate of change consistent with its intended goal. As incremental changes are adopted (versus status quo changes) capacity increases to accommodate the change. This expanded capacity can then be exploited to meet future demand for change. Defenders focus more heavily on capacity investments to increase the efficiency of the system. Prospectors, in contrast, are less concerned with capacity in favor of increasing capabilities and Analyzers strike a balance between the two ends. A feedback loop for learning occurs to reduce stress as the organization handles status quo change events increasing the organizations confidence as shown in Equation 3:
$H(S) = \begin{cases} 
S - \frac{A - IS}{4}, & \text{if } I \times A \leq CP \text{ and } I \times IS \leq CB \text{ and } S - \frac{A - IS}{4} \geq 0 \\
0, & \text{otherwise}
\end{cases}$

Equation 3: The Decrease of Stress from Increased Knowledge Capabilities

Learning stabilizes each strategy by increasing capacity and capabilities levels to a point where Prospectors increasingly perform as Defenders in our earlier simulation experiment, experiencing a lower number of discontinuities due to decreased levels of cumulative stress. The effect of organizational learning is hypothesized as follows, based on an the organization’s strategy:

**H3:** Increases in capacities and capabilities of products will result in fewer discontinuous enhancements to the system for all strategies when compared to Experiment 1.

### 3.4 Experiment 4: An Integrated Simulation Model

Finally, a set of models were tested that incorporates each of the variables discussed above. Strategy provides the foundation for the behavior of scope and reach, as well as investments in capacities and capabilities. The expected result is a balanced model where the increase in discontinuities resulting from scope and reach will be offset to a degree as investments are made to capacity and capability. The result is a decreasing number of discontinuities. The expected behavior is predicted by the following hypotheses:

**H4:** Increases in capacity and capability from learning offsets the increases in product scope and reach, causing the number of discontinuities to be equal to or less than those seen in Experiment 1.

### 4. Simulation Results

Figure 2 provides an example of how the three strategies behaved in Experiment 1 accumulating inertia (black line), and stress (gray line), over a ten year period, or half of the simulated time. With each discontinuous change inertia and stress are reset. The level of inertia, as seen in the Figure, is higher for the Defender and lowest for the Prospector. For the Defender, stress builds slowly and the organization operates under stress for longer periods of time before reaching the threshold for change.
Table 1 contains the number of status quo, incremental, and discontinuities experienced for each strategy in the four experiments.

In comparing the three strategies, Defender has the fewest discontinuities and the highest level of inertia (see Figure 2). The Prospector has a much higher number of discontinuities (80) than the Defender or Analyzer and the lowest level of inertia. The findings support Hypothesis 1.

For Experiment 2, the addition of scope and reach to the first set of experimental models indicates an increase in discontinuities for all three strategies indicating support for Hypothesis 2. For example, the Defender experienced three discontinuities versus the two seen in Experiment 1.

The effect of learning exhibits a decrease in number of discontinuities over time for each strategy. Thus, Hypothesis 3 holds true for the third experiment. There is also a related trend of increasing inertia, due to higher levels of capabilities to handle change (Figure 1).

The final simulation experiment examines the full model behavior. Each model had fewer discontinuities as predicted by Hypothesis 4. Inertia in each run is higher than previous models, indicating that a slight interaction effect between scope and reach variables and the capacity and capability variables may exist.

Table 1: Change by Strategy for Each Experiment

5. DISCUSSION

The behavior observed in the simulations corresponds with the behavior observed in the historical case studies referenced above. The Defender in the final model had one discontinuous change in 20 years, which is closely approximated by the Defender strategy in our simulations. The Prospectors and Analyzers in this simulation study also mirrored the behavior of the organizations observed in that study.

The simulations themselves behaved as intended. The first set of models set the baseline by which to compare the other models. The addition of scope and reach creates more discontinuities due to the increase of magnitude and instability associated with the changes, thus all strategies behave more as Prospectors as time increases due to the increase in discontinuities. The addition of organizational learning as a stress reducer creates a set of models where strategies behave more and more like Defenders over time with fewer discontinuities. Finally, the last set of models exhibits the expected cancellation of increasing inertia and stress from the effect of scope and reach due to the ability of an organization to handle more inertia through learning. For Experiment 4, the simulation behavior is dictated primarily by strategy in the same manner as the first experiment. The findings for this set of experiments has illustrated
that the behaviors predicted by the research model can be simulated. The findings provide the foundation for this ongoing research project. The findings contribute to the MIS field by providing a set of simulations that model IS strategy, an area of research that is of continuing interest to the field (Sabherwal, et al. 2001).

6. LIMITATIONS AND CONCLUSION

The experiments conducted in this research were designed to model and operationalize the process model proposed above. The study examined the role of strategy in the adoption of changes to IS within the organization in response to changes in product scope and reach in addition to increases in capacity and capability. The simulations successfully illustrated the behavior predicted by the model.

There are associated limitations with the study. The first limitation is in using simulations to approximate organizational behavior. While the simulations are complex, they do not account for all possible variables seen in the adoption of IS change. Yet, limiting the number of variables in the model is necessary to make the simulation models parsimonious and testable. Secondly, sensitivity analysis is not included here. Sensitivity analysis is necessary to determine the robustness of the models with regard to extreme cases of behavior. Archival industry data can be used to set parameters and compare behavior across an industry as a step toward validating the process model. Once behavior is consistent within one industry, the model can be tested and the predictive behavior can be assessed. Finally, testing the scope of the model across industries will be an important step in examining the explanatory value of the process model.

This study has taken steps to create simulations that approximate the behaviors predicted by a process model. The next step is to integrate this research with historical data to further test the validity of the model. The final result will provide insight into how strategy, knowledge capabilities, and IT capacities can improve organizational performance. The success of this study will allow the research to proceed to the next step, the calculation of model parameters from a subset of the historical data collected via case studies. Simulation performance can then be compared with the remaining case data to validate the model. Once validated, the simulations will provide a useful tool to model changes in strategy and provide insight into when organizations should adopt a particular strategy.

EMPIRICAL COMPARISON OF METHODS FOR INFORMATION SYSTEMS DEVELOPMENT ACCORDING TO SOA

Offermann, Philipp, Deutsche Telekom Laboratories, Ernst-Reuter-Platz 7, 10587 Berlin, Germany, philipp.offermann@telekom.de

Bub, Udo, Deutsche Telekom Laboratories, Ernst-Reuter-Platz 7, 10587 Berlin, Germany, udo.bub@telekom.de

Abstract

While service-oriented architecture (SOA) as an architectural principle for information systems is gaining momentum in research and industry, the field of methods for designing information systems according to SOA is still poorly developed. However, the implementation of SOA design principles, e.g. service reusability, business alignment and autonomy, demands a methodical approach. In order to overcome the shortcomings of current methods, we have developed the SOA method (SOAM). The method is based on existing methods for SOA. Activities are specified along with roles, techniques, modelling notations and a meta-model. A tool supports all necessary modelling notations as well as the generation of XSD, WSDL and WS-BPEL from the models. The newly developed method has been compared to other methods using a laboratory experiment with students. Different methods have been used on different company scenarios; the results have been recorded using a questionnaire. Results show that according to the evaluated criteria, SOAM together with IBM’s method gets the best scores. With respect to the alignment of the software architecture with business processes, one of the primary goals of SOA, SOAM received a better rating than IBM’s method.

Keywords: Method construction, service-oriented architecture, SOA, design science, software engineering
1 INTRODUCTION

The service-oriented architecture (SOA) provides concepts for designing and implementing information systems. Its widespread adoption has been made possible by generally accepted technical standards such as WSDL (Web Service Description Language), SOAP (formerly Simple Object Access Protocol, now proper name), UDDI (Universal Description, Discovery and Integration) and WS-BPEL (Business Process Execution Language). While technical standards have reached an acceptable level and agreement on SOA design principles is growing, discussions on how the software architecture according to SOA is to be defined and how the architecture can be designed continue. When planning to introduce an SOA, a methodical approach is of great importance if business-aligned, reusable services are to be designed and implemented.

We have developed the SOA method (SOAM) based on existing methods for SOA. The method should overcome weaknesses in existing methods; its applicability should be proven in practice. The method that we developed specifies activities, necessary roles and modelling notations and is supported by a tool. We have evaluated the method in different companies using action research. It was possible to show that the method is highly usable and facilitates the design of an SOA system that adheres to the SOA design principles. In this article, the results of a laboratory experiment comparing SOAM to existing methods are presented.

First, service-oriented architecture is introduced. This is the foundation on which methods for SOA are based. Then the weaknesses of existing methods are presented. Our SOA method is explained in detail in this article. Finally, the results of the laboratory experiment are described.

2 SERVICE-ORIENTED ARCHITECTURE

Service-oriented architecture (SOA) combines elements of software architecture and enterprise architecture. It is based on the interaction with autonomous and interoperable services that offer reusable business functionality via standardised interfaces. Services can exist on all layers of an application system (business process, presentation, business logic, data management). They may be composed of services from lower layers, wrap parts of legacy application systems or be implemented from scratch.

The underlying principle for SOA is the service. A service is a software component that can be accessed using commonly known communication technologies. In most cases, Web service technologies are used to implement SOA software. Service types can be deduced from application systems layers:

- Business process service: a service that orchestrates other services according to a business process. Implemented e.g. by using WS-BPEL.
- Presentation service: a service that provides a user interface to perform a user interaction. Data processing is not done automatically, but by the user.
- Business logic service: business logic like calculations, data verifications, transformations etc. that make business sense. Business process activities on the finest level of granularity are usually supported by this type of service.
- Data management service: data management for business entities (data object types). Usually, operations like create, read, update and delete (CRUD) are offered.

The aim of SOA is to create reusable, flexible and business-aligned IT systems. Especially the alignment of software systems with business processes is a step that has not been achieved yet. In order to facilitate the alignment, methods have to take into account business requirements for the design of technical artefacts (Erl 2007). Legner and Heutschi (2007) have summarised nine
publications on design principles. They identified four classes of design principles: interface orientation, interoperability, autonomy/modularity and business suitability.

3 EXISTING METHODS

Methods (sometimes also called methodologies) describe a way to transform an initial state into a target state. (Cronholm and Ågerfalk 1999; Wynekoop and Russo 1997) Activities explain what has to be done. They may be structured hierarchically, e.g. in phases, activities, tasks and steps. The sequential order of the activities is the process model. For each activity, executing roles should be specified. Activities produce results, but may also use existing results as inputs. Results may be linked, e.g. lanes in a process model to organisation units on an organisational chart. Techniques support the generation of results and, therefore, are used by activities that need to create such results. Finally, a meta-model for the results can be specified for clarity and consistency.

The construction of SOAM is based on several published methods. All of these methods have some major or minor weaknesses. SOAM is designed to overcome these.

• Erl published a very comprehensive book on SOA (Erl 2005, pp. 366-370). Within the book, a method for SOA system development is described. The method combines a top-down with a bottom-up-approach and positions an agile procedure as a compromise. On a coarse level, the method contains the steps “service-oriented analysis”, “service-oriented design”, “service development”, “service testing”, “service deployment” and “service administration”. Unfortunately, Erl’s method does not sufficiently take into account legacy systems. Legacy systems are only used as a source for requirements, not as elements for system integration. Additionally, roles are not specified consistently.

• The method of Papazoglou and van den Heuvel (Papazoglou and Heuvel 2006) encompasses the phases from planning to execution, but only analysis and design are specified in detail. During planning, it is decided if a Greenfield-approach is taken or if analysis should proceed top-down, bottom-up or out-of-the-middle. Interestingly, processes are not used for analysis but are rather treated like services. The main problem of the method is the confusing documentation and missing proves for its practical relevance. There is no integrated example; the application of the method seems difficult. No application in practice has been published yet.

• The method of OASIS (OASIS 2005) has a somewhat different focus compared to the other methods. It only defines the specification of Web services. Analysis of business processes and legacy systems and the identification of services is not part of the method. Therefore, business processes are not represented in IT systems and legacy systems are not integrated.

• The method published by IBM (Arsanjani 2004; Endrei, Ang, Arsanjani, Chua, Comte, Krogdahl, Luo and Newling 2004) is very well specified. It consists of the phases “domain decomposition”, “goal-service model creation”, “subsystem analysis”, “service allocation”, “component analysis”, “structure components and services using patterns” and “technology realization mapping”. As can already be seen from the phases, services are identified from domains and goal and not from business processes. Business processes only play a subordinate role. We are conducting a laboratory experiment to determine which approach gives better results.

• The method of Jones und Morris (Jones and Morris 2005) is very pragmatic. It explicitly starts with a domain analysis and identifies services based on a domain decomposition. Unfortunately, the method ends after the identification of services. Further analysis and modelling is not provided. Therefore, the process of designing SOA software is not completely specified.

• Erradi et al. define a framework for SOA development (Erradi, Anand and Kulkarni 2006). The framework consists of the phases “information elicitation”, “service identification”, “service definition”, “service realization” and “roadmap and blanning”. Unfortunately, the process description is rather confusing. Roles and modelling notations are not specified. A case study is only described very briefly, many aspects remain unclear.
• Marks and Bell describe services identification, analysis and design (Marks and Bell 2006). However, no process model is defined. The description is narrative, mixing different aspects of a method. As the description is not systematic and is lacking a consistent chronological order, it is difficult to evaluate and compare the method.

4 THE SOA-METHOD

We developed the SOA method (SOAM) based on the existing methods and their shortcomings. It has a high integrity and consistency regarding the constituent elements and supports the architecture realms “workflow management”, “application architecture” and “enterprise application integration”. It is vendor-independent and explicitly states the architecture goals, which is not the case with any other method. The six phases of SOAM contain all necessary activities, various activities containing several steps. Every activity is specified with executing roles, input and output artefacts and supporting tools. All necessary modelling notations are supported by a tool. The SOAM tool can generate XML schemata (XSD), WSDL files and WS-BPEL process descriptions directly from the graphical models. Action research on the method has been published in (Offermann 2008).

![Figure 1. Phases of SOAM](image)

The sequence of phases can be seen in figure 1. The method uses the top-down approach and the bottom-up approach in parallel. The company requirements are analysed following the top-down approach. Required service operations are discovered based on this. Following the bottom-up approach, legacy systems are identified and analysed regarding data and/or functionality that can be wrapped. Top-down requirements and bottom-up findings are then consolidated. Finally, services are designed and service properties ensured. Processes are prepared for execution. In the remainder of the section the method is explained along these phases.

4.1 Company Analysis

Company analysis focuses on business strategies, business processes and functional domains to identify company requirements. The guideline is that business processes have to be supported by services, but reusability can only be ensured by functional specialisation. All activities in this phase are performed by a business analyst.

In a first, optional step, a business motivation model is created according to the OMG specification (OMG 2006a). Based on the company strategies, business processes required to support the company’s strategies can be identified. Next, business processes or parts of business processes that should be supported by an SOA system have to be identified. Among the criteria for deciding which processes to choose are the frequency of process changes, the current level of integration of legacy systems along the process and the degree to which the process can be predetermined and is based on division of labour (Heutschi 2007).
The processes are modelled down to a level of granularity where each process activity is a single step from the business perspective. A good indicator for this is a clear, non-divisible transformation on a data object. Each task is classified according to whether it can be executed automatically (class “business service”), whether it requires an interaction between a user and the software system (class “user interaction”) or whether the activity is purely manual (class “manual”). The modelling notation supported by the SOAM tool is the Business Process Modeling Notation (BPMN) (OMG 2006b). The data flow should be annotated as far as possible in the process models. Each data object (e.g. “customer”, “order”) is created in a data model (see below). If a domain data model exists in a company, it should be used for annotating the process data flow. Figure 2 shows a business process on the finest granularity level modelled in BPMN.

Parallel to business process modelling, a layered model of functional domains (FD) is created. The top levels of the model can be guided by a functionally organised organisational chart. On lower levels, data objects used in an FD can be used as a guideline to identify refined functional domains. The modelling notation used for the FD model is based on UML Use Case diagrams. Each activity in business process models is linked to a functional domain. If there are more than seven activities assigned to an FD, the FD has to be refined and the activities reassigned. Business process and FD
modelling are iterative. The link between activities and functional domains is later used to ensure the reusability of services. Figure 3 shows a model of functional domains.

4.2 Service Operation Discovery

After having analysed business processes and functional domains, service operations that support the process activities can be discovered. This is done by FD. The activities in this phase are performed by a software architect. For each FD, all activities assigned are analysed per class. For service tasks, service operations that support the activities are modelled in a service model. For user tasks, the user interface (UI) is specified. If two tasks are similar, a service operation that supports both activities can be defined. Each individual service operation and UI is assigned to a functional domain, usually to the same unit as the activity the operation supports. As there is no standardised modelling notation for services, we have developed a notation of our own (see figure 6).

Until now, the service operations and UI discovered only support business process activities. This facilitates process flexibility. Reusable services could also exist on a more technical level. Therefore, service operations and UI use cases are modelled. These are use cases as seen from an operation or UI point of view (e.g. “get clients” and “store order” for an order creation dialog). The use cases are again assigned to FD and classified (e.g. “business logic”, “data management”). The UML Use Case Diagram is used as a modelling notation. The use cases are then ordered by FD and class. If there are similar or equal use cases, a service operation can be defined to support them. When implementing the original service or UI, the service operations derived by the use cases can be called.

4.3 Legacy Systems Analysis

Usually, legacy systems have to be integrated in the SOA software systems. Therefore, in parallel to the company analysis, legacy systems that are used to support the processes are analysed. First, an IT analyst has to identify the relevant systems. Then, these systems are analysed with regard to functionality and/or data that can be accessed by a wrapping service. Possibilities are existing APIs, accessible databases, software components that can be wrapped or even command line invocation. A
modelling notation for legacy systems has been developed to support this activity. Figure 4 shows a legacy systems model.

Every possibility found is then modelled as a service with service operations. Operations are assigned to an FD. Also, used data objects are modelled in the data model. Each object in the data model is assigned to an FD. In the SOAM tool, the UML profile for Core Components (UN/CEFACT 2006a; UN/CEFACT 2006b) is used as a modelling notation.

4.4 Consolidation

After analysing top-down requirements and identifying existing systems bottom-up, consolidation is necessary. It is performed by the software architect and done for data object types and for service operations. For data objects, redundancies have to be identified and merged (e.g. address with country vs. address without country). This can be done by FD, if functional domains have been annotated to data object types. When merging, data object types from legacy systems have precedence because the systems already exist. Only if the discrepancy with top-down requirements is too big can a change in a legacy system be considered. In case two object types cannot be merged, a mediator has to be created. Figure 5 shows the model of data objects types.

![Data object types from Vattenfall Europe](image)

Service operation consolidation is also done by FD and guided by class. Operations that are similar (e.g. “get customer data” and “get customer address”) are merged. Thereby, reusability is assured. Again, operations from legacy systems have precedence. A change in a legacy system can be considered if the discrepancy between requirements and the existing system is too big. When the operations are consolidated, data input and data output are added for each operation based on the consolidated data model.

4.5 Service Design

Once a uniform model of service operations has been established, services can be designed. Usually, a service consists of several operations. Therefore, service operations have to be grouped by service. The software architect uses rules specific to each service class. Operations of class “business logic” are grouped by business logic. Each operation of class “user interaction” is usually represented by a
single service. Data management operations are grouped by business entity. Again, only operations from the same FD are considered for grouping. Therefore, there will only be very few services per FD.

Once services are designed, the design principles that could not be guaranteed during earlier steps have to be enforced. For each service, the software architect has to consider if it is stateless, if rollback operations exist to implement transactional behaviour and if services are loosely coupled. To manipulate the service, the software architect can use operations such as “unification”, “intersection”, “decomposition”, “subset” and “subtraction” (Marks et al. 2006, pp. 111-117). If services become too big during this process, they have to be split up and rerun through the steps above. Figure 6 shows a simple service model. Finally, services are implemented and tested. For these steps, known software engineering methods can be used.

![Figure 6. Services as modelled in the SOAM tool](image)

4.6 Process Preparation

After the services have been defined, the processes have to be prepared for execution by the developers. Service operations have to be assigned to each activity that is supported by a service. Exception handling that has not been modelled before has to be included in the process models. The data flow has to be verified to ensure executability. If necessary, data mediators have to be built. Finally, the tool translates the BPMN models into WS-BPEL. The user interfaces that have been designed earlier have to be included in the process specification. Usually, these steps depend heavily on the middleware infrastructure.

5 EMPIRICAL METHOD COMPARISON

A laboratory experiment was carried out to compare the newly developed SOAM with SOMAM, MSA, SDS, WSIM and SODDM. The comparison was done by using the methods on different company scenarios, rating the experiences of the application using a questionnaire and carrying out a
subsequent statistical analysis of the answers. A company scenario consists of models of a company that are relevant for the application of the methods. The models represent e.g. business processes, organisational charts, data object types and legacy systems. By using predefined company scenarios, it was possible to apply different methods under the same conditions and thereby to retrieve comparable results. This is usually not possible in a company setting. Often, companies are not prepared to provides the resources necessary to apply several methods. Also, because of a possible time shift of method application, general conditions (e.g. legacy systems, staff responsible) might change. On the other side, practical relevance of a laboratory experiment might be limited. A practical application of SOAM is presented in (Offermann 2008).

The first part of the questionnaire is based on the theoretical model for validating information systems design methods by Moody (2003; Moody, Sindre, Brasethvik and Sølvberg 2002). Using a questionnaire, “perceived ease of use”, “perceived usefulness” and “intention to use” can be evaluated. Because all methods evaluated were concerned with SOA, for the usefulness, in addition to general questions, the quality of the realisation of SOA design principles and the achievement of goals of enterprise application system design were evaluated. In the second part of the questionnaire, completeness, consistency and applicability of the method’s components (Greiffenberg 2004) were evaluated.

When designing the questionnaire, 5-point Likert scales were used to simplify the analysis. As the survey was conducted in German, English translations are given here. For the first part of the questionnaire, a scale of accordance strongly agree (5), agree (4), undecided (3), disagree (2), strongly disagree (1) was used. For the second part, a scale of intensity extremely (5), a great deal (4), moderately (3), a little bit (2), not at all (1) was used. The German version of the scales used corresponds to the scales used by Bortz and Döring (2002). They are equidistant as far as possible. The numerical value used for the statistical analysis is given in brackets.

The survey was conducted amongst graduate students of computer sciences and industrial engineering in the time from October 2007 till February 2008 who, alone or in pairs, used different methods on a scenario. According to (King and He 2006), results from students of relevant subjects are comparable to results from professionals. Because the documentations were sufficiently well specified, the methods SOAM, SOMAM, MSA, SDS, WSIM and SODDM were used. To reduce falsification due to the properties of a specific scenario, every team used a different scenario. The scenarios used were “order processing of a mail order snowboard store”, “material management and provisioning of an automotive manufacturer”, “conduction of an acquisition event of a consulting company”, “order processing in industry” and “address and bus bar management of a power utility company”. The student were handed all available written documentation for each method. No questions related to methods were answered.

There were 43 usable responses to the questionnaire. The focus of the method comparison was, in accordance with a prior theoretical comparison, on SOAM and SOMAM. These methods were used most often. For analysing the first part of the questionnaire, first of all the validity is checked using factor analysis. The analysis of the questions concerning usability shows that one component can explain 70% of the variance. This is also the only component with an eigenvalue bigger than 1. For the questions concerning usefulness, only 62% of the variance can be explained by one component. By leaving out questions concerning “clearly specified service contracts” and “abstraction from implementation”, the value is increased to 66% so that only one component has an eigenvalue bigger than 1. For the questions concerning the intention of use, one component explains 94% of the variance.

The second part of the questionnaire evaluates the completeness, consistency and applicability of a method components’ specification. The questions relating to “roles” and “techniques and tools” had to be excluded from the analysis as not all methods specify these components and therefore there are only a limited number of answers. By using an inter-item correlation analysis, it can be shown that the answers for completeness, consistency and applicability are highly correlated (see table 1). All
correlations are highly significant and have a value bigger than 0.6. Therefore, the answers to the three parts of the questions are combined. A factor analysis of the combined questions shows that 88% of the variance can be explained by one component. Hence the quality of the method components can be interpreted as one construct.

Finally, the reliability of the constructs is verified by calculating Cronbach’s Alpha for the four constructs “usability”, “usefulness”, “intention to use” and “quality of method components”. The results are summarised in table 2. All values are bigger than 0.8. This means that more then 80% of the variance is systematic and must be attributed to errors in measurement.

Table 3. Summary of results of method comparison (Likert scale 1-5)

By using a t-test against the value 3, the significance of a deviation from a neutral ranking was determined (table 4). Values smaller than 0.05 are counted as being significant. “+” means that the value is significantly bigger than 3. “-” means that the value is significantly smaller than 3. “o” means that no decision can be made. The results for SOAM and SOMAM are significantly bigger than 3. For
SODDM, the results are significantly smaller than 3. The significance of the value for the intention to use of SODDM could not be calculated because the standard deviation was 0.

Table 5. Significances of t-test on mean equality between SOAM and SOMAM

One of the architecture goals of enterprise application systems is the alignment of IT functions to business processes (Heutschi, (Heutschi 2007)). Because of the similarity of the results between SOAM and SOMAM, the answers to “The method ensures a good representation of processes in the software architecture.” were analysed separately. For SOAM, the mean value was 4.09 (agree) with a high significance (0.000) of being more than 3 (t-test on neutral value). For SOMAM, the mean value was 3.40 with a significance of 0.269. Therefore, for SOMAM it can’t be excluded that the real ranking is “undecided”. This is probably due to the fact that SOMAM doesn’t analyse business processes directly. It can be deduced that by using SOAM, business processes are better represented in the resulting SOA-system then by using SOMAM.

6 CONCLUSION

The field of methods for SOA is still poorly developed. In this article, the SOA-method (SOAM) is presented. It aims at overcoming the weaknesses of existing methods. SOAM was developed using action research. To compare SOAM to existing methods, a laboratory experiment was performed. Evaluating the results of the experiment, it can be said that the ranking of all methods is relatively close to neutral. It is important to investigate whether there is a general problem in the way methods are being described. The laboratory experiment nonetheless shows significant differences in quality between the methods. SOAM and SOMAM received the best results. MSA has high usability but comparatively low usefulness. The goal to align IT functions, especially services, to business processes, can be better reached using SOAM rather than SOMAM.

SERVICE-ORIENTED ARCHITECTURES: MODELING THE SELECTION OF SERVICES AND PLATFORMS

Widjaja, Thomas, Technische Universität Darmstadt, Hochschulstraße 1, 64289 Darmstadt, Germany, widjaja@is.tu-darmstadt.de

Buxmann, Peter, Technische Universität Darmstadt, Hochschulstraße 1, 64289 Darmstadt, Germany, buxmann@is.tu-darmstadt.de

Abstract

The Service-Oriented Architecture (SOA) paradigm promises to facilitate the integration of software services provided by different vendors and thus enables users to benefit from Best-of-Breed solutions. In order to support software architects we present the Multilayer Standardization Problem (MSP) to analyze the trade-off between possibly enhanced utility versus higher assembling costs of Best-of-Breed SOA solutions. We implemented a software prototype to support decision makers during the data input and the subsequent analysis of the solution’s robustness. The MSP for the SOA-case is formulated as a linear 0–1 optimization model and extends the established Standardization Problem (SP) by modeling the user preferences and considering varying granularity as well as integration relationships in addition to communication relationships. These characteristics are common to numerous systems – thus the general MSP can serve as a basis for further research in this field.

Keywords: Compatibility, Decision Support Systems, Service-Oriented Architecture (SOA), Standards
1 INTRODUCTION

The basic idea behind the SoA paradigm is the support of business processes by IT systems consisting of services. Those services are clearly encapsulated, and loosely coupled entities, which deliver a defined business functionality. (Erl 2006, p. 290ff; Papazoglou & van den Heuvel 2007, p. 389). Current literature accredits SOA-based software systems various benefits compared to traditional monolithic systems such as enhanced agility, straightforward integration of heterogeneous IT environments, etc. (Krafzig et al. 2006, p. 251 ff). However, in order to leverage those benefits, new or adapted methods and tools are needed to support decision makers.

The technical realization of the SOA paradigm is the focus of various research efforts, see e.g. (Erl 2006; Krafzig et al. 2006). The SoA concept itself is technology-independent; however SoA is mostly seen in direct correlation with the Web-Service technology and associated standards. This technical standardization significantly decreases the costs of integrating software services implemented by different vendors, thus making the realization of Best-of-Breed software systems more feasible. (Erl 2006, p. 63) This paper focuses on the trade-off between possibly enhanced utility versus higher assembling costs of Best-of-Breed SOA solutions, i.e. solutions in which the SOA system is composed of components that are provided by different (and often specialized) vendors.

Software systems based on the SOA paradigm can be structured in two layers: Based on an integration platform (layer 0), loosely coupled services (layer 1) are combined to support business processes (see Figure 1). In this paper the term integration platform is used in a broad sense to refer to all infrastructure components of an SOA-based software system, e.g. enterprise service bus (ESB), service repository, application server, and process server. See (Krafzig et al. 2006) for a more detailed description of the integration platform. This abstract and two layered perspective is a simplification but it is possible to extend the proposed model in order to consider the SOA platform in greater detail (see chapter 5 for further research).

![Figure 1. Two layers of a SOA-based software system.](image)

In the following, we will focus our analysis on the market for Enterprise Resource Planning (ERP) software. In this market, some software vendors offer services and platforms, e.g. IBM (WebSphere), Oracle (Fusion) and SAP (NetWeaver), while others provide only a platform, e.g. Red Hat (JBoss Enterprise SOA Platform), or only services (e.g. a specialized demand forecasting service in the context of inventory management). The discussed decision problem is related to a broad literature stream analyzing the process of selecting (web) services with differing Quality of Service attributes in order to maximize user satisfaction – see e.g. (Zeng et al. 2004) for a middleware platform that addresses related issues; (Canfora et al. 2005) for a composition approach based on genetic algorithms, (Yu et al. 2007) for a related knapsack and optimal path problem; and (Blau et al. 2009) for a mechanism design approach. However, to our knowledge no other optimization model yet considers the selection of integration platforms and services and explicitly analyzes the trade-off between the possibly enhanced utility versus the higher assembling costs of Best-of-Breed SOA solutions. Such a model that investigates the decision problem from the standardization perspective could be useful for several reasons. First, it supports software architects during the selection of the services and platforms. “Intuitive” approaches can result in suboptimal solutions: An example is the selection of the set of services and the platform which provides the highest “net utility”, i.e. the highest difference between utility and necessary implementation costs (i.e. neglecting information and integration cost). Second,
the presented model can support the software architect in communicating decisions (especially in cases in which it is optimal to choose not the service preferred by the users). Third, such a model provides a first step towards a theoretical basis for the analysis of Best-of-Breed solutions in SOA-based software systems. Furthermore, the presented model can be applied to various domains beyond the SOA-case. Thus, general insights regarding the described decision problem may be even more valuable than the actual application of the model in a concrete situation. In this paper we present the Multilayer Standardization Problem (MSP) in order to support software architects determining the optimal set of services (layer 1) and platforms (layer 0). The MSP considers the following three cost categories: costs for services and platforms, costs of integrating services mutually, and costs of integrating services and platforms. We will keep the model as simple as possible in order to focus on the trade-off between possibly enhanced utility of a Best-of-Breed solution versus the higher assembly cost. Note that, the proposed model examines the described decision problem from a standardization perspective and therefore does not consider all factors that can influence the selection of services and platforms – e.g. the vendor choice is partially driven by strategic considerations and various difficult to quantify “soft factors”.

This paper is divided into five sections. Following this introduction, we will describe the MSP based on the Standardization Problem (SP). In the third section, we will present a general schema to apply the MSP to the SOA-case and a software prototype to support decision makers. Section four discusses the limitations of the presented model, and the paper closes with conclusions and possible directions for further research.

2 A MODEL TO SUPPORT THE SELECTION OF SERVICES AND PLATFORMS

In two following subsections the modeled aspects which cause the assembly cost advantage of “single-vendor” solutions are discussed. In the third subsection it is discussed how varying user preferences can result in a trade-off between the possibly enhanced utility of a Best-of-Breed solution versus the higher assembly cost. In the last subsection a possible formulation of the MSP as linear 0–1 optimization problem is presented.

2.1 Common standards facilitate the communication between services

In this section, we examine the service layer of a SOA-based software system in more detail. We focus our analysis in particular on aspects that promote a homogenous service landscape. The basic underlying assumption is that common communication standards implemented by the communication partners facilitate information exchange. There are various examples of situations in which communication standards simplify the exchange of information: a common spoken language during a discussion between two individuals, a common file format for two different word processors which exchange data, a semantic definition of business terms during the exchange of XML files between web services. We assume that all services provided by a certain vendor implement the same communication standard. Thus, the exchange of information between software services provided by the same vendor is facilitated, whereas it is not in the case of cross-vendor communication. Note that throughout this article, the term “communication standard” is used to refer to technical (e.g. data formats) as well as semantic aspects (e.g. meaning of business terms).

The economic analysis of standardization decisions is mainly shaped by the network effect theory. Network effects occur if the utility that a user derives from a good depends on the number of other users of the same kind of good. (Farrell & Saloner 1985; Katz & Shapiro 1985) Communication standards show positive network effects: e.g. the more people who speak a certain language (thus the more possible communication partners exist), the more utility this language provides to the individual “adopters”. In the SOA-case the following example is illustrative: The more information a certain functionality exchanges with (already implemented) services that are provided by a specific vendor, the more beneficial the use of a service provided by this specific vendor for the analyzed functionality is. A broad stream of literature analyzes the implications for users and vendors of network effect goods. Topics on which these works focus include start-up-phenomena (see e.g. (Oren & Smith 1981;
Rohlf's 1974)), path dependencies (see e.g. (Arthur 1989; David 1985; Liebowitz & Margolis 1995)), and "tippy networks" (see e.g. (Arthur 1989; Besen & Farrell 1994; Katz & Shapiro 1994)). Based on these insights, various strategies for users and vendors of network effect goods have been derived, see e.g. (Buxmann 2001) for selected results on the software industry. Most of the models regarding network effect theory are based on an aggregated perspective and thus abstracting from individual relations between the different actors. In contrast the Standardization Problem (SP) (Buxmann et al. 1999) explicitly considers these relationships and thus seems to be a sound foundation for the examination of the service layer. The SP considers the following trade-off: On the one hand, the adoption of communication standards (languages, file formats, or XML formats) facilitates information exchange. On the other hand, the implementation of communication standards often involves costs. The SP answers the resulting question: Which actor should implement which standard to maximize the aggregated savings through standardization with respect to the costs? Various research has been performed related to the SP; see e.g. (Buxmann et al. 1999; Miklitz & Buxmann 2007; Schade & Buxmann 2005; Weitzel et al. 2006; Westarp et al. 2000). One major focus of the research related to the SP is how the degree of autonomy of the different actors affects the structure of the optimal solutions; see e.g. (Buxmann et al. 1999; Weitzel et al. 2006). In the case of the centralized SP a superior instance determines – often based on perfect information – the set of standards each actor should implement. In contrast to that, in the case of the decentralized SP, every actor (or a coalition of actors), decides autonomously whether to implement a certain standard or not. Due to the analysis of the software architects perspective, i.e. a “central” decision maker, we use the centralized SP as a basis for our research. Furthermore several studies regarding efficient solution techniques of the SP have been performed. (Domschke & Wagner 2005; Kimms 2003)

Various aspects of the SP can be directly applied to the problem of selecting services and platforms for a SOA. Parallel to the SP the foundation of the MSP is a graph: Based on the business processes a function graph \( G^{\text{Comp}} := \left( N_{\text{Service}}, E^{\text{com}} \right) \) with \( E^{\text{com}} \subseteq \{(i, j)|i, j \in N_{\text{Service}} \text{ and } i < j\} \) is defined. The vertices of this graph \( i \in N_{\text{Service}} \) represent (IT-) functions that support the business processes. A software architect will typically use the proposed model and the respective Decision Support System (DSS) to analyze coarse-grained services and high-level business processes. Nevertheless, the level of abstraction can vary: A vertex can represent a complex function, e.g. a set of CRM functions or also a elementary function, e.g. a simple credit assessment. Based on the analyzed business process, information exchange between functions \( i \) and \( j \) may be necessary. This is modeled by the edge \((i, j)\) in the function graph. Note that not every function necessarily exchanges information with all other functions, i.e. this graph does not need to be complete. We assume that each function \( i \in N_{\text{Service}} \) can be fulfilled by services \( r \in R_{\text{Service}} \) provided by various vendors. Some vendors provide a wide variety of services (e.g. SAP and Oracle) but other (more specialized) vendors offer only services for selected functionality. Some services fulfill exactly one function (e.g. a service for the credit assessment) while other, more coarse granular services can fulfill several of the demanded functions (e.g. the core banking module of a large ERP system vendor). The parameter \( a'_i \) takes the value 1, if and only if service \( r \) can fulfill function \( i \), otherwise the value is 0. The set \( R_{\text{Service}} := \{r \in R_{\text{Service}}|a'_i = 1\} \) contains all services that can fulfill the function \( i \). The acquisition or implementation of a service \( r \) incurs costs, e.g. additional hardware, software licenses, and training. We model these costs in the parameter \( a'_i \) and refer to these costs as implementation costs. Already existing services, i.e. an installed base, can be modeled by \( a'_i = 0 \) and services that are realized as facades for legacy systems typically incur lower implementation costs than services provided by external vendors. We assume that every function has to be implemented by exactly one service to derive a valid SOA system (see Miklitz & Buxmann 2007) for a similar assumption – they propose an extension of the SP to support decision makers during the selection of IT systems in the context of Mergers & Acquisitions).

A basic assumption of the MSP is that the information exchange between services is realized via communication standards. Each service \( s \in R_{\text{Service}} \) is modeled as a bundle of a communication standard (i.e. the associated semantic and syntactic standards) \( k' \in K \) and a software product that provides certain (business) functionality. Although the SOA paradigm can be realized by several technologies, current discussion focuses on the technology of web services, see e.g. (Alonso et al. 2004; Newcomer & Lomow 2005). Thus, it is often assumed that services based on this technology can be combined
easily. We argue that this perspective is overly simplified, since the standardization to the technology of web services in particular affects the syntactical compatibility of services. However, the composition of SOA-based systems by simply plugging together existing building blocks is often inhibited by semantic differences between the services. Furthermore, various vendors extend the existing web service standards by proprietary increments. In our opinion, it is necessary to model the communication of services as point-to-point communication until a technical and semantic standard (in the respective company) exists. Therefore we assume that each vendor equips all offered services \( r \in R_{\text{Service}} \) with a certain communication standard \( k' \in K' \). Especially “big” software vendors attempt to establish de-facto standards, and niche developers are often aligned to such a standard. Therefore, “standard-ecosystems” evolve around the standards of big players. (see for related aspects (Petrie & Bussler 2008)) Figure 2 shows a simple function graph: services \( s_1 \) and \( s_2 \) are offered by the same vendor \( B \), i.e. \( k'^i = k'^3 = B \), which is indicated by the same shading. Furthermore, \( \alpha'^i = \alpha'^3 = 1 \), since \( s_2 \) supports function 1 as well as function 2.

![Figure 2 The business process as basis for the function graph.](image)

We pointed out that communication between services provided by the same vendor is “facilitated”. In order to consider this phenomenon we model information cost for each pair \((s,t)\) of service candidates \( s \in R_{\text{Service}} \) and \( t \in R_{\text{Service}} \) that can fulfill functions \( i \) and \( j \) with \((i,j) \in E_{\text{com}}\). Information costs model the cost for the information exchange, e.g. costs that are associated with pre- or post-processing of data, which is partially caused by incompatibilities between the communication standards. For a possible way to evaluate information cost and a more detailed description of the concept, i.e. the incorporation of possibly higher value of the exchanged information, see e.g. (Buxmann et al. 1999). The information costs are modeled by the parameter \( C_{ij}^p((i,j) \in E_{\text{com}} \) and \( s \in R_{\text{Service}} \) and \( t \in R_{\text{Service}} \) (see the right side of figure 2). We assume that, \( C_{ij}^p \leq C_{ij}^s \) if \( k'^i = k'^j \) and \( k'^i \neq k'^j \), i.e. information cost for the communication between services provided by the same vendor are at most equal to information cost for the information exchange between services offered by different vendors. The justification for this assumption is analogous to the argumentation of (Buxmann et al. 1999) for the SP: Technical and semantic incompatibilities between the communication standards cause additional information cost. This causes a network effect for communication standards of the services: As more functions are implemented by services provided by a distinct vendor (i.e. fulfill a distinct communication standard), the more beneficial (from the information cost perspective) the usage of services from this specific vendor (i.e. this communication standard) for the remaining functions with which information is exchanged becomes. Note that, the strength of the network effects depends on the availability, comprehensiveness, and diffusion of domain specific (open) communication standards. If a (more coarse grained) service \( r \in R_{\text{Service}} \) is able to implement two communicating functions, i.e. \((i,j) \in E_{\text{com}}\) and \( \alpha'i = \alpha'j = 1 \), cost for information exchange can be modeled but typically those costs will be close to zero.

The function graph of the MSP is not directed, though the chronological and logical structure of business process implies a directed graph. By aggregating the mutual communication cost between the service candidates of two functions \( i \) and \( j \) into one parameter \( C_{ij}^d \), the directed graph can be simplified; this is analogous to the corresponding modification in the classical SP. (Domschke & Wagner 2005)
2.2 Interplay of services and standards: The layer structure

The classical SP focuses on communication relationships among actors and examines the trade-off between standardization costs and possible savings of information cost between communication partners by standardization. The MSP extends the SP by considering a second type of relationship: the integration relationship. This extension is necessary to analyze the described decision problem in the SOA context because the costs to use a service (layer 1) depend to a significant degree on the integration platform (layer 0) the service is supposed to run on (see Figure 1). Since many platform vendors “enrich” open integration standards by various proprietary extensions, services provided by a given vendor typically operate better on that vendor’s platform than on any other platform. For example, the integration of a SAP service with the NetWeaver platform is often easier than with any other platform. These extensions allow for example better performance or ensure a higher security level. Typically, the services that are offered by the platform vendor take advantage of these extensions without any modification. Vendors that only provide services – but no own platform – often “align” (and certify) their services for use with a specific platform. Similar problems are discussed in the literature related to “Mix and Match” and the “Hardware Software Paradigm” (see e.g. Economides 1996; Einhorn 1992; Katz & Shapiro 1994; Matutes & Regibeau 1988). To model these aspects in the SOA-case, two layers are necessary: Layer 1 consists of functions \( i \in N_{\text{Service}} \) that are fulfilled by services provided by possibly different vendors in order to support a business process. On layer 0 – the platform layer – one abstract function \( n_p \) (i.e. the integration platform) is modeled (see Figure 3). Thus, the graph of the MSP for the SOA-case consists of one service layer with \( n \) vertices (layer 1) and one platform layer (layer 0) with one vertex \( n_p \). As already described, the term “integration platform” relates to all infrastructure components that are necessary to support the services. The set \( N \) of functions is defined as \( N := N_{\text{Service}} \cup N_{\text{Platform}} \) with \( N_{\text{Platform}} := \{ n_p \} \). In the following we subsume services and platforms as artifacts. The set of artifacts is defined as \( R := R_{\text{Service}} \cup R_{\text{Platform}} \). Analogous to \( R_{\text{Service}} := \{ r \in R_{\text{Service}} | \alpha' = 1 \} \) the sets \( R_{\text{Platform}} := \{ r \in R_{\text{Platform}} | \alpha'_p = 1 \} \) and \( R := \{ r \in R | \alpha'_p = 1 \} \) are defined. Analogous to services the implementation of a platform \( p \) incurs implementation cost \( d^p \). In a first step, we assume that platforms fulfill no other functions except \( n_p \), i.e. \( \alpha'_p = 0 \forall i \in N_{\text{Service}} \) and \( r \in R_{\text{Platform}} \). Furthermore, we assume that a valid solution implements exactly one platform – federated system landscapes with multiple “platforms” can be modeled in the extended model (see chapter 5).

The MSP considers vertical (in)compatibilities by integration relationships and a compatibility graph weighted with integration costs \( d^p \) (see Figure 3 for an example). In the SOA context integration costs can be interpreted as costs that are necessary to make a service executable on a certain platform (e.g. cost for the deployment and fine adjustment).

![Function graph (layer 0 and layer 1) with communication and integration relationships](image)

![Integration cost for service and platform candidates](image)

Figure 3: Integration relationships weighted with integration cost.

We assume that each service \( s \) has to be integrated with a platform \( p \) to receive a functional SOA system. The integration of a service and a platform is realized via interfaces, which fulfill “integration standards”. Note that besides the communication standards on the service layer, integration standards between the two layers also influence the assembly cost of the SOA system. For the purpose of simplification, we assume that each vendor offers exactly one integration standard for all artifacts (i.e. services and platforms). This allows us to summarize integration and communication standards for the artifact \( r \in R \) in the parameter \( k^r \in K \). Thus \( k^r \in K \) can be interpreted as vendor of artifact \( r \).
range suppliers such as SAP or Oracle offer services besides the platforms to fulfill nearly every functionality – thus in such cases a “full standardization” on both layers is possible. Pairs of services and platforms \((s, p)\) which are provided by the same vendor fulfill \(k^s = k^p\). The integration of such artifacts is often preconfigured, well documented, and supported by specialized tools. For these reasons we assume that \(d^p \leq d^q\) holds, if \(k^s = k^p\) and \(k^q \neq k^p\). If a certain service \(s\) is totally incompatible to a platform \(p\), \(d^p := M\) holds.

2.3 Preferences for services and platforms

The aspects of the decision problem already described – i.e. the possible savings of integration and communication cost by choosing only one vendor to provide both the demanded services and the platform advocate the choice of a “single vendor” solution. However, in some situations, there is no single vendor who offers artifacts for all necessary functions. Another reason to decide on more than one vendor is, that the users have different preferences regarding the services and platforms and not all preferred artifacts will likely be provided by a single vendor. In order to consider the preferences of the users, it is necessary to model the utility of the services and platforms. The preference of the user for artifact \(r \in R\) implemented in function \(i \in N\) is expressed in monetary units in the utility parameter \(b_r\). The monetary estimation of the preference can be supported by a weighted decision-matrix. The user defines a set of weighted functional and non-functional criteria upon which the potential artifacts are scored. An example of possibly relevant criteria for service candidates are maximal data transfer rate, security aspects, and the design of the graphical user interface. Note that the utility \(b_r\) of an artifact is function specific but the implementation cost \(a\) are associated with the artifact itself. This means that the cost \(a\) are incurred if artifact \(r\) fulfills at least one function. Note that the model allows to consider “function-specific” costs by subtracting them from the utility \(b_r\) of the artifact - receiving a “implementation specific net-utility”. For simplification, we assume throughout this article that all costs are “artifact-specific”. This aspect is related to a major difference between communication and integration relationships. Communication relationships exist between implementations of functions by artifacts, whereas integration relationships exist directly between artifacts, i.e. the service-platform pairs \((s, p)\). Furthermore, the integration relationship is directed: a distinct service needs a platform to operate, not vice versa. If the first service is used, at least one platform has to be implemented to host this service and then for subsequent implemented services the usage of this platform is “free of charge”. This points out the infrastructure character of the platform. Since every function \(i \in N = N_{Service} \cup N_{Platform}\) has to be fulfilled by one artifact in the presented version of the model, this infrastructure character is hidden.

(Chou 2007) advertises that in hybrid systems, i.e. systems that are composed of components provided by different vendors, utility losses due to incompatibilities are possible. We observed in the SOA-case that not every service-platform combination \((s, p)\) harmonizes in the same manner. For example, the data transfer rate of a certain service \(s_i\) could be vastly higher than the maximum data transfer rate of a platform \(p_i\). This means that the whole combination of \(s_i\) and \(p_i\) can only operate at the data transfer rate of the platform. Thus the relevant characteristics of the complete system are determined to a certain extent by the composition of the system and not only by the addition of the individual utilities. We propose the following approach: During the assessment of the artifacts, an “ideal” environment should be assumed – thus no utility losses due to incompatible complementary components should be considered. Afterwards the assumed utility losses can be integrated by additional costs added to the parameter \(d^p\).

2.4 Model for the MSP in the SOA-case – A mathematical formulation

We introduce four binary variables \(w^s, x^s, y^p, z^p \in \{0, 1\}\) for the formulation of the MSP as a linear optimization problem of the MSP. Table 1 summarizes the introduced notation.

The objective function maximizes the utility derived by the artifacts implementing the functions with respect to the implementation, information, and integration costs. Note that all terms are expressed in monetary units.
Table 1 Notation of the model for the MSP

The model for the SOA-case MSP is formulated as follows:

Maximize $F(w, x, y, z) = \sum_{i \in N} \sum_{r \in R^i} b^r_i x^r_i - \sum_{i \in N} \sum_{r \in R} \alpha^r_i w^r_i - \sum_{(i, j) \in E^{com}} \sum_{s \in R^i} \sum_{t \in R^j} c_{ij}^{st} y_{ij}^{st} - \sum_{s \in R^i} \sum_{p \in R^i_{platform}} d_{sp}^{op} z_{sp}^{op}$ [1]

s.t.

$x^r_i - w^r_i \leq 0 \quad \forall i \in N$ and $r \in R^i$ [2]

$\sum_{r \in R} x^r_i = 1 \quad \forall i \in N$ [3]

$y_{ij}^{st} - x^r_i \leq 0 \quad (i, j) \in E^{com}$ and $s \in R^i$ and $t \in R^j$ [4]

$y_{ij}^{st} - x^r_i \leq 0 \quad (i, j) \in E^{com}$ and $s \in R^i$ and $t \in R^j$ [5]

$\sum_{s \in R^i} \sum_{t \in R^j} y_{ij}^{st} = 1 \quad \forall (i, j) \in E^{com}$ [6]

$w^r_i - \sum_{p \in R^i_{platform}} z_{sp}^{op} \leq 0 \quad \forall s \in R^i$ [7]

$z_{sp}^{op} - x^r_i \leq 0 \quad \forall s \in R^i$ and $p \in R^i_{platform}$ [8]

$w^r_i, x^r_i, y_{ij}^{st}, z_{sp}^{op} \in \{0, 1\} \quad \forall (i, j) \in E^{com}$ and $i' \in N$ and $p \in R^i_{platform}$ and $r \in R^i$ [9]
The set of constraints [2] guarantees that variable \( w' \) has to take the value 1 if at least one implementation of the artifact \( r \) is part of the solution. Note that \( w' \) can take the value 1 if \( a' = 0 \), even if the artifact is not implemented. Constraint [3] guarantees that each function is implemented by exactly one artifact. This constraint is necessary since all functions have to be fulfilled by a service in order to receive a valid SOA. Note that the constraints [4] and [5] are similar to the formulation of the SP by (Domschke & Wagner 2005). Constraint [6] ensures that each pair of communicating functions incurs information costs. Constraint [7] ensures that each service is hosted on one platform. Constraint [8] guarantees that, if a platform hosts any services, this platform must be implemented. The set of constraints in [9] specifies the binary domains of the variables.

3 THE APPLICATION OF THE MSP IN THE SOA-CASE

Figure 4 shows the general schema of the application of the MSP in the SOA-case. We implemented a Eclipse-based software prototype to support decision makers during data input (e.g. import of BPEL-based process descriptions), to solve the MSP and to analyze the solution’s robustness (figure 5).

![Figure 4: The application of the MSP in the SOA-case. The whole process is supported by the DSS.](image)

The input parameters of the MSP are classified in four groups: Input 1) the communication graph \( G^{com} = (N_{service}, E^{com}) \) on the service layer (layer 1), Input 2) information regarding the artifacts (i.e. implementation cost \( a' \), functions that the artifact can implement \( a'_i \), function-specific utility \( b'_i \), and vendor of the artifact \( k' \)), Input 3) information cost \( c^{ij}_w \) for the relevant pairs of services, and Input 4) integration cost \( d^{ij}_p \) for the service-platform combinations. In the first step, the functions that should be covered by the SOA system must be identified, i.e. the set \( N \). Note that, a finer granular analysis of the functions induces a higher complexity during the data collection and solution process of the resulting MSP instance. Based on the relevant business processes the communication relationships \( (i, j) \in E^{com} \) between the functions have to be assessed. The software prototype allows to import existing BPEL process descriptions (e.g. created in other process modeling tools). In the next step, different service and platform candidates \( R = R_{service} \cup R_{platform} \) must be assigned to the functions in order to determine \( a'_i \). It seems to be useful to consider only those service and platform candidates that are able to fulfill mandatory requirements of the decision makers (especially with regard to security and data transmission aspects). The user has to assess for each artifact the implementation cost \( a' \) and the (expected) utility \( b'_i \). Based on the expected intensity of communication and the degree of the compatibility of the communication standards, the information cost \( c^{ij}_w \) for all pairs of functions \( (i, j) \in E^{com} \) are assessed and finally, the integration costs \( d^{ij}_p \) for each service-platform combination are estimated. Based on these parameters the (under the given assumptions) optimal configured SOA is determined by the open source Mixed Integer Programming (MIP) solver “lp_solve” (version 5.5). (see http://lpsolve.sourceforge.net for details)
The configuration is optimized with respect to the information cost \( c_{ij}^w \), integration cost \( d_{ij}^w \), the user preference \( b_{ij}^r \), and the standardization costs \( a_{ij}^r \) of each artifact and function. The implemented DSS allows to conduct a Monte Carlo analysis with various graphical outputs to visualize the robustness of selected solutions.

4 LIMITATIONS OF THE PROPOSED MODEL

The limitations of the MSP model are similar to the limitations of the classical SP models, which are well studied in the literature. According to e.g. (Schade & Buxmann 2005) three types of limitations of the SP model exist; the data problem, the complexity problem and the implementation problem. The data problem refers to the difficulty collecting accurate data for the necessary parameters. Note that the MSP requires additional parameters compared to the SP. In general, the user must consider to which extent additional costs incurred by data collection (in particular regarding the mentioned “soft factors”) are justifiable by the improvement of data-quality. Especially the determination of parameter \( b_{ij}^r \) is related to the general problem of evaluating an IT-system’s economic value. However, IT-investment-decisions are economic decision-problems and therefore economic methods should be applied. Preliminary experiences from two case studies currently being conducted indicate that it is better to estimate the parameters in workshops with enterprise architects, rather than solely based on the (existing) business case for the investment decision. If detection and assignment of utility in a specific instance of the problem is too expensive, the cost-minimal solution for this SOA system can be achieved by defining \( b_{ij}^r := 0 \forall i \in N \text{ and } r \in R^i \). In this case, the parameter \( d_{ij}^w \) does not incorporate costs for utility losses due to incompatibilities in hybrid systems. The complexity problem arises in situations where bigger instances of the SP are solved, i.e. complexity increases when the number of vertices in the graph or the number of available artifacts increases. (Schade & Buxmann, 2005) By transformation into a warehouse location problem (WLP) it can be shown that the SP with more than two standards is NP-hard. (Domschke & Wagner, 2005) The implementation problem refers to the difficulties that arise when the implementation of a certain configuration is to be enforced.

The aim of the MSP is to analyze the described decision problem from a standardization perspective, knowing that various other relevant perspectives exist which are also of possible interest; e.g. it is observable that some software architects prefer to ensure a certain heterogeneity of the IT architecture to reduce dependency on single software vendors. Although the suggested model is a static one, some parameters can exhibit dynamic aspects, e.g. operating costs. These dynamic rates of the parameters can be derived by estimation and discounting. Nevertheless the presented model doesn’t allow an iterative transition between different IT-architecture landscapes. A further general limitation of the proposed model is the simplified (i.e. deterministic and linear) objective function.
5 CONCLUSIONS AND AVENUES FOR FURTHER RESEARCH

The aim of this article was to analyze the optimization problem regarding the choice of services and platforms in a software system based on the SOA paradigm in order to support decisions of software architects. We address two interdependent questions of the decision makers, which arise during the composition of SOA-based software systems: Which set of services should be chosen, and which platform should host those services? We presented an application of the Multilayer Standardization Problem (MSP) to the two layered SOA-case, its formulation as a linear 0–1 optimization problem and a according Decision Support System (DSS). The MSP extends the Standardization Problem (SP) by incorporating differing user preferences (utility of the artifacts), varying granularity of services and considering integration relationships in addition to communication relationships.

The general MSP is able to analyze more complex systems (n layers), which is useful to model the integration platform in a more detailed way, i.e. to model the integration platform as a system which itself contains communication and integration relationships. Another application of the general MSP is the examination of other domains e.g. a PC system with three layers: layer 0 (hardware), layer 1 (operating system), layer 2 (application software). A further possible direction for future research is the formulation of a dynamic decision model and the investigation of decentralized multilayer standardization problems. It would also be interesting to develop enhanced solution techniques for large problem instances – possible approaches include reformulations to provide tighter upper bounds for pruning in a Branch and Bound algorithm, or the development and use of (meta)heuristics. This article focused on the software architect’s perspective during the composition of SOA-based ERP systems. Future research regarding the analysis of strategies for software vendors’ can use the MSP to anticipate the reaction of users. In this context, strategies regarding compatibility and bundling (service/service as well as service/platform) are interesting topics.

Acknowledgments

We thank the anonymous reviewers for their constructive comments. We also thank Stephan Faßbender, Joachim Kanbach and Florian Weichand for their valuable contributions to the implementation of the presented DSS. Thomas Widjaja’s research is supported by a research grant from the FAZIT-Stiftung.

Abstract

Today’s analytical information systems demand innovative architecture concepts in order to address requirements like flexibility and faster time-to-market. Service-oriented architectures (SOA) as a current trend might meet these challenges. So-called BISOA describes the approach of deploying SOA in Business Intelligence systems. We identified two research questions aiming at finding insights about the interdependencies of BISOA and the organization’s system landscape: What are the dominant design factors of BISOA and what are the distinct realization approaches of BISOA? The paper answers the questions by means of empirical research. Besides the factor describing the degree of BISOA realization, three further design factors resulted from the analysis: excellence in embedded Business Intelligence (BI), process orientation, and excellence in data management. Depending on the factors distinct approaches of real-world organizations to deploy SOA in BI systems were derived. These profiles allow us to gain insight which aspects have to be considered besides mainly technical oriented implementation issues for BISOA. Surprisingly, there does not exist such a strong correlation between BISOA and operational BI as often assumed.

Keywords: Business Intelligence (BI), service-oriented architecture (SOA), operational BI, empirical analysis.

1 INTRODUCTION

Service-oriented architecture (SOA) dominates as a recent trend the discussion about today’s IT architectures. It is currently establishing as an accepted and useful concept for information system architectures in organizations (Baskerville et al., 2005; Kraftig et al., 2005; Schelp & Winter, 2007). Organizations are faced with major challenges in order to adapt fast changing organizational structures in a flexible way and to support new or modified business processes. The challenges encompass not only business aspects but also technical issues such as reducing complexity of the application landscape. Service-oriented architectures are aimed at providing support in this context.

On the other side, analytical information systems represent meanwhile an essential component of the enterprise application landscape. Business intelligence (BI) as the underlying concept is used as an umbrella term to describe the processes and systems dedicated to the systematic and purposeful analysis of an organization and its competitive environment. Also analytical information systems demand increasingly innovative architecture concepts in order to address new challenges like realizing operational BI approaches (cf. Section 2.2). Furthermore, organizational units responsible for development and operations of analytical information systems have to assess if the SOA paradigm might apply to analytical information systems as well and have to design a possible integration of
SOA in the current architecture landscape. In the following, we designate the term “BISOA” to the situation that SOA is applied to analytical information systems and BI systems, respectively.

According to a survey of Ventana Research about the status of SOA in BI, only 33% of organizations reported they believe their internal IT personnel have the knowledge and skills to implement BI services (Everett, 2006). However, the decision, if and how to apply BISOA and to develop an appropriate procedure model requires know how about the interdependencies between BISOA and the current system landscape.

We have reviewed both scientific and practitioner oriented publications in order to assess the state-of-the-art of BISOA. Whilst there are numerous articles published by consultancies, research and advisory firms, and software vendors, only little work can be attributed to the scientific community. The paper at hand aims at providing insights to the aforementioned interdependencies, based on the results of an empirical analysis. Moreover, it tends to assist the selection and adaptation of frameworks from information systems research, which may support the introduction of BISOA concepts in organizations. In the past, design research artefacts including models and methods were rather generic and did not differentiate enterprise specific needs. Thus, concepts in design research have evolved which aim at enhancing generic problem solving approaches such as adaptable conceptual models (vom Brocke, 2007; vom Brocke & Buddendick, 2006) or situational method engineering (Becker et al., 2007; Ralyté & Rolland, 2001). By means of these approaches, existing models and methods can be refined to ensure that a model or method fits better to problem-specific requirements than a generic one does. The study at hand investigates relevant design factors, which influence the application of relevant design research artefacts (methods or methods fragments of e.g. a BISOA introduction). In addition, it tends to reveal BISOA profiles these artefacts are applied for. Consequently, the following two research questions will be discussed:

1. What design factors dominate the realization of BISOA?
2. Based on these design factors: Which distinct approaches to BISOA are pursued by real-world organizations?

The remainder of the paper is organized as follows: Section 2 provides an overview of SOA and its deployment in analytical information systems (“BISOA”), respectively. In Section 3 the empirical investigation for identifying design factors as well as BISOA approaches using data collected from a written survey is described. Following, Section 4 discusses an interpretation and discussion of the survey results. Section 5 concludes and provides an outlook on further research.

2 THE CONCEPT OF SOA AND BISOA

2.1 The SOA paradigm

The main idea of SOA is to encapsulate business functionality into small loosely coupled services, which – once implemented on a software level – may be flexibly orchestrated to match the particular and ever changing business requirements (Krafzig et al., 2005). Consequently, rather than providing a technical solution, the SOA concept presents a business driven architecture paradigm. SOA aims at designing an ideal IT architecture, which is not built by monolithic applications but by standardized components (services) that are designed according to underlying business functionalities.

Many expectations concerning various and extensive benefits come along with the service-oriented paradigm, in particular addressing the need for improvement of existing IT architectures. The main benefits of SOA are amongst others:

**Increased reuse rate:** Many business functionalities that are realized in software are reused in various business processes. By means of SOA these software functionalities can be used by several processes
via standardized interfaces. Consequently, redundant development can be avoided (Endrei et al., 2004).

**Reduction of complexity**: SOA facilitates the decoupling of business process control from the technical functionality. The coordination mechanisms are shifted to an integration layer and are therefore separated from the functional components. In addition, the interface standardization allows a reduction of the number of interfaces.

**Increased manageability**: Several applications might simultaneously benefit from further development of services – assumed an appropriate version management has been established. As the service functionalities are encapsulated via interfaces the underlying software might be (ex)changed without requiring adaptations in the corresponding components.

**Faster time to market**: Due to more efficient deployment mechanisms SOA enables the IT departments to react faster to changing business requirements. Consequently, agility and flexibility are enhanced (Bieberstein et al., 2005; Schelp & Winter, 2007).

Evolutionary extensibility, cost savings, investment protection, and outsourcing potentials are considered as further advantages. A detailed discussion about SOA can be found e.g. in (Endrei et al., 2004; Krafzig et al., 2005; Keen et al., 2004).

### 2.2 SOA for BI systems (BISOA)

The aforementioned Ventana Research survey confirmed the relevance of BISOA. More than 81% of respondents said SOA was important to BI due to its powerful combination of business and IT benefits. From the business side, nearly 50% felt that BI services would help make information more broadly available, while also improving the business's ability to respond faster to change. From the IT side, nearly 66% felt that BI services would help IT departments to respond to business needs in a better way, with another 33% viewing ease of integration and lower lifecycle management costs as key benefits (Besemer, 2007). These benefits are similar to the generic SOA advantages as presented in Section 2.1.

BI systems can act either as service provider or as service consumer. In addition, functionalities within BI systems can be realized via services. Nowadays, there is a (more or less) common understanding which services can be differentiated in BI systems / architecture, although classification criteria, terminology, and the service types in details still vary (Besemer, 2007; Gordon et al., 2006; Martin & Nussdorfer, 2007; Wu et al., 2007). The most popular service types are given below:

**Sourcing (Backend) services**: Operational data sources are connected to the data warehouse via dedicated extraction services or via already existing services provided by operational applications (Gordon et al., 2006; Keith et al., 2007).

**Transformation services**: Transformation functionality within ETL (extraction, transformation, loading) processes is realized by means of services. Examples are aggregations, encoding, etc. (Gordon et al., 2006; Wu et al., 2007).

**Analytical (Frontend) services**: BI data and products are made available to end users and other applications via services. An overview of analytical services like reporting, dashboard, alerting services can be found amongst others in (Gordon et al. 2006; Martin 2006; Martin & Nussdorfer 2007).

**Infrastructure services**: Tasks with infrastructure character such as meta data, master data, and data quality functionalities are realized by means of services (Gordon et al., 2006).

In addition to these use cases, which correspond to the typical data warehouse architecture layers, operational BI is often mentioned as an application area for BISOA, e.g. in Besemer (Besemer 2007; Blasum 2006; Eckerson 2007; Keny & Chemburkar 2006). There is not yet a common understanding about the term operational BI. Some authors focus on specific aspects, others like Eckerson (2007),
consider operational BI as an umbrella term: “Operational BI delivers information and insights to a 
broad range of users within hours or minutes for the purpose of managing or optimizing operational or 
time-sensitive business processes”. Eckerson (2007) presents a survey conducted about operational BI. 
Respondents being asked amongst others for main challenges in deploying operational BI, rated 
“Architecting the system” to the top. Moreover, other authors point out the significance of SOA to 
near/real time data delivery (data warehousing) (Abrahem, 2007; Wu et al., 2007).

Considering the various fields of applications for SOA in analytical information systems mentioned 
above and driven by the demand for innovative BI architecture concepts, it seems worth the effort to 
consider BISOA as an alternative or enhancement of established architectures. In the next section we 
will elaborate the predominant design factors and analyze their impact on the realization degree of 
BISOA.

3 EXPLORATIVE ANALYSIS

3.1 Research method

Explorative analysis was used as the underlying research method. By means of a factor analysis we 
identified the predominant design factors (indicators) for BISOA realization. This method is used in 
order to extract a small number of relevant mutually independent factors from a multiplicity of 
variables (of a data set) (Härdle & Simar, 2003). In the field of factor analysis two different 
approaches with different goals can be distinguished: confirmatory factor analysis (CFA) and 
exploratory factor analysis (EFA) (Thompson, 2004). A CFA approach requires “a firm a priori sense, 
based on past evidence and theory, of the number of factors that exist in the data, of which indicators 
are related to which factors, and so forth” (Brown, 2006). In contrast to that, researchers using the 
EFA approach may not have any specific expectations regarding the number of underlying factors. 
The explorative nature of the article at hand implicates therefore the application of EFA.

A cluster analysis of the extracted factors was then performed in order to identify different BISOA 
approaches. Clustering as a combinatorial data analysis technique investigates “a set of objects in 
order to establish whether or not they fall […] into groups […] of objects with the property that 
objects in the same group are similar to one another and different from objects in other groups” 
(Gordon, 1996). Initially, these groups are unknown and need to be determined. Various clustering 
methods for different purposes are available. They can be categorized by the types of algorithm used 
to obtain the clusters. Most important clustering techniques include agglomerative, divisive, 
incremental, direct optimization, and parallel algorithms (Gordon, 1996). According to Härdle & 
Simar (2003) agglomerative algorithms have the largest significance in practice. Thus the clustering 
method of the paper at hand is based on such an algorithm. Starting with n clusters, each containing a 
single object, an agglomerative algorithm reduces the number of clusters by merging the two most 
similar ones at each step. In our context, the cluster analysis aimed at determining the correlations 
between the indicators (reflecting the design factors) and BISOA approaches in organizations and 
consequently, at evaluating the relevance of these indicators.

3.2 Data collection and selection

Data for the empirical analysis was collected by means of a written survey that was conducted at a 
practitioner conference on data warehousing and business intelligence held in Switzerland. The 
conference was attended by 137 specialists and executives with primarily large and medium-sized 
companies in the German-speaking area. The questionnaire used for the survey was designed to 
answer the research questions (cf. Section 1), i.e. to assess design factors for BISOA and to identify 
BISOA approaches. Prior to the survey, the questionnaire was revised by experts from both the 
scientific community and the entrepreneurial world in terms of completeness and comprehensibility.
The items of the questionnaire cover a broad range of layers relevant to the context of BISOA (cf. Section 3.3). The respondents were asked to indicate their agreement with several statements on a five-tiered Likert scale (0 to 4) from the perspective of the organization they are working for. There was a dedicated time slot during the event to fill in the questionnaire. The objectives, structure, and terminology used in the written survey were explained to the attendees. A total of 68 questionnaires were returned. This corresponds to a return rate of approximately 49.6%. If a data set was incomplete (11 questionnaires) or apparently inconsistent (checked by control questions; 6 questionnaires), the questionnaire was discarded. Fifty-one duly completed questionnaires were used as foundation for the analysis, resulting in an overall return rate of about 37.2%. The data set is considered to constitute an adequate basis for an explorative analysis.

Respondents of the survey were employees from organizations in the German-speaking area. Large and medium-sized organizations accounted for the largest share: 23.5% of all organizations have 1000-5000 employees, 36.5% more than 5000 employees. In particular the industry sectors banking (22.0%), insurance (11.8%), and retail (8.8%) were mainly represented.

3.3 Description of the data set

For the purpose of information system analysis in organizations frameworks, differentiating several layers, are often used in order to facilitate a transparent overview of complex correlations between information systems and objects, respectively (e.g. processes) (Alter, 2004; Winter & Fischer, 2007; Zachman, 1987). The deployment of BISOA affects several levels in such frameworks. Therefore, the questionnaire of the empirical analysis incorporated with regards to its content and structure all layers being relevant in this context, namely process level, integration level, and application level.

The process level, which is addressed by all approaches of aforementioned authors, includes all processes along the organization’s value chain. That level was covered in the questionnaire by asking e.g. about the definition of process output and process owners. The application layer, also part of the aforementioned models, subsumes all software artefacts like software services and data structures. The questionnaire addressed this level by primarily technical questions, e.g. about functionality or usage of analytical information systems (Wixom et al., 2008). Finally, the integration layer according to (Winter & Fischer, 2007), links the process layer and the application layer and enables the integration of software components and processes. Considering this layer, questions also addressed integration options of business processes and BI applications, such as support of process execution through analytical information or process monitoring (Kueng, 1999) or interface configuration. In addition to questions focusing on these three layers, statements were asked describing the degree of BISOA realization – in order to derive the corresponding correlations.

3.4 Factor analysis

As stated above, the factor analysis method of this empirical research is based on EFA (cf. section 3.1) in order to identify the predominant design factors for BISOA (cf. research question 1 in Section 1). The overall objective is to find a common term embracing multiple items. The input for the factor analysis comprised of 15 items. Prior to the EFA, the adequacy of the data set is verified using two criteria. Variables (items) are suitable for factor analysis, if and only if the anti-image of the variables is as low as possible. In such a case the off-diagonal elements of the anti-image covariance (AIC) matrix are as close as possible to zero. As suggested by (Dziuban & Shirkey, 1974) a correlation matrix can be seen as unsuitable for factor analysis, if the percentage of the off-diagonal elements unequal to zero (> 0.09) in the AIC matrix is 25 % or more. The criterion of the data set at hand is about 18.5%.

As second verification criterion the measure of sampling adequacy (MSA), proposed by (Kaiser & Rice, 1974), can be applied. MSA represents an indicator for the extent, to which the input variables belong together, and therefore provides information on whether a factor analysis can reasonably be
performed or not. Kaiser and Rice (1974) appraise a value of 0.7 or more as “middling”, i.e. the data set is considered to be appropriate for applying factor analysis techniques (Kaiser & Rice, 1974). According to (Kaiser & Rice, 1974) a value of 0.7 is to be seen as average and 0.8 as good. In the present case the value is 0.802 which justifies the data set as suitable for the factor analysis.

Within the fields of factor analysis two main techniques can be distinguished – the principal components and principal axes factors analyses, which can be counted by far to the most commonly used factor extraction methods (Thompson, 2004). The higher the number of variables of the data set the more similar the results of principal components and principal axes factor analyses will be (Ogasawara, 2000). According to (Thompson, 2004) principal components analysis (PCA) has some additional preferable properties and is probably the most frequently used EFA extraction method for empirical studies. Thus, PCA is used as factor extraction method in the paper at hand. In order to determine the desirable number of factors, two statistical verification methods are applied, the Kaiser-Guttmann criterion and the scree test. According to the Kaiser-Guttmann criterion (Guttman, 1954; Kaiser & Dickman, 1959) the number of factors to be extracted should equal the number of factors with eigenvalues larger than 1 (cf. Table 1). This results in the extraction of four factors explaining 72.3% of the total variance. The scree plot points to the same solution.

Table 1. Eigenvalues

As final step the nature of the underlying constructs has been clarified by applying the Varimax method as the most common factor rotation method with Kaiser normalization (Thompson, 2004). The rotated component matrix is depicted in Table 2. Items are assigned to a factor if the factor loading adds up to at least 0.5 (Härdle & Simar, 2003). The four factors vary in the number of items with a range from three to four items.

Table 2. Results of factor analysis (rotated component matrix)

The following paragraphs discuss the identified factors and give a short interpretation for every factor.

**Factor 1: Excellence in BISOA**

Four items were found to have significant impact on the first factor. Their common denominators are maturity aspects of BISOA realization in organizations. According to our analysis, there are four indicators for the achievement of excellence in BISOA: First, dedicated projects aiming at deploying SOA in BI projects, second SOA is (selectively) deployed in the context of upcoming projects, third, know how of introducing SOA concepts into BI system architectures, and forth, SOA usage degree within operational systems. The last indicator seems to be obvious since in most organizations BISOA will probably not be addressed independently of other SOA activities. Ideally all (BI)SOA activities are synchronized to achieve synergy effects.

**Factor 2: Excellence in embedded BI**

The second factor is made up by four items that essentially account for embedded BI, also called “composite applications” in (Eckerson, 2007). Our findings suggest that the level of excellence in embedded BI depends on the usage of analytical information for automatic process execution and the support of analytical information for the execution of business processes. In addition, excellence in embedded BI is positively influenced by the degree of the combination of analytical information and process information. The degree of the measurement of relevant performance indicators for relevant business processes has impact on this factor as well. Especially the first three items are similar to the understanding of operational BI (i.e. the integration of BI and business process management), as described e.g. in (Marjanovic, 2007). Eckerson (2007) (cf. Section 2.2) differentiates several levels of operational BI. The variables loading on the second factor correspond to one of these levels: “facilitate processes” by embedding BI into operational applications.

**Factor 3: Process orientation**

Three items exhibit high loadings on the third factor. In summary, they can be characterized by the term “process orientation”. All variables describe relevant preconditions for alignment of business activities to business processes: All activities and their dependencies as well as process output and process owners are defined for all relevant business processes.

**Factor 4: Excellence in data management**

Finally, four items covering relevant data management aspects were found to have substantial positive impact on the fourth factor, namely master data management, data quality management, meta data management, and data ownership concept.

### 3.5 Cluster analysis

In order to identify distinct realization approaches of BISOA, cluster analysis was applied on the data set using the calculated factor values of the four previously identified factors as input data. The Ward algorithm and the squared Euclidean distance have been used as fusion algorithm and distance measure, respectively. In literature the Ward algorithm is recognized as an efficient partitioning mechanism (it reveals the appropriate number of clusters with a similar number of observations in each cluster at the same time) generating good clustering results (Hair Jr et al., 2006; Ward Jr, 1963).
Thus, it is applied in the study at hand. Starting with individual cases each representing a single cluster, Ward’s method continues by combining them into clusters until each and every case belongs to the same cluster. For determining which clusters have to be merged next, the sum of the squared Euclidean distance between each case and the mean of its cluster is minimized. While also other clustering algorithms and distance measures have been tested best results in terms of interpretability, context, and purpose of the study at hand could be realized by means of the Ward method in combination with the squared Euclidean distance. The so-called dendrogram (cf. Figure 1) provides a visualization of the hierarchical clustering process. By means of the dendrogram the number of clusters to be built for a particular clustering problem can be graphically derived. In the context of the study at hand this heuristic suggests that the construction of four clusters (representing four distinct realization approaches of BISOA) is the most reasonable solution, marked in the dendrogram between the two dotted lines.

![Figure 1. Results of cluster analysis (dendrogram)](image)

Table 3 exhibits the arithmetic means and the standard deviations of the four calculated factor values of the four clusters. A graphical representation of the arithmetic means is added in form of pie charts (please note: the pie charts are representing relative, not absolute values).

Table 3. Results of cluster analysis (arithmetic means and standard deviations of factor scores for each cluster)

Based on this information, the clusters can be characterized as follows:

**Cluster 1: Data management experts**

Those 21 organizations (i.e. the majority of all respondents) that are grouped into the first cluster are characterized by the most advanced degree of BISOA realization and by high levels of excellence in data management but by average level of excellence in embedded BI and of process orientation. These results correspond e.g. to (Gordon et al., 2006) who claim data management aspects like data ownership, enterprise data, etc. as critical success factors for BISOA.

**Cluster 2: Process orientation experts**

The second cluster is made up of 9 organizations. Although the cluster is characterized by nearly the same degree of BISOA realization as the first cluster, the remaining design factors differ significantly. In contrast to the first cluster these organizations exhibit a high level of process orientation but low levels of embedded BI and data management.
**Cluster 3: Embedded BI experts**

The third cluster merges 14 organizations that are characterized by a low degree of BISOA realization, but the highest excellence level of embedded BI. On the other hand the maturity level regarding data management and process orientation is rather low.

**Cluster 4: Freshmen**

Nine organizations where embedded BI and process orientation get the lowest attention in comparison to the other clusters are grouped in this cluster, which is characterized by the lowest degree of BISOA realization. The maturity level of data management is on average.

According to the values determined in the cluster analysis, the four realization approaches to BISOA can be arranged in a two-dimensional matrix (cf. Figure 2). “Excellence in data management” (factor 4) is being depicted on the horizontal axis and “Excellence in BISOA realization” (factor 2) is being displayed on the vertical axis. For both dimensions, high and low parameters (i.e. high and low levels of implementation) are distinguished for clarity. Thus, the classification scheme resembles a 2x2 matrix. Within each of the four segments, we furthermore differentiate between the “Process orientation (factor 3, horizontal axis) and “Excellence in embedded BI” (factor 2, vertical axis). Cluster 4 (“Freshmen”) might also be assigned to the lower left side of the matrix as its maturity level of data management represents an average value, which cannot be clearly allocated to high or low values.

**Figure 2. Realization approaches of BISOA**

4 DISCUSSION AND INTERPRETATION OF RESULTS

We have identified four relevant BISOA profiles in Section 3. In the following, two aspects regarding the results of the empirical analysis and the cluster analysis will be discussed in detail. Further interpretation of the results might be useful and interesting.

**Improvement of the BISOA maturity**

Figure 2 illustrates the fragmentation of surveyed organizations into two main groups: One group is characterized by a high degree of BISOA realization and the second group by a low degree, respectively. However, within these groups there is no homogeneity concerning the maturity levels of the remaining (design) factors. Obviously, there is no single and definite approach to deploy BISOA or to increase BISOA maturity levels, respectively. According to the analysis results, a high BISOA maturity level corresponds either to excellence in data management or to a high degree of process...
orientation. There are no organizations (at least among the respondents) that are characterized by high maturity levels of both, data management and process orientation, or even of all three factors (including embedded BI).

In the survey we also asked to indicate the same statements for the future. These values are not in the focus of the paper at hand and of the empirical analysis presented so far. However it is evident that nearly all organizations aim at improving the degree of BISOA realization. This is also true for organizations with a high degree of BISOA realization in the cluster analysis (cluster 1 and cluster 2). This might be explained by the reason that these factor values have to be regarded as relative, not absolute. I.e., even organizations belonging to cluster 1 and 2 do not realize a true mature level of BISOA so far. According to the analysis results it might be concluded that activities to increase the degree of BISOA realization might be positively influenced by simultaneous improvement of the remaining (design) factors (data management, process orientation, and embedded BI). Regarding the fact that very few organizations are characterized by mature levels of all three “dimensions” (factors), it seems that organizations with comparatively mature BISOA (cluster 1 and cluster 2) still have significant potential for further improvement regarding BISOA.

Relevance of BISOA for operational BI scenarios

As mentioned in Section 2.2 many authors link SOA with operational BI and praise operational BI as the main use case for BISOA. The analysis results have revealed that this coherence cannot be seen as evident as it is often claimed. At least regarding the facets of embedded BI / composite applications – according to (Eckerson, 2007) one stage in operational BI - do not correlate unambiguously to BISOA. In cluster 1 and cluster 2, which include organizations with a comparatively high mature BISOA approach, both enterprises types, with an advanced degree of embedded BI and with a low degree, have been found. Accordingly, the same situation can be observed in cluster 3 and cluster 4 (organization with a comparatively low mature BISOA approach). Thus, BISOA does not necessarily constitute one or even the only driver for operational BI and vice versa. At least it seems that coherence and interdependencies between BISOA and operational BI are not as straight and definite as often assumed, especially in practice. In fact, other factors also have impact, namely the degree of process orientation and the maturity of data management, as the study at hand has shown. One-track argumentation regarding BISOA and operational BI and significant correlations in-between should consequently be seen more carefully, at least if any coherencies are only assumed and not somehow proved.

5 SUMMARY AND OUTLOOK ON FUTURE WORK

Deploying the SOA paradigm to analytical information systems, promises progress in realizing the vision of closed action loops between operational systems and analytical information systems. However, BISOA so far is not addressed extensively by scientific community. Consequently, we identified two research questions aiming at finding insights about the interdependencies of BISOA and an organization’s system landscape. A factor analysis and a cluster analysis were applied in order to identify predominant design factors for BISOA in an explorative way. We also determined typical scenarios for BISOA and explored the impact of relevant EA layers on the shaping of those scenarios.

The resulting design factors might support the application of models and methods in information systems research for organizations that are planning or currently realizing BISOA. The factors represent dimensions in which BISOA profiles differ from each other. As mentioned in Section 4, approaches for BISOA deployment vary in the surveyed organizations. Thus, models and methods that tend to support the deployment phase should be adaptable in order to address the design factors and different maturity levels (“BISOA profiles”) elaborated in the study at hand. For instance, data management as an essential aspect should be incorporated in a method while considering the specific maturity level of data management in the organization.
Moreover, the design factors can serve as a guideline and provide recommendations for actions. Due to their identified impact on the maturity level of BISOA, they clarify which issues should be addressed in addition to the usually technical dominated implementation aspects of BISOA. In other words, it is not recommended to regard BISOA as an isolated IT project – indeed, the coherencies to other aspects (represented by the design factors) should be considered carefully.

Surprisingly, the cluster analysis depicted that correlations between BISOA and operational BI (at least when focusing on the facet of embedded BI) are not as evident as often supposed. It seems that additional factors influence BISOA simultaneously.

The analysis results might serve as the basis for further research. On the one hand, it seems worth to further detail the scenarios and to elaborate their characteristics. Possible development paths for BISOA and more detailed recommendations may result in a comprehensive procedure model and a maturity model, respectively. On the other hand, as already mentioned, in the survey the respondents were also asked about their assessments for the future. Since this information is not included in the empirical analysis so far, further research might generate new interesting insights. Finally, the survey might be expanded to further organizations in order to put the empirical analysis on a firmer footing.

Abstract

The term Cloud Computing represents a paradigm for offering different kind of Web services, which can be dynamically developed, composed and deployed on virtualized infrastructure. This work will extend the concepts known from the revenue management to the specific case of Cloud Computing and propose two models, bid price control and a variant of dynamic pricing, that will compete with the commonly used static pricing. Both models will try to maximize revenues by controlling the availability or price of every offered fare class. The aim is to understand from a Cloud Computing company’s perspective, how decisions about the pricing and the optimal allocation of the given resources for the various Cloud Services can be supported. As expected, simulation results show that an optimally adjusted dynamic pricing model will outperform any pricing model with static prices and will simultaneously contribute to slightly smoother resource utilization in some cases. However, we will see that the adjustment itself is difficult to realize, and if conducted suboptimal, it may also have certain disadvantages compared to static prices. In combination with a reasonable product differentiation, the bid-price method performed very solid and in nearly any case better than the pure static pricing model.

Keywords: Cloud Computing, revenue management, pricing, IT services
1 INTRODUCTION

Cloud Computing has recently become very popular as a new paradigm to shift IT resources and software from locally independent computers to a more collaborative level (Hayes, 2008). The hub-and-spoke system known from the client-server model is replaced by a geographically distributed cluster system. The concept of cloud computing comprises many existing technologies and architectures like on-demand or utility computing, software as a service and AJAX. Providers like Amazon or Rackspace offer products on the infrastructure level to run individually configured operating systems. Server farms remain idle most of the time. 99 percent of the entire computing capacity of a company is only used 10 percent of the time (Weiss, 2007). Additional revenue can be earned by utilizing resources. The resource demand is mostly both dynamic and unpredictable. Defining demand based pricing policies can influence the behavior of price sensitive customers (Desiraju and Shugan 1999). Customers, whose utility is highly depending on prices, would shift their computational jobs to a time, where resources are cheap. Business customers, though, are less flexible and are thus less price-sensitive. Their utility is increased by getting the job done on time or getting a better service. When prices are relatively fixed and demand outweighs supply, providers have to manage their capacity by deciding whether to accept and incoming request or waiting for a future request demanding a higher valued service. This will probably induce higher revenue. This problem is also known as the capacity management problem from the Revenue Management domain (Talluri and van Ryzin, 2004). Solutions have been successfully applied to the airline sector in the majority of cases (McGill and van Ryzin, 1999).

In this paper, we analyze how Revenue Management concepts can be useful to the Cloud Computing domain. The aim is to understand from a Cloud Computing company’s perspective, how decisions about the pricing and the optimal allocation of the given resources for the various Cloud Services can be supported. Our contribution is threefold. At first, the requirements for applying Revenue Management to Cloud Computing have to be analyzed. In section three we derive a mathematical model to determine appropriate policies when to accept or reject requests for Cloud Services. Two models are compared, namely bid price control and dynamic pricing. As a supplementary benchmark, we use a static pricing model. The proposed bid price model and dynamic pricing models are evaluated via simulation in section four. Section five concludes the paper.

2 RELATED WORK

2.1 Cloud Computing

The term Cloud Computing is currently used in various ways and is often confounded with the term Grid Computing. Grid Computing accrued in the mid 1990s and originally denoted a scientific network to share computation power for computationally intensive jobs. The main characterization of a Grid is the distribution of a computing job in a somehow connected network. Accordingly, jobs for Grids are divided in several small jobs which are distributed to independent servers or desktop computers (Foster et al., 2001). This opens the possibility to share resources between institutions that are dispersed among different geographical locations. However, sharing computing resources is also a central aspect of Cloud Computing, but with a focus on virtualized instances that usually run on a server cluster (Buyya et al., 2008). A server cluster typically distributes computation power among several locally connected servers and hosts the virtual instance, which has been allocated to a certain customer. In scientific Grids the institutes are provider and consumer similar to P2P networks. Cloud Computing is commercially driven and most of the providers do not consume the resources they offer. The role between provider and consumer is currently disjointed. Some providers offer services in Clouds, which are based on other services like Rackspace, Rightscale or MorphExchange. In particular, services in this case are distinguished. For example, the product MorphExchange is a
platform providing a Tomcat server for uploading and hosting Java web applications (Platform as a Service). It uses Amazon’s Simple Storage Service (Infrastructure as a Service) for storing the applications. On top these services, software or data can be provided as a service as well like StrikeIron offering a data service in combination with Salesforce’s Customer Relationship Management software service. Lawton describes the cloud applications (Software as a Service) as Web-based applications accessed via browsers but with the look and feel of desktop programs (Lawton 2008). Skillicorn already emphasized in 2002 the advantages of composing simple services together to a new Web service with an added value for the customer (Skillicorn 2002).

Another aspect is the relationship between Clouds and Grids. Grid and Cloud Computing can be viewed as integrating several instances of one or multiple Clouds in a Grid. For example, we can use Grid technology for connecting multiple Clouds that do not have to be allocated at the same geographical location to combine computation power and furthermore distribute utilization (Boss et al., 2008). This definition implies a standard protocol to interact between several cloud instances. However, this is strictly depending on the providers, who supply Web Services to their products. Moreover, currently the Grid is more academia driven, while Cloud Computing is focusing on commercial application (Weinhardt et al., 2009). Earlier approaches from IBM or SUN Microsystems to commercialize Grid Computing have not been successful yet.

2.2 Revenue Management

The term Revenue Management is most commonly used for the theory and practice of maximizing expected revenues by opening and closing different fare classes or dynamically adjusting prices for products (Talluri and van Ryzin, 2004). The development of scientific research methods in this discipline started after the deregulation of the American Airline industry in 1978. They relaxed restrictions over standardized prices and profitability targets enabling dynamic pricing and resource allocation, although the first approach was back in 1972 by Littlewood (Littlewood, 1972, Belobaba, 1987). (Netessine and Shumsky, 2002) define Yield Management as a part of Revenue Management although boundaries between both are often ambiguous.

The perishability of the offered products is one of the main characteristics of Revenue Management. For example, a hotel cannot save up one room for the next day. Instead, an unused room becomes worthless without creating any revenue (Netessine and Shumsky, 2002). To get an efficient return from utilizing Revenue Management techniques the arriving customers have to be segmented into different classes. Every customer segment can be distinguished by different needs and thus by higher or lower reservation prices. Consequently, the main goal in Revenue Management theory is to find the combination of customers which seems to provide the highest possible revenue (Kimes, 1989). Therefore, we have to choose between opening a certain product class for sale or protecting it for a more profitable customer. However, future demand is not certain what causes this problem to get far more complex. If the vendor decides to protect a product for future demand, he takes the risk of ending up without selling the product (Goldman et al., 2002, Netessine and Shumsky, 2002). Although the vendor would face lower risk by immediately using the possibility to sell the product, we assume for all models presented in this work that these transactions are repeated often enough to justify a risk-neutral approach (McGill and van Ryzin, 1999, Bitran and Caldentey, 2003).

2.3 Application of Revenue Management in Clouds

The application of Revenue Management to other domains is only feasible, if several requirements are fulfilled. The requirements enable a comparison to traditional Revenue Management approaches which will be useful to formulate and optimize the unique optimization problem analogously to established strategies.

a. Time horizon: Like the Amazon EC2, the duration of every service is defined as a finite time period. With this assumption, we can handle every full hour as a separated product, what makes it comparable with a seat on one flight leg in airline industry or a room for one night in a hotel (Kimes, 1989).
b. Perishability: The perishability of the offered products is one of the main characteristics that have to be fulfilled for an appropriate use of Revenue Management (Weatherford and Bodily, 1992). The usage of resources on servers is limited to a point of time. Afterwards they are worthless, since they are not storable. As long as enough IT resources are left to provide at least one product, the revenue is still not maximized.

c. Production Inflexibility: IT resources are largely fixed and can only be extended at disproportional costs in relation to their running expenses. Product supply is thus limited and not extensible in a specific time horizon (Weatherford and Bodily, 1992). As most Cloud Computing providers offer their services on relatively huge server cluster. The integration of an additional resource like buying a new server will incur high additional fixed costs due to integration and increasing maintenance cost for the provider of infrastructure services.

d. Possibility of booking future products: Advance reservation has some relevant benefits (Boss et al., 2008, Dube et al., 2005). On the one hand, it gives the user the possibility to ensure a prospective computation demand by reserving the required products for the desired time. On the other hand, it provides the seller with the ability to easily discriminate customers by their valuation.

e. Customer segmentation: The offered products have to be differentiated by adding or restricting certain features to reach the desired customers for every price class. In most cases, the demand for these price classes differs particularly in their valuation for special product features and price sensitivity (Talluri and van Ryzin, 2004). For example a service level might indicate the minimum percentage of availability. Additionally, we might also identify different needs for resource combinations between price segments and with future booking enabled. Moreover, restrictions for reservation changes can be adopted commonly known from the airline industry.

f. Multiple products based on same resources: For Cloud Computing we have the desired advantage of flexible products. The resources of a Cloud Computing center are able to provide different service offerings using the same IT resources. Several products or product bundles can be defined, e.g. containing different amounts of CPU power or memory and defining individual service levels as aforesaid. The flexibility of the initial capacity provides plenty of resource combinations (Bitran and Caldentey, 2003).

h. Overbooking: The Cloud Computing overbooking procedure would be to sell more of the computing and storage capacity than the computing center has. In this case, not every costumer will exploit its reserved resources completely. Overbooking of Cloud Computing resources allows more flexibility. (Urgaonkar et al., 2002) show that the usage of overbooking techniques can increase utilization drastically: Already an overbooking rate of just 1% may increase the utilization of the whole computing cluster by a factor of two without losing meaningful availability guarantees.

It is important to consider customer needs. On the one hand, we believe, that in contrast to most traditional Revenue Management industries there is a market for open-end requests, which explicitly do not have certain end dates. That is because these virtual computing resources are likely to replace local computers which are in most cases also bought without a fixed time horizon for its usage. This issue is considered in our model. On the other hand, these requests would lead to the loss of an accurate resource schedule for future booking requests, so we will assume for the following, that there are no open-end requests, instead these have to be formulated as a long-term request with a finite time horizon (Boss et al., 2008).

3 PRICE DETERMINATION

The goal of a provider is to identify the appropriate price to maximize his revenue and satisfy the consumer demand. To give the customer the highest possible flexibility, we will allow every possible hardware configuration based on the given resources $k = 1...K$. This approach can already be observed
in the industry. For example the Enterprise Cloud of terremark\(^1\) has the capability to offer individually configured servers. The user can assemble the desired product by choosing in each case a certain amount of processing power, storage size and memory size.

### 3.1 Scenario

Products are requested over time. Within a product planning period \(T_p\) resources can be planned and allocated at \(t_p = \{0, \ldots, T_p\}\). Every product and thus every resource \(k\) for every point in time \(t_p\), will be offered in different fare classes \(c\). The price differences between classes will be justified with different service levels. For example, the higher valued class A will ensure 99.9\% availability while the lower valued class B will only provide 99\%. Other services may be faster reaction times or higher security specifications like redundancy checks. Following (Bitran and Caldentey, 2003), the connection between price and demand dependent on the time \(t\) will be expressed by the stochastic demand function \(D(t, p, \xi)\) with noise parameter \(\xi\). This assumption implicates myopic customer behavior.

Furthermore, we will not enclose any approach that considers demand between fare classes as dependent. The introduction of probability dependencies like passenger diversion or degradation costs (Botimer and Belobaba, 1999) would make the problem far more complex and too hard to compute. Variable costs of a Cloud Computing center are relatively low. Because servers and computers in general only have a minimal abrasion, the costs of one additional customer can be reduced to the energy consumption costs that increase because of the higher utilization. However, empirical studies have shown that an idle server needs nearly 90\% of the average power consumption (Fan et al., 2007). Thus variable costs will be neglected in this paper. Consequently, with marginal costs being close or equal to zero, the marginal profit equals the turnover and so every sold product will contribute to the gained profit, regardless of the price.

### 3.2 Basic model

A common assumption is that for every time \(t\) there is at most one request from any customer. However, with Cloud Computing services being a time dependent service, the time interval of the offered product has to be predetermined. In the majority of the current business cases these are full hours (e.g. Amazon’s EC2 product). To overcome this problem and to relax this assumption, a second time scale \(t_r = 0, \ldots, T_r\) is introduced. Simultaneously a restriction is required for the number of arriving requests per time interval which will be set to \(R\). Then, the connection between the product planning time \(t_p\) and the request time \(t_r\) can be defined as \(t_r = \left\lfloor \frac{t_p}{R} \right\rfloor = t_p\). Accordingly, the time horizon for the request time \(T_r\) can be formulated as \(T_r = R T_p\). This term allows us, on the one hand, modeling the complex situation and, on the other hand, using the assumption that there is at most one request in every time interval \(\Delta t\) between to sequent points of \(t_r\).

The capacity left for sale in \(t_r\) will be represented by the matrix \(X_{t_r} = (x_{k,t_p}^{t_r})\) for every request time \(t_r\). As we reckon that initial resource capacity \(\Gamma_k\) of product \(k\) will not change over the time horizon \(T_p\), we can define the initial capacity matrix for every resource \(k\):

\[
X_0 = (x_{k,t_p}^0) \text{ with } x_{k,t_p}^0 = \Gamma_k \forall t_p \in \{1, \ldots, T_p\}.
\]

The next important step is to unify a booking request. As we have stated above, the request has to include the amount of desired resources for every possible resource \(k = 1, \ldots, K\). So, we define a vector \(r\) with elements \(r_k\) for every resource \(k\). Additionally, we also need the information about the requested start time \(s \in \{t(t_r)+1, \ldots, T_p\}\) and the duration of the service \(d \in \{1, \ldots, T_p - s + 1\}\). Consequently, every submitted request has to contain the vector \(r\) as well as the variables \(s\) and \(d\). The

\(^1\)http://www.theenterprisecloud.com/
dependency of these variables is expressed in the request matrix $R^{tr}$ for every request time $t_r$ as follows:

$$R_{t_r} = (r_{k,t_p}) = \begin{pmatrix} 0 & \ldots & 0 & r_{1,s} & \ldots & r_{1,s+d-1} & 0 & \ldots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \ldots & 0 & r_{K,s} & \ldots & r_{K,s+d-1} & 0 & \ldots & 0 \end{pmatrix}$$

Let $R^{tp}_{t_r}$ denote the column $t_p$ of $R_{t_r}$. This definition will be important for the model formulation and will even allow requests that have varying resource needs over time. The goal of Revenue Management is to maximize the profit. Therefore, let $V(t|X)$ be the expected revenue at time $t$ and with the state of available resources $X$. Next, we present different models to determine the expected profit.

### 3.3 Static pricing

The first model that we will look at fixes all prices for the whole time horizon. Therefore, it has to set the price vector $p^c = (p^c_0, \ldots, p^c_K)^T$ which contains prices for every resource $k$ for every fare class $c$. Marbach introduced a similar problem which tries to optimize the general static pricing problem for a network service provider. However, they do not consider multiple resources (Marbach, 2004). Because prices are fixed for the whole time, the optimization for the static pricing model has to be done only once, more precisely before the first time interval of the time horizon. To accomplish this task, we have to solve the general optimization problem, depending on the price-response-function $D_c(t, p, \xi)$ for class $c$ like it has been introduced above:

$$\max_{p_k} V_{t_r}(X_{t_r}) = \sum_{t_{p=1}}^{T_p} \sum_{k=1}^{K} \sum_{c=0}^{C} p_k E[D_c(t_p, p_k^c, \xi)]$$  \hspace{1cm} (1)

As long as we do not know anything about $D_c(t, p, \xi)$ yet, we assume that all prices $p_k^c$ are given by the market and we have no possibility to change them at any point.

### 3.4 Bid price model

The bid-price model can be seen as an extension to the static pricing model introduced above (Goldman et al., 2002). They both have in common, that prices for every fare class and for every resource are fixed over the whole time horizon. Consequently, to find optimal prices, a similar optimization problem has to be solved (Williamson, 1992, Talluri and Ryzin, 1998). For every request matrix $R^{tr}$ that arrives at request time $t$, with start point $s$ and duration $d$, we can define the revenue that is gained by accepting this request as

$$\sum_{t_{p=1}}^{s+d-1} (p^c \top R^{tp}_{t_r})$$  \hspace{1cm} (2)

In case the provider would accept a delivered request $R^{tr}$, he will gain the profit like we have just seen, but simultaneously the available resource for the next request time $t, +1$ will lower exactly by the amount of the request to $X_{t_r+1} = X_{t_r} - R_{t_r}$. So, the expected revenue for the remaining capacity $X_{t_r+1}$ will be

$$V_{t_r}(X_{t_r+1}) = V_{t_r+1}(X_{t_r} - R_{t_r}).$$  \hspace{1cm} (3)

However, the provider, who receives a request, does not have very much room for different strategies. He simply has to choose whether to accept or reject an incoming request. The decision is defined by the indicator variable $u \in U = \{0,1\}$ with one for acceptance and zero for rejection. With the preceding formulas, we can formulate the Bellman equation similar to (Talluri and Ryzin, 1998) to find the optimal decision $u^*_{t_r}$

$$V_{t_r}(X_{t_r}) = \max_{u_{t_r} \in U} \sum_{t_{p=1}}^{s+d-1} (p^c \top R^{tp}_{t_r} u_{t_r}) + V_{t_r+1}(X_{t_r} - R_{t_r} u_{t_r})$$  \hspace{1cm} (4)

s. t. $x_{ij} - r_{ij} \geq 0 \forall i, j$
The bid-price approach is very intuitive by comparing immediately realizable revenue with their opportunity costs. Let \( S_k^p = (s_{k,t_p}) \) a \( K \times T_p \) matrix where the element \( s_{k,t_p} \) equals 1 and every other element equals 0. With the assumption that the function for the expected revenue \( V_t(X) \) has a derivative \( \frac{\partial}{\partial x_k} V_t(X) \) for the resource \( k \), the approximated condition for accepting a request for a single resource \( k \) at time \( t_p \) with price \( p_k^c \) is (Talluri and van Ryzin, 2004):

\[
p_k^c \geq V_t(X_{t_p}) - V_t \left( X_{t_p} - S_k^p \right) = \frac{\partial}{\partial x_k} V_t(X_{t_p}) = \pi_{t_p}^k. \tag{5}
\]

Next, (5) has to be extended for a whole request, including start time \( s \), duration \( d \) as well as multiple resources \( k \). This simply can be done by summing up all relevant prices for the requested fare class \( c \) and comparing it with the total sum of all relevant bid-prices for the given request. This approach allows us to compensate resources that may be sold under value with ones that will be sold for a higher price than expected. For pre-calculated bid-prices vectors \( \pi_{t_p} = (\pi_{t_p}^1, \ldots, \pi_{t_p}^K) \) we can reduce the necessary inequality that a request for fare class \( c \) has to satisfy to

\[
\sum_{t_p=s}^{s+d-1} p^c T_{t_p} \geq \sum_{t_p=s}^{s+d-1} \pi_{t_p}^c R_{t_p}^f . \tag{6}
\]

This condition ensures that the provider will only sell resources in fare classes that at least gain the revenue that he is expecting to gain. Consequently, an incoming request should be accepted if and only if the inequality (6) is fulfilled. We can formulate the optimal decision function as

\[
u^*_r = \begin{cases} 1 & \text{if (6) is satisfied and } x_{k,t_p}^r - t_{k,t_p}^r \geq 0 \forall k, t_p \\ 0 & \text{otherwise.} \end{cases} \tag{7}
\]

Because we only know the actual request at time \( t_r \) we cannot directly use the recursive definition of (4). Instead, we have to find a heuristic that uses another method to get the expected revenue of any remaining capacity \( X \). In turn, the knowledge of the expected revenue together with (5) will enable the calculation of every necessary bid-price \( \pi_{t_p}^k \).

For the following, we want to present one of several possibilities to value a certain state \( X \) of the available resources \( k \). In any case, we need to model the expected demand to say anything about the valuation of the resources that are left. Thus, a demand function \( D(k, t_p) \) is required that will return the estimated demand for resource \( k \) at time \( t_p \). However, the valuation cannot exceed the available capacity stored in the vector \( X_{t_p}^r \), and the demand function has to be adapted by

\[
D(k, t_p) = \min \left[ \bar{D}(k, t_p), x_{k,t_p}^r \right]. \tag{9}
\]

Let \( p_k^f(C | C = c) \) the probability of any demand for resource \( k \) at time \( t_p \) to equal fare class \( c \) considering that higher valued classes have to be handled primarily to the disfavor of the lower valued ones. The expected revenue can be calculated by

\[
V_t(X_{t_p}) = \sum_{t_p=t_1(t_r)+1}^{T_p} \sum_{k=1}^{K} \sum_{c=0}^{C} p_k^c D(k, t_p) P_k^f(C | C = c) \tag{10}
\]

s.t. \( \sum_{c=0}^{C} P_k^f(C | C = c) = 1 \forall k \).
### Algorithm 1 Transform $\tilde{D}(c)$ to observe capacity restrictions

**Require:** expected demand $\tilde{D}(c)$ for fare class $c$

**Ensure:** expected demand $D(c)$ under capacity restrictions

1. $X \leftarrow$ capacity left
2. for $c = 0$ to $C$
   1. if $X > \tilde{D}(c)$ then
      1. $D(c) \leftarrow \tilde{D}(c)$
      2. $X \leftarrow X - D(c)$
   2. else
      1. $D(c) \leftarrow X$
      2. $X \leftarrow 0$
3. endfor

### 3.5 Dynamic pricing

The following Pricing Model does not try to derive a benefit from denying requests for lower valued fare classes, instead it attempts to adjust prices for every fare class. Consequently, we can increase the price for a product to maximize profits rather than just limiting the capacity of a product and leaving the rest of the demand unused. The intuitive issue behind this approach is that fluctuations in demand can be compensated while simultaneously increasing revenues.

The frame of the optimization problem is very similar to the bid-price model of the preceding section. However, the big difference will be the variable that we are going to optimize. In both preceding models we had to decide whether to accept an incoming request or not, what was represented by the decision variable $u$. In this case, we will primarily accept any incoming request that will not exceed our remaining capacity, but we will influence demand by adapting the price. Consequently, the variable that we have to optimize is the price for every fare class $c$. As we will not allow every real number as a possible price for a fare class $c$, we assume that we have to select one element of the set $\mathcal{P}_{c,k}$, which contains all possible prices for fare class $c$ and product $k$. The use of such a discrete set is very common in business practices. Especially conventional retailing industries often use price steps of at least one full monetary unit or in higher price regions even steps of integer multiples of those (Talluri and van Ryzin, 2004).

The difference to static pricing models is that we have to know something about the relation of price and demand to solve most optimization problems. Since we do not know the exact price-demand function, we assume that we have such a function $\tilde{D}(k, t_p, c)$ which returns the demand dependent on the price $p$. Analogous to the bid-price model, we have to transform this function with the algorithm 1 or with (9) to fulfill capacity restrictions. A probability distribution has to distribute the demand to the different fare classes (similar to the bid-price model). The revenue calculation also has to be slightly changed to include the price dependent demand function and different prices for every time interval. So the optimization problem that has to be solved is $\max_{p \in \mathcal{P}_{c,k}} p \cdot D(k, t_p, c)$. As this optimization problem has to be done for every resource $k$, fare class $c$ and planning time $t_p$, we can formulate the Bellman equation that will recursively return the expected revenue:

$$V_{t_r}(X_r) = \sum_{t_p=s}^{s+d-1} \sum_{k=1}^{K} \sum_{c=0}^{\mathcal{P}_{c,k}} \left( \max_{p \in \mathcal{P}_{c,k}} p \cdot D(k, t_p, c, p) \right) + V_{t_{r+1}}(X_r - R_{t_r}). \quad (11)$$

There are still two practical problems to directly use this term: On the one hand, we have to know or approximately assume a specific relation between price and demand. On the other hand, it is obvious that this calculation will be very complex, as we have to solve at least $d \cdot (C + 1) \cdot K$ different optimization problems and we still do not know the valuation of the future time period $t_{r+1}$. Therefore, we want to present a heuristic that will adjust prices depending on the variables $k$, $c$ and $t_p$. This heuristic will calculate a parameter $\gamma$ for every resource $k$, time $t_p$ and fare class $c$ by setting a
specific relation between the expected demand $D(k, t_p, c)$, the capacity left $x_{k,t_p}$ and the time that is left until the requested start time $s - t_r(t_r)$:

$$
\gamma(k, t_p, c) := \frac{\text{Expected Demand}}{\text{Capacity Left}} \ln(\text{Time To Go}) = \frac{D(k, t_p, c)}{x_{k,t_p}} \ln(s - t_r(t_r)).
$$

We assume that every parameter $\gamma(k, t_p, c)$ is positively correlated to the valuation of the customers and can serve as an approximation for the price-demand relation that we still do not know. Let $P_{c,k} = \{\hat{p}_{c,1}^k, \ldots, \hat{p}_{c,P}^k\}$ the set of possible prices for fare class $c$ and resource $k$ with the ascending order $\hat{p}_{c,1}^k > \hat{p}_{c,2}^k > \cdots > \hat{p}_{c,P}^k$. We can define the function

$$
p(k, t_p, c) := \begin{cases} 
\hat{p}_{c,1}^k & \gamma(k, t_p, c) > \tau_1(k, c) \\
\hat{p}_{c,2}^k & \tau_1(k, c) \geq \gamma(k, t_p, c) \geq \tau_2(k, c) \\
\vdots & \\
\hat{p}_{c,P-1}^k & \tau_{P-1}(k, c) \geq \gamma(k, t_p, c) \geq \tau_P(k, c) \\
\hat{p}_{c,P}^k & \text{otherwise}. 
\end{cases}
$$

(13)

to get the proper price for resource $k$, time $t_p$ and fare class $c$ with the threshold values $\tau_i(k, c) \forall i \in \{1, \ldots, P\}$. We assume that all $\tau_i(k, c)$ will be defined manually at the beginning of our time horizon, primarily based on empirical knowledge. A possible orientation might be the expected value of the parameter $\gamma(k, t_p, c)$, so every $\tau_i(k, c)$ might be expressed as

$$
\tau_i(k, c) := \alpha_i E[\gamma(k, t_p, c)]
$$

(14)

with the freely chosen real multiplier $\alpha_i > 0$ and the expected value $E[\gamma(k, t_p, c)]$ of $\gamma$ for every $t_p$.

4 Evaluation

4.1 Scenario

As requirements mostly cannot be foreseen even by the customers, we will only allow requests for a fixed amount of every resource $k$ for a certain time period $\Delta t = d$. Forecasting of future demand and utilization are essential for overbooking decisions in the specific Cloud Computing case. Since this task is not in the focus of this paper, so some relatively simple, but intuitive approaches will be applied. Demand is independently distributed over time, so a very intuitive step is to use historic demand data to estimate future demand. To eliminate smoothing effects, not all the historical data will be considered, but a limitation to the last $r$ values. In this case, the historical data consists of the observed demand $D(k, t, c)$ for product $k$, time $t$ and fare class $c$. The expected demand at the request time $t_r$ for every future time $t_p \geq t_r(t_r)$ can be expressed as

$$
D_{t_r}(k, c) = \frac{1}{N_D} \sum_{t=t_r-N_D}^{t-r-1} D(k, t, c)
$$

(15)

where the last $N_D$ values of the observed demand are taken into account. The variable $N_D$ might be increased for a smoother demand forecasting or decreased for a quicker adaptation to market changes.

For utilization, we will assume that the utilization behavior will change over the time of day, while the progress will be similar from day to day. For overbooking decisions in a Cloud Computing environment, we have to set some kind of a service level which indicates that how many resources may be additionally sold. Let $\bar{U}_n(t, k)$ the recognized usage of customer $n$ for the product $k$ at time $t$. With $N_D$ last values and resource $k$, we can define the average value and the variance of the past utilization as

Proceedings ECIS 2009
With a predefined service level $SL$ and the assumption that the utilization of every product follows a normal probability distribution, we can solve the following equation and adapt the available capacity accordingly to ensure that we can provide our services with the probability of $SL$:

$$P(\hat{u} \leq SL) = \int_{-\infty}^{\infty} \frac{1}{\sigma_{k,t,r} \sqrt{2\pi}} e^{-\frac{1}{2} \left( \frac{t - \mu_{k,t,r}}{\sigma_{k,t,r}} \right)^2} dt \leq SL$$  \hspace{1cm} (17)

We have already defined the behavior of the sellers by formulating the different pricing models above, but furthermore, we have to explicitly determine the buyers’ behavior. We will implement two different types of buyers, namely short term buyers who tend to request the product last-minute and long term buyers who are more likely to reserve earlier (Shen and Su, 2007). The amount of delivered workloads over the course of a day is modeled according to (Calzarossa and Serazzi, 1985).

### 4.2 Simulation results

The first simulation set tested the performance of each seller in a monopolistic environment under different demand situations (e.g. 10 short-term buyers). The planning horizon $T_p$ of every seller has been set to 1500 what approximately equals two month when one tick is considered as a full hour. While providers have no information about demand and utilization at the beginning of each simulation run, the first ticks are not very representative, so only the time span from 300 to 1020 has been considered for the evaluation. This time span contains 720 ticks or hours what equals one month. For utilization and demand forecasting, parameters have been set to $ND = 50$, $NU = 5$ and $SL = 99.5\%$. Three possible fare classes were defined with the price vector $p_1^c$ used by the static and bid-price seller for resource 1 (Table 2). Other resources are adapted according to the relation used in the Amazon EC2. In contrast to the other models the dynamic seller needs to have a price matrix which includes prices for every resource and fare class. For the simulation, the prices have been chosen in accordance with the prices for the static models with additional ones below and above. Additionally, the threshold values $T$ have to be set to define price change behavior for every price class $c$ and resources $k$ (Table 3, setting I).

![Figure 1](https://example.com/figure1.png)  \hspace{1cm} (a)

**Figure 1.** Utilization and revenue of a dynamic provider facing 20 short and 5 long term customer for 100 timeslots (excerpt for $t = \{300, \ldots, 400\}$) (Figure a) and difference between simulation setting I and II (Figure b).
It can be observed that the dynamic seller performs particularly well in cases where demand is high. Even when demand is low, the dynamic seller achieved some acceptable outcome. The worst case, when there were only ten short term buyers, the dynamic seller had only 3.0 % lower revenue than the static seller. In the best case, he even gained 78.9 % more revenue. Also the bid-price seller performed surprisingly good and achieved as expected always higher revenue than the static seller, even when demand was low. In these cases, he even outran the dynamic seller (Figure 4a). It can be summarized that both revenue management adaptations performed very solid in the monopolistic environment and managed to significantly increase revenues in nearly any cases. However, the threshold values \( \tau \) for the dynamic seller have been adjusted on simulation results. When we chose to slightly change these values for every price class \( c \) and resources \( k \) (Table 3, setting II), the dynamic seller behaves different and results in considerably decreased revenues in most cases (see Figure 1b). Consequently, an optimally or nearly optimal adjustment of the dynamic seller has to be done what may be difficult and expensive to achieve in some cases. Figure 1a illustrates the utilization and revenue trend of a dynamic seller. The time period is exemplarily set to 300...400. We can also observe how the utilization over the time of day changes.
CONCLUSION

Cloud providers like Amazon, Google or Rackspace have to consider to whom which products are offered at a certain time to increase revenue, when resources are scarce. Future incoming requests are oftentimes unpredictable. Revenue Management concepts enable to implement a decision policy to accept or reject requests and to influence the behavior of the consumers. Price sensitive consumers will shift their demand to low-demand time, when prices are low as well. Depending on the utilization of his resources the provider can set prices or decide about accepting a request.

At first we analyze if revenue management requirements are fulfilled by a Cloud Computing scenario. The scenario comprises several products using the same pool of multiple resources. Then, we compare dynamic pricing and bid price control according their revenue outcome. In contrast to traditional Revenue Management approaches, we used a matrix to interpret a request and introduced a second time scale which allows multiple requests in one interval of the planning horizon. The proposed model allows the service providers to decide about accepting or rejecting incoming service requests based on expected revenue, expected demand and a given set of resources.

In future, the modeling of buyer according to the customer choice behavior is an interesting challenge. Then, dependencies between fare classes have an impact on the revenue. Customers, who are not allocated, could probably decide to change to a higher fare class which increases the revenue. Furthermore, the bid price as well as the dynamic algorithm can be optimized by more complex heuristics and learning algorithms.

Abstract

Market mechanisms are deemed promising for distributed resource allocation settings by explicitly involving users into the allocation process. The market considers the users’ and providers’ valuations to generate efficient resource allocations and prices. In theory, valuations are assumed to be known to the user. In practice, however, this is not the case. It is a complex burden for both users and providers to assess their true valuation for a certain combination of resources and services and to efficiently communicate this valuation to the market.

This paper contributes to the theory of designing distributed allocation models in that (i) we propose a model for preference elicitation, which allows users and providers to assess their valuations as a function of their resource requirements and strategic considerations, (ii) we show how this model can be encoded within so-called bidding agents which interact with the market on behalf of the user, and (iii) we evaluate our approach in a numerical experiment to illustrate how the bidding agent adapts to the dynamic market situation. As this evaluation shows, the model outperforms technical schedulers and can thus be used for decision support in electronic markets.

Keywords: Distributed Resource Allocation, Preference Elicitation, Automated Trading.
1 INTRODUCTION

In recent times, enterprises have been facing increased pressure to host resource-demanding applications that exhibit fluctuating utilization patterns. At the same time they are forced to provide flexible infrastructures at low cost. A meta-study by IT critic Nicholas Carr (2005) revealed that enterprises only utilize on average 40-50% of their data centres’ storage capacity and only 10-35% of their available processing power.

Grid and cluster technologies help enterprises deal with this dilemma. Enterprises no longer need to build up vast server farms in order to be able to serve few peak loads on their system. Instead, they only need to accommodate the basic load and tap into external computing, storage and application services on demand. The possible cost savings have been estimated to amount to 30% of total IT spending (Minoli 2004). Such grids can be located within enterprises to serve the various business units and departments, or spread across organizational boundaries to allow for dynamic resource (re-) allocations across enterprises. Prominent examples for the industry take-up of grid technology are the initiatives of Sun Microsystems, Google, IBM and Amazon. With its network.com platform, Sun offers computing resources for a fixed price of $1 per CPU hour. With Amazon’s Elastic Compute Cloud (http://aws.amazon.com/ec2) and its Simple Storage Service (http://aws.amazon.com/s3), users can configure virtual servers and remotely run their applications and store their data on Amazon’s infrastructure, only paying for what they use.

However, so far only few customers have adopted these offers. While Sun and Amazon both employ fixed pricing schemes, there is doubt whether this static model can adequately deal with the dynamic nature, which is inherent to grids as demand and supply are highly fluctuating. With fixed prices, users cannot express their priorities (i.e. valuations) for resources, thus leading to inefficient allocations and unrealized profit (Lai 2005).

Market mechanisms are deemed promising to provide a better fit to this dynamic setting by explicitly involving users into the allocation process. The market considers the users’ and providers’ valuations in order to generate efficient resource allocations and prices. Consequently, the market takes the responsibility of producing prices, which reflect the true scarcity of resources by adequately matching demand and supply. While market mechanisms exhibit compelling features, two important building blocks are missing which hampers their practical use: preference elicitation and automated bidding. It is a complex burden for both users and providers to (i) assess their true valuation for a certain combination of resources and services and to (ii) efficiently communicate this valuation to the market.

While we focus on grid settings, our results are fundamental for all market-based business relationships, where users have to formulate bids. Literature frequently assumes that the preferences are fully known to the user. We will relax this strong assumption by proposing a model for preference elicitation. As such, this paper contributes to the theory of designing distributed allocation models in that

- We propose a model for preference elicitation, which allows users and providers to assess their valuations as a function of their resource requirements and strategic considerations.
- We show how this model can be encoded within so-called bidding agents, which interact with the market on behalf of the user.
- We evaluate our approach in a numerical experiment to illustrate how the bidding agent adapts to the dynamic market situation and how even fuzzy approaches can lead to more efficient allocations than technical schedulers.

The paper is structured as follows. In Section 2, we briefly discuss previous work on preference elicitation and automated bidding. Subsequently, we introduce the tasks of a bidding agent and existing approaches to preference elicitation from the marketing research domain in Section 3. In Section 4, we present our model which illustrates one approach for how such bidding agents can combine preference elicitation and trading protocols to dynamically adapt to the situation on the market. Clearly, this model represents just one approach; others are also possible. Thus, we need to thoroughly evaluate our approach via numerical experiments. This evaluation is covered in Section 5, where we present a sample market mechanism and
show the interdependency between the mechanism, the competition in this market, and the bidding agent’s behaviour. Section 6 summarizes the paper and points to future research directions.

2 RELATED WORK

As pointed out in the introduction, we combine two aspects of the interaction between human users and the market for resources and services: preference elicitation and automated trading. Probably the largest body on preference elicitation stems from the domain of combinatorial auctions (cf. Conen and Sandholm 2001, Zinkevich et al. 2003, Parkes 2005, Nisan and Segal 2005). However, this previous work focuses on a separate issue: If users know their valuation, but communication between the users and the market is costly, how to efficiently query users for their valuations given the specific structure of the underlying allocation problem. This problem is inherent to combinatorial auctions, where the user has to submit valuations for all \(2^n-1\) possible bundles which can be composed of \(n\) goods. Different from this literature, we use the term preference elicitation to denote the users’ problem of determining their true valuation, i.e. questions such as “What am I willing to pay for using a server with application X, a dual-core processor and 2 GB of memory for one hour?” There is currently not much research available in this area, which is surprising as it is a prerequisite for any market-based approach.

Preference elicitation has been widely studied in the area of decision / negotiation support systems, where participants have to decide about their preference for an alternative or a good that is specified by multiple attributes. Typically, Multi-Attribute Utility Theory (MAUT) is used to aggregate the single attributes’ values to an overall score or ranking (e.g. Bichler and Kaukal 1999). In MAUT, the negotiator’s utility function is modelled as the weighted sum over the attributes’ utility levels. In the INSPIRE (Kersten and Noronha 1999) and NEGOISST (Jertila and Schoop 2005) negotiation systems, a so-called hybrid conjoint analysis is applied (Green and Krieger 1996) to determine the attributes’ relative importance. We defer a detailed discussion of conjoint analysis to Section 3.1. Vetschera (2007) investigates whether the preference structure of negotiators has an impact on their behaviour and the ultimate outcome.

Similar to our approach, Byde et al. (2003) also try to combine the problems of determining the value for specific resources and of allocating these scarce resources via markets in an automated manner so as to maximize the overall system value. In their setting, a utility centre operator has signed (long-term) service level agreements with various users and now has to decide how to serve these requests based on its actual situation. Byde et al. (2003) do not introduce bidding agents on the users’ side, but solely on the provider’s side. Each service request is represented by an application agent and a business agent. The application agent is responsible for monitoring and predicting the applications resource consumption. The business agent then translates this prediction into an estimated business value (from the provider’s perspective) based on the underlying service level agreement, agreed metrics, penalties, rewards etc.

MacKie-Mason and Wellman (2006) study the automation of the user-market interaction by means of trading agents. By equipping users with such (at least partially) automated tools, the communication with the market can be drastically simplified since human users do not constantly need to monitor the market outcome and update their requests. One prominent outcome of this research is the TAC trading agent competition (www.sics.se/tac/) where research teams compete in designing trading agents for a specific market mechanism.

In summary and to our best knowledge, hitherto there has been no research that tries to combine the issues of preference elicitation and automated trading from the user’s perspective in an auction context.

3 PREFERENCE ELICITATION

We propose the use of bidding agents that essentially have three levels of “intelligence”:

1. **Prediction of resource demand**: The bidding agent learns the technical requirements of the grid application. This information could either be static, e.g. the user could manually configure the agent with the required amount of processing power, memory, and storage. But the agent could also dynamically adapt
its information, e.g. by estimating the resource requirements based on historical information using statistical methods (Degermark et al. 1997, Smith et al. 1998).

2. **Preference elicitation**: The bidding agent estimates the user’s valuation for a specific application and combination of resources. This will be the core of this paper.

3. **Automated bidding**: The bidding agent interacts with the market in an automated fashion in order to obtain the right resource level – possibly according to a workflow of tasks – and considering the current market situation to achieve the best possible price.

The agent can then use information about the market outcome and the application’s resource consumption to refine its estimates. For example, after the market has cleared, the agents can refine their bidding strategies. Furthermore, the user could review the bidding agent’s preference elicitation by rating its accuracy, and the agent can compare the applications resource consumption with its prediction.

While we will focus on bidding agents for users in the remainder, note that the same principles can be applied to design bidding agents for the provisioning side of the market. We model our setting as a multi-attribute combinatorial allocation problem. A grid application is typically characterized by multiple attributes, such as the required amount of CPU, memory, storage, bandwidth, software libraries etc. The application can only be run if all such required resources are obtained in the right quality (Schnizler et al. 2008, Subramoniam et al. 2002).

More formally, we assume that an application $A$ can be characterized by a finite set of attributes $X^A = (X^A_1, X^A_2, ..., X^A_n) \in \mathbb{N}^n = \Omega$, where $\Omega$ is the space of possible application profiles.

**Multi-attribute valuation function**: Let application $A$ be characterized by the finite set $X^A$ of attributes. Then the user’s valuation $v^A$ of user $i$ for this application $A$ is a function $v^A: \Omega \rightarrow \mathbb{R}$ with

\[
v^A(x) = \begin{cases} 
> 0, & \text{if } x_j \geq x_j^A, j = 1, ..., n \\
= 0, & \text{else}
\end{cases}
\]

In the following, we will assume that the bidding agent has some estimate of application $A$’s resource profile $x^A$, and we will focus on the preference elicitation and the automated bidding as well as the iterative refinement of the estimated user valuations.

The bidding agent essentially faces two decision or learning problems:

- What is user $i$’s valuation function?
- How should the agent interact with the market to obtain the resource set $x^A$ so as to maximize its user’s benefit?

In this section, we will discuss several preference elicitation approaches which can be used to estimate a user’s valuation for a specific application and a combination of attributes.

3.1 **Conjoint Analysis**

Conjoint analysis has its roots in the 1960’s and 70’s and has become the most widely used technique in marketing research to measure consumer preferences (Luce and Tukey 1964, Green and Rao 1971, Marder 1999). Conjoint analysis allows to ask the user “What if” questions. The technique begins by defining the number of attributes and possible values, so-called “attribute levels”. The aim of the conjoint analysis is to estimate the user’s value for each attribute. The analysis essentially creates a number of attribute combinations and attribute levels, so-called “profiles” (e.g. specific products), and asks the user to evaluate these profiles, e.g. by ranking or rating the profiles. For instance, a computing server may have the attributes CPU, memory, and bandwidth. Conjoint analysis would then generate specific server profiles, e.g. (price/hour, CPU, memory, bandwidth) = ($1, 2, 2 GB, 10 MB/s), ($2.5, 4, 3 GB, 100 MB/s) etc.

The key to conjoint analysis is the “partitioning assumption” (Marder 1999), which refers to the aggregation of the values for the attribute levels makes up the user’s value for a specific profile. To simplify the analysis, one possibility is to follow the approach by Keeney and Raiffa (1976) and to use
additive independent valuation functions, where each resource (attribute) represents an additive term multiplied by a scale factor which encodes the relative importance of this resource attribute in comparison to the other resource attributes:

Additive independent valuation function: The attributes $X_1^A, \ldots, X_n^A$ are mutually independent and $v^A$ can be written as

$$v^A(x) = \begin{cases} \alpha_1^A x_1 + \alpha_2^A x_2 + \cdots + \alpha_n^A x_n, & \text{if } x_j \geq x_j^A, j = 1, \ldots, n \\ 0, & \text{else} \end{cases}$$

with scale factors $\alpha_j^A \in \mathbb{R}, j = 1, \ldots, n$.

Conjoint analysis estimates the user’s value for a certain attribute level by performing regression analyses on the user’s feedback to the presented attribute profiles.

The main drawback of this method is that the full-profile method presents all possible profiles to the user, which is clearly infeasible already for small numbers of attributes and attribute levels. Thus, as pointed out above, especially negotiation support systems employ hybrid and adaptive models, which restrict the number of profiles and mathematically determine the best profiles to present to the user (Green and Krieger 1996). Moreover, conjoint analysis relies on the partitioning assumption to be able to link the user’s evaluation of the profile to the valuations for the individual attributes. But it is problematic to assume a common relationship between the overall profile and the attributes across all users.

3.2 Analytical Hierarchy Process

In contrast to the conjoint analysis method which aims at determining the value of a certain attribute, the analytical hierarchy process tries to determine the relative importance of a certain attribute among a set of attributes (Saaty 1980). The user has to compare the relative importance of attributes in a pairwise manner based on a predefined scale from 1, 3, ..., to 9 (and $1/3, \ldots, 1/9$ respectively), e.g. “CPU is 3 times as important as memory”. Ultimately, a matrix is generated containing all pairwise comparisons, from which a vector with the various attributes’ relative importance is computed, e.g. (CPU, memory, bandwidth) = $(\frac{1}{2}, \frac{1}{3}, \frac{1}{6})$. Saaty has also proposed a method to check the consistency of the user’s comparisons based on the matrix’s eigenvalue.

The analytical hierarchy process suffers from the large number of pairwise comparisons that the user has to perform to generate the matrix from which the relative weights are computed. With $n$ attributes, the user essentially has to do $n - 1$ comparisons. Furthermore, while the method ultimately gives the relative weights of the attributes, the question remains about the value of a specific combination of attributes.

In summary, both conjoint analyses and the analytical hierarchy process are not appropriate for practical auction-based settings with a large number of attributes and attribute values and frequent trades. Furthermore, they depend on the assumption about a specific structure of the user’s valuation function, e.g. an additive independent valuation function, which seems somewhat arbitrary.

4 THE MODEL

Thus, we propose to take an evolutionary approach. This approach is based on the assumption that a consumer who wants to buy some good does generally not exactly know his valuation for this good, i.e. if asked, the user would not be able to state a valuation. Instead, the user only has a rough estimate of his own true valuation. That is, when the consumer is confronted with an offer and a specific price, he decides whether to accept the given price, or to continue his search and look for alternative offers.

We adopt a similar approach in that the user initially indicates the request’s priority, e.g. “high”, “medium” or “low”. After each market clearing, the agent presents the results to the user, and the user may indicate whether he is satisfied with the outcome or not. Based on this user feedback, the agent iteratively updates...
its estimate of the user’s valuation. So step by step, the agent approximates the results of a full-profile conjoint analysis and successively refines its estimates.

The evolutionary preference elicitation process goes as follows:

1. **Initialization:** In contrast to presenting all possible profiles to the user a priori, the agent initially assumes a valuation $v^A_0$ for application $A$ based on the application’s resource specification $x^A$, the current price for each resource which is published by the market mechanism in a price vector $p_0 \in \mathbb{R}_{+}^n$, and an initial priority $\theta^A_0 \in \mathbb{N}$ set by the user: $v^A_0(\theta^A_0, p_0, x^A) = \theta^A_0 p^T_0 x^A$.

If the price is only published for a bundle of resources, we assume that the market imputes and publishes prices for the individual resources (cf. Xia et al. 2004).

For example, a given application $A$ requires 2 CPUs and 1 GB of memory for one minute, i.e. $x^A = (CPU, Memory, Runtime in mins)$ and $x^A = (2, 1, 1)$. CPU has last been traded for $1 per hour, consuming 1 GB of memory for one hour cost $2. The user indicates a medium priority $\theta^A_0 = 2$. The bidding agent then initiates its estimate of the user’s valuation for this task as $v^A_0(\theta^A_0, p_0, x^A) = 2 \cdot \left( \frac{51}{60} \cdot 2 + \frac{32}{60} \cdot 1 \right) \approx 0.133$.

This naïve approach might be extended by applying case-based reasoning (Hu and Haddawy 1998) or neural networks (Haddawy et al. 2003).

Subsequently, for each run $j$ of the application:

2. **Bidding:** The agent bids on the market according to its estimate $v^A_j(\theta^A_j, p_j, x^A)$ and some bidding strategy.

3. **Refinement:** There are two possible outcomes of the bidding process:
   a. **Successful:** The agent obtains the necessary resources at an overall price $p_{j+1}^T x^A = \sum_{i=1}^{n} p_{j+1,i} x^A_i \leq v^A_j$, and reports this information to the user. The user then indicates whether he is satisfied with the outcome or not, and the agent refines its estimate.

   If the user indicates that he was satisfied with this price ($\theta^A_{j+1} = 1$), the agent does not update its estimate.

   If the user indicates that the price was too high ($\theta^A_{j+1} = 0$), the agent updates its estimate of $v^A$ according to some update factor $\rho \in [0, 1]$:

   $$v^A_{j+1}(\theta^A_{j+1}, p_{j+1}, x^A) = \begin{cases} v^A_j(\theta^A_j, p_j, x^A), & \text{if } \theta^A_{j+1} = 1 \\ \rho p_{j+1}^T x^A, & \text{if } \theta^A_{j+1} = 0 \end{cases}$$

   b. **Unsuccessful:** The agent was not able to obtain the necessary resources at a price $p_{j+1}^T x^A = \sum_{i=1}^{n} p_{j+1,i} x^A_i \leq v^A_j$.

   If the user indicates that the price was indeed too high ($\theta^A_{j+1} = 1$), the agent does not update its estimate. If the user indicates that he would have preferred to pay that price rather than not getting the resources ($\theta^A_{j+1} = 0$), the agent updates its estimate of $v^A$ with the current price:

   $$v^A_{j+1}(\theta^A_{j+1}, p_{j+1}, x^A) = \begin{cases} v^A_j(\theta^A_j, p_j, x^A), & \text{if } \theta^A_{j+1} = 1 \\ p_{j+1}^T x^A, & \text{if } \theta^A_{j+1} = 0 \end{cases}$$

In our example, assume the agent was able to obtain the resources at a (total) price of $p_1 = $0.08 < $0.133 = v^A_0$ and the user indicated that this price was too high (Case a and $\theta^A_1 = 0$). Then the agent updates its estimate to $v^A_1(\theta^A_1, p_1, x^A) = 0.9 \cdot $0.08 = $0.072$ for an update factor of $\rho = 0.9$. 

Proceedings ECIS 2009
The agent will iteratively try to converge its estimate to the user’s true valuation and at the same time assist the user in identifying that valuation by presenting the user a series of simpler decision problems rather than forcing the user to directly reveal his valuation.

It is important to note that this approach does not depend on any assumption about the structure of the user’s valuation function. But similar to conjoint analysis and the analytical hierarchy process, one critique may be that the user still needs to give feedback to the agent. But obviously such feedback loops cannot be avoided if the agent is to at least approximate the user’s true valuation. However, we hypothesize that the agent can already obtain a good estimate with just a few such feedback loops. It will be an interesting question for future research if this assumption is valid, and if so, how many feedback loops are required to obtain a “good” estimate.

5 EVALUATION

As pointed out above, we hypothesize that grid users will generally not be able to state an exact number if asked for their valuation for a certain application. Instead, users will only approximate this valuation over time with the bidding agent’s assistance. This inherently precludes a “hard” evaluation of the proposed evolutionary approach to preference elicitation, as we cannot simulate this process. However, we will evaluate two complementary aspects of grid markets:

- We will show that the use of grid markets leads to efficiency gains over simple technical schedulers, even if the bidding agent uses a simple rule for initializing its estimate about the user’s valuation as presented above.
- We illustrate for a sample setting how the bidding agent strategically misreports the user’s (estimated) valuation so as to maximize its user’s benefit.

Of course the market outcome and the agent’s behavior depend on the actual market mechanism. Thus, before we turn to our analysis, we will briefly introduce a sample mechanism.

5.1 The Market Mechanism

The following mechanism has been proposed by Stößer et al. (2007) and is tailored towards usage in grids (Amar et al. 2007). Market mechanisms essentially consist of three elements: the bidding language which determines how users and providers specify their resource requests and offers, the allocation scheme which assigns resource requests to offers, and the pricing scheme which determines corresponding payments.

5.1.1 The Bidding Language

A user \( j \) who would like to submit a computational job to the grid system reports the job’s characteristics \( (v_j, c_j, m_j, s_j, e_j) \) to the market mechanism where \( v_j \in \mathbb{R}_+ \) denotes \( j \)'s valuation (i.e. \( j \)'s maximum willingness to pay) per unit of computing power and time slot, \( c_j \in \mathbb{N} \) and \( m_j \in \mathbb{N} \) the minimum required amount of computing power and memory respectively, and \( s_j \in \mathbb{N} \) and \( e_j \in \mathbb{N} \) specify the job’s estimated runtime (start and end). We require the market mechanism to make atomic allocations in the sense that each job can only be executed if there are sufficient resources available in all requested time slots. Furthermore, jobs can potentially be migrated between several compute nodes over time but each job can only be executed on one node at a time.

A provider \( n \) who would like to contribute a compute node to the grid system reports the node’s characteristics \( (r_n, \bar{c}_n, \bar{m}_n, \epsilon_n, \lambda_n) \) to the market mechanism where \( r_n \in \mathbb{R}_+ \) specifies this node’s (pretended) reservation price per unit of computing power and time slot, \( \bar{c}_n \in \mathbb{N} \) and \( \bar{m}_n \in \mathbb{N} \) the maximum amount of computing power and memory available on this node, and \( \epsilon_n \in \mathbb{N} \) and \( \lambda_n \in \mathbb{N} \) the time frame during which the node can be accessed. Given sufficient resources, we assume that each node is able to execute multiple jobs in parallel.
5.1.2 **The Allocation Scheme**

The objective of the market is to generate efficient resource allocations. This can be modelled as a combinatorial allocation problem as proposed in Stößer et al. (2007). However, due to the resulting computational complexity, Stößer et al. (2007) propose a greedy heuristic as follows:

1. The resource requests are sorted in non-ascending order of their valuations \( v_j \). Resource offers are sorted in non-descending order of their reservation prices \( r_n \).

2. The heuristic loops over the ranked list of requests and successively constructs a feasible allocation schedule by assigning the requests with the highest valuations to the cheapest offers.

5.1.3 **The Pricing Scheme**

Subsequently, the allocation schedule generated by this heuristic needs to be complemented by corresponding prices. K-Pricing was introduced in Schnizler et al. (2008). The basic idea is to distribute the welfare generated by the allocation algorithm between users and resource providers according to a factor \( k \in [0,1] \). For instance, assume an allocation of resources from a specific provider to a specific user. The user values these resources at \$10\) while the provider has a reservation price of \$5\). Then the (local) welfare is \$10 - \$5 = \$5\) and \( k \cdot \$5\) of the surplus is allotted to the user – thus having to pay \$10 - k \cdot \$5 – and \((1 - k) \cdot \$5\) is allotted to the provider – thus receiving \$5 + (1 - k) \cdot \$5\). Besides allowing for fairness considerations, the main advantage of K-Pricing is that it can be determined in polynomial runtime. On its downside, however, it only yields approximately truthful prices and payments on both sides of the market, i.e. users and providers may benefit from misreporting their valuations.

5.2 **Data Generation**

The problem with numerical evaluations of grid markets is that there is no log of real-world workloads which contains all parameters according to our bidding language specified above, in particular as regards the users’ valuations. We thus created synthetic workloads using the distributions specified in Table 1, which is in line with Feitelson (2002).

<table>
<thead>
<tr>

*Table 1.* Distributions used for generating the synthetic workloads.

We analyze four settings with varying degrees of competition: 20 requests and 20 offers, 40 requests and 20 offers, 60 requests and 20 offers, and 80 requests and 20 offers. For each of these four settings, we generated 200 problem instances. In the remainder, we will report the averages across these 200 runs to account for stochastic outliers.

5.3 **Data Analysis**

5.3.1 **Efficiency Gains from Preference Elicitation**

In this subsection, we analyze the performance of our preference elicitation scheme with respect to allocative efficiency, which is defined as the aggregated utility across all users and providers: How well does our preference elicitation scheme perform (i) compared to the market mechanism presented in
Subsection 5.1 if users know their valuations and truthfully submit these to the mechanism and (ii) compared to a technical scheduler which does not consider user preferences? As mentioned above, it is not possible to evaluate our iterative preference elicitation approach as such. Instead, we will evaluate the initialization step in which the agent estimates the user’s valuation based on the application’s resource requirements, current market prices, and a fuzzy priority assigned by the user.

We configure the bidding agent to initialize its estimate of the user’s valuation as follows. Since the heuristic from Subsection 5.1 ranks resource requests according to their valuation per CPU and timeslot, the bidding agent initializes its estimate of the user j’s true valuation as

$$v_{j0}(\theta_{j0}, p_0, x_j) = \theta_{j0} p_0 \cdot \text{CPU}.$$  

We assume that users can distinguish between three job priorities \{1,2,3\}, e.g. “high”, “medium” and “low” priority. The initial user priorities are (recall that we draw the true valuations from U(1, 30))

$$\theta_{j0} = \begin{cases} 1, & \text{if } 1 \leq v_j \leq 10 \\ 2, & \text{if } 11 \leq v_j \leq 20 \\ 3, & \text{if } 21 \leq v_j \leq 30 \end{cases}$$

The effect is that, assuming all agents apply this initialization rule, the requests get clustered into three blocks, requests with \(v_{j0}(\theta_{j0}, p_0, x_j) = p_0 \cdot \text{CPU}\). \(v_{j0}(\theta_{j0}, p_0, x_j) = 2p_0 \cdot \text{CPU}\), and \(v_{j0}(\theta_{j0}, p_0, x_j) = 3p_0 \cdot \text{CPU}\). For example, let job j require one CPU and 100 MB memory for three timeslots. The user’s true valuation is $3 per timeslot. One CPU has last been traded for $1 per timeslot. Then the user indicates an initial priority of 1, and the agent estimates a valuation of \(v_{j0}(\theta_{j0}, p_0, x_j) = 1 \cdot 3 = 1\). Ultimately, assuming truthful behaviour, the agent reports \((v_{j0}(\theta_{j0}, p_0, x_j), c_j, m_j, s_j, e_j)\) to the market.

Technical schedulers only aim at maximizing resource utilization or balancing the system load. As a proxy for such technical schedulers we implemented a scheduler which randomly assigns jobs to feasible nodes that offer sufficient resources in the right timeslots.

The numerical results with respect to allocative efficiency are reported in Table 2.

<table>
<thead>
<tr>
<th>Number of requests and offers (ratio of allocated requests)</th>
<th>Efficiency with true valuations</th>
<th>Efficiency with initialized preference elicitation</th>
<th>Efficiency of randomized (technical) scheduler</th>
</tr>
</thead>
<tbody>
<tr>
<td>20 requests, 20 offers (97.3%)</td>
<td>3.687.08</td>
<td>3.679.11 (99.8%)</td>
<td>3.664.66 (99.4%)</td>
</tr>
<tr>
<td>40 requests, 20 offers (82.4%)</td>
<td>6.852.75</td>
<td>6.693.97 (97.7%)</td>
<td>6.013.25 (87.7%)</td>
</tr>
<tr>
<td>60 requests, 20 offers (61.6%)</td>
<td>8.734.67</td>
<td>7.885.82 (90.3%)</td>
<td>6.561.02 (75.1%)</td>
</tr>
<tr>
<td>80 requests, 20 offers (48.8%)</td>
<td>9.776.49</td>
<td>8.366.91 (85.6%)</td>
<td>6.716.23 (68.7%)</td>
</tr>
</tbody>
</table>

We successively increased the competition in the market, indicated by the first column. With 20 requests and 20 offers, almost all requests get allocated. But with 80 requests and 20 offers, only 48.8% of the requests can be accommodated. The economic performance of technical schedulers will decrease as competition in the market increases. If competition is low, technical schedulers will be able to accommodate most of the requests, so the negative effect of not considering the users’ valuations is comparably small. But obviously this negative effect increases with the scarcity of the resources. This general reasoning is confirmed by our results. For the most competitive setting with 80 requests and 20 offers, the technical scheduler only achieves 68.7% of the efficiency which the market mechanism achieves with true valuations. Interestingly, despite the simple initialization rule and without considering the iterative refinement of the agents’ estimates, the market mechanism combined with bidding agents still achieves 85.6% of this benchmark. This result underlines the case for considering economic principles in the allocation of grid resources, even if the hard informational assumptions regarding user valuations are relaxed.

5.3.2 Strategic Considerations with Automated Bidding

In this subsection, we will illustrate the general idea for how bidding agents can implement strategic behaviour when interacting with the market in order to maximize the users’ benefit. As outlined in Section 3, this is a learning task in itself which is complementary to preference elicitation. We assume the bidding...
agent to have an estimate \( v_{j0}(\theta_{j0}, p_0, x_j) \) about user \( j \)’s true valuation. We model the one-dimensional action space of the agent to consist of a factor \( \beta \in \mathbb{R}_+ \). Consequently, the agent reports \( (\beta \cdot v_{j0}(\theta_{j0}, p_0, x_j), e_j) \). The question is how the agent should choose \( \beta \).

As is common in agent-based simulations, this choice can be modelled using reinforcement learning, e.g. Q-learning (Watkins 1989). This is basically a trial-and-error approach, where the agent tests different strategies (i.e. choices of \( \beta \)) during the exploration phase. After this exploration phase, the agent chooses the best strategy according to some policy, e.g. the \( \beta \) which resulted in the highest utility (the so-called epsilon-greedy selection policy). Then, during the exploitation phase, the agent plays this best strategy. In our setting, the agent may initially submit the true (estimated) valuation \( v_{j0}(\theta_{j0}, p_0, x_j) \) to the market. Then it successively explores its strategy space by deviating from this true valuation, e.g. by only bidding 50% of its true estimate, 55%, 60%, up to 150%.

The results of this strategy (\( \beta \in [0.5, 1.5] \)) for our numerical evaluation are illustrated in Figure 1, where we again employed the heuristic above complemented by K-Pricing with \( k = 0.5 \). The graphs show the utility relative to truthful bidding for the four settings.

![Figure 1. Efficiency gain from misreporting.](image)

The results show that, for each setting, it is the best strategy on average to report the true estimate. Intuitively, the higher the competition, the higher the risk of not being allocated anymore if the agent reports a valuation below its true estimate, thus yielding a smaller utility for the user. The discrete priority values \( \theta_{j0} \in \{1, 2, 3\} \) are reflected in the step-like shapes of the relative utility when underbidding \( (0.5 \leq \beta < 1) \). Assuming all agents apply the same initialization step with \( n \) discrete job priorities, we get \( n \) clusters of requests with identical \( v_{j0}(\theta_{j0}, p_0, x_j) \) in the ranking of the allocation heuristic. Consequently, as soon as \( \beta \cdot v_{j0}(\theta_{j0}, p_0, x_j) \) falls within the next lower cluster in the ranking, we get a drop in the relative utility.

If the agent overbids, there are two possible consequences. If the request was allocated with truthful bidding, then the request will still be allocated if the agent reports a higher valuation. However, with K-Pricing the user will receive a smaller fraction of the true welfare, and thus have a smaller utility. If the request was not allocated with truthful bidding, the request either remains outside of the allocation if the agent reports a higher valuation, thus leaving the user’s utility unchanged, or the request gets allocated, yielding a positive utility as long as \( \beta < 2 \) with zero reservation prices (cf. K-Pricing rule). However, as the results show, the overall effect of overbidding is slightly negative on average. This property is important, as agents have no incentive to misrepresent their priority.
Overall, the results indicate that the agent should truthfully report $v_{j0}(\theta_{j0}, p_{a}, x_{j})$ during the exploitation phase in our experimental setting.

6 CONCLUSION & OUTLOOK

The idea of applying market mechanisms to the allocation of scarce resources in dynamic and distributed settings is certainly not new. In such settings, markets exhibit many desirable features, in particular they promise to lead to more efficient allocations than traditional technical approaches. However, we argue that markets are facing two main obstacles:

- Users will generally not exactly know their true valuations for the resources, but only have a fuzzy estimate.
- Users cannot be expected to continuously monitor and interact with the market, but this interaction is costly. For instance, human users incur opportunity costs and have bounded perceptivity.

Surprisingly, these two barriers have largely been neglected in the vast body of literature on market mechanisms. Instead, existing work simply assumes perfect information on the users’ side and costless interaction with the market. The aim of this paper was to take a first step towards overcoming this obvious gap between theory and real-world settings. We briefly discussed previous work on preference elicitation and automated bidding in Section 2. In Section 3, we introduced the learning tasks of bidding agents and existing approaches to preference elicitation from the field of marketing research. At the core of this paper, we proposed a new model for preference elicitation and automated trading in distributed settings. To evaluate the initialization step of this model and the strategic behaviour of bidding agents in more detail, we performed a numerical experiment with a sample market mechanism, whose results we reported and interpreted in the previous section. In summary, these results underline the case for considering market mechanisms in the allocation of distributed resources, even if the hard informational assumptions regarding user valuations are relaxed. Instead, we propose the use of bidding agents, which (i) assist the user in finding his true valuation using an evolutionary approach, and (ii) shield parts of the underlying infrastructure’s and the market’s complexity from the user by acting on his behalf.

This work suggests several natural extensions for future research. The preference elicitation task of the agent requires further analyses, in particular as regards the iterative refinement of the agent’s estimates. How should the agent be parameterized, e.g. as regards the update parameter $\rho$ and the discrete user priorities $\theta_{j0}$? As pointed out above, the use of case-based methods (Hu and Haddawy 1998) and neural networks (Haddawy et al. 2003) might be interesting approaches. And how many iterations does this process take to get within x% of the user’s true valuation? Moreover, the automated trading of bidding agents offers interesting research questions. How does the agent behaviour depend on the specific market mechanism and vice versa? And what exploration and exploitation strategies should such agents apply? These questions can certainly not be answered with our rather static analysis, but call for agent-based simulations.

Abstract

Many existing IT applications exhibit strongly varying demand patterns for resources. Accommodating an ever increasing and highly fluctuating demand requires continuous availability of sufficient resources. To achieve this state at reasonably costs, a high degree of flexibility with respect to the given IT infrastructure is necessary. Facing this challenge the idea of Cloud computing has been gaining interest. In so-called Clouds resources such as CPU, storage and bandwidth can be bundled into a single service, which is offered to Cloud users. These services can be accessed in oblivion of the underlying IT infrastructure. This way Cloud Computing facilitates the introduction of new products and services without large investments in the IT infrastructure.

Cloud Computing is a promising approach with a high impact on business models. One aspect of business models is clearly the revenue model, which defines how prices should be set to achieve predefined revenue level. The decision about accepting or denying requests has a high impact on the revenue of the provider. In this paper we analyze two approaches that support the cloud provider in its decision. We show that predefined policies allow increasing revenue compared to widely used technical models such as first-come-first-serve.

Keywords: Cloud Computing, Revenue Management, Decision Mechanisms
1 INTRODUCTION

Many existing IT applications (e.g. data mining, portfolio analysis or numerical simulations) exhibit strongly varying demand patterns for computing resources. Demand for computing resources is further increased by the introduction of new products and processes. Accommodating an ever increasing and highly fluctuating demand requires that sufficient resources are available. Building an adequate infrastructure requires significant investments in the infrastructure and instructing and hiring of personnel. However, many enterprises face increasing competition on global markets. This leads to the challenge to make use of new applications, reduce process times, and introduce innovative services for customers on one side and cut the costs of their IT-infrastructures on the other side (Carr, 2005).

To achieve this goal it is necessary to maintain a very high degree of flexibility with respect to the IT infrastructure. Facing this challenge the idea of Cloud computing has been gaining interest lately. The term Cloud Computing was initially coined by Amazon.com, which were among the first companies to offer Cloud services on a large scale. In the Cloud resources (e.g. processing power, storage and bandwidth) can be bundled as services, which are offered to Cloud users. These Cloud services can be accessed without knowledge of the underlying infrastructure. Cloud Computing also allows the introduction of new products and services without large investments in installing or upgrading of the IT infrastructure. The New York Times managed to convert 4TB of scanned images containing 11 million articles into PDF files in very little time using Hadoop, a framework for distributed applications and Amazon’s Cloud services. The actual conversion process took only 24 hours cost merely 240 US-$. New Projects and websites like Justin.tv or SmugMug.com would not have been able to adapt to such a rapidly growing user base without the help of Cloud services. Don MacAskill, CEO of SmugMug, estimated his company saved about 339,430 US-$ in 7 month, spending only 84,255 US-$ on Amazons Simple Storage Service. According to analysts at Gartner “The projected shift to Cloud Computing will result in dramatic growth in IT products in some areas and in significant reductions in other areas.

In order to remain attractive for customers Cloud services must meet user demands concerning price, availability and quality of service. The more providers offer their services, the more likely it is that they can be accessed in quantity and quality. Therefore it is important to attract more providers. However, Cloud providers will only offer their services if they can realize a sufficient level of profit. Providers have to plan their resource usage carefully and be aware of dynamic changes of the incoming requests for their services. With state-of-the-art technology, this assimilation is hampered, as the components facilitating the deployment of the services are not designed to incorporate economic issues (e.g. price, expected demand). To improve performance in the commercialization of distributed computational resources decisions about the supplied resources and their management should be based on both technical and economic aspects (Kenyon and Cheliotis 2004).

In recent times, several research projects have started to develop price-based resource management components supporting the idea of grid or utility computing, which could be applicable for Cloud providers in some cases. Those approaches are devoted to scheduling by using price mechanisms such as auctions. Clearly, this means that technical issues such as resource utilization are ignored for scheduling. Furthermore, these approaches require a tight integration with the infrastructure of the provider, as well as the interface to the customer. In cases where a provider offers a wide range of services and customers might use different providers at the same time, it is often not feasible to undertake a complex and time consuming bidding process. Technical resource management systems typically offer the possibility to include priorities for users. Purely price-based schedulers do not distinguish important from less important partners, as only current price matters for the allocation. In this work we propose two mechanisms which increase revenue of Cloud providers by deciding which job or service requests are accepted and or rejected. The first mechanism provides an elegant way to introduce utilization based pricing in real world systems. Integration of concepts from revenue
management in the second mechanism allow increasing overall revenue even in fixed-price scenarios which dominate Cloud Computing so far.

This paper is novel because it proposes mechanisms for fixed price, as well as pay-as-you-bid scenarios which can be used in real-time and advance reservation scenarios. At the same time our mechanisms can be implemented in real world scenarios with relatively few changes to existing architectures. With increasing competition among Cloud providers work covering this topics is highly relevant in the research area of information systems. The paper is structured as follows. In the next section we introduce motivational scenarios and the requirements they impose. Subsequently we present work related to our model. Section 4 contains a description of our approaches and the models they are based on. An evaluation based simulations follows in section 5. The paper ends with a conclusion and brief outlook of future work.

2 MOTIVATIONAL SCENARIOS AND REQUIREMENTS

In this section we present three major real world scenarios, which motivate the use of automated policy decisions. The scenarios impose different requirements on the decision making unit concerning the timeframe, which is available for determining the decision.

2.1 Motivational Scenarios

Scenario I: A service provider offers a number of different cloud services on the market, similar to like Salesforce.com or mor.ph. Most of these services have to be accessible within very short time spans. Each service has a different profile of resource requirements. Some service are computationally intensive, others require large amounts of memory or storage. Currently, the provider has no mechanisms to adequately deal with utilization approaching maximum capacity. All incoming jobs are accepted as long as there is capacity left. Because demand for the different services vary greatly situations where one type of resources (e.g. CPU) operate at nearly full capacity while others still have a significant buffer left arise regularly.

Scenario II: A company Y has a lot of computationally intensive tasks in their business processes. They have built and maintain a number of large datacenters providing different services for their own business processes. Due to the nature of their business utilization of the resources is very uneven. The company has accumulated important knowledge in the management of their infrastructure and can provide the services efficiently. Providing these services has become a core competence for the company. Therefore, they consider offering these services to external customers as a new product. This allows them to enter a new business segment, achieve a more even utilization of their resources and at the same time take further advantage of economies of scale. However, the sale of services to external users must not have any negative impact on their own business processes. Especially, it should not result in decreased resource availability for internal users. Because of this, jobs users from within the organization should always be preferred when deciding which jobs are accepted.

Scenario III: The service provider offers a wide range of cloud services for different areas of application, such as data mining, numerical simulations or rendering. Like in the first scenario the profile of resource requirements varies greatly between these services. However, in contrast to scenario I the service provider has more time to take a decision whether to accept a job or not, since resources are reserved in advance. Furthermore jobs are significantly larger and cost more, justifying the introduction of more complex optimization methods. We assume that the provider has not the option to dynamically change his prices. He rather has fixed prices like Joyent.com offering a subscription model or Flexiscale.com with a pay-as-you-go model. An important aspect is to consider the time of arrival, when jobs come into the system. The request time for a service has a great impact on the forecasting models and the revenue expectations. We assume that large jobs are often well planned and scheduled more in advance than small jobs.
2.2 Requirements

From these scenarios the research question arises “What pricing mechanisms can be used to increase provider revenue?”. These mechanisms have to consider different circumstances such as real-time decisions or further constraints like a strict minimum capacity available for internal users. Naturally there are myriads of options whose study covers a very wide research area. In this paper we investigate mechanisms, which try to increase revenue by accepting or denying service requests. We consider fixed price situations as well as simple pay-as-you-bid mechanism. We restrict our analysis to these types of mechanisms as they are relatively simple to implement in real world systems.

Scenario I imposes some requirements on a mechanism. To effectively deal with this scenario a mechanism must have very low computational cost; it simply needs to calculate the decision within a very short time span. Furthermore, the mechanism should take utilization of each resource type into account, when deciding whether or not a job is accepted. For this scenario we assume the application of a pay-as-you-bid mechanism. Scenario II adds the need to guarantee one class of users a certain capacity or implement some kind of prioritization of some users. The requirements for the third scenario are slightly different. In this case there is more time to take the decision. Therefore a mechanism can do a more complex optimization as long as it leads to higher revenue. Scenario III uses a fixed price mechanism. Using the requirements of all three scenarios it is obvious that it would be very difficult - if not impossible - to find a single mechanism which excels in all situations. Therefore we present two different mechanisms which are deemed promising to work in our scenarios. There exists no one-size-fits-all-mechanism. Efficiency is widely used as a requirement and metric. However, Cloud providers’ main focus is on revenue not efficiency. Since they decide which mechanisms to implement we focus on revenue optimization in this paper.

3 RELATED WORK

There are two main streams of work existent that deal with the problem of admitting job requests. The first one considers technical and rule based optimization. The second one investigates the use of concepts from Revenue Management.

Technical and rule based optimization stems from the computer science perspective, as we will see in the following: Ferguson, Nikolaou, Sairamesh, and Yemini (1996) discuss the application of economic theories to resource management. Aiber, Gilat, Landau, Razinkov, Sela, and Wasserkrug (2004) present an architecture for autonomic self-optimisation based on business objectives. Elements of client classification such as price discrimination based on customer characteristics have been mentioned in other papers (Newhouse et al. 2004 and Buyya 2002). They did however not consider other discrimination factors. Chicco, Napoli, and Piglione (2006) describe data-mining algorithms and tools for client classification in the electricity grids but concentrate on methods for finding groups of customers with similar behaviour. An architecture for admission control on e-commerce websites that prioritizes user sessions based on predictions about the user’s intentions to buy a product is proposed by Poggi, Moreno, Berral, Gavaldà, and Torres (2007). Boughton, Martin, Powley, and Hormann (2006) present research on how workload class importance should be considered for low-level resource allocation.

One approach to realize advance reservation and end-to-end quality of service is the Globus Architecture for Reservation and Allocation (Foster et al. 1999). This approach uses advance reservations to achieve QoS. Another way to achieve autonomic QoS aware resource management is based on online performance models (Kounev et al. 2007). They introduce a framework for designing resource managers that are able to predict the impact of a job in the performance and adapt the resource allocation in such a way that SLAs can be fulfilled. Both approaches do not consider economic factors such as pricing.
As resources, e.g. processing power, storage and bandwidth, are usually bundled as services in the Cloud, providers have to plan their resource usage carefully and be aware of dynamic changes of the incoming request. Although, advance reservation diminishes the unpredictable requests, users can still submit important jobs on-demand and cancel queued jobs or their reservation (no-shows). The provider can apply revenue management strategies to enhance revenue and optimally allocate his resources to the consumers. He can set booking limits for his services and accept a certain amount of customers. An acceptance strategy is required due to the competition for the resources by the services. The resources in a cluster are accessed by different services. It is important to know which service request should be accepted now to gain enough revenue in the future. The described problem is an instance of the dynamic inventory network capacity control (NCC) for finite time horizon $T$. Therefore work about Revenue Management concepts for IT is a key part of our related work.

The first paper analyzing Revenue Management concepts for cluster systems was published by Dube et al. (2005). In the suggested model one resource is offered for different prices. By assuming the customer behavior follows a logit model, the authors analyzed an optimization model for a small number of price classes and provided numerical results.

Cancelations and no-shows reduce the efficiency of resource usage. Sulisto et al. (2008) analyzed how overbooking strategies can be applied to maximize revenue. Different prices were charged for one resource. Three overbooking policies were implemented and compared via simulation. The benefits of overbooking for shared hosting platforms were emphasized by Urgaonkar (2002) as well. He did not optimize the revenue by classifying different services, but only the throughput rate.

Anandasivam and Neumann (2009) presented a framework for applying Revenue Management in Grid Computing. They gave an introduction and outlined some requirements, which have to be fulfilled. Their theoretic model comprises bundles of resources and shows how they can be priced. This framework can be adapted for Cloud Computing as well. However, none of these papers analyzes capacity planning strategies of resource bundles via simulations.

Nair and Bapna (2001) introduced Revenue Management concepts for a similar application domain: Internet Service Provider. The provider has to decide whether to accept an incoming customer or to reject. The application domain is different from Cloud Computing as it does not take advance reservation and bundles into account. Customers can only instantly get an internet access.

Policy based decision modeling and capacity planning for fixed prices and advance reservation have been partially studied. Nevertheless, in the context of cloud computing, requirements are different than the domains studied in the literature before. The settings were already outlined in the scenarios. In the next section we present our own model comprising QoS and client classification for online allocation and decision support for advance reservation.

4 \hspace{1cm} \textbf{THE MODEL}

One of the key questions for resource providers is whether a job should be accepted at the time and for the price for which it was submitted. The standard approach used nowadays is to always accept a job if there is enough capacity available to fulfill it. Capacity is allocated on a first come first serve basis. However, since our main objective is to maximize the revenue of the provider those jobs that achieve this objective should be chosen. This can be done by solving the following maximization problem:
Where $T$ is the set of all timeslots; $J$ is the set of available job requests; $p_i$ is the price paid for job $i$; $x_i$ is a binary allocation variable indicating whether job $i$ was accepted or rejected; $c_{ir}(t)$ is the capacity required by job $i$ in timeslot $t$; and $gc_r(t)$ is the total capacity available of resource $r$ during timeslot $t$.

The problem can be formulated and solved as a linear program. However there are two problems when choosing this approach. The first one is that this is an instance of the knapsack problem, to be more specific the temporal knapsack problem. As such it is NP-hard and therefore computationally intractable. Furthermore to solve the problem, it is necessary to have the information on the future jobs, the capacity and runtime they require, the prices, etc. In general this information is not available before a job is submitted.

We propose two approaches to solve this problem. The first approach uses policies as a heuristic. This approach has very low computational costs, decisions can be calculated very fast and useful policies can be already generated with very limited information about future demand. Therefore this approach can be used in a very wide range of scenarios, even real-time scenarios where decisions have to be taken immediately. The second approach introduces more complex mechanisms used in classic revenue management. It requires more time and resources for calculations than the first approach as well as a forecast for the demand. Therefore it cannot be used in such a wide range of scenarios as the first approach. In return, however, in those scenarios where it can be used it promises higher revenue than the first approach.

4.1 Policy based heuristic

The first approach is based on previous work presenting an earlier version of an architecture for an economically enhanced resource manager (Püschel et al. 2007). The idea is to use policies as a heuristic for maximizing the revenue without having the exact information about future jobs. These policies can be based on requirements from Service Level Agreements (SLA), company policies and information gained from historic workload traces, utilization curves, prices, etc. If available, such policies can also be based on forecasts or information about the statistical distribution of job size, runtime and prices. This approach is especially well suited for motivational scenario I and II.

In this work we will extend two aspects of our policy based approach. The first aspect is dynamic pricing based on various factors, such as projected demand or utilization. The second aspect is job priority based on client classification. The idea behind utilization based pricing is that when utilization is high demand for the resources is high as well and therefore customers are willing to pay higher prices for resources. If utilization is low lower prices are charged to attract more customers.

In scenarios where various services with different profiles of resource requirements are offered the (reservation) price can be calculated based on the overall utilization or on the utilization of each resource type (e.g, CPU, memory, storage). If prices are calculated based on utilization of the individual resource types those services that need a lot of capacity of scarce resources have a higher price increase than services which only need little. Such a pricing mechanism reduces the risk that some resources have a lot of free capacity but no jobs can be accepted because one type of resources is used to capacity.

For certain users it may be very important to always have access to the resources. This is the case in our third motivational scenario; sufficient resources have to be available for jobs from internal users. To achieve this a type of client priority on job acceptance can be used. When the utilization of the system is low jobs from all classes of clients are accepted but when the utilization of the resources rises and there is competition between the clients for the resources, jobs from certain clients are preferred. There can be two types of priorities: strict priorities and soft priorities. Strict priority means that when a certain utilization threshold is reached only jobs from clients with this priority are accepted. Soft priority means jobs from clients with priority are generally preferred but standard clients have the chance to outbid clients with priority. Therefore clients can still submit jobs when the threshold is reached as long as they pay a higher price.
To keep the system adaptable it includes a Policy Manager, a component which stores and manages the different policies, such as policies concerning pricing and client classification. Policies are formulated in the SWRL, the Semantic Web Rule Language (Horrocks et al. 2004). SWRL combines the Web Ontology Language (OWL) and the Rule Markup Language (RuleML) and is de facto standard concerning rules languages that offer semantic integration. A simple example rule from a pricing policy in SWRL is the following rule which expresses that if the utilization is between 71% and 100% there is a surcharge of 5 on the general reservation price:

\[
\text{Utilization(?utilization)} \land \text{InsideUtilizationRange(?utilization, "71\% - 100\%")} \\
\Rightarrow \text{SetSurcharge(?utilizationsurcharge, "5")}
\]

The overall architecture for an economically enhanced resource manager is implemented in a prototype in an EU project; the extensions presented in this work are implemented in a simulator.

4.2 Bid price optimization

4.2.1 General description

Each offered service represents a booking class, which has a fixed price. The provider has to decide, if a service request should be accepted or denied. Thus, a limit defining how many requests are operable for each booking class has to be identified, which is known as capacity control. Nested booking limits allow preventing that bookings for services with high revenue are being rejected in favor of bookings with low revenue. They define how much capacity is reserved for a certain booking class. Every service has limited access to the resources like CPU, storage or bandwidth. Due to multiple resources a nested booking limit control must be defined for each resource. This is called virtual nesting control (Talluri and van Ryzin 2004). It is difficult to forecast demand appropriately for virtual classes. The requirement of mapping services to virtual classes increases the complexity. Furthermore, the assumption that demand for low-class services occurs earlier than high-class products is quite static, and when demand is stochastic the strict low-to-high order is less appropriate. It is assumed that customers book the services for usage at a certain time in the future. The low-before-high arrival is expressed by a high booking probability of low-fare services at the beginning of the booking period. This probability decreases during the time period. Contrarily, the probability of booking high-fare services is low at the beginning of the booking period, and increases until the end of the time period.

For the application of bid-price controls, at any point in time a simple threshold value for each resource has to be stored. Bid prices are interpreted as an approximation for the opportunity cost (Bertsimas and Popescu 2003) for reducing the resource capacities, which are needed to satisfy incoming service requests. Moeller et al. (2007) describes bid prices as monetary values of single capacity units, and the resource demands of a request weighted with the corresponding bid prices must be summed. If this sum exceeds the revenue yielded by the sale of one unit of the respective product, the request is rejected, otherwise it is accepted. Regular updating of bid-price values is necessary to guarantee a continuous precision of the bid prices. Less accurate bid prices can lead to accept/reject decisions of minor value. Continuously updated bid prices are based on the current booking situation at a certain point in time \( t \in \{ T, T-1, \ldots, 0 \} \). That is, if a high amount of capacity has already been sold, the bid prices turn out to be higher.

The decision of accepting or denying a request depends on the policy how the decision is made. Capacity control and dynamic pricing known from Revenue Management are an instance of linear programming models. Since speed of computation matters, bid price control is an approximation method to define policies very fast. It provides a good estimate, but not always an optimal solution. Especially in the NCC setting, the calculation of the optimum increases exponentially with the number of resources \( m \) and products \( n \) (Talluri and van Ryzin 2004). In the following we assume that the provider has three resources \( h \in \{1\ldots m\} \) with \( m=3 \) available and offers three services \( i \in \{1\ldots n\} \) with \( n=3 \). For example resources are CPU, storage and bandwidth, whereas services can be low medium and high instances like the Amazon Web Services. Resources have to be quantifiable. The
The bid-price function is based on two parts. The first part ($\alpha_h \cdot c_{ht})$ is responsible for the increase of the respective bid price over time. $c_{ht}$ is the amount of capacity of a resource $h$ reserved at time $t$. If a request for a service $i$ is accepted, the bid price of a resource increases by the delta of the value $c_{ht}$, which equals $a_{hi}$ capacity units, and on the value of $\alpha_h$. Thus, the bid price of a resource $h$ only is only increased by the acceptance of incoming requests. This corresponds to the fact that the amount of available resources decreases due to sales and hence become more expensive.

The second part of the formula ($\beta_h \cdot u_{hi}$) decreases the bid price for every occurring request. A decrease is required because if some requests are rejected, some future requests can be accepted again. If there was no decrease in the function, the bid price only would rise, and from a certain point every future request would be rejected, and no more sales could take place. $u_{hi}$ is the capacity required to satisfy the demand for the products $i \in A_h$ until $t$. The demand until $t$ for a product $i \in A_h$ can be calculated by $D_{iT} - D_{hi}$. It requires forecasts of the total demand per product $i$ ($D_{iT}$), as well as forecasts of the demand-to-come ($D_{hi}$) for every point in time $t$ until the end of the booking period. $u_{hi}$ is calculated by

$$\sum_{i \in A_h} a_{hi} \cdot (D_{iT} - D_{hi})$$

For every product its demand for resource $h$ $a_{hi}$ is multiplied with the expected demand until $t$ $D_{iT} - D_{hi}$, and the sum of these products is taken. The values of $u_{hi}$ increase over time as more demand
is realized. The bid-price decreases with time proceeding. The two parts of the resource-oriented bid-price function make sure that the total value of a bid price $\pi_{ht}$ increases only, if a request is accepted. The increase amplifies if the amount of reserved capacity $c_{ht}$ is high.

The parameters $\alpha_h$ and $\beta_h$ attach importance to variables. They have a strong impact on the accept/reject decisions. For instance, very high values for coefficient $\alpha_h$ and very low values for coefficient $\beta_h$ lead to more frequent reject decisions because the increase of the bid-price function turns out too high. This would imply losses in revenues due to rare sales. In the opposite case, very low $\alpha_h$ values and very high $\beta_h$ values result in an "accept all" policy, and thus, it can happen that capacity is mostly sold to low-fare classes (requests for low-level services) also leading to potentially lost revenues. Because of these reasons promising values for the control variables should be obtained by simulation-based optimization.

An enhanced approach to adopt the bid-price function is to artificially raise the bid prices depending on the current degree of reservation. Thereby, low-class requests occurring at the beginning of the booking period can be rejected explicitly in order to reserve capacity for requests yielding higher revenues. This kind of policy can be realized using a set of variables $\gamma_i$ which depend on the average of the degree of reservation denoted by $z_t$ calculated each time a request occurs by

$$z_t = \frac{\sum_{h=t}^{\infty} z_h}{t}.$$ Given $z_t$, the provider can set utilization thresholds which specify when to use a specified $\gamma_i$, e.g. as follows:

- If $z_t < 0.4$: use values $(0.12, 0.02, 0.01)$ for $\gamma_i, i \in \{1,2,3\}$.
- If $0.4 \leq z_t < 0.75$: use values $(0.02, 0.025, 0.05)$ for $\gamma_i, i \in \{1,2,3\}$.
- If $0.75 \leq z_t \leq 1$: use values $(0.005, 0.05, 0.1)$ for $\gamma_i, i \in \{1,2,3\}$.

$\gamma_i$ is added to control variable $\alpha_h$, thereby increasing the bid prices.

$$\pi_{ht} = (\pi_{ht})^\alpha_h \cdot (\alpha_h + \gamma_i) - \beta_h \cdot \frac{c_{ht}}{U_{ht}}$$

In the case when demand strongly fits to the assumptions stated above, this contributes to more frequent rejections of service-1 requests at the beginning of the booking period, and to more frequent rejections of service-3 requests close to the end of the booking period.

5 EVALUATION

For the evaluation we considered the following three types of services with requirements for processing power, memory, and storage according to table 1. For each of the proposed mechanisms a scenario matching the requirements from the motivational scenarios was created and a simulation was run. The same service types and their resource profiles were used in both cases. The first simulation was based on real workloads, for the second mechanism a very challenging scenario using fixed prices fixed runtimes and relatively constant rates of arrival were used.

5.1 Policy based heuristic

The approach was evaluated using generated workloads as well as workloads based on real world scenarios, from the Parallel Workload Archive (Feitelson 2007). The setting of the evaluation matches the requirements for the first motivational scenario. The runtimes and offsets between submit and start time were generated using a lognormal distribution. For the workloads based on real world scenarios, the SHARCNET log, which was graciously provided to the Parallel Workload Archive by John Morton (john@sharcnet.ca) and Clayton Chrusch (chrusch@sharcnet.ca), was used. The SHARCNET log was chosen as a basis because it contains a large variety of jobs with different runtimes, numbers of used CPUs, and varying submit and start times. Job runtimes where rounded down to full hours to allow a timeslot based allocation. After filtering invalid jobs and those jobs which were considered too long or too short 566,701 jobs were left and used for the scenario. For each of these jobs a service type was randomly drawn. Based on these jobs ten joblists with different prices were generated. A capacity of 8200 for each of the resource was used to be able to accommodate some of the larger jobs from the workload. A simple pay as you bid mechanism was assumed and pricing information was generated using a normal distribution with the mean price from table 1 and variance of 0.5.

<td>52.39%</td>
<td></td>
</tr>
</tbody>
</table>

Table 2. Revenue increase using policy based approach.

As can be seen in table 2 the average revenue the benchmark, a simple first-come-first-serve (FCFS) policy, was 54190907.26. A policy using utilization based pricing managed to increase the revenue on average by 63.38% resulting in an average revenue of 88697433.21. Introducing strict priority without charging preferred users for the privilege obviously reduces the achieved revenue. However since the preferred users in our scenario are internal users it is reasonable that they get the privilege without a charge. The average revenue for a policy combining utilization based pricing with strict priority we achieved in our simulation is 80480832.63 which is an increase of 48.51% compared to the FCFS policy. Since soft priority allows outbidding preferred clients revenue is higher than in a policy using strict priority, however this results in slightly decreased resource availability for preferred users. A policy with soft priority and utilization based pricing resulted in a revenue increase of 52.39% compared to FCFS. Runtime for one simulation run with 566,701 job requests varied between 55 and 60 seconds, each job is accepted or rejected within fragments of a second. This makes the mechanism suitable for scenarios where job acceptance has to be decided in less than a second.

5.2 Bid price optimization

For the evaluation of bid price optimization we assumed the setting in scenario II. Instead of prices drawn from a normal distribution the prices were set according to table 1. Naturally, this leaves significantly less room for revenue increase compared to scenario I. Thus the bid price approach focuses more on forecasting and capacity planning. The bid prices are in every timeslot. Parameters like the current amount of capacity reserved, the total expected demand and the already realized demand are taken into account. For each incoming request at time t, the bid prices are updated. Bid prices increase, if the amount of reserved capacity rises due to the acceptance of requests. They decrease, if incoming requests are rejected and no additional capacity is being reserved. Given the bid prices, an approximation of the opportunity cost is calculated by weighting the resource demand of an incoming request with the bid prices. If the revenue yielded by the sale of one unit of the respective service exceeds this approximation, the request is accepted. This simulation setting differs from the policy-based approach described above, since the bid price optimization considers advance reservation of resources, while in scenario I resources are instantly consumed. The capacity of a resource provider was fixed to a maximum of 750 units for every resource. The simulation was performed with a
booking period of length T=2000 for five job files. The SA-BP model yielded an average revenue of 1860.5. The average revenue of a FCFS policy was 1810.08 (increase of 2.79%). In the best case the revenue increase was 11.26%. The performance of SA-BP is based on the accuracy of the forecasting data. With inaccurate forecasting models, the revenue of SA-BP can even be lower than the FCFS. The runtime of SA-BP is similar to the FCFS computation. This is due to the heuristic approach of SA-BP. More complex revenue management models require long runtimes to calculate the optimal allocation. In both policies the runtime for 2000 jobs were about 6 seconds. In practice, a longer time horizon is necessary for calculation, which will increase the runtime exponentially.

The reason why SA-BP performed better than FCFS was due to rejections of most service-1 requests in the first third of the booking period. Thus, more capacity was kept free for later arriving service-2 and service-3 requests. The SABP3 policy accepted more service-1 requests in the second third of the booking period. Furthermore, the acceptance of service-3 requests decreased over time, thus enabling more accepts of later occurring service-1 requests. The FCFS policy accepted all incoming requests in the first third of the booking period until the capacity was completely reserved. SA-BP rejected early arriving service-1 requests, and thereby, later arriving requests for services 2 and 3 could be accepted.

5.3 Discussion

The evaluation shows that the proposed mechanism can increase revenue. The policy based mechanism fulfils all requirements imposed by the first two motivational scenarios. Revenue is significantly increased and computational costs are very low. The concept of strict priorities enables Cloud providers to guarantee availability of a predetermined amount of capacity for certain users. Unless these users are charged for this privilege it results in a revenue decrease compared to the pure utilization based pricing. Soft priorities can be used to mitigate this effect; however, they can result in a reduction of resource availability for preferred users. The bid prize optimization mechanism can be used to increase revenue in motivational scenario three. Even in a challenging setting with fixed prices and the same profit margin for all services it still managed to deliver revenue increases. Computational costs are higher than for the policy based approach but still acceptable for many scenarios.

6 CONCLUSION

Cloud Computing is a promising approach with a high impact on business models. One aspect of a business model is revenue and how prices should be set to achieve predefined revenue goals. The decision about accepting or denying requests has a high impact on the revenue of the provider. Revenue Management concepts known from the airline comprise interesting policies. In this paper we analyze two approaches. Predefined policies allow increasing revenue compared to static models like first-come-first-serve. Such policies include utilization based pricing as well as client classification.

We furthermore present how to apply more complex revenue management concepts in Clouds. When price are relatively fixed, an optimization of the capacity over bid price concepts seems to be a promising approach. A bid price optimization enables to determine the minimum price a consumer has to pay for requesting a service. The complexity arises when services utilize the same resources. The bid price is applicable for a scenario, where advance reservation is possible. Our proposed policies and models were validated via simulation. For the first of our proposed mechanisms we were able to use real world workload traces. By using these real workload traces the models are applicable in practice to some extent. However we still had to generate pricing information, therefore complete external validity of our results cannot be assumed. We showed that well-defined pricing strategies can notably increase revenue. Future work will comprise an implementation in existing middleware considering architectural design and technical feasibility. Moreover, the heuristics and policies have to take learning algorithms into account to analyze, whether it will lead to better results.

A TEACHING CASE: TOWARDS BRIDGING DISCIPLINARY DIVIDES IN IT EDUCATION

Abstract

Information Technology (IT) now plays a central role in almost all aspects of business. However to best realise the potential of IT, it is vital that educators adopt strategies that challenge rather than reinforce existing disciplinary divides in IT education and business. This paper supports the application of active learning, via the use of a serial teaching case, towards bridging disciplinary divides in IT education. Specifically, the case calls for the design, development and implementation of an Integrated Management Information System. Students are therefore required to demonstrate analytical as well as technical skill-sets in the areas of IT, accounting and business. The paper describes the business context facing AHN Ltd. and illustrates the pedagogic use of the case as a means of integrating IT with aspects of accounting and business knowledge, towards helping educators contribute to answering the calls from academia (Panko, 2008) and industry (Chan and Reich, 2007) for graduates with a hybrid of business and IT skill-sets.

Keywords: Business Case, Active learning, Linkage, Knowledge.
1  INTRODUCTION

Active learning approaches, such as case-based learning and problem-solving, have been advocated as ways of fostering deeper learning (Boyce et al., 2001; Biggs, 1994). Organizations such as Microsoft and Financial Services have been using problem-solving scenarios such as simulations to both test and train employees. Use of such scenarios and role play will through real world problem-solving enhance the learner’s logical reasoning, numeric abilities and spatial thinking. Realising the potential of such methods however requires active engagement from educators and learners alike (Baskerville, 2008; Healy and McCutcheon, 2008). For many educators willing to engage in such methods, the lack of appropriate materials and guidance is often perceived as a barrier. This paper presents one approach to active learning, via the use of the AHN Ltd. case study.

AHN Ltd. is a serial teaching case based on the ongoing analysis of AHN Ltd., a manufacturer of electronic toys. The case, described in the next section and discussed in section 3, is used as a fictional business scenario whereby students assume the role of an entity tendering for and then offering a prototype IT solution to meet the business needs of AHN Ltd. The materials are structured in a manner whereby a given instructor can focus on one particular aspect or disciplinary perspective (e.g. that of a programmer or of a management accountant); alternatively the case can be used more generally, to link IT to business, thereby mitigating the possibility of silos or islands of knowledge being created around the individual modules of a given programme of study. Use of the case also facilitates a key pedagogical component of any learning experience: that of real world problem-solving, where the problem is not phrased like a question from the textbook.

Problem-solving skills require the use of a number of different learning strategies and types of knowledge. The learner’s own experience, internal mental models, and other ‘cognitive structures’ are necessary to ‘construct’ their own knowledge when faced with new information or different situations (Baskerville, 2008; Reeves, 1997). This case is organised to provide the student with a detailed description of the company. Attention is drawn to the inadequacies of the current IT infrastructure to enable students to identify and develop solutions to address these. The case has been successfully used on a module in a postgraduate programme in IT and Management Accounting. Used in total or in part the case illustrates and develops the practical as well as the theoretical alignment of business and IT. Individual lecturers can decide based on resource constraints and student capabilities to make elements we have included in the teaching note available to their students, for example Figure 1 or multiple components of Figure 2. Section 4 describes, in detail, the approach used to teaching the AHN Ltd. case.

2  THE TEACHING CASE: AHN LTD.

AHN Ltd. makes electronic toys. In recent years production and sales levels have grown rapidly and without corresponding attention being paid to the information systems (both financial and non-financial) within the organization. What was once a small operation now has a turnover of €35 million and close to 100 employees. AHN Ltd wishes to embrace the philosophy of ‘continuous improvement’ throughout all its operations and administrative activities, stream-lining manufacturing processes, reducing costs and improving quality and customer satisfaction. A web presence is also under serious consideration.

There are three main product lines: ‘Space Contender’, ‘Corporate’ and ‘Executive’. Details of the three products are as follows:

- **Space Contenders**
  This a hand-held game device aimed primarily at the Christmas toy market; thus demand is seasonal, peaking in the months of September, October and November. The ‘Space Contenders’ line is a cost
leader in the marketplace and a replacement/substitute for a highly popular imported product. AHN Ltd. produces the product to stock, primarily to use up excess resources as they arise. The current sales price is €20 per unit.

- **Corporate**
  This is an executive hand-held game device, consisting of a basic plastic console unit for which individual game modules can be purchased. Basic units are mass-produced, and then individually tailored to customer requirements. A key aspect is the customization of the accompanying gaming software. AHN Ltd. offers its customers the opportunity to incorporate their logos and promotional features into the games, providing them with an unusual and innovative means of advertising. Selling price is dependent on the quantity of an order and the amount of customization required. The ‘Corporate’ line is sold mainly, though not exclusively, through corporate advertising agencies to large multinational clients. Orders are large and demand is fairly constant throughout the year.

- **Executive**
  The ‘Executive’ line is similar to the ‘Corporate’ model, but cheaper in price. Distribution is mainly through office supplies wholesalers.

The current manufacturing facility was purpose built to accommodate the initial products, ‘Space Contender’ and ‘Corporate’. A state-of-the-art plastic moulding machine was installed to produce unit casings. Polymer resin compound is moved from the raw material storage area and delivered to the moulding machine, where it is processed into moulded casing units. A second moulding machine was purchased to facilitate production of ‘Executive’ casings. Finished casings are then stored until required for assembly. Production of finished units takes place along three modern assembly lines. The process of loading software onto each of the products is largely automated and currently operates at 60% capacity. Completed units are then sent to Quality Control for Inspection/Testing. Defective products are returned to the assembly area for re-processing. Checked and passed Finished Goods are placed in pre-printed boxes and stored for shipment. The entire warehouse area is fully racked and spacious, and complies with all current Health and Safety regulations.

2.1 **Sales Activity**

AHN Ltd. has three markets regions: Republic of Ireland, Northern Ireland and the U.K. Five full-time sales persons service this market. Each sales representative is provided with a company car and paid a basic salary, plus commission (calculated monthly), equal to 5% of gross sales revenue. AHN Ltd.’s total customer base of approximately 1,760 clients includes an estimated 310 dormant accounts. Sales Invoices number (on average) 1,100 per month.

Sales Orders are posted, phoned or faxed by customers or Sales Representatives to the Sales Support/Customer Services personnel. Orders received are written up manually on Sales Order/Dispatch Forms. These forms come in pre-printed books with four carbon copies. Original Sales Order/Dispatch Forms are passed (physically) four times daily, to the Production Director. Copy orders are passed to the Sales/Marketing Director, the Accounting Office and the final copy is retained in the Sales Order/Dispatch Form Book. The Production Director passes orders for in-stock finished goods items to the Credit Controller for Credit Checking. Sales Orders passed by the Credit Controller are then forwarded to Dispatch and given to warehouse personnel to use as a picking list. Filled orders are deposited in the Dispatch Area and warehouse personnel sign off the Sales Order/Dispatch Form. The Dispatch Clerk also signs off on the Form and makes two photocopies of it. The original is enclosed with the goods for delivery; one copy is placed on file in Dispatch and the other photocopy is passed to Accounting for entry into Invoicing on the accounting system. Invoices are batch processed and update takes place every evening. During update the system can be accessed.
only for information purposes – no data can be entered or edited. Invoices are printed daily and posted to customers. Statements are printed at the end of every month and posted to customers. Sterling invoices however are typed separately and are currently not entered into the accounting system at all. At the end of each accounting period, sterling sales activity is accounted for via a series of journal entries to the monthly accounts.

Goods returned by customers are checked by the Storeman and written up on a pre-printed (triplicate) Goods Returns/Credit Claim Form describing the reason for claim: typically breakages, rejected goods, wrong location. The original document is sent to the customer, one copy is kept in the Stores and the other copy is passed to Accounting for processing. Goods Returns/Credit Claim Forms are entered into the accounting at the end of each month before customer statements are printed and posted. During peak periods the paper trail can break down. Before further expansion can take place this shortcoming must be addressed.

2.2 Production Activity

Production scheduling is done on a weekly basis, using an excel spreadsheet, and is normally based on budgeted sales for the period. The Production Manager gives a (verbal) daily production report to the General Manager. Production output is also recorded on Output Sheets, which are filled in twice daily and used by the Storeman to maintain finished goods stocks in the accounting system. Invoicing updates automatically update finished goods stock levels. However the present system ignores items salvaged from damaged reworked product returns returned to finished goods stocks for re-sale.

AHN Ltd. deals with 149 suppliers. Where possible, raw materials are sourced locally. All transactions are conducted in Euros. Purchase Orders for raw materials are created manually using pre-printed Purchase Orders. AHN Ltd. generates an average of 180 purchase orders per month and issues approximately 162 cheques each month, although the organization does hope to implement paperless transactions within two years in compliance with Irish Payment Services Organization (IPSO) regulations. Authorized Purchase Orders are posted to suppliers, with a copy held by the Storeman for comparison purposes when goods are received. Typically however the Storeman signs for all goods received as being ‘received unchecked’ given the distance between his office and the goods inward section of the production facility. At the end of each shift, the Storeman uses the delivery dockets to enter the receipts of that day on the accounting system. He then forwards the delivery dockets to the Accounting office.

2.3 Existing Information Systems

AHN Ltd. is equipped with a dated Nixdorf computer system that currently runs linked Invoicing, Payroll, Accounts Receivable, Accounts Payable, and General Ledger on a group of four networked terminals. When the system is in ‘end-of-period’ mode, data cannot be entered or edited and system querying is limited and slow. It takes approximately four hours to run all the reports (assuming all goes well and the run is not accidentally interrupted); therefore the company does not generate reports on a weekly basis. Payments received from customers are manually recorded in the Cash Book on a daily basis and entered from the Cash Book onto the Nixdorf system at the end of each month prior to generation of end of month reports. Monthly customer account statements are printed, in duplicate, with the original posted to the customer and the copy kept on file in the Accounting office. A sales report is also generated at the end of each monthly accounting period, listing all invoices and credit notes printed from the system. However the system offers no facility to analyse this data. Recently an accounting intern used the printout to generate sales analysis reports (using Excel) of the profitability of major customers and of the total commission payments associated with these sales.

The R&D department is equipped with two powerful workstations used for computer-aided design (CAD) and word-processing. All other departments have stand-alone PCs using Microsoft packages.
AHN Ltd. finds the Microsoft products to be user friendly and is attracted to the free download of upgrades. Many of AHN’s administrative personnel have successfully completed the EDCL course and the company is, therefore, favorably disposed to the use of Microsoft Access and VB.Net for the development of future computer systems.

2.4 The Need for Change: Invitation to Tender

AHN Ltd. wishes to update its existing system (along with the informal paper-based recording that has built up around it) and convert to a more modern, user friendly, flexible, open platform system. The company has issued an ‘Invitation to Tender’, inviting suitably qualified organizations to respond. Tenders are sought for the investigation, design, development and implementation of an Integrated Management Information System (hereafter referred to as an IMIS). The new system should be menu driven, be user friendly with an on-line help facility, and have security and control systems including password levels at Operating System Level and Application Level, to control user access and system audit trails. Live demonstration of a prototype of the proposed system will also be required of all those short-listed in the tendering process. Specifically, contracting organizations must:

- Prepare a full analysis of the requirements of the IMIS Project;
- Outline proposed software development, implementation and project management techniques;
- Submit a profile of proposed project team members and the role(s) they will play;
- Demonstrate an understanding of potential problems and risks involved;
- Attend regular meetings with AHN Ltd. personnel, providing progress reports and demonstrating work done on the prototype to date;
- Present a working prototype solution of their proposed system, including pro forma statements of all paper-based elements;
- Provide supporting documentation, including ‘trouble shooting’ advice and a users’ manual.

3 DISCUSSION AND CONCLUSIONS

In recent years, research has increasingly advocated active learning strategies (Boyle et al., 2001; Biggs, 1994). Active learning strategies will initially challenge most students. However careful introduction can and does offer benefits even to those who were not originally technically oriented. Research on the use of cases as a teaching strategy indicates that the difficulties that can arise relate to the application of active learning methods, rather than with the method in and of itself (Healy and McCutcheon, 2008). Our experience of using the case presented in this paper demonstrates that such difficulties can be overcome, provided lecturers maintain a two-way communication flow with students. The emergent nature of the eventual case ‘solution’ must also be recognised from the outset and viewed as an opportunity for (rather than a constraint to) the on-going development of the eventual prototype solution.

One of the key advantages of the AHN Ltd case is its hybrid orientation towards IT and Business. This dual focus facilitates students in developing a broader range of competences and an increased understanding of two key dimensions of software development: the technical dimension concerned with how to develop systems; and the business relevance dimension concerned with what features to develop. In our use of the business case, staff from the disciplines of Management Accounting and Information Systems are equally involved and play the role of users whose requirements must be met by specific features of the software. The problem-solving approach offered via the AHN Ltd case also generates a multiplier effect which results in students demonstrating a much greater familiarity and expertise with the development platforms they use than the content of formal lectures and tutorial sessions provided to them would otherwise offer. Working on the case study also gives students the occasion to understand the need for hybrid IT-Business expertise. For example in the area of systems development methods, the difference between theoretical knowledge and practical understanding is readily visible, as students re-label existing methods and mix them together to suit the needs of the
project requirements. Some groups are attracted to rapid application development (RAD) type methods and claim to deliver quicker, cheaper software, while others swear allegiance to traditional systems development life cycle (SDLC) and play the purity game. The search for a ‘single right answer’ becomes forgotten as students focus on continuously improving their own solution to the problem posed in the case description. Additionally, for our students, this has led to greater confidence and greater likelihood of attracting potential employers in interview situations.

Classes are divided into teams (with all of the dynamics of a group of developers) and asked to form consultancy companies with the ultimate goal of winning a tender. The teams compete with one another to develop a system for a customer, AHN Ltd., which is a represented by staff teaching on the degree programme utilizing the case to integrate business and IT topics. Therefore learners experience a broad range of tasks and problems inherent in commercial software development (Baskerville, 2008; Yang et al., 2008). The communication that must develop between the developers and their users of the AHN Ltd. prototype is quite realistic and reveals the gaps in understanding that can arise between individuals from different functional backgrounds. This aspect of the case gives students practical experience of the difficulties in discussing and presenting technical concepts to non-technical users. Students are forced to realize, acknowledge and understand the integration of materials taught in distinct stand-alone modules, often by staff from a number of disparate departments. Students are also encouraged to utilize their existing knowledge instead of waiting for the materials to 'come to them' as typically happens in a traditional lecture-based learning environment. The resulting skills-set developed through such activity meets the calls for same in both professional and academic sources (Panko, 2008; Chan and Reich, 2007). In conclusion, the AHN Ltd case described in this paper provides a useful vehicle for enabling lecturers to support students towards bridging disciplinary divides in IT education.

4  TEACHING APPROACH

The case study was designed to facilitate and support understanding and learning of the links between IT and its business applications. The company (AHN) description and tendering process presents students with an opportunity to play the role of practitioners tendering for the contract to develop an IMIS system. Topics covered through the AHN Ltd. teaching case include: analyzing IS requirements; developing the enterprise database; creating interfaces; designing reporting systems and project management. Table 1 outlines the how these topics can be taught and assessed through the AHN Ltd. case. The paragraphs that follow discuss how we have used the case in our own teaching.

At the start of the teaching period, the class is divided into teams of 4-6 members, depending on the size of the group. We ask for volunteer team leaders at the first class meeting; then once each class member has introduced themselves and summarized their academic background in terms of areas of prior studies, the team leaders take it in turns to select team members. Each group is expected to meet at least once a week. Project Teams are asked to record minutes of all meetings and these must be kept for review by the co-ordinators throughout the year (there may be little advance notice of reviews given). Microsoft Project is used to co-ordinate the work effort; thus planning of tasks and workloads well in advance will form an essential element of the overall assignment.

The case is structured to run as a series of workshops (see Table 2) to gradually build knowledge of the subject domains while simultaneously simulating 'real world' situations when the groups are asked to deliver a series of requirements to determine their level of understanding of the business case. At the end of each workshop the goals for the next workshop are set, based on the level of knowledge and understanding demonstrated by students up to that point. When presenting their deliverables at the beginning of each workshop it fast becomes evident if they do not fully understand the content delivered or required. This enables a post-mortem evaluation approach (Kasi et al., 2008). Workshops also provide an opportunity for students to evaluate each others work – in the past, we have
approached this by asking individual groups which aspects of each others systems they would most covet and which they would recommend making changes to. The pace of the work will determine the intervals required between workshops. Typically we hold workshops every three weeks, over the course of a 24-week teaching time.

**Table 1:** Topics Taught Through the AHN Ltd Case

The final workshop serves as a showcase for the end result of the process (Table 2 – Industry Panel). As the lecturers co-ordinating the game, we do not participate in the discussion and evaluation process during this workshop. However, we ask some of our colleagues to attend this presentation, in lieu of the senior management members of AHN Ltd – thus simulating a real-world tendering process and enhancing the overall learning experience of the students. We also invite relevant professionals from industry to attend and evaluate the IMIS solutions. In all instances, this has served as both recognition of the student inputs throughout the learning process and as a showcase of student capabilities. The final presentation also brings closure to case and a sense of achievement to students and lecturers alike.

**Table 2: Workshop Structure**
The IMIS consists of four sub-systems; Purchasing, Manufacturing, Inventory, and Sales/Ordering. Figures 1, 2 and 3 illustrate a sample solution. The focus in this instance is the Sales/Ordering (Figure 1). However this does not preclude selective inclusion of any or all of the other components. Lecturers are therefore enabled to select content which best matches with their overall teaching goals and student learning outcomes as well as the resource constraints of the learning context. Tables 1 and 2 illustrate the capabilities of the case as a pedagogic device - but allow individuals to also tailor their contents as appropriate. For example, different groups within the class could be assigned particular sub-systems to complete.

Table 3 provides a suggested grading structure totalling 200 marks (based on a module worth 10 ECT credits). Each Project Team is assessed not just on their final project submissions but also on performance over each stage and ‘deliverable’. The emphasis is on the learning process throughout the duration of the exercise, feedback is always provided following each scheduled presentation (for post-mortem evaluation). Again, individual instructors can tailor this scheme (or abandon it totally) to meet their own requirements.

**Table 3: The Grading Structure**

In conclusion, we have found the use of the AHN Ltd case to be an enriching, rewarding experience for all participants. Each year, we as co-ordinators learn something new from the process, as well as enabling our students to attain levels of understanding and appreciation for the underlying subject areas that have heretofore been difficult (if not impossible) to achieve in more traditional teaching contexts. Soft skills in terms of presenting, team-work, problem-solving and conflict resolution are embedded into the delivery of the case solution. The unanimous sense of satisfaction and achievement anecdotally reported by our students (despite the initial difficulties they encountered in the learning process) has convinced us of its power and capability to aptly serve as a means of bridging disciplinary divides in IT education.

Abstract

Surprisingly, in addition to inexperienced computer users, also those who have used different software applications at least to moderate extent can have feelings of anxiety with their use of computers. This paper examines the role of training in decreasing anxiety among experienced computer users. More specifically, the role of training is studied in relation to computer anxiety, behavioral beliefs and self-efficacy, which are the key mental constructs training may impact. 96 adult and university students, who attended a CDL course on voluntary basis, participated in this longitudinal study. The results suggest that training is an effective tool to decrease anxiety and promote self-efficacy even among experienced users. In addition this study calls in the question of the relation of computer anxiety and ease of use.

Keywords: training, anxiety, Computer Driving License, ease of use, self-efficacy
1 INTRODUCTION

Personal computers have been on the market and on the desktops of employees already for a quarter of a century. Today PCs are also an essential domestic appliance with broadband channel connections. Although the ubiquitous role of information and communication technology (ICT) in people’s everyday lives has grown significantly, average users’ skills to exploit basic computer applications efficiently are still low, and many people feel nothing less than anxiety when having to use computers (Kohrman 2003; Tekinarslan 2008). Computer anxiety can be defined in terms of a psychological response, such as, computer phobia, or in terms of a cognitive reaction, that is, apprehension of using computers (Jancour, Sinclair et al. 1994). As our focus is on more experienced computer users, we will use the latter definition in this study.

Computer anxiety is widely thought to impact early perceptions about the ease of use of a new system (Venkatesh and Davis 2000; Chee Wei, Sutanto et al. 2006). Hence, computer anxiety influences indirectly also the intention to use the system. As computer anxiety exerts such a negative influence on intention to adopt information technology attenuating its effects should remain a high priority. It is commonly argued that training decreases anxiety, yet, empirical evidence on the effect of training is ambiguous. To better decrease levels of computer anxiety among average users, we should possess a clearer picture on the effects of our main tool, training, on anxiety, and that is, precisely, the aim of this study.

In this paper, we report the findings of a longitudinal study on the effect of training on computer anxiety and behavioural beliefs about use of the target system. The study explores remedying the impact anxiety exerts on the perceptions of ease of use and usefulness related constructs. We are especially interested in how training, in our case a CDL-course, influences these perceptions in the presence of anxiety. CDL, or Computer Driving Licence, is a standardized examination developed for providing basic computing skills. It is a hands-on test, including the most commonly used software, such as, word processing, spreadsheet, graphics, databases, and graphical operating systems.

Our main research questions are as follows: 1) How does CDL-training influence user acceptance of information systems among relatively experienced users? 2) Does CDL training decrease computer anxiety? We will also test the relative importance of self-efficacy, as it has been suggested to exert a stronger effect on computer anxiety than that of experience (Wilfong 2006)

The structure of this paper is as follows: In section 2, we introduce the key constructs of anxiety, training, self-efficacy, perceived ease of use, perceived usefulness and intention to use, and introduce our research model. In Section 3, we briefly describe the empirical data collection method, and then present the results of the analyses in Section 4. Summary and conclusions, as well as directions for future research, are discussed in Section 5.

2 ANXIETY AND TRAINING

The rapid development of new computer applications and continuing software upgrading require lifelong learning. Many users remain uncomfortable using new applications, and often revert to using traditional methods to accomplish tasks that could be performed quicker or more efficiently with some software or software features. Because of feelings of uncertainty or anxiety, users remain unaware of many useful computer applications on the market and software features of the applications in use.

In the following, we will review earlier literature on computer anxiety and constructs that have been found to have effect on it, and formulate our research hypotheses based on the earlier research.
2.1 Anxiety (ANX)

We understand computer anxiety in terms of a cognitive reaction that manifests itself as apprehension of using computers (Jancour, Sinclair et al. 1994). In practice, this means that people experience uncertainty, and they are a little uncomfortable working with computers. Anxiety, then, can be viewed resulting from the beliefs an individual holds, rather than as an antecedent to these beliefs (Saade and Kira 2007).

Overall, results of many studies indicate that computer anxiety is an important predictor of the use of technology (Czaja, Charness et al. 2006; Tung and Chang 2007). Although the results of the earlier studies regarding interdependencies between anxiety and behavioral beliefs (discussed in more detail in section 2.4) are inconsistent, anxiety clearly seems to have negative effects on performance of the users.

2.2 Training

It is commonly agreed that training decreases anxiety (Igbaria 1990; Torkzadeh and Angulo 1992; Popedavis and Vispoel 1993; Torkzadeh and Koufteros 1993; Martocchio 1994; Shelley 1998; Beckers and Schmidt 2001). Effects training has on anxiety have been studied both in mandatory and voluntary settings, focusing mainly on particular new technologies, and users with limited experience. Earlier studies have found that increasing computer experience may help reduce computer anxiety (Igbaria 1993; Chang 2005), and that anxiety level decreases also while computer knowledge increases (Kay 2008). On the other hand, it has also been argued that computer self-efficacy beliefs have a stronger impact on computer anxiety than computer experience or use do (Wilfong 2006). Thus, we posit that training will decrease computer anxiety also among experienced users, whose earlier computer training is limited or missing, and we formulate our first hypothesis as follows:

Hypothesis 1 (H1): CDL training will decrease individual computer anxiety level.

2.3 Self-efficacy (SE)

Computer self-efficacy beliefs are expected to have a greater impact on computer anxiety than computer experience and use (Wilfong 2006). Self-efficacy has been defined as “people’s judgments of their capabilities to organize and execute courses of action required to attain designated types of performances” (Bandura 1986, p. 391). This means that self-efficacy is concerned not with the skills one has, but with judgments of what one can do with whatever skills one possesses (Bandura 1986). Thus, self-efficacy is simply the person’s confidence in performing a particular behaviour. In the context of computer use, self-efficacy has been defined as a judgement of one’s ability to use a technology (e.g. computer) to accomplish a particular task (Compeau and Higgins 1995a). A number of researchers agree that computer anxiety and computer self-efficacy are negatively related (Bandura 1977; Henderson, Deane et al. 1995; Igbaria and Ilvari 1995; Compeau and Higgins 1995a; Fagan, Neill et al. 2003; Chang 2005). Hence, we formulate our second hypothesis as follows:

Hypothesis 2 (H2): Reduced computer anxiety will increase computer self-efficacy.

2.4 Perceived ease of use (PEOU) and perceived usefulness (PU)

According to Davis’ technology acceptance model (TAM) (Davis 1989; Davis, Bagozzi et al. 1989) user acceptance of a new technology can be explained by two salient beliefs: perceived ease of use (PEOU) and perceived usefulness (PU). Perceived ease of use has been defined as the degree to which a person believes that using a particular system would be free of effort (Davis 1989). There is a strong negative interdependence between anxiety and PEOU (Venkatesh 2000). However, PEOU’s impact on intention is expected to decrease when experience increases (Davis, Bagozzi et al. 1989).
Computer anxiety has been offered as one of the anchors that determine early perceptions about the ease of use of a new system and it is modeled as an indirect determinant of intention (Venkatesh 2000). In particular, computer anxiety has been found to be an antecedent of perceived ease of use (Venkatesh 2000; Chee Wei, Sutanto et al. 2006). Computer anxiety has been found to have a strong negative effect on perceived usefulness (Igbaria 1993), and also resistance to change is claimed to be a significant determinant of PEOU (Nov and Ye 2008). On the other hand, it has been argued that perceived ease of use and perceived usefulness of microcomputers have a direct inverse effect on computer anxiety (Ferguson 1997).

The nature of the anxiety-PEOU relationship is further complicated by the dispute over whether the relationship is direct or not. System experience has been found to be significantly related to perceived ease of use and the effect of experience fully mediated by computer anxiety (Hackbarth et al. 2003). On the other hand, some studies report that even though anxiety has no mediating role on the impact of computer experience on perceived ease of use, it has some moderating influence on the relationship (Saade and Kira 2007).

While the nature of the anxiety-PEOU relationship remains under dispute, there appears to be a general agreement that anxiety and the salient beliefs of computer use are related. We deem that the weight of the body of literature is in support of anxiety influencing behavioral beliefs. Accordingly, we formulate our third hypothesis as follows:

Hypothesis 3 (H3): Reduced computer anxiety will increase perceived ease of use (PEOU).

2.5 Intention to use (ITU)

Computer anxiety has also been found to have a strong negative effect on behavioral intentions (Igbaria 1993), and only indirect effects on usage, mainly through perceived usefulness (Igbaria and Iivari 1995). In the context of Web-based learning, anxiety has been found to have a significant negative effect on individuals’ continuance intentions of technology usage, (Chiu and Wang 2008).

While some studies have found anxiety’s impact to usage to be insignificant (Compeau and Higgins 1999), many studies have indicated that computer anxiety is indeed an important predictor of the use of technology (Czaja, Charness et al. 2006; Tung and Chang 2007). We thus formulate our fourth hypothesis as follows:

Hypothesis 4 (H4): Reduced computer anxiety will increase intention.

2.6 Proposed model

Based on the above hypotheses, we present our research model in figure 1:

\[ \text{Figure 1. Research model} \]
3 EMPIRICAL STUDY

The empirical data for our study was collected at the Helsinki School of Economics during 2004 – 2007, from altogether 243 students attending eight CDL courses. The duration of each course was seven weeks and the course was voluntary. The data was collected with two sets of questionnaires upon the completion of the first and the last laboratory session. Having a longitudinal set of data made it possible to investigate the possible changes in the level of anxiety and other key constructs.

Our sample consists of fairly experienced users of computer technology. The software applications in question are those included in the widely used Microsoft Office package of software, that is, word processing (MS Word), spreadsheet (MS Excel), graphics (MS PowerPoint), and database applications (MS Access), and the Windows operating system.

All the constructs in our model were validated by previous research (see Appendix 1). The question items were measured using a seven-point Likert scale, with 1 anchored at totally agree and 7 anchored at totally disagree. The detailed measures used can be found in Appendix 1.

4 RESULTS

In this longitudinal study, we explore anxiety’s impact on the perceptions of ease of use and usefulness of computer applications, our particular interest being in how training, in our case a CDL-course, changes these perceptions.

4.1 Descriptive statistics

We analyzed 96 respondents in our first and second data collection. The participants were 50 adult students and 46 university students, of which 25 were males and 71 females. The average age of the respondents was 32 years, and their work experience varied between 0 and 40 years, the average being approximately 9 years. The respondents had on average 10 years of earlier experience with computers (range: 0 - 24 years). The respondents used computers on average for about 3 hours a day. Computer skills prior to the CDL course were acquired mainly (66 %) at work or through self study. Forty percent of the respondents reported having no prior formal computer education (for more details, see Table 1.).

4.2 Data analysis

We estimated the instrument’s validity in terms of internal consistency, and convergent and discriminant validity (Straub 1989). Internal consistency was tested using Cronbach’s alpha. In both rounds of data collection, all constructs except intention to complete training, displayed an alpha value higher than 0.7 indicating reliability on the common acceptable level (Nunnally 1978) (see Appendix 2).

The instrument’s discriminant and convergent validity was evaluated using a principal component factor analysis of Orthogonal varimax with Kaiser normalization rotation. All measurement items showed high loadings on their respective factors, thus proposing the instrument exhibited satisfactory convergent and discriminant validity (see Appendix 2.)

The summary constructs (mean) of each original construct before and after training are below in Table 2:

Table 2. Descriptive statistics before and after training

Before training, computer anxiety (ANX) was not very high (5.6), and after training it was not high at all (6.0). PEOU of basic pc tools changed from being 2.8 before training to being 2.3 after training. The changes of these two construct (ANX and PEOU) were also statistically significant, measured by partial t-test. The other measured constructs did not change significantly. Directions of changes are presented in Table 3 below.

</table>

Our first hypothesis (H1: CDL training will decrease individual computer anxiety level) was supported. Training significantly influenced anxiety by decreasing it. Anxiety level before training was 5.6 and after training 6.0, and t-test showed the change to be significant. These results confirm the findings of earlier studies (Igbaria 1990; Torkzadeh and Angulo 1992; Popedavis and Vispoel 1993; Torkzadeh and Koufteros 1993; Martocchio 1994; Shelley 1998; Beckers and Schmidt 2001). Also our second hypothesis (H2: Reduced computer anxiety will increase computer self-efficacy.) was supported. The change in the level of self-efficacy before and after training was very low and not statistically significant, but when we look at the correlations of these changes, it can be seen that changes of anxiety and self-efficacy correlate significantly at the 0.05 level (-.222) (see Table 4). The negative correlation between computer anxiety and computer self-efficacy confirm the results of earlier studies (Bandura 1977; Henderson, Deane et al. 1995; Igbaria and Iivari 1995; Compeau and Higgins 1995a; Fagan, Neill et al. 2003; Chang 2005), but our study demonstrates the relationship also in context of longitudinal training.

Our third hypothesis (H3: Reduced computer anxiety will increase perceived ease of use) was, however, not supported. Even though the measurements of anxiety and ease of use showed significant changes after training, the change for ease of use being the strongest, the correlation between the changes of anxiety and ease of use was not significant. A possible explanation to this might be that the users did not experience that the lower anxiety level results in ease of use but instead in use of new features, i.e. the lower the anxiety level, the more prone the users are to learn more advanced functions. This finding is in contrast with earlier studies that have argued a strong relationship between ease of use and anxiety (Venkatesh 2000; Chee Wei, Sutanto et al. 2006; van Raaij and Schepers 2008).

Our fourth hypothesis (H4: Reduced computer anxiety will increase intention) was, again, supported. The negative correlation (-.295) between changes on computer anxiety and intention was significant at the 0.01 level. This means that reduced computer anxiety could increase intention to use, and that anxiety, in general, can have a negative impact on intention to use. There are contradicting findings for this in earlier research (Igbaria 1993; Compeau and Higgins 1999; Kluwin and Noretsky 2005; Chiu and Wang 2008), clearly calling for future research on the issue.
We hence conclude that training decreases computer anxiety and increases perceived ease of use. Training was found to influence user acceptance of information technology, decreasing anxiety and increasing perceived ease of use. There is a negative relationship between computer anxiety and self-efficacy also after training. Contrary to earlier research, there was no relationship between the changes of levels of computer anxiety and ease of use. In addition, anxiety seems to impact intention to use technology.

Our results can be summarized as follows (see Figure 2): Firstly, training, or a CDL course in our study, decreases individual anxiety level (ANX). Secondly, reduced anxiety has a positive impact on self-efficacy (SE). Thirdly, anxiety does not correlate with perceived ease of use (PEOU), which might mean that users do not experience that the lower anxiety level results in ease of use. Fourthly, reduced anxiety increases intention (INT). We have included in our model also the relationships between self-efficacy and intention, self-efficacy and perceived ease of use, perceived ease of use and perceived usefulness (PU), perceived ease of use and intention, and perceived usefulness and intention, but these were not hypothesized, nor tested, in this study, but left for future research.

Our findings suggest that training significantly decreases computer anxiety, and at the same time, increases perceived ease of use among relatively experienced computer users. This means that training has a clear positive influence on user acceptance of these computer applications, Microsoft Office tools in our case. In addition, training seems to strengthen the negative relationship between computer anxiety and self-efficacy. The most surprising outcome was that the relationship between computer anxiety and perceived ease of use was not clear. After training changes in both constructs were statistically significant, perceived ease of use increased and anxiety decreased, but the changes did not correlate. Some scholars argue that anxiety is an anchor of perceived ease of use (Venkatesh 2000; Chee Wei, Sutanto et al. 2006) or vice versa (Ferguson 1997). Furthermore, anxiety has been suggested to be a result of the beliefs an individual has, rather than an antecedent to them (Saade and Kira 2007). While we found that changes at the levels of anxiety and ease of use do not correlate, the
findings of our study indicate that the relationship between these constructs needs deeper investigation. Our results also demonstrated a strong relationship between computer anxiety and intention to use technology.

While our study provided interesting findings about the relationship between anxiety and ease of use the study has a few limitations. Our study examined and reported anxiety’s impact only on perceived ease of use, self-efficacy, and intention. More research is needed to test anxiety’s impact on other user acceptance related beliefs such as perceived usefulness, subjective norm, job-relevance and compatibility.

APPENDIX 1: Measures Used in the Study

**Computer Anxiety (ANX)** (Drawn from the Computer Anxiety Rating Scale (Heinssen et al., 1987):

1. It scares me to think that I could cause the computer to destroy a large amount of information by hitting the wrong key.
2. I feel apprehensive about using computers.
3. I hesitate to use a computer for fear of making mistakes that I cannot correct.

**Computer Self-Efficacy (SE)** (Compeau and Higgins 1995a; Compeau and Higgins 1995b; Compeau and Higgins 1999):

I could complete my job using the technology if….
1. I had seen someone else using it before trying it myself.
2. Someone showed me how to do it first.
3. I could call someone for help if I got stuck.
4. I had used similar packages like this one before to do the job.
5. I had a lot of time to complete the job for which the software was provided.
6. Someone else helped me get started.

**Perceived ease of use (PEOU)** (Davis 1989; Davis, Bagozzi et al. 1989):

1. It would be easy for me to become skillful at using the system.
2. Learning to operate the system is easy for me.
3. I believe that it is easy to get the system to do what I want to do.
4. Overall, I believe that the system is easy to use.

**Perceived usefulness (PU)** (Davis 1989; Davis, Bagozzi et al. 1989):

1. Using basic PC tools makes it easier to do my job.
2. Using basic PC tools increases my productivity.
3. Using basic PC tools enables me to accomplish tasks more quickly.

**Intention to use (ITU)** (Hu and Chau (1999):

1. Whenever possible, I intend to use this basic software in my job/study.
2. I intend to use this software versatility in my job/study.

All items measured using a seven-point Likert scale (1=totally agree, 7=totally disagree).

THE DEVELOPMENT AND TEST OF A RELATIONSHIP MODEL ON SYSTEM USE, JOB LEARNING, AND IMPACT

Abstract

This exploratory study examined the role of job learning on the relationship between information systems use and impact. Data from 308 end-users were analyzed to evaluate the relationship between systems use, job learning, and technology impact. System use was conceptualized as decision support, work integration, and customer service. Technology impact was conceptualized as effect on management control, task innovation, task productivity, and customer satisfaction. Two sets of hypotheses are presented for these relationships. Results suggest that the pattern of system use significantly and positively influenced job learning. Job learning was found to significantly and positively influence technology impact. We theorize that individuals learned about their job as a result of systems usage. In turn, job learning influenced technology impact. The study findings are discussed.

Keywords: system use, job learning, information technology impact.
THE DEVELOPMENT AND TEST OF A RELATIONSHIP MODEL ON SYSTEM USE, JOB LEARNING, AND IMPACT

1. INTRODUCTION

Information technology continues to play a pivotal role in the structure of work and human productivity. Organisations often attribute their high performance to effective application of information systems. Increasingly, information system executives are required to explain technology expenditures in terms of individual benefits and organisational outcomes. Specifically, organisations are becoming increasingly concerned about what technology use means in the context of the organisation. For example: changes in management control, innovation, productivity, and customer satisfaction. Because of this, the system success paradigm has progressed from an emphasis on ‘suitability for use’ where design features such as content, accuracy, format, and ease of use are considered important, to an emphasis on ‘benefit of use’ where systems’ impact on the individual and the organisation is considered essential (Melone 1990, Torkzadeh and Doll 1999).

Research studies have addressed information technology impact from a variety of perspectives including: new ventures (Fairlie 2006), business performance (Brynjolfsson & Hitt 2000), competitive advantage (Sethi & King 1994), organisational strategy (Mahmood 1991), time management (Sulek & Marucheck 1991), and industry level (Segars & Grover 1994). Increasingly, the relevant question about information technology impact relates to the nature of that impact and how it occurs. Impact through use is one area of investigation suggested (Torkzadeh & Doll 1999). Although it is quite obvious system use would lead to impact, the unanswered question is how. We propose job learning as one possible mechanism in this regard.

As individuals interact with system applications, they learn about their job, and as a result, become more productive. Information technology plays an important role in job learning, and individual productivity. Because of this, information technology plays a critical role in the expansion of knowledge: learning becomes a new form of labor (Zuboff 1988). “Learning is no longer a separate activity that occurs either before one enters the workplace or in remote classroom setting.” “Learning is the heart of productive activity”(Zuboff 1988, p. 395). For the individual, information technology holds promise in terms of job enhancement and the outcome of labor. Information technology impacts how a job is performed and what the outcome might be. Thus, there is a need for better understanding the nature and outcome of the interaction between people and technology in an organisational context.

This exploratory study examines the relationship between system use, job learning, and technology impact. Previously published measures of systems use and technology impact as well as a newly developed measure of job learning are used to collect data from 308 end-users and to examine this relationship. Measures of system use exhibit patterns of use in terms of decision support, work integration, and customer service. Measures of technology impact evaluate perceived outcomes in terms of management control, task innovation, task productivity, and customer satisfaction. Measures of job learning reflect technology influence on the ability to learn and perform job functions as well as to improve the quality of work. In the following section we will review the relevant literature, develop hypotheses, describes the structural model and measures, describe our results, and finally draw conclusions.
2. REVIEW OF LITERATURE AND RESEARCH HYPOTHESES

2.1 System Use

The measurement of information systems success continues to be an important topic for research and practice. At least two perspectives exist in the literature for measuring systems success: the design perspective and the outcome perspective. The design perspective has a strong tradition in the MIS field and involves evaluating systems relative to design specifications or user needs. The outcome perspective calls for performance-related evaluations that focus on outcomes. Measures of user satisfaction (Doll & Torkzadeh 1988) and perceived usefulness (Davis 1989) are widely accepted examples of the design perspective. Measures of technology impact on work (Torkzadeh & Doll 1999) and technology impact on competitive advantage (Sethi & King 1994) are good examples of the outcome perspective.

System use has also been considered as a measure of system success in earlier research studies (Hamilton & Chervany 1981, Ives et al. 1980, Ein-Dor & Segev 1978). It has been viewed as an important construct in conceptualizing information system success (Doll & Torkzadeh 1998, DeLone & McLean 1992). However, other studies argue that the critical success factor in technology investment is not system use in and of itself, but the net benefits to organisations that occurs from that use (Seddon 1997, Szajna 1993). Therefore, while system use is a pivotal link in the ‘system-to-value chain’ from technology adoption to social and economic impact (Doll & Torkzadeh 1991), it is the outcomes of use that reflect system success. In this taxonomy user satisfaction and perceived usefulness are expected to influence system use.

There is a great diversity of system use constructs in information system research (Burton Jones & Straub, 2006). While the emphasis of IS literature on system use is more concerned with the justification for creating and/or utilizing information systems, the social science literature on the nature of work views information technology as being used by individuals in a work context to perform certain organisationally relevant functions (Doll & Torkzadeh, 1998). For example, information technology is used to communicate with subordinates and superiors, to facilitate problem solving, to plan team work, to service customers, and to rationalize decisions, etc.

In order to measure how information technology is actually used by individuals in an organisational context, Doll and Torkzadeh (1998) developed a multidimensional instrument for technology utilisation for the three functions of decision support, work integration, and customer service. The decision support function was defined in terms of ‘problem solving’ (the extent that information technology is used to analyse cause and effect relationships and to make sense out of data) and ‘decision rationalisation’ (the extent that information technology is used to improve the decision making processes or explain/justify the reasons for decisions). Work integration was defined in terms of ‘horizontal integration’ (the extent that information technology is used to coordinate work activities with others in one’s work group) and ‘vertical integration’ (the extent that information technology is used to plan one’s own work, monitor performance, and communicate vertically to coordinate one’s work with superiors and subordinates). Customer service was defined as: the extent that information technology is used to service internal and external customers. These constructs are adopted for the current study.

2.2 Job Learning

Job learning is an important aspect of performance. Although most positions require evidence of capabilities/skills from employees, a large part of learning occurs as the work is being performed. Learning in the workplace has been characterized as the process of seeking technical, referent, and normative information (Morrison 1993). While employees are charged with the responsibility
to exhibit learning behaviour, the organisation needs to provide the opportunities for the employees to learn. Extending work-based learning from the individual, to the group, and to the entire organisation prompted the development for the concept of learning organisation. Implementation of knowledge management systems is one consideration for organisation to provide and/or enhance work-based learning through application of information technology.

Although there is a long history of information systems use at the workplace, research on how this use affects job learning is very limited. As individuals interact with technology to accomplish tasks, they learn more about their job and become more innovative in carrying out responsibilities (Ruiz-Mercader, et al. 2006). Information technology enables employees to deliver more value to the customer (Harvey et al. 1993). The use of information technology is expected to enrich and broaden jobs (Long 1993). Employees use information technology in innovative ways to enhance their customer service. Customer relationship management (CRM) systems are a good example of applications that help employees to develop new and innovative ways of providing customer service. Cross-functional integration and effective data processing provided by CRM applications enable employees to access customer profiles and product information and even predict customer needs (Torkzadeh et al. 2006, Reinartz et al. 2004).

Since the focus of this study is based on system use, we need to examine job learning in the same context. Therefore, we define job learning as a user’s perception of the extent an application enhances learning about the job/task performed. As an employee uses systems for decision support, s/he would likely learn more about the decision variables that need to be included as well as justification for the decision. By using systems to coordinate and communicate with others, the user would see the benefit of the system for learning about the people and work flow related to the task at hand. The enhancement of job learning through system use should eventually produce positive outcomes.

2.3 Impact

Information technology has influenced the nature of work, the process of learning and ways of accomplishing organisationally relevant tasks. Organisations are increasingly interested in the extent and the nature of their IT investment outcomes, and how application development and acceptance benefits their bottom line. While adoption and use of information technology continues to be an important goal of information system executives, there is an increased emphasis on the net benefits that emerge from system use (Seddon 1997). Information system executives are expected to explain the value and contribution of information technology expenditure in terms of increased productivity, quality, and competitiveness (Myers et al. 1997).

Traditional approaches for measuring technology impact emphasize productivity and management control. The extent of information technology use and its influence on productivity and management control has long been the focus of attention (Weick 1990, Zuboff 1988, Braverman 1974). MIS researchers have devoted considerable attention to the impact of information technology on productivity (Sulek & Marucheck 1992, Cooper & Zmud 1990, Kraemer & Danziger 1990, Hirschhorn & Farduhar 1985). More recently that emphasis has included technology impacts on innovation and customer service. In addition to productivity and management control, information technology impacts on innovation and customer satisfaction have also gained increased attention (Filiatrault et al. 1996, Harvey et al. 1993, Davis 1991, Curley & Pyburn 1982).

To help management distinguish between effective and ineffective applications, Torkzadeh and Doll (1999) developed a set of outcome measures in the context of management control, task innovation, task productivity, and customer satisfaction. Management control was defined as: the extent that the application helps to regulate work processes and performance. Task innovation
was defined as: the extent that an application helps users create and try out new ideas in their work. Task productivity is defined as: the extent that an application improves the user’s output per unit of time. Customer satisfaction was defined as: the extent that an application helps the user create value for the firm’s internal or external customers. To the extent that these constructs relate to organisationally relevant outcomes they are appropriate for the context in which this study was carried out. We adopt these concepts of technology impact in this study.

Based on review of the literature presented in this section, two sets of hypotheses are presented that describe the relationship between system use and job learning, and job learning and the impact of technology on work and its components. In this model, job learning is considered the intervening variable between system use and technology impact, as depicted in Figure 1.

H1: Systems use measured in terms of decision support is expected to be positively related to job learning.

H2: Systems use measured in terms of work integration is expected to be positively related to job learning.

H3: Systems use measured in terms of customer service is expected to be positively related to job learning.

H4: Job learning is expected to be positively related to information technology impact in terms of management control.

H5: Job learning is expected to be positively related to information technology impact in terms of task innovation.

H6: Job learning is expected to be positively related to information technology impact in terms of task productivity.

H7: Job learning is expected to be positively related to information technology impact in terms of customer satisfaction.
3. RESEARCH METHODS

3.1 Operationalisation of Constructs

To examine the relationships depicted in Figure 1, a combination of published and newly developed measures were used to collect the data. In this study, the three-factor measurement model developed by Doll and Torkzadeh (1998) was used to operationalise system use. The instrument consists of 13, 11, and 5 items for decision support, work integration, and customer service, respectively. Examples of system use items include: ‘I use this application to control or shape the decision process,’ ‘I use this application to plan my work’, and ‘I use this application to improve the quality of customer service’.

To measure technology impact, the four-factor measurement model of information technology impact developed by Torkzadeh and Doll (1999) was used. Each of the four constructs (task productivity, task innovation, customer satisfaction, and management control) is measured using 3 items. Examples of technology impact items include: ‘This application improves management control’, ‘This application helps me create new ideas’, ‘This application increases my productivity’, and ‘This application improves customer service’. Both system use and technology impact instruments were measured using a 5-point Likert-type scale anchored by (1) ‘Not at all’ and (5) ‘A great deal.’

Job learning was operationalised using eight items that asked respondents how information technology influenced their job learning. Although there is a broad understanding that information technology is a learning tool and that it has the potential to help employees learn more about their jobs and how to better perform, to the best of our knowledge, there are no job learning measures linking technology to job learning. Literature on productivity and organization provide a broad background to the understanding of how technology might influence individuals as they go about learning about their jobs and performing their tasks (Weick 1990, Braverman 1974, Zuboff 1988). That literature suggests that information rich organizations are learning environments with the purpose to be more productive (Zuboff 1988). Job learning in this study...
was conceptualized in terms of how technology assists individuals become more skillful at doing what they are supposed to do as well as help them to better perform their assigned tasks.

Survey items were generated to operationalize technology as it helps the individual “how to do things, rather than what to do or why” (Zuboff 1988, p. 206). This conceptualization also suggests that technology helps the individual to understand the job better as well as to perform the job more effectively. Survey items also intended to assess whether information technology would increase employees’ capabilities to enrich and expand jobs (Lang 1993). Examples of job learning indicators in this study include: ‘This application increases the ability required to do my job’, ‘This application helps me learn how to improve the quality of my work’, ‘This application increases the capabilities required to do my job’, and ‘This application helps me better understand my job’. A Likert-type scale similar to the one used in system use and technology impact measures was used for these questions. The job learning measure was found to be both reliable and valid (reported below).

3.2 Sample

A survey questionnaire comprised of 30 items measuring system use, 8 items measuring job learning, and 12 items measuring technology impact was used to collect data. The survey was also used to collect respondent information, type of application, and the level of use.

The respondents relied heavily on specific applications for completing their job functions. By collecting data from users who relied heavily on the use of a specific application, the researchers were confident that respondents could identify patterns of application use in their organizational context, how the application helped them learn about their job, and how they viewed the impact of job learning on how the technology impacted their work. Demographics revealed a broad industry representation. Respondents worked for government agencies (19.5%), manufacturing (16.2%), health service (14.6%), transportation (12.6%), education (9.3%), finance (8.8%), wholesale and retail (4.9%), and others (14%). Several incomplete responses were discarded and a sample of 308 complete responses to all constructs was used for analysis. Discarded responses were considered too few to suggest a meaningful difference between incomplete and complete responses. Major applications include office automation applications (22.5%), financial applications (20.9%), and accounting applications (13.5%).

4. DATA ANALYSIS AND RESULTS

We used partial least squares (PLS-Graph 3.0) to analyze the proposed relationships. PLS is suitable because the aim of the study is to examine the predictive validity of the ‘system use’ and ‘job learning’ constructs. In addition, PLS relaxes certain distributional assumptions and is considered appropriate for exploratory. Kolmogorov-Smirnov’s test of normality indicates that none of our measurement items are normally distributed. All items are modeled as reflective according to their original design. The measurement and structural model were tested simultaneously. Since PLS does not produce fit statistics, we followed the general criteria of item loadings above .7, path coefficients above .2 (Chin 1998), and t-statistics for item loadings and path coefficients generated from bootstrapping (100 resamples) to evaluate the analysis results.

Because the items for ‘job learning’ were developed for this study, we first ran exploratory factor analysis to examine the factor structure for these items. All eight items loaded on one factor with strong loadings that range from .745 to .854 and explained 66% of the available variance. Cronbach’s alpha for the eight items is .92 and all corrected item-total correlations are above .7, indicating good internal consistency. Thus all eight items for the job learning’ measure were retained.
Results of the PLS measurement model (i.e., item loading, cross-loading, t-statistics, composite reliability, and AVE) are presented in the Appendix. Most item loadings are above .7 and all loadings are significant. Although a few items have marginal loadings, we decided to retain them to be consistent with the original instruments. Although some cross-loadings were observed, all items loaded highest on their respective factors. The composite reliabilities and AVE of all factors are above the accepted .7 and .5 level, respectively. The discriminant validity of the measures is verified by comparing the square root of AVE and cross-construct correlations. As can be seen on Table 1, all correlations are smaller than its respective square-root of AVE. These results provide evidence for convergent and discriminant validity for the measures of ‘job learning’ construct as well as the system use and technology impact constructs.

Bold = square root of AVE.

The results of the PLS structural model are presented in Figure 2. All system use constructs significantly affected job learning with path coefficients above .2 explaining over 40% ($R^2=.437$) of the variance. Effect sizes were calculated based on the procedure recommended by Chin (1998), and are 0.4, 0.4, and 0.14 for Decision Support, Work Integration, and Customer Service, respectively; indicating small to medium effects. This supports hypotheses 1-3. Job learning also significantly affected each of the ‘impact’ constructs. Path coefficients ranged from .526 to .676, indicating that ‘job learning’ strongly influenced the ‘impact’ constructs. Job learning also explained a significant amount of variance in the impact constructs (.277 to .457). This supports hypotheses 4-7.

5. DISCUSSION AND CONCLUSION

Employees use information technology in an organisational context to accomplish specific tasks and carry out responsibilities. The measurement of information technology use in information systems research has progressed from the traditional focus on the level and frequency of computer use to the conception that incorporates intent and pattern of use. Research interest in this domain has moved from how much technology is used to ways in which technology is used. This latter conceptualization has implications for evaluating technology impact on work; how we evaluate the influence of system use on the nature of work and productivity.

Individuals interact with technology applications to explore ways to improve their job performance, and in that fusion of exploring and doing, they learn and enhance their knowledge about their job. Learning becomes a part of what they need to do in order to do it better. Learning processes occur in the context of work and employees learn as they go about solving problems (Bereiter 2002). In evaluating technology impact, we must go beyond what individuals currently do and examine how prepared they are to do what they need to do next. Formal training is expected to provide the individual with core competency and fundamental knowledge to know how to learn on the job. Employee skills are developed in a learning environment that includes work settings, tools, problems, and co-workers who have common purpose (Lambrecht et al. 2004). Because we are evaluating the impact of technology in organisational contexts we are evaluating the interaction of people and technology in an organisational environment rather than separately evaluating the individual, the technology, or the organisation. This conceptualization is helpful in explaining the perception of a widening gap between the potential of information technology and its actual use, and, represents a major contribution towards work in this important area.

This view of system use and technology impact in an organisational context influenced the researchers during the design and implementation of the current study. Our premise is that when information technology is used by individuals in new ways, that interactive effect has important implications for the nature of work, the need to learn and innovate, and the approach to decision problems. Specifically, our objectives were: (a) to evaluate system use in terms of a ‘function’ that individuals could easily relate to in their work context (e.g., to rationalize decisions, to make sense out of data); (b) to evaluate technology impacts in terms of organisationally relevant outcomes (e.g., improved customer service, improved productivity); (c) to evaluate job learning as a behavior that links system use with the perceived impact of technology; and (d) to extend the conception of technology impact beyond the traditional focus on productivity and management control and to include dimensions of customer satisfaction and task innovation that are relevant to the success and survival of modern organisations.

We encourage confirmatory studies of these findings for specific industries (e.g., service), in specific settings (e.g., in an environment where user participation in system development is strong or where the majority of developmental activities are offshored), and for specific technologies (e.g., customer relationship management). Studies that are more focused on an industry, environment, or technology would demonstrate the potential benefits for research and practice in these specific settings. In these follow up studies, part or all of the ‘system use’ and ‘technology impact’ constructs may be appropriate.

THE ENTERPRISES SIMULATION IN SECOND LIFE. THE CASE OF PERTING LTD

Tampieri, Laura, Bologna University - Forlì Faculty of Economics, Piazzale della Vittoria 15, 47100 Forlì, Italy, laura.tampieri@unibo.it

Abstract

The diffusion of ICT applications in virtual worlds as Second Life (SL), Forterra, There and Multiverse created many interesting research opportunities, particularly in knowledge management and e-learning. Virtual worlds are strongly immersive and produce entrepreneurial and social initiatives in which personal, professional and business relationships move quickly and could be transferred into the real environment.

Enterprises, Municipalities, Universities and Chambers of Commerce are increasing the use of SL enforcing the methodological relevance of networking, a new approach that bases its impact, for the development of business, on the creation and maintenance of net links.

This paper will consider the case of Perting Ltd, the simulated enterprise created in 2001 by Forlì Faculty of Economics, that established in February 2008 its premises in SL and started managing businesses in different sectors.

The main subject of this analysis is the use of virtual reality in management not only for business but also in research and didactics. In managerial theories the research would be an opportunity for a new perspective to know the symmetries among ICT business platforms and to understand, in a better way, how the learning process could support organizations in their approach to the market of internet relationships.

Keywords: virtual world, simulation, e-learning, knowledge management systems
1 FROM INFORMATION SYSTEMS TO VIRTUAL WORLDS

It is widely accepted that ICT offers increasing opportunities for implementing innovative structures and processes in organizations. ICT is connected not only to the low cost processing of information, but opens new perspectives for networking\(^1\), interacting and communicating across the world overcoming physical distances (Ndou, Troshani 2008).

In recent years the increasing interaction between ICT and organizational systems moved the evolution of information systems towards the search of a major integration and coordination among the different business functions / area / departments and external relationships with customers and suppliers (Di Donato 2003).

The use of virtual reality by enterprises and public administrations showed the relevance of visual and perceptual impact on organizational behaviour and contributed to the implementation of BPR through the introduction of subjective factors and intangible assets as key – factors in the management of e-business (Carignani 2005).

In a few years the targets of Internet usage changed from information distribution to the creation of business web sites including knowledge platform linked to products, services and enterprises, based on interactive processes as forums and blogs.

The same purpose derives from the creation and management of virtual worlds (3D Web) as NORRATH (The first virtual space which introduced a virtual currency convertible in the market), MMORPGs (Massively Multiplayer Online Role-Playing Game), METAVERSE (Fully immersive 3D virtual spaces as SL), MMOLEs (Massively Multiplayer Online Learning Environment), FORTERRA, THERE and MULTIVERSE, enable the business development in virtual environment (Kish 2007).

The 3D creates the illusion of the real business world with Avatars which materialize the image of the decision makers, users and visitors moving in SL. One of the main features of the virtual world is the interactivity among Avatars that interact on the basis of an informatics platform appearing as landscape, buildings, roads, etc.

The organizational studies undertaken on management and technology (De Marco 2000) stressed the relevance of Practice Community (Brown, Duguid 2002) and the impact on individual behaviour and trust (Giddens 1990). Moreover it is emphasized their influence on the process of professional and entrepreneurial culture building, together with their dynamism and differentiation, opening the possibilities of a deeper specialization (Bertolotti et al. 2003).

Also the outsourcing of knowledge process (Virtuani 2005) coming from the network through data mining activities support business flows with a new approach based on links among the virtual world actors that represented a huge innovation comparing to the internal and traditional way of information management (Ciborra, Hanseth 2006).

Many Scholars pointed out the difficulties to define the “Virtual World” and the “Virtual Community” (Schoereth, Schrott 2001) owing to the multidisciplinary attitudes needed to approach the subject (Krcmar, Leimeister 2005) and considering the variety of languages used to this purpose by academic and unacademic Authors (Preece 2000).

Choi (2007) analyses the threshold to cross from the informatics and technology to business and network dynamics, defining the Virtual World as an environment in which the participants,\(^1\) Although it is connected to the concept of Networking approach used by Authors to define a way of creating new organizations by stabilizing and implementing links with other entities, networking is used in the meaning of activity oriented to establish links among different individuals on a common knowledge platform, Real, Simulated and Virtual (RSV).
represented by Avatars, coordinate their business actions with an unknown speediness and overcoming the normal space and time limits (Table 1).

</table>

Table 1. Some relevant definition of “Virtual World” and “Virtual Community”

In SL, the most diffused virtual world (Table 2), the language is very specialized (Thomas, Peters 2007). By the way Land is defined as a place in which it is built the store/shop; Group is a community of residents sharing common interests and needs and People is the residents’ nickname.

3 Second Life is a 3D virtual world launched in 2003 and developed by Linden Lab. The users, named “residents”, interact each other through “Avatars” providing an advanced level of a social network service. Residents can participate to individual and group activities, create and trade items (virtual property) and services with one another. Second Life uses an internal currency called the “Linden Dollar” that are usually obtained by changing real money. http://www.secondlife.com
4 Linden Labs defines residents as the accounts created in Second Life. www.secondlife.com
5 Population is defined as the total of enrolled users
6 It is defined as the complex of users that have subscribed an account Premium and have bought Linden with real currency. www.secondlife.com

Table 2. The general profile of activities in SL^7

The use of Internet stressed by SL moves from the management input-output processes to the coordination of transactions focused on actors, relationships, operative activities, integration mechanisms and technologies (Virili 2008).

To this purpose the diffusion of different ICT tri-dimensional premises^8 is performing a strong impact on the structures and processes of trade, mainly in term of knowledge management ^9, assuming an increasing function of support and assistance in managing changes (Barabasi 2004) from the direct product-driven to the indirect one (Buttle 2004). This translation of perspectives is based on the personalization and on the maintenance of business links through an adequate knowledge management completely based on specialized software typed on CRM.

Together with the 3D relational marketing we have to consider, in addition, the opportunities of networking among operators that from the traditional concept of “fair” and “business meetings” or “business tours”, have been developed in events, forum and blog building^10 structured as instant media.

2 SECOND LIFE AND THE ENTERPRISE SIMULATION

Many public and private organizations set a place inside SL, exploring the way in which virtual worlds may change their business management. In recent times SL is considered as an effective entrepreneurial environment. For many individuals the first business experience into SL is represented by the creation of a store for marketing and branding targets but other key business areas have been explored to this purpose (Table 3).

The usage of SL in the enterprise simulation has the main aim of allowing the residents to interact directly with the teachers and students during lectures and seminars enforcing an interactive approach that can be considered the added value achieved by this methodology rather than the traditional e-learning platforms by which students can only download the didactical materials.

The attitude of SL in enterprise simulation is particularly useful for the development of entrepreneurship in transition countries, characterized by scarce entrepreneurial initiatives and an environment not favourable to entrepreneurship, in which the virtual reality could be considered as a

^7 For 2005, 2006 and 2007 the data refer to 31th December, for 2008 at 31th May.
^8 In each activity of support and transformation of supply chain we can consider different operative applications of Internet: for the infrastructure management, human resources, technologies development and purchase, the ICT tools are intranet, knowledge management and community; the e-commerce refers to logistics in and out; the conversion process uses CAD (Computer-Aided Design) and CAM (Computer-Aided Manufacturing); while marketing and selling uses the e-franchising, email and web site. The service post sale utilizes the mailing list, forum and extranet (Benassi 2005).
^9 In the era of e-commerce the problem of channel management is linked to the conflicts management of different and new channels of communication (Castaldo 2001).
^10 In the fashion sector, www.fashionblog.it; www.fashionteen.it/blog/.

</tr>
</tbody>
</table>

Table 3. Emerging key business areas in SL

Another area of interest refers to the operative marketing with the target of increasing the revenue by products selling according to CRM strategies implementation to know and fidelize the customers. At the same time SL could work as test laboratory to develop new products and services, that can be realized in the real world.

In the education field the framework of enterprise simulation proposed opportunities in the: 1) Definition of the educational process: each participant rotates among the different departments, carrying out tasks connected to the job and to the organizational goals achievement; 2) Development of behavioral capacities, both internal to the enterprise simulation, and external with other foreign companies; 3) Providing adequate and consistent responses to the needs of real companies; 4) Learning to manage a role with the process of know-how transfer; 5) Increasing the basic motivations through greater participation in the processes of learning and cooperative environment; 6) Problem solving activities with customers and suppliers; 7) How to learn and work in team.

The applied methodology is the learning by doing based on the synergy between the knowledge acquired during the studies and the practical skills achieved through the simulated activities.

Enterprise simulation program faces the ICT challenges in using Internet as the main tool to manage relationships with customers and suppliers, together with the communications within internal departments. Last implementation in SL increased the enterprise simulation innovation for didactic and research purposes.

Particularly the ICT sector on the use of virtual reality is resumed by Carpenter, Harrison and List (2005) through researches on boundaries and networking establishing new benchmarking for private and public organizations. On this purpose more than 300 Universities and educational organizations have set up platforms in virtual worlds and are exploring ways and concepts for distance learning purposes.

Virtual Worlds enable new ways of communication and collaboration over the Internet by applying 3D environments and VoIP technologies. Through the combined use of innovative Internet technologies and due to their immersive features, virtual worlds offer new possibilities for the computer-mediated communication and co-operation. Hence, virtual worlds provide innovative learning arrangements and are particularly suitable to transfer experimental knowledge. Students can take part in a distance learning environment to develop a real sense of community in which they cooperate with each other and there is a regular sense of classroom interaction.

Furthermore, Virtual Worlds offer new opportunities for enterprises to interact and understand their existing and potential customers’ needs and desires (Lang, Fetscherin, Lattemann, 2008).
3 THE CASE OF PERTING LTD

Most of the key business areas in SL, above mentioned, are implemented in Forlì Laboratory for enterprise simulation. Forlì Laboratory reproduces for didactical and research purposes the structures and the activities of an enterprise simulating the business in connection to an international network of other simulated enterprises named Europen.

This experimental activity is managed by students under the mentoring and supervising of the teacher and tutors. The sector chosen in Forlì is the business services and IT products trade, under the brand of Perting ltd, a simulated enterprise with its general meeting and board of directors. In the network this enterprise makes business with other firms of the Europen Network operating as suppliers and customers (Table 4).

Table 4. The profile of activities carried out by Perting

The corporate purpose of Perting Ltd is the consulting in management, accounting and internet business. Moreover Perting is committed in the trade of informatics equipments (PC, printers, photo cameras, modems, software and so on).

From the academic year 2008-2009 the Laboratory used SL as innovative tool to realize lectures, video conferences and interactive e-learning platforms improving the didactic and research activities. By using SL the number of contacts activated by Perting highly increased from 172 to 1613 enforcing the networking approach creating a network of individuals and organizations.

---

11 The Laboratory is managed by University of Bologna – Forlì Faculty of Economics.
12 The data linked to the number of teachers, tutors, students and hours of activity refer to the first semester. The data related to the number of customers, supplier and visitors in SL refer to 31th October 2008.
13 The data linked to the number of teachers, tutors, students and hours of activity refer to the second semester. The data related to the number of customers, supplier and visitors in SL refer to 31th March 2009.
Summarizing the main relevant steps of Perting Ltd:

- In October 2001 the creation of Perting Ltd was the first milestone of the enterprise simulation Laboratory\textsuperscript{14} connected with the course of Business Management\textsuperscript{15} and supported by Fondazione Cassa dei Risparmi of Forlì. Perting Ltd operated in organizational consulting, business networking and merchandising of ICT products as the first unit of Enterprise simulation established by an Italian University\textsuperscript{16}.

- In 2004 Perting participated to its first international project for the “Formation and technical assistance for SMEs development in Durazzo harbor district”, financed by the Ministry of Foreign Affairs. To this purpose the first Simulated Unit supported by Perting was created in Shkoder (Albania): the KK Personal Robe, operating in textile sector.

- During A.Y. 2005-2006 Enterprise simulation Laboratory of Forlì contributed actively to the start up of the Unit “NoRisk” at Economics’ Faculty of Parma University, a simulated company offering insurance services and trade of products for the safety at the workplace.

- In 27th February 2008 Perting opened its headquarters in SL, becoming the first enterprise simulation created by a University and seat in this virtual world (Figure 1).

![Figure 1. The headquarters of Perting Ltd in SL\textsuperscript{17}](http://slurl.com/secondlife/Kouhun/246/248/54)

The simulation is very realistic because all the managerial processes, from the business plan to the product/service conception, to the delivering of orders and related invoices are carried out as in the reality. At the end of each year on the basis of cost and revenues a balance sheet is prepared and submitted to the Europen Center that certifies the result.

This activity allowed the students to realize a real internship in a concrete job while applying of knowledge received in theoretical courses. This learning is connected to the building of the sense in entrepreneurship and self achievement. For this reason the Laboratory was involved in many international projects for the development of small and medium business in transition countries. As it could reproduce entrepreneurial and marketing practices Perting ltd was used in researches on enterprise start up and on the management of relationships with suppliers and customers.

In the premises of Perting in SL the reception desk, the departments (Figure 2) and the conference room are located. In the reception the residents can ask information and join the Perting group. There are the offices in which, with the mentoring of the tutors, the students can receive visitors carrying out the operative activities and the conference room in which the participants organize meetings. The Forum Area is addressed to perform lectures and video conferences and the international projects exhibition that shows the initiatives in which the simulated enterprise participated (Figure 3).

Figure 2. The departments  
Figure 3. The forum area

The new challenges of Perting are connected to the start up of a new business represented by New Fashion Perspectives (NFP), a micro enterprise in fashion sector, with a Laboratory in which the operative tools as clippers and stapler can be used by Avatars to simulate the real activities reproducing the true premises of a micro business undertaken by a mentor supporting didactics from the real market (Figure 4).

Figure 4. The laboratory of NFP in SL

The reason of this support, although the impressive harvest of contributions published on line (Barabasi 2004), is the main source of practical knowledge on the rapidly evolving world of micro enterprises, particularly in fashion sector, could be individuated only in the real market.

18 The mentor or « impresa madrina » is a real enterprise owned by Etienne Meite, supporting the simulation with its practical and continuous up to date know how. The relevance of this support is stated by the basic simulation methodology (Gualdi 2001)

4 EARLY EMPIRICAL STATEMENTS

At the moment we would focus on some hypothesis about Perting case and the experimental materials gathered from the impact of virtual reality on previous seven years of experiences in enterprise simulation:

1. The relations among real, simulated and virtual different levels of representation, operate within a multi dimensional symmetry.

2. The real, simulated and virtual business platforms, although working on the same entrepreneurial subject, could apply different strategies and operative methods.

3. The Virtual world is mainly based on exploring strategies while the exploiting refers to the simulated environment.

4. The level of strength and weakness in relationships among organizational entities changes significantly moving from Real to Virtual world.

The research focused on the relationships expressed by the number of contacts with suppliers and customers in real, simulated and virtual world. In particular the research sample composed by New Fashion Perspective (Virtual) Perting (Simulated) and the Mentor Micro Enterprise, evidenced the increasing level of networking when previous stages of simulation started to move in SL.

One of the first problems was to understand the role of the three levels of real, simulated and virtual in making business.

A basic topic is concerning the symmetrical relationships among three steps in business development as a) Business in Real World b) Business Simulation and its transfer to the Virtual platform c) Business purely virtual among actors and organizations living in 3D.

The Figure 5 summarizes these Symmetries on a two axes basis as a framework to manage the business simulation in the virtual world underlining the role of interpersonal links overcoming difficulties in perceiving the indirect real, simulated and virtual connections.

![Figure 5](image)

Figure 5. The multiple symmetry among real, simulated and virtual world

These links enhance the central position of trust processes deepened in recent years on the mechanisms requested for individual and business relationships (Sitkin, Weingart 1995) and on the indirect approach among actors or decision makers. The combination among real, simulated and virtual worlds underlines the range of business opportunities together with the need of selecting strong and personal relationships not only on the basis of trust but on the selection of most reliable links too so as to limit the enormous and uncontrollable mass of contacts and connected information. In these terms the approach to face the start up of new businesses and particularly of new enterprises operating...
in real, simulated and virtual worlds can be linked to the balance between the trust towards new relationships according with an exploring strategy and, on the other side, the trust on existing links as the result of an exploiting approach. The first one is addressed to a higher renewal of system elements and so to weak links among the organizations that belong to the environment. The exploiting strategy is mainly addressed to a low renewal and so is adequate to strong organizations that have overcome the start up phase (Dittrich, Duysters 2007).

On this purpose weak and strong links coming from respectively by the exploring and exploiting strategies produce a low and high level of commitment, measured by the scarce and high frequency of collaborations in the partnership.

In particular the exploiting strategy aims to widen the existing technological capacities, to enhance strong links due to the high trust in the commitment and so to establish equal agreements.

The exploring is characterized by the search for new technological capacities producing, in the start up period, weak links with the adoption of opportunistic behaviour and of low commitment, that allow the organizations to establish not equal agreements.

In the relationships between real, simulated and virtual worlds is possible to survey an operative symmetry, as agreed by many Researchers on the setting up (Mei Alves de Oliveira 1994) but also in the analysis of organizational borders (Bianchi 2003).

The Enterprise Simulation is based on the reproduction of interactive internal and external processes in order to improve the performance of participants. On this purpose the falsification of symmetry in the reproduction of organizations can be recognized as a criterion for performance evaluation (Bianchi, Tampieri 2008). Moreover the increasing interaction among real, simulated and virtual environments can be expressed by the e-commerce and the virtual platforms built by real enterprises for branding and marketing targets. Concentrating the attention on R-V comparison, the analysis of organizational relations (Table 5) could be defined as a set of contacts in which the enterprises are inserted.

*Table 5. The network structure*

Considering the processes of structure building, the Network Dynamics approach faces the competitive and environmental complexity analyzing the inter organizational network (Reagans, McEvily 2003) as the passage from atomistic structures and processes with separated entities to the network and the metaorganization (Antonelli 2004), in which, in a restricted perspective, the hyperlink (Bianchi 2001) that involves structure and process elements, allows to define the phenomena in a synthetic way (Bruni, Perrotta 2007).

The different structures of network (Vicari 2001) aim to develop a variety of coordination forms able to create an adequate dialogue among organizational systems. To this purpose the fundamental elements of network organization (Grandori 1998, 1999) in virtual environment are: the entities, the relational objective of network, the links form and the institutional mechanisms of coordination as social and contractual ones (Lomi 1997; Mercurio, Testa 2000). In particular the links network can assume different forms according to the modalities through which the entities interact each others. In recent years these new innovative business models belonged to b-web (business-web) (Tapscott et al
In this perspective the issues related to real, simulated and virtual world will be the target of further studies as one of the main mission for didactics and business management.

References

The b-web is defined as a system of suppliers, merchandisers, commercial societies, customers that use Internet as the main channel of communications and transactions.

WHAT HABBO GOERS DO IN PRACTICE? DECOMPOSING ATTITUDINAL BELIEFS

Jani Merikivi, Turku Centre for Computer Science, 20520 Turku, Finland, jani.merikivi@tse.fi

The popularity of social virtual worlds (SVWs) stems from the proficiency of designing appealing activities. In a volitional use context, hedonic outcomes, such as pleasure and enjoyment, along with social interactivity are fundamental attitudinal beliefs fostering the success of SVW. As such, the attitudinal beliefs affecting attitude toward using SVWs with multiple functions is worth studying. The practitioners should however focus on the actual behavioural success factors beyond using SVWs. Using Habbo as an example, this study paper develops a research framework and examines how attitude toward using SVWs mediates Habbo goers’ attitudinal beliefs on the actual behavioural incentives. Based on a review of prior literature a decomposed theory of planned behaviour suggested by Taylor and Todd (1995) is employed. The research model is tested with data collected from 1225 active Habbo goers. The main findings of the study suggest that while the Habbo goers desire for social interaction within Habbo the construct of attitude toward using the service fails to reflect it. This indicates that following the omission of discovering the proper attitudinal beliefs behind the actual behavioural factors investments may well be lost.

Keywords: Social Virtual world, Decomposed Theory of Planned Behaviour, Continuous Use, Attitude
1 INTRODUCTION AND BACKGROUND

Social virtual worlds, such as Habbo, Club Penguin, Teen Second Life, Precious Girls Club, and Poptropica, are analytically separable from game worlds which offer the users an opportunity to contend with each other adherence to a set of rules (cf. Bartle, 2004). While possibly including games for pastime SVWs may be described as simulating the physical space of everyday existence, not entirely conjured up by one’s imagination. SVWs are practically persistent environments with no specific narrative goal structures congruent with games. These social environments are attracting an enormous group of people sharing somewhat common interest, that is, a need for social interaction (see Fetscherin & Lattemann, 2008). In comparison to virtual communities which are largely designed for communication, SVWs, for example, serve as a technological tool to make videos or design clothes, and contain graphic elements such as avatars in either two or three dimensional virtual environment in order to create an immersive experience.

From users’ perspective, successful SVWs aimed particularly at the young perform multiple functions. What these SVWs provide is, however, as individual as the uniqueness of the young themselves. But for nearly every young person they generally are social interaction and gaming. Habbo, for example, is a popular and influential commercial social virtual world among those targeted for preteens and teens aged 10 to 18. It provides a free access to over 30 local portals with several public facilities such as virtual parks, and cafés, and millions of user-generated private virtual rooms. In Habbo, the young Habbo goers are able to communicate with one another and play various non-violent online games. To express themselves the Habbo goers may customise their walking, talking, shouting, and dancing avatars which are representations of themselves or their alter egos, and buy Habbo credits to create and furnish their very own personal virtual rooms. The positive attitude toward participating in free events, running distinct groups, or activities, and creating the content, for example, to honour celebrities has extended beyond the boundaries of the service, motivating them to establish an infinite number of fan sites on the internet (Global Habbo Youth Survey, 2006). Especially the live visits of famous real-life athletes and artists from the music and film industry have endeared Habbo to the young (Global Habbo Youth Survey, 2008). Not building on access fees but commercials, and voluntary premium services Habbo has so far succeeded in holding the critical mass of the young and translated their loyalty directly into monetary value.

The technology acceptance and post-adoption behaviour have attracted prominent and extensive research coverage within IS discipline (Agarwal & Prasad, 1997; Bhattacherjee, 2001; Hsu & Lin, 2008; Karahanna, Straub & Chervany, 1999; Venkatesh & Brown, 2001). Furthermore, prior studies have focused on virtual communities and their unique characteristics through various methods (Bagozzi & Dholakia, 2002; Wellman & Gulia, 1999). Little information is, however, available on expanding the understanding of continued use intention of using SVW with multiple purposes. Consequently, SVWs offer opportunities for testing theories and models in a new context. Hence, for thoroughly grasping the phenomenon regarding the behavioural incentives behind using SVWs calls research in several disciplines such as sociology, economics, and psychology, to mention only a few.

To better complement these existing approaches and to focus more explicitly on examining the conceptualised role of attitudes and the accessible behavioural beliefs behind them, this study exemplifies the theory of planned behaviour (TBP) (Ajzen, 2005). Moreover, agreeing with Shimp and Kavas (1984), who suggest that cognitive constructs of belief cannot be combined to single conceptual determinant, the study expands upon decomposed TPB (Taylor & Todd, 1995; Hsieh, Rai & Keil, 2008) as it provides a comprehensive framework for analysing the information on the antecedents of attitude toward using SVWs. It should, however, be worth noting that behavioural models, such as the theory of reasoned action (TRA) (Fishbein & Ajzen, 1975), the technology acceptance model (TAM) (Davis, Bagozzi & Warshaw, 1989; Davis, 1989) and TPB (Ajzen, 2005)
are constrained to analysing only one behaviour of interest. Applying these theories is rather challenging when examining the use of any technological innovation serving multiple purposes. Consequently, this study is confined here to dealing only with factors regarding attitude toward using SVWs, for which the decomposed TPB is assumed to provide a valuable framework.

In this study, the focus is on Habbo, which is favoured by many active young people because they use it for playing games, trading in virtual furniture, familiarising themselves and communicating with online and offline friends (Global Habbo Youth Survey, 2006; 2008). In other words, meeting with new and old friends and creating, sharing, and consuming the interesting content influenced by norms, values, and offline life is perceived important within such pleasuring and enjoyable virtual environment (Bagozzi & Dholakia, 2002; Hagel, 1999). The SVWs have clearly moved beyond mere entertainment into social realm. Therefore, attention is particularly paid on hedonic and social outcomes. Developing the construct of attitude toward use is of major importance, as it may increase the risk of losing information instead of identifying the actual evaluative variables to distinguish in details why exactly SVWs are being used and how the accessible beliefs are linked to them.

As a result, the purpose of this study paper is to develop a framework and examine how the attitude toward using SVWs mediates the impact of Habbo goers’ attitudinal beliefs on the underlying actual behavioural interests. This study paper has three primary goals. First, by identifying the actual factors behind using SVWs it should enhance theoretical knowledge of developing behavioural frameworks utilised in other online services as well, and, second, provide better managerially relevant and readily discernible in-depth understanding of true behavioural incentives that are beneficial in designing features and services for SVWs. Thirdly, by examining particularly the existing Habbo goers it accumulates the post-adoption user behaviour research (Limayem & Cheung, 2008; Premkumar & Bhattacherjee, 2008).

2 RESEARCH MODEL

Individuals use information technology from both extrinsic and intrinsic motives (Davis, Bagozzi & Warshaw, 1992; Vallerand, 1997), also articulated in consumer behaviour (Venkatraman & MacInnis, 1985) and IS literature on technology acceptance (Hsieh et al. 2008; van der Heijden, 2004; Venkatesh & Brown, 2001). Extrinsic incentive propels individuals for achieving a specific goal, whereas intrinsic, in other words, hedonic is the degree to which users experience pleasure, joy, or satisfaction derived from a specific behaviour (Deci & Ryan, 1980). Teo, Lim, and Lai (1999) have empirically shown that intrinsic incentive has a significant effect on using computer and the internet. In a post-adoption context, users may obtain, at least in part, pleasure through appealing environmental characteristics but more salient is the need for maintaining the concentration and curiosity, as well as satisfying the entertainment purposes (cf. e.g. Ahn, Ryu & Han, 2007; Igarria, Schiffrman & Wieckowski, 1994). For example, the Habbo goers look for a playful job or task inside Habbo in a form of a role play and work as fashion models walking on virtual catwalks. As a result, perceived enjoyment (ENJ) is an emotionally fulfilling activity, and playfulness (PLA), which represents the user’s short-term cognitive involvement, are believed to influence attitude toward using SVWs (Woszczynski, Roth & Segars, 2002). It is, thus, postulated that:

\[ H1: \text{Enjoyment (ENJ) positively affects the attitude toward using Habbo.} \]

\[ H2: \text{Playfulness (PLA) positively affects the attitude toward using Habbo.} \]

It is assumed that leisure-oriented post-adoption user behaviour is not driven by strong productivity but rather instrumental value as to effectively communicate and develop social identity (Bagozzi & Dholakia, 2002). In SVWs, the interaction occurs with one another, not between users and the system as mentioned by Heijden (van der Heijden, 2004). The behaviour may still be extrinsic when the purpose of exchanging information or resources through computers is to accomplish tasks, for instance, to express uniqueness. Unfortunately, it may, however, be extremely difficult to differentiate extrinsic from intrinsic behaviour since interaction may as well carry positive or negative emotions not
necessary in achieving external objectives (Yuan & Gay, 2006). Therefore, within this study paper, interaction with one another implies to social outcomes such as social connectedness (CON), self-exploration (UNI), and status (STA), indicating that these three concepts should be distinguished from intrinsic and extrinsic, and discussed separately.

The Habbo goers have an access to a virtual network that facilitates the exchange of social closeness and status. The need for belongingness reflects subjective awareness of interpersonal closeness (Lee & Robbins, 1995; Lee & Robbins, 1998). Therefore, social connectedness particularly relates to self-fulfilling emotional outcomes such as affiliation and support in bringing individuals together both in offline and online (Baumeister & Leary, 1995; Chiu, Hsu & Wang, 2006; Rheingold, 2000; Wellman & Gulia, 1999). As a result, it is hypothesised, that:

**H3:** Connectedness (CON) positively affects the attitude toward using Habbo.

Social status pertains to the probable instrumental value and is, therefore, conferred on individuals as a result of adopting a technological innovation (Moore & Benbasat, 1991; Venkatesh & Brown, 2001; Venkatesh & Davis, 2000). In SVWs, through participation individuals are volitionally pursuing to gain the esteem, in which others hold them. The relative position of individuals in SVWs is closely linked to the need for uniqueness in differentiating themselves from others through consumption of virtual items (cf. e.g. Ruivo, 2008; Snyder & Fromkin, 1977; Tian, 2001). In Habbo, to appeal the users’ desire for uniqueness Habbo goers are able to express their true or idealised identity via acquiring and possessing products such as avatars and virtual furniture that are not recognised as being outside of the norm. To encourage the Habbo goers to purchase and possess new and vintage virtual furniture it is designed to convey product-scarcity, uniqueness, and nonconformity. On the other hand, the Habbo goers exploit the opportunity to use avatars reflecting their offline appearance, expressing sometimes provoking messages, or releasing themselves from offline social norms (Vasalou, Joinson, Bänziger, Goldie & Pitt, 2008). For empowering the Habbo goers to seek status and uniqueness it is hypothesised that:

**H4:** Self-exploration (UNI) positively affects the attitude toward using Habbo.

**H5:** Status (STA) positively affects the attitude toward using Habbo.

In SVWs, where individuals are geographically separated and it is literally impossible to touch one another, they share the illusion of being physically in the same virtual environment in the guise of fictional characters conveying and embodying real-time socio-emotional behaviour such as movements and facial expressions (Bente, 2008; Bailenson, 2005). The feeling of closeness of another individual refers to the concept of social presence (PRE) in a mediated interaction (Biocca, Harms & Burgoon, 2003; Rice & Love, 1987; Short, 1976). If the shared virtual environment and the existence of avatars enable the users to experience non-verbal cues, they both facilitate the experience of social presence in virtual encounters and strengthen the positive evaluation of using Habbo. Therefore, it is postulated that:

**H6:** Social presence (PRE) affects positively toward using Habbo.

Development of the scales to measure the evaluation summary of attitude toward behaviour of interest is generated based on the suggestions of Ajzen (2005). The construct of attitude is the degree to which using Habbo is valued. In order to investigate the suitability of the construct of attitude used in prior IS literature, the construct of attitude should thus reflect the evaluation of performing the actual behaviour of interest since it would be challenging to specify every action beyond using technologies with multiple functions. The attitude of construct must therefore be accordingly determined. As a result, the following hypotheses are proposed:
H7: Attitude toward using Habbo mediates the actual willingness to social interaction with one another.

H8: Attitude toward using Habbo mediates the actual willingness to collect virtual furniture.

H9: Attitude toward using Habbo mediates the actual willingness to play games within Habbo.

Figure 1. Research model

3 EMPIRICAL RESEARCH

3.1 Research design and data collection

First, to explain the key factors why Habbo is actually being used the attitudinal beliefs were drawn from prior literature. Second, the research model was developed on the basis of TPB and the constructs as represented in IS research with one exception: those constructs founded on the key factors indicating the actual behaviour beyond using SVWs were formed using exploratory factor analysis (EFA). After the key factors were found, pilot study was conducted prior to the primary data collection. Finally, the goal of the empirical part of the study was to validate and test the research model (Figure 1) with confirmatory factor analysis (CFA), and investigate causal relationships between the latent variables.

The actual online survey instrument was built, and, in July 2008, the quantitative data from the users of Habbo Finland was collected. The survey was available approximately for a week and it contained worded items which respondents had to evaluate on a 7-point Likert-scale adapted from existing measures. To receive only one response from a single respondent a reward of any kind was not offered to the respondents (O’Neill & Penrod, 2001). In addition, multiple submissions were software-disallowed by excluding any responses from the same computer. The results reported here, are the responses of those willing to participate. That is to say, those Habbo goers who were the focus of the study were able to reach out.

A total of 3265 usable responses were received. To ensure the best possible quality of the responses, only fully completed responses were totally included in the analysis. After excluding cases with missing or incomplete responses 1225 fully completed and usable cases were retained for the analysis. Large drop of valuable responses was due to a long survey. 94 % of the respondents were between 10 and 18 years old.

To test the applicability of the research model AMOS 16.0.1, the maximum likelihood estimation method was applied here since it has been considered robust against the moderate violation of
multivariate normality with sample sizes exceeding 100 cases (Muthén & Kaplan, 1985; Steenkamp & van Trijp, 1991). The distortion of chi-squares and standard errors is likely if most of the skewness and/or kurtosis are larger in absolute value than 2.0, and the correlations are 0.5 or higher. According to Bollen (1989), all normal distribution estimations methods, including maximum likelihood, are consistent even if the assumption of normality is moderately violated. The test for normality showed that the skewness of only a few observed variables was higher than 2.0, thus, implying that the data is moderately non-normal, and therefore maximum likelihood would be an appropriate and robust estimation method. Asymptotical distribution free is suggested as superior to maximum likelihood only when the observed variables have an average univariate kurtosis larger than three and the sample size greater than 400 (Hoogland & Boomsma, 1998). The assessment of normality showed that every univariate kurtosis was below three.

3.2 Measurement Model and Results

The adapted constructs of the research model were evaluated by examining internal consistency and convergent validity. To do this, the item-construct-loading, composite reliability, and average value extracted (AVE) were assessed. As regards item reliability, item loadings exceed 0.707 (Agarwal & Karahanna, 2000), the composite reliabilities 0.707 (Nunnally, 1978) and AVE values 0.50 (Fornell & Larcker, 1981). The information on the loadings of the measures used in the research model, descriptive statistics, and the reliability of the constructs are represented in table 1. The results showed that all reflective measures fulfilled the recommended levels of composite reliability and average variance extracted.

Table 1. Loadings, Composite Reliability, and AVE
Discriminant validity was investigated by examining whether the AVE was higher than the squared correlation for each construct (Fornell & Larcker, 1981). The correlations provided clear evidence that the relationship among all constructs were below the AVE in question (Table 2). Model fit indices address (GFI=.921, TLI=.954; NFI=.953, CFI=.962, and RMSEA=.058) that the proposed model was acceptable with the exception that AGFI (0.896) went slightly below the recommended threshold (see (Gefen, Straub & Boudreau, 2000).

Table 2. Squared pairwise correlations and assessment of discrimination validity

In total, the results support six of the nine hypotheses. Contrary to initial postulations, connectedness (CON), self-exploration (UNI), and status (STA) had no significant effect on attitude (ATT). Playing games (PLA) (0.13) alongside social presence (PRE) (0.12), a noteworthy exception of those measures associated with social outcomes, had only a moderate impact on ATT, whereas ENJ (0.52) had the strongest influence, a finding consistent with past research. On the other hand, the path coefficients from ATT to becoming friends (SOC) (0.46), trading in furniture (TRA) (0.40), and GAM (0.47) were statistically significant and interpretable if only somewhat surprising, given that the strength of paths from CON, UNI, and STA were statistically insignificant. The attitudinal constructs examined within this study paper explained 52 percent of the variance in the Habbo goers’ evaluation of using the service. ATT, for one, explained 21 percent (SOC), 16 percent (TRA), and 22 percent (GAM) of the variance in Habbo goers’ actual behavioural incentives. Figure 2 represents the path coefficients and the squared multiple correlations.
4 DISCUSSION

4.1 Findings

The results showed that 52 percent of the variance in the Habbo goers’ evaluation of using Habbo attitude (ATT) was shaped by enjoyment (ENJ), playfulness (PLA), and social presence (PRE), indicating that those social outcomes, such as connectedness (CON), self-exploration (UNI), and status (STA), had no significant influence on attitude. However, a post hoc analysis revealed that when paths from connectedness, self-exploration, and status were directly connected to becoming friends (SOC), trading in furniture (TRA), and playing games (GAM), the actual behavioural incentives beyond use were better explained. Thus, in the context of SVWs with multiple functions aimed particularly at the young, the users are not only craving for pleasure but social interaction with one another. These findings are in line with empirical evidence presented in prior literature examining virtual communities (Bagozzi & Dholakia, 2002; Rheingold, 2000; Wellman & Gulia, 1999) and leisure oriented technologies (van der Heijden, 2004). Taken as a whole, the users who volitionally have engaged with SVWs are especially driven by enjoyable social activities, such as playing games, collecting virtual items, and becoming friends with other users.

4.2 Implications for theory and practice

Empirical evidence on how both hedonic and social outcomes can be included in a research model adapted to virtual worlds, has been somewhat an open question. This study paper examines this issue by demonstrating, that among the experienced young users, hedonic and social aspects are pivotal factors for successful hedonic information systems. Contrary to prior studies that focus on social influence (i.e. social pressure to perform behaviour), this study has introduced the lack of a sophisticated attitudinal construct that measures the need for social interaction (cf. e.g. the distinct between playing video games alone or with other individuals). Therefore, the represented research model expands upon the current continued use model by underscoring the user’s need for enjoyable experiences and social interaction, postulating a direct path between them and the attitude toward continued use of SVWs. First, by identifying the actual key factors behind using SVWs the study enhances theoretical knowledge of developing behavioural frameworks built upon the IS research. Second, since practitioners are responsible for designing attracting virtual environments, the study has focused on providing better managerially relevant in-depth understanding of true behavioural incentives that contributes to the building of user commitment. The results suggest that managers should not concentrate only on the technology use but the actual reasons why it is being used. When adding or removing features it is important to be aware how attitudinal beliefs affect the actual behavioural incentives. Thirdly, by particularly examining the experienced Habbo goers the study accumulates the post-adoption user behaviour research (e.g. Limayem & Cheung, 2008; Premkumar & Bhattacherjee, 2008).

To develop a robust research model for examining the use behaviour, it is likely that the items related to the attitude toward using SVWs must cover the social aspect as well. Since only a few, if any, studies that focus on developing behavioural constructs to measure the use of SVWs exist, this study paper offers a theoretical implication for IS research.

4.3 Limitations and future research

Employing IS theories is rather challenging when examining the use of any technological innovation serving multiple purposes. Consequently investigating SVWs is confined to dealing only with factors regarding attitude toward using SVWs, determined by the individual’s assessment of the outcomes associated with the behaviour (Ajzen, 2005). Determinants such as subjective norms and perceived behavioural control have been deliberately omitted. The future research is, thus, required to examine how subjective norms, and perceived behavioural control, in addition to attitude, affect continued use intention in the context of SVWs. Furthermore, large drop of valuable responses due to a long survey
may have limited the accuracy of the results. Also, generalising these results into context other than SVWs should be handled with care. It is proposed to take into account that the results depend on respondents’ subjective assessment (see Straub & Limayem, 1995) and their socio-cultural backgrounds that may have a significant impact on usage behaviour. This is of great importance especially when the service is globally available. Finally, this study represents a cross-section of behavioural incentives beyond using SVWs. When the appropriate measures are discovered longitudinal study examining post adoption behaviour may provide better understanding of the users’ behaviour, their motivation, and their intentions.

5 CONCLUSIONS

Providers of SVWs should focus on the actual behavioural incentives beyond using the technology. Creating interactive and hedonic services to the young is a fundamental goal which is virtually as central as the technical characteristics of SVWs. The present study paper exemplifies a decomposed theory of planned behaviour in order to represent an important step toward examining and developing the construct of attitude toward using SVWs with multiple functions aimed at the young. Most importantly, using Habbo as an example, study paper empirically demonstrates how TPB-grounded research model explains a significant amount of variance in the Habbo goers’ evaluation of using SVWs but, at the same time, relegates the social aspects into the background. The findings indicate that, in the context of SVWs, the construct of attitude toward using the technology, must include items related to social outcomes together with hedonic outcomes.

ACKNOWLEDGEMENTS

I would like to state my gratitude to Finnish Youth Research Society, Foundation for Economic Education, and Sulake Corporation for assistance in conducting this study, as well as Jussi Puhakainen, Tommi Hoikkala, Mikko Ketokivi, and Matti Määttymäki.

ON THE EVOLUTION OF ONLINE TOURISM COMMUNITIES

Network Battle or Long Tail Niches?

Felix-Robinson Aschoff, Department of Informatics, University of Zurich, Binzmühlestrasse 14, CH-8050 Zürich, aschoff@ifi.unizh.ch

Abstract

Even though the emergence or respectively the construction of online communities is of great interest for scientists and community engineers, only few empirical data has been presented on community growth. This article starts with a reflection on possible growth curves of virtual communities. It contrasts a network externality perspective that produces clear winners and losers in a market with a long tail perspective that also allows small niche products to be successful. These considerations are empirically tested with a sample of 74 travel communities whose numbers of registered members were recorded at two measure points. The results show that online travel communities develop into an archetypical long tail. A very small number of communities with exceedingly high numbers of members are accompanied by a vast amount of communities with only few members. An analysis of the long tail, however, reveals that the community tail is not dead but is populated by a large number of especially regional communities that show considerable growth rates.

Keywords: evolution, online communities, growth rates, network effects, long tail
THE EVOLUTION OF ONLINE COMMUNITIES

Online communities have been the object of extensive research within the last 25 years (for an overview see Preece 2000; for a multi-disciplinary topology Porter 2004). Within these decades of research the phenomenon has been highlighted from different perspectives. One commonly cited source is Rheingold (1993) who describes online communities as technological enablers for communication among community members. The social interaction is the focus of the author’s attention and the mutual support (e.g. in case of illnesses) is vividly described. Hagel & Armstrong (1997) in contrast, focus on the economic potential online communities offer to companies. The authors see them as platforms to redefine and strengthen a company’s relationship to customers, suppliers, and competitors. From the customer’s point of view, Hagel & Armstrong (1997) conceive communities as the option to be a more informed bargainer than in traditional markets. For the domain of tourism see Wang et al. (2002) who take the more social perspective by Preece as well as the economic perspective by Hagel & Armstrong to discuss implications for marketing and design of travel communities.

These two perspectives are reflected by approaches for the construction of communities as well. Preece (2000) proposes a community-centered approach which is related to a member or user-centered approach. In accordance with a participatory-design approach Preece claims user needs and social aspects to be crucial pillars for the development of a community (another practical guide on community development is provided by Kim (2000)). Hagel & Armstrong (1997), again, conceive community members more as potential customers. They claim that communities fulfil four basic needs: interest, relationship, fantasy and the need for transaction and bartering (like e.g. purchasing goods). In accordance with this potential-customer perspective their development strategies focus on binding the members to the community. Consequently, their strategy to reach a community’s critical mass point comprises three stages: generating user traffic, concentrating traffic and locking in traffic.

Just like Hagel & Armstrong (1997) and Hummel & Lechner (2002), we also conceive Online Communities as phenomena that realize network effects. This implies that the benefit users receive from using a product or a virtual community is influenced by the number of persons who also use this service or product. For most communication products within networks like traditional telephone networks it is the case that the personal benefit increases with a rising number of other persons who also use the network (cf. Shapiro & Varian 1999). Crucial aspects of a networks’ evolution is the fact that they can evoke positive as well as negative feedback loops and that they follow an S-shaped curve in three phases: a) flat during launch, b) a steep rise during takeoff as positive feedback kicks in and c) leveling off as saturation is reached (ibid.). Figure 1 depicts the assumed growth curve of virtual communities based on this network effect assumption.

![Figure 1: Assumed growth curve of online communities due to network effects (cf. Shapiro & Varian 1999)](image)
From a practitioners point of view it is relevant to know at which number of users the accelerated growth curve starts for a specific community. If a common point or interval could be estimated for a specific community domain, it would be possible to predict the growth of different communities within the near future.

In accordance with this idea of a network market, virtual communities within one domain (e.g. English-speaking forums covering travel-related questions) cannot be considered to be independent from each other. Traditional off-line communities are to a strong degree bound to geographical aspects as well as aspects of affiliation. This means that originally one did not choose a community but one was born into one. Geographical boundaries as well as barriers between social classes were difficult to transgress. Even though this has changed to some degree since the industrial revolution, off-line communities are still rather a fate than a choice. This situation is considerably altered by the net situation: It provides the real choice to become a member of one community or the other.

This, however, implies that forum communities within one confined domain can be said to compete for users like products on a market compete for customers. From a neutral users’ point of view it should always be more beneficial to join a community that has at least reached the take-off phase (for evidence that higher user activity indeed leads to better information quality within a community see Prestipino et al. 2006, Aschoff et al. 2007). If one community within a domain reaches this point, this would on principle be a good precondition for a monopolistic development. Wikipedia seems to be an interesting example of this situation. Only one main Wikipedia platform has developed up to now, even though some of the described topics on this platform are highly controversial. The positive network effects are so strong that users do not seem to be willing to launch competing knowledge sharing platforms. Figure 2 shows this division into winners and looser in a network market. Winners are said to enter a virtuous cycle while loser are said to enter a vicious cycle (Shapiro & Varian, 1999).

Thus, a market with strong network effect tends to produce clear winners that are able to gain big revenues as well as clear losers that are not able to reach the positive feedback zone. This creates a situation in which a company either has to gain considerable amounts of the market share or will seize to exist.

In contrast to this situation, we see the conception of a long tail market as described by Anderson (2006). In these markets, products can be profitable in very small niches due to the decreased costs of warehousing and distribution in the digital economy (for a description of a long tail market for the business of online bookselling see Brynjolfsson et al. 2003). In these markets, the aggregated revenue from all the products that sell only in small numbers can equal or exceed the few hit products that sell in vast amounts. Thus, from an economic perspective it pays off to offer niche products for a small customer segment as long as the distribution costs are minuscule.
A market can show network effects as well as a long tail distribution. The characteristics of this market will, however, depend on how dominant either of these influences are. A market that is dominated by network effects will, as described above, favour one winner and one or more losers. This is especially given when systems or products are incompatible with each other, i.e. the user of one system cannot communicate with the user of another system. This can eventual lead to format wars (e.g. the recent competition between the HD DVD and the Blue-Ray format; for numerous additional examples see Katz & Shapiro 1994). In contrast to this, a long tail market allows products with far smaller consumer than the hit products to be “economically sustainable”. For a related controversy that contrasts a long-tail assumption that favours “underdogs” with a head-of-the tail assumption that favours “superstars” refer to Elberse & Oberholzer-Gee (2008). Applied to the market of online communities these perspectives lead to different predictions:

a) The network effect perspective would predict a winner-takes-it-all market, i.e. few large online communities with considerable growth rates are accompanied by a number of small communities with stagnating or declining growth.

b) The long tail perspective would predict small communities in the tail to be successful as well, i.e. they would show user activity and growth rates.

2. Empirical Method

To empirically test these two assumptions, we assembled a comprehensive collection of online communities that dealt with travel-related questions. This search started in February 2008 and we only selected platforms that met the following characteristics:

a) In this research, we focussed on classical online forum platforms. These forums are characterized by a communicational structure in which one community member starts a thread by sending an initial post (like a question) and possibly receives a number of replies. In contrast to wikis, product recommendation sites or newer social networking platforms (like e.g. www.facebook.com), these online forums have been developing on the Internet for more than 20 years. By now they cover a wide area of topics including cooking, health-related issues, computer problems or mobile phone technology. For an early account of the online forum community “The Well” founded in 1985 refer to Rheingold (1993). To obtain a more homogeneous sample, we confined our sample to browser-based forums.

b) The main purpose of the forum had to be travel-related information exchange. Prominent examples are the Thorn Tree forum1 run by the Lonely Planet Publisher Group or the Virtual Tourist platform2. The forum members had to discuss typical travel related topics (like e.g. How do I get to a certain place? How can I solve travel related problems? What are suggestions for attractive travel routes or locations? etc.).

c) The language used by the community member to communicate had to be English.

The following search engines were used for this research: Google, Yahoo!, Altavista, Live Search by Microsoft as well as the meta search engine Mamma. In addition Boardreader was used which is a search engine specialized on finding online forums. The used key words comprised: “Travel Forum”, “Traveler Forum”, “Travel Board”, “Independent Traveler Forum”, “Independent Traveler” and “vbulletin travel”.

The number of registered members was registered at two measure points. The first measure point was between February and July 2008 and the second measure point was in November 2008. The number of

1 http://www.lonelyplanet.com/thorntree/index.jspa
2 http://forum.virtualtourist.com/
registered users was measured by reading out the respective number from the websites of the communities.

3. Results

The described search procedure resulted in 120 travel-related online discussion forums. The first measure point was between February and July 2008 and the second measure point was in November 2008. The number of the community members is not displayed by all communities and some communities seized to exist or were temporarily offline at one of the two measure points. In addition to this, two communities were so massively spammed at the time of the second measure point that travel related communication was hardly taking place anymore. We excluded these forums from the sample. Finally, we were able to measure 74 online communities at two points in time. Figure 3 shows the 74 communities with their respective numbers of member at the second measure point in November 2008.

![Figure 3: Number of registered members at the second measure point (Nov. 2008) for each forum](image)

The distribution of the absolute numbers of registered members shows an archetypical long tail for this community sample. Based on this distribution we can roughly distinguish three groups of communities that are separated from each other by about one order of magnitude. We have one community which claims to have more than 100,000 registered members. The second group consists of three communities between 100,000 and 300,000 members. The third group starts with communities with about 50,000 registered members and entails 70 communities whereas the smallest communities only have between 10 and 20 members. The data shows that those forums above 50,000 constitute only about 5% of the forums in the sample. One the other hand, note that the forum with the highest acclaimed number of members already has more members than all the remaining forum communities.

We calculated the absolute growth rates of registered members as well as the growth rates relative to the absolute number of registered members at the first measure point for each community per month. Overall, communities in our sample grew by an absolute average of 393 members per month which relates to a relative monthly growth of 17.7%. The absolute growth rate of the largest community with about 100,000 members amounted to 8085 members per month (0.78%). The second group between 100,000 and 300,000 members had two forums with only marginal or even negative monthly growth (924.5 members (0.76%) and -1155.2 members (-0.66%). The third forum in this group, however, showed a considerable growth rate with 14267.56 additional members per month (11.16%).
Figure 4 shows the absolute growth rates per month of communities below 30,000 registered members. The Loess fit line (Epanechnikov-Kernel with 50% of points to fit, entire sample included) indicates a steady increase in the absolute number of new members per month with considerable derivations. Overall, the absolute increase of members correlates significantly with the size of the community at the first measure point (Pearson = .336). This part of the sample consists of 70 communities out of which 62 communities show a positive growth level while 8 communities show zero growth or a negative growth level. The average growth level of these communities amounts to 17.66% (7.56% without one extremely fast growing community).

Thus, while this tendency is hard to prove due to the small number of communities at the head of the long tail, this data may indicate a certain saturation point. Overall we see a clear tendency that the biggest relative growth does not happen in the head of the curve but in the tail. Figure 5a shows these relative growth values for the range between 0 and 5,000 members. Figure 5b shows the range between 5,000 and 30,000 members.
Again, the data show a considerable variance among the different forums. Most of the forums grow between 1 and 20%. A notable high number of forums show increased growth rates in the interval between 0 and 500 members. To gain insights into the considerably high growth level at the end of the long tail we categorized our community sample into different subsamples.

**What grows in the long tail?**

As mentioned we see an archetypical long tail with very few communities with exceedingly high numbers alongside a vast amount of communities with only few members. Figure 6 shows the number of communities at the very end of the long tail only depicting communities with less than 10 000 members.

![Frequency histogram for communities with less than 10 000 members](image)

*Figure 6. Frequency histogram for communities with less than 10 000 members*

Note that 53 communities fall into the range between 0 and 10 000 community members. This is already 72% of the entire community sample whereas the largest communities have more than 100 000 members. In addition, the interval with the most communities within this range lies between 0 and 500. The network effect approach as well as the long tail approach would expect a diversification of the communities at the end of the tail. From a user perspective a community in the tail should provide some special good that cannot be offered by the big communities. Only based on the probability to obtain good answers to posted questions or the chance to meet many new people, the larger communities should always be in advantage of gaining new users. To test this assumption we divided our sample into three groups. The first group of communities are communities that on principal cover all regions of the globe. The second group are communities that are specialized on certain regions like specific continents or countries. The third group, finally, focusses on special interest groups like mounting biking, diving, or travelling by motorcycle.

Figure 7 shows the end of the long tail with communities below 10 000 members divided by these three groups. As could have been expected the ratio between worldwide and regional forums changes if the sample is divided by this threshold. Above 10 000 the sample contains 10 worldwide forums and 7 regional forums, and below this threshold the sample contains 10 worldwide forums and 37 regional forums.
Thus, we can conclude that there is a vast number of small communities that grow at a considerable rate. We assumed that regional forums in the end of the long tail would grow faster than worldwide. To diminish the effect of the extreme outliers within the sample we transformed the relative growth variable into a ranking scale and performed a non-parametric Kruskal Wallis Test. The mean ranks for the global forums as well as for the regional forums proved to be almost identical (36.47 and 37.42) whereas the specialized forums had lower mean ranks of 24.39. The test failed to reach significance with p=.212. Thus, the data indicate that small global communities grow at a similar rate as small regional communities.

Limitations
The research is yet limited due to the fact that the number of registered members in a forum is only a very indirect measurement of the activity within a forum. Future research has to substantiate our findings by additional measures like e.g. the number of written posts per month recorded over a longer period of time.

4. Discussion of the results

With respect to the absolut numbers of registered members our sample shows an archetypical long tail. Very few travel communities with an exceedingly high number of members (ca. 100 000 members and more) are accompanied by a large amount of small communities (between ca. 10 members and ca. 30 000 members). With respect to growth rates, however, the data show that this long tail is not dead but shows considerable average growth rates. Hence, the long tail does not seem to be populated by losers but rather by communities that are developing in a promising way. This leads to the question why end user would join a smaller travel community if they also have the chance to join a “market leader”. This can have a number of reasons:

a) Differentiation. Some small communities might offer a special service or cover a special aspect that is not provided by the communities at the head of the tail. This might be related to special travel-related interests (e.g. diving, hiking) or special region-related coverage (e.g. communities specializing only on Thailand). However, our current data does not support this claim. There are more specialized communities at the long end of the tail compared to communities with a worldwide coverage. However, these worldwide communities show growth rates that are similar to the growth rates of the more specialized communities. Further analysis considering additional characteristics (like e.g. degree of commercialization etc.) has to show whether variables can be found that separate the long tail communities from the
communities in the head of the tail. Another possibility is that the size of the community is a differentiating characteristic by itself. A number of Internet users might prefer smaller communities for different reasons: the risk of information overload is decreased, it is easier to gain a higher social status and the feeling of social belonging might be stronger in a smaller community.

b) Intransparency of the online community landscape. The idea of the network effect driven community market assumes that Internet end users have a choice to become a member of any arbitrary community. Obviously, this implies that Internet user have an overview over a more or less transparent market situation. Since central repositories for online (travel) communities are not very widely spread, most users probably do not even know what kind of choices they have. This might lead to a situation in which a user engages into the first online community she finds more or less suitable without being aware of other options. Further research especially in the field of information behaviour can yield fruitful insight as to how Internet users actually search for virtual communities and how they decide which one to join.

These results also underline the fact that online communities assumably do not only have positive feedback loops but also negative feedback loops as they increase in size. This negative feedback loop is caused by information overflow that can be caused if too many persons ask questions (this means for example that each question gets less attention) or too many replies are given. In addition, the transaction costs are increasing for a single user if she has to manage relationships to many points within the social network of the community. This aspect sets online forums apart from cooperatively constructed online encyclopedia like Wikipedia. At least for the vast amount of passive consumers of Wikipedia, an increased user community only has the positive effect of increased quality without the negative effects of information overload or increased transaction costs. This might have led to the monopolistic position wikipedia is holding today.

This argumentation points to a relationship between community size and perceived value of an online forum that is rather characterized by a U-shaped function opening downward than by a steady increase as depicted in Figure 1. Further research should focus on the lower as well as on the upper boundaries of this value curve. This is also related to the question whether online forums need a minimum number of members for a sustained development. Our current data shows considerable relative growth rates for communities between 10 and 500 members. Additional future measure points of our sample will reveal whether these developments are persistent over time. Practical implications of this research arise especially for the field of online community development. Approaches in this domain up-to-now have often been of a prescriptive or design-oriented nature. These rules of community development, however, have to be complimented by quantitative models of online community evolution that are empirically well founded.

Acknowledgements
We thank Johnny Nia, Salvatore Bonaccorso and Mary-Anne Kockel for supporting the data collection. This research was partly funded by the Richard Büchner-Stiftung as well as by the Gebert Rüf Stiftung.

Abstract

This paper investigates the characteristics of federal and modular organizations and elicits conclusions on their requirements for IT controlling through a literature review. The literature review showed that different organizational structures create specific conditions concerning IT and IT controlling. Although experience in the regulation and controlling of IT in large and complex organizations has been reported, the characteristics of these specific organizational conditions and the resulting requirements for the design of an IT controlling concept have not been extensivively researched. Creating the missing link between the characteristics of federal and modular organizations and their requirements regarding IT controlling may serve as a foundation for future research and the development of a comprehensive IT controlling concept which encompasses the characteristics and key drivers of this specific organizational form.

Keywords: IT controlling, IT governance, federal organizations, modular organizations.

1 INTRODUCTION

Alignment between business strategy and information technology (IT) strategy is regarded as a key driver for realizing value from IT investments (Henderson and Venkatraman 1999, Luftman 2006). This high level of importance may result from the fact that IT investments constitute a major part of IT costs but the benefits of IT usage are not always obvious and therefore difficult to justify. This phenomenon is often described as ‘productivity paradox’ (e.g. Brynjolfsson 1998, Carr 2003). Nevertheless some organizations manage to specify accountabilities for IT-related business outcomes better than others because of more effective IT governance (Weill and Ross 2004). Weill and Ross have researched forms of IT governance and classified underlying structures by the location where IT decisions are made. According to this classification, six types of decisions from ‘central decisions’ to ‘decentralized decisions’ are to be distinguished:

- Business monarchy: Decisions taken by a member of the management or a group of managers;
- IT monarchy: Decisions taken by the IT director or a group of IT directors;
- Federalism: Decisions taken by executives of the middle management of all operative divisions and the integration of the IT direction is also considered;
- IT duopoly: Decisions taken by IT direction and a group of members of the management;
- Feudalism: Decisions taken autonomously by respective divisions;
- Anarchy: Decisions taken autonomously by a user or a group of users.

This classification is not only relevant for decision making but also to inform decision makers about the origin of input (Weill and Ross 2005). A study conducted on 197 mainly ‘Global 1000’ companies showed that firms with a federal IT organization had a significantly higher IT/business alignment maturity than others (Luftman and Kempaiah 2007). A cluster analysis of 40 companies by Gordon and Gordon (2002) showed similar results. Nevertheless a federal IT organization is “no silver bullet” (Luftman and Kempaiah 2007) and federal IT governance is described as demanding a great deal of management attention (Weill 2004). For example, in large and complex multunit organizations with interdependent information resources where federal IT is particularly useful, conflicts and coordination difficulties are likely to occur. Tsai (2002) describes the phenomenon of “coopetition” in which subunits of large multunit organizations which are supposed to cooperate become instead competitors when it comes to using internal resources and are therefore likely to reject information sharing.

How can a federal organizational form for structuring IT be attained while avoiding its disadvantages? One solution is using a shared controlling concept across units to enable federal organizations to make use of the advantages of a federation and to steer clear of intra-organizational competition (Wenninger-Zeman 2003). Current research, however, has not considered specific IT controlling styles as they relate to the organizational and governance perspectives that characterize organizations. The available literature offers a broad range of tools and concepts for controlling IT (e.g. Krcmar 2005, Weill and Ross 2005) and has developed various approaches for avoiding intra-organizational competition in multunit organizations (e.g. Brass et al. 2004, Schaefer 2008). Still, there is a lack of research evidence which supports combining IT controlling concepts with the special requirements of federal organizations.

The objective of this paper is to understand the reasons for the contradictions that exist between the theories and practice of IT controlling in federal organizations. On the one side, many IT controlling concepts and elaborated general organization types do exist. On the other side, the interrelation between a specific organizational form and the need for IT controlling is missing and thus many organizations are not capable of effectively controlling their IT. This paper uses organizations governed by federalism as an example and describes the key drivers of federally governed organizations and their specific needs for IT controlling. Further, existing IT controlling concepts are compared and their suitability for federal organizations is evaluated. The following research questions are addressed in this paper:

1. What are the constitutive elements of federal organizations and which key drivers characterize their specific (IT) controlling needs?
2. Which experiences, approaches and implementations for structuring and designing IT controlling already exist?

3. What are possible appropriate approaches and concepts for successful IT controlling in federal organizations?

2. LITERATURE REVIEW

2.1 Parameters of Federal and Modular Organizations

The word federalism is derived from Latin ‘foedus’ (confederation, confederacy, treaty, alliance) (Rudolf 1981). Frantz (1962) called federalism the leading principle for the social, governmental and international organization. According to him, the structure of a state has to be federative to achieve political freedom. Such a structure is characterized by districts and provinces having their own legislation which they advance autonomously (Frantz 1949). The larger a state is, the stronger the central power needs to be. Federalism described from the political perception includes larger autonomous political entities formed by the union of smaller political units who maintain their autonomy as well as the existence of coequal statehood of the whole state and the member states (Thöni 2005). A pure political perception of the term is not sufficient (Kinsky 2004); federalism as aggregation of uniformity and diversity can rather be a model for a great number of societal structures even beyond the state, for example in companies, associations, clubs or unions.

Although, the term federalism is rarely used in a context outside of societal structures, the underlying principles of autonomy, cooperation, solidarity, contractual or consensual conflict resolution, two-way control and distribution of power, subsidiarity and participation, are the same. Autonomy is based on self-determination of the particular members of a federal structure as well as the voluntary collaboration within the federal organization. Cooperation means that conflicts between units and the federal organization are not being solved by power, but based on specified authorizations. The specific units operate in solidarity. Compromises are often the conclusion of conflict resolution. Two-way control of federal units is realized by equal distribution of power between the units. Decisions are, according to the principle of subsidiarity, made where they occur. By contrast, competencies have to be transferred to the headquarters where reasonable.

Handy (1995b) expanded the established understanding of federalism to non-governmental environments and described federal organizations independent from purpose and scope of the organization. While the headquarters of a typical organization may be the center of decision-making, it is characteristic for federal organizations that initiative and dynamics result mainly from the subunits. According to Handy, the emergence of federalism in organizations is not conscious but emerges rather because the core of the organization cannot cope with all the information that is being provided by the decentralized units. As many organizations downsize their headquarters, they stop information overload and stop centralized control of the organization. That is when, as stated by Handy, decentralization turns into federalism.

The headquarters of federal organizations only define long-term objectives and leave the implementation of the objectives to the subunits. However when making decisions, headquarters must consider the opinions of the subunits. This is described as a place where persuasion has to be achieved and discussions lead to consensus (Handy 1995a). Constraints will be accepted on a subunit level if the acceptance of constraints benefits the superordinate unit. Picot, Reichwald and Wigand (2003) describe this type of organization as modular characterized by being split in legally autonomous units. The relatively small headquarters takes over coordinating tasks whereas the subunits are capable of acting legally autonomously and handle the more operational tasks (Picot et al. 2003). With few staff, management develops long-term strategy and coordinates cross-sectional activities. Following the creation of units in the modular organization, management must keep the number of interaction dependencies as low as possible (Weber 2001). Small units are characterized by flat hierarchies,
simple structures, and low division of work, which, in combination with personal responsibilities and integration of functions, leads to long range autonomy (Weber 2001). The strengths of both centralized and decentralized units have to be recognized and utilized accordingly. The advantages of specialization are either in the specificity of processes of customers, in the specificity of overall organizational infrastructures, or cross-specific functions (Picot et al. 2003). Therefore, tasks of the first group, where knowledge about specific customer-oriented workflow for problem solving is important, should be handled in the decentralized departments. In contrast, tasks with a high impact of overall methodical and technical aspect for problem-solving should be undertaken by centralized departments (Picot et al. 2003).

Table 1 summarizes the characteristics of federalism and federal and modular organizations leading to the requirements of IT and IT controlling in federal organizations. The structure of an organization is important to the thesis of this paper in terms of analyzing interrelations between the organizational form of federalism and IT controlling. Governance principles are taken into account as they influence controlling decisions (Weill and Ross 2004). The principles of cooperation are important as they are a main source of conflict (Tsai 2002).

Table 1: Characteristics of federalism, federal and modular organizations

The structure of any federal administration, company, or modular organization is crucial for organizational embedding of IT. Thus, the integration of the value-added chain requires organization-wide coordinated IT systems which support the coordination of autonomous units and guarantee the supply of information for each unit (Picot et al. 2003). Subunits responsible for the handling of a special task can be connected via IT infrastructure. To guarantee access to essential data at any time and to guarantee problem-oriented handling of data, a continuous integration and networking of all operational information systems is required (Picot et al. 2003). Coordination and cooperation of the particular units is realized by the means of IT through common and shared information databases and knowledge databases (Picot et al. 2003).

In the context of governance of federal organizations, the main aim is the localization of IT and IT controlling decisions (Weill and Ross 2004). Due to changing market conditions, the localization of decisions might be subject to change and different types of federalism can emerge over time. Depending on current governance structures, different requirements for IT and consequently for IT controlling arise. Although headquarters might delegate IT-related responsibilities to subunits, headquarters must retain control of IT in terms of being informed about operations performed in the
organizations to monitor and if necessary take corrective action on IT matters (Weber 2001). Weber (2001) proposes to provide the responsible divisions with a criterion for performance measurement and to communicate at what point headquarters is expected to intervene. To design the process of control comprehensively, individual agreement on the objectives for the unit and the documentation and review of compliance with these objectives is required.

The delegation of service activities is one trait of decentralization that impacts on the functions of controlling in an organization (Horváth 2006). It is assumed that a high level of delegation at the formation of a (controlling) system leads to a higher differentiation of the created system. In addition to spacious and technical characteristics, the organizational aspect of centralization and decentralization of information systems has to be taken into account (Lehner et al. 1991). This aspect specifies the degree of decentralization in planning, implementing and maintaining systems. A central solution has the advantage of a simpler construction of integrated solutions with coordinated data and being able to meet the information demand of management. Furthermore, centralized IT reduces the risk of redundant work and incompatibilities and facilitates the operation of organization-wide application systems. Similarly, creation, implementation and application of tools and standards are simplified and calculating load is optimized using a central IT organization. In contrast, in an organization with autonomous divisions, modifications in IT must be made promptly and units must be flexible in order to satisfy the needs of the decentralized units. Usually, the IT staff in decentralized units is more experienced than staff in centralized IT units in dealing with the problems of a particular division. Table 2 summarizes the requirements regarding IT and IT controlling that result from the characteristics and parameters of federal organizations as found in the literature review and described above.

Table 2: Requirements regarding IT and IT controlling
2.2 IT Controlling

IT controlling is, according to Krcmar (2005), the control of IT-related operations in the organization. The goal is to ensure efficiency and effectiveness of IT operations while providing, quality, functionality and compliance to deadlines in information processing. IT controlling has a monitoring function as well as a coordination function for the management of information.

An institutional and a functional view of controlling can be distinguished (Britzelmaier 1999). A multiplicity of controlling conceptions is discussed in the literature with differing emphasis depending on the application field. Vöhringer (2004) for instance, differentiates between profit-oriented, reporting system-oriented or key figure-oriented, and coordination-oriented controlling conceptions. The Anglo-American research area rarely uses the term controlling at all (Schauer 2006); it is being replaced by the associated contentual questions. This is why there is a differentiation made between IT/IS (Information Systems) (investment) evaluation, IT/IS (performance) measurement, and measurement of IT/IS costs, and benefits. Table 3 presents IT controlling concepts published within the last five years. The selection of the concepts follows criteria proposed by Schauer (2006): The presented approaches are to give an overview about functions and methods of IT controlling and not to be limited to some aspects. Moreover, the concepts should not be older than five years. They are presented in alphabetical order of the authors.

The controlling concepts presented in Table 3 serve as a basis to research possible criteria and starting points for organization-specific adjustments regarding controlling frameworks for federal organizations. The implementation of controlling in federal organizations should be a combination of central and decentralized controlling. Whereas central IT controlling deals with strategic planning, decentralized controlling is concerned with the implementation of the controlling concept in a particular division. Central strategy development, planning, controlling and regulating allow the longer-term alignment of an IT landscape to the corporate strategy in the subunits of federal organizations. The aim of strategy development is the definition of a nominal condition and to derive options and needs for action. On the basis of options and needs for action, agreements on objectives are made with the subordinated units and the objectives are connected with corresponding indicators (operating figures). An essential part of the IT strategy is the longer-term alignment of IT on decentralized operational processes. The planning of IT intentions and IT projects is, therefore, necessary. Decisions are not usually made at the operational unit level in federal organizations. By analyzing all possible interdependencies, the strategic relevance and effectiveness of the IT portfolio of the complete organization can be guaranteed (Krcmar 2000).

Table 3: Survey of introduced IT controlling concepts
There as a complete controlling concept comprises a holistic view on controlling, the core of a controlling concept is its applied methods. One of the widely-used methods is the Balanced Scorecard (BSC) which was first introduced by Kaplan/Norton (Kaplan and Norton 1992) and represents the central method of IT controlling (Rehäuser 1999, Rehäuser and Krcmar 1995). The BSC is the ideal controlling method for federal organizations because it is not limited to the presentation of the entire organization but can be used for the controlling of particular organizational domains, divisions or projects (Heilmann 2001). In the range of federal organizations, ratio systems are best used for organization-wide controlling that reflects the objectives of particular subunits. Such a controlling ratio system can be derived from the BSC. Its adoption does not occur with regard to its content, but rather its structure. Activity and cost data of IT have to be represented in management ratios in a way that using benchmarking, comparisons between the subunits of federal organizations can be made to increase transparency. Process oriented cost accounting offers the possibility to measure costs where they emerge (Aurenz 1990). A prerequisite for the strategic use of results of IT controlling in federal organizations is an established reporting system of the decentralized units among each other as well as between the subunit and headquarters. Because recipients of the reports make decisions in different areas and vary in their need for information, it is appropriate to consider, recipient, form, and date of the report when creating reports or planning the reporting system (Tiemeyer 2005).

Table 4 compares the requirements of IT controlling in federal organizations to possible approaches of existing IT controlling concepts structured by methods and instruments. Both columns result from a comparison of the literature reviews on IT controlling and federal organizations depicted above, conducted by the authors.

3 CONCLUSION

In summary, the major challenges for IT controlling in federal organizations lie in the provision of information about the decentralized, operational units for the centralized, strategic management. In addition, the decentralized units have to document their compliance with strategic objectives and their performance must be measureable. The literature review shows that existing controlling concepts use different methods and instruments to meet the IT controlling requirements of federal and modular organizations. The unique characteristics of decentralized units in federal and modular organizations make it difficult to implement one particular concept. This literature review focuses on German publications. Future reviews should include international literature. Research in this area should explore the application of existing instruments and methods of IT controlling in federal organizations in order to enable the transfer of information by controlling. Different theories, such as principal-agent theory or contingency theory, might provide an explanation as to how to improve the relationship between centralized and decentralized units in federal organizations. The resulting explanations could be further investigated in practice, for example by conducting case studies in a real world federal organization.

Abstract

Health care services in German hospitals are causing immense expenses. Successful IT Governance might help to support specific challenges for every organization with an adequate use of IT. The market structure of hospitals in Germany is very heterogeneous, e.g. in size and sponsorship. This paper analyses the state of the art of IT Governance based on a survey among 220 IT executives in German hospitals. The quantitative analyses of collected survey data reveal that hospitals govern their IT differently according to size and sponsorship. In addition, our analyses show that decision-making authority for the IT budget rises with hospital size and is positively correlated with the fraction of IT projects in the overall IT budget. We also show that the investments in innovative IT projects increase with hospital size. Our study revealed that a high number of private and larger hospitals lack a systematic IT Governance approach within the decision domain on IT projects. This study is the first to shed light into the empirical situation of IT Governance in German hospitals.

Keywords: IT Governance, IT Management, German hospitals, eHealth.

1 INTRODUCTION

The expenses for healthcare services in the German healthcare sector were estimated at 239 billion euros in the year 2003, which constitutes an 11.1% share of the gross domestic product of the Federal Republic of Germany (Destatis 2006). Based on this background Germany is listed in the Top 10 of OECD countries for per capita expenses on health care services (Anderson et al. 2006) and according to the Federal Healthcare report of the Federal Statistical Office (2008b), about 59 billion Euros are spent in the hospital sector.

In many industrial branches innovative information technology (IT) and its use are key drivers for increasing effectiveness and efficiency in production processes for goods, services and successful business processes (Leimeister et al. 2009). The effect of IT usage in healthcare is found in medical service provisions (Jähn and Nagel 2004, Schweiger et al. 2007) and administrative support processes (Haas 2005, Lehmann 2005). Hacker and Schommer (2004) report on increased effectiveness and efficiency in examination, treatment and administrative processes in hospitals. IT usage can be a driver for diversification in competition and the creation of innovative strategic competitive advantages in hospitals and the health care sector (Piccoli and Ives 2005). Multiple studies report success of IT-driven improvements in administrative and business processes, e.g. information systems for the input and integration of treatment data, reminder functions, medicament management and medication...
(Crane and Raymond 2003, Leimeister et al. 2005, Raymond and Dold 2002). Since the early 1990s, studies have shown that cost reductions are not only generated by the automation of information accumulation and processing but additionally by contemporary and optimized information allocation for decision makers (Borzekowski 2002). This fact verifiably induces improved treatment quality (Apkon and Sighaviranon 2001, Hacker and Schommer 2004) and fostering of patients (Leimeister et al. 2008b, Nahm and Poston 2000).

Despite the economic importance of the health care sector and important role of hospitals, Information Systems research has not been able to generate empirically collected data and declarative and conceptual models on IT management and information allocation in hospitals. A number of recent studies are either driven conceptually or are missing hypotheses testing on an empirical basis (Sachs 2005). Other studies focusing on special tasks of IT management, e.g. investment and budget decision making (Bernnat 2006), are missing the application of statistical analysis methods (Riedel 2006) or lack statistical significant results because of low participation numbers (Irving and Nevo 2005).

To close the gap in academic research and based on the above-mentioned immense expenses for health care services in Germany, a unique and empirically broad state of the art descriptive study on IT Governance in German hospitals was conducted.

1.1 Motivation for the study

In conducting this study, we were inspired by the approach taken by Weill and Ross (2004), who describe two sources of motivation when conducting a study on IT Governance in corporations. Weill and Ross were motivated by the stock-market premiums given to firms with excellent corporate governance and therefore “suspected a similar premium existed for excellent IT governance” (Weill 2004) and the “fact that relatively sophisticated financial governance in most enterprises could provide a good model for IT Governance” (Weill 2004). In addition, we identified a previously described gap in academic research on IT management and specifically IT Governance in German hospitals. Our motivation derives from the assumption that differences in IT Governance structures and operationalization exist across hospital size and sponsorship. The foundation of our motivation derives from the results of survey studies conducted in the scope of the Krankenhaus-Barometer (Blum et al. 2007), which indicates differences in types of sponsorship and hospital size.

*Table 1. Importance of future objectives across hospital sponsorship (extract from (Blum et al. 2007))*

Table 1 displays the importance of hospital future objectives based on arithmetic mean and ranks results according to the type of hospital sponsorship. Although, the primary future objectives are identical across the three types of hospital sponsorship, we also see major differences. In all types of sponsorship, patient satisfaction, high process quality, the good image of the hospital and intensification of the relationship between hospital and medical practices, are the most fundamental objectives. However, private hospitals focus more on economic objectives than public (e.g. university)
and non-profit hospitals (e.g. comparable by type of sponsorship to organizations like the Red Cross). Increasing revenue, realizing profit and achieving the highest possible return on investment are ranked higher by survey participants from privately sponsored hospitals. We reflect that the realization of the mentioned objectives is achievable through a value proposition of IT utilization based on findings by Fähling et al. (2009), who found that IT utilization traces back to decisions and that these decisions are primarily influenced by the IT Governance. To consolidate our assumption of the influence of IT Governance, we hereby derive (1) revenue increase by the utilization of administrative information systems that support process cost controlling and increase the rate of return on capital employed through the allocation of (information) resources, (2) realization of profit by the utilization of medical information systems that enable new business models and treatment methods and (3) highest possible return on investment by optimized and more efficient treatment methods supported by medical information systems.

Table 2 displays composite results of a survey conducted by the Deutsches Krankenhausinstitut (Blum et al. 2007) which describes the differences in hospital size (measured by the number of beds) on the basis of three survey items. We assume that the chosen items: cooperations between hospitals, mergers between hospitals and new allocation of tasks between medical and non-medical staff, call for different IT Governance cultures and models.

<table>

</tbody>
</table>

Table 2. Importance of objectives across hospital size (extract from (Blum et al. 2007))

Cooperations and mergers between hospitals require a flexible and interoperable IT landscape, which should have consequences for the IT Governance — especially in large hospitals. To enable and support many reallocations of tasks between medical and non-medical staff, IT managers should have a high degree of decision-making authority, and must understand the requirements of their medical and non-medical clients.

2 IT GOVERNANCE IN HOSPITALS

Weill and Ross (2004) state that “the difference between management and governance is like the difference between a soccer team running harder and practicing longer and the stepping back to analyze its composition and game strategy”. The result of an analysis may be that a team needs to introduce new coaches or different playing positions or provide diverse decision making responsibilities. Therefore a company and respectively a hospital organization needs to involve different people in “IT decisions, designing new ways or making IT-related decisions, or developing new techniques for implementing IT decisions” (Weill and Ross 2004) to achieve more value from IT artifacts. Along with other definitions of IT Governance (IT-Governance-Institute 2000, Krcmar 2005, Van Grembergen 2003), Weill defines IT Governance as “specifying the framework for decision rights and accountabilities to encourage desirable behavior in the use of IT” (Weill 2004). The definition implies a strict separation between management and governance. Whereas management talks about the specific decisions that are made, governance “is about systematically determining who makes each type of decision (a decision right), who has input to a decision (an input right), and how these people (or groups) are held accountable for their role” (Weill 2004). Consequently, the IT Governance framework proposes five major decision domains and six exclusive governance archetypes for making IT decisions. These were adopted and linguistically adjusted and translated into German to fit common expressions used in praxis and the German health care sector. Table 3 displays information on the
decision domains according to Weill (2004) and the corresponding terminology used in the underlying study and analyses (see Figure 3).

Table 3. Decision domains according to Weill (2004)

Based on considerations of corporate governance, state governance and information politics, Weill and Ross identified six IT governance archetypes; namely, Business Monarchy, IT Monarchy, feudal, federal, IT Duopoly and anarchy, through a logical combination of above mentioned decision maker types. Table 4 displays the IT Governance archetypes which describe the combination of people who have either decision rights or input in IT decisions (Weill and Ross 2004) and short descriptions outlining each archetype.

1 Polyclinic is a clinic for ambulant therapy.
Federal: C level executives and at least one other business group (e.g., CxO and business unit leaders)—IT executives may be an additional participant. Equivalent to a country and its states working together.

IT Duopoly: IT executives and one other group (e.g., CxO or business unit leaders).

Anarchy: Each individual user

Table 4: Six IT Governance archetypes (Source: according to Weill (2004) and Weill and Ross (2004))

Additionally, Table 4 shows the results of the organizational and hierarchical entity mapping between corporation and hospital decision makers. The aim of the underlying study is to deliver first insights regarding the empirical situation of IT Governance in German Hospitals by conducting a descriptive analysis of collected data.

3 RESEARCH DESIGN

3.1 Research method

In order to explore the IT Governance in German hospitals, we conducted 12 expert interviews on IT Governance in German hospitals to structure the research objective and questionnaire. The data was collected through a standardized online questionnaire. The questionnaire was adjusted linguistically to fit the professional domain terminologies of IT executives in German hospitals. The duration of the survey was three months, from March to June 2008. The questionnaire forms were pre-tested among ten experts and adjusted in advance where required. Address data was collected from commercially available domain-specific address data collections and internally compiled address data sets. After consolidation of address data sources and validation of doubles, 2391 different hospitals and medical institutions could be identified as potential participants. The numbers show that multiple contact persons in the same professional domain per institution/hospital were contacted. All mailings included an individual code to avoid multiple participations. The average response time for the questionnaire was approximately 30 minutes. The data collection included two follow-up calls for participation through email and postal mailings. Additionally, two articles describing the study, including a call for participation, were published in professional journals: Krankenhaus-IT Journal and Management & Krankenhaus. The results presented below are based on descriptive analysis of relative frequencies, t-tests and correlations with the use of the correlation coefficient by Spearman.

3.2 Structure

After two researchers independently and iteratively conducted a data cleaning process, 206 data sets (11 anonymous) were collected from IT executives through the online questionnaire. More than two thirds of the IT executives (70%) hold an academic certification, whereas 30% graduated with an apprenticeship certificate.
Table 5. Sample structure (n=200)

For further analysis, the data set was segmented based on two segmentation attributes: type of sponsorship and size of the hospital as discussed previously. The size of the hospital was measured in number of beds. We adopted the classification of the hospital size from Leimeister et al. (2008a). Hospitals were classified into three categories “under 200 beds”, “200 to 799 beds” and “800 and more beds”. This segmentation is based on an interview series among experts from the German medical and hospital environment. The type of sponsorship is partitioned to three categories: “public”, “private” and “non-profit” and corresponds with the German hospital market structure.

Table 6. Comparison between German hospital market structure and our sample (according to Destatis 2008a)

When compared with data from the Federal Statistical Office, our sample is not consistent with the statistical data about German hospital market structure (see Table 6). While our sample consists of 40.5% non-profit hospitals, only 25.62% of the hospitals in Germany are under control of a non-profit sponsor. In contrast, our sample contains only 19% of private hospitals, whereas 38.37% of hospitals in Germany are held privately. We also see differences in hospital size between our sample and the German hospital market structure. Within our sample only 20% of all hospitals are small compared with 55.54% in the German hospital market. By contrast large hospitals are overrepresented in our sample, with a share of 16.5% compared to 3.92% in the German hospital market. Based on the structure of the sample displayed in Table 5 and Table 6, we accept that the informative value of conducted t-tests might be limited and its application restricted.

4 EMPIRICAL DATA

4.1 IT-budget

In a first step, we analyzed the distribution of the IT budget. The respondents could assign 100% of the IT budget to three different categories. The first category Operations contains all costs for the operations of current IT systems in the hospital. The second category Projects includes all expenses for projects beyond operating tasks. This part of the IT budget is invested to develop new and innovative IT solutions within the hospital. The last category Organization involves all personnel expenses.

The three left bars in Figure 1 show the comparison between the hospitals by size (n=203). The rightmost bar represents the average values across all hospitals (n=203). The IT budget for the IT organization in large hospitals with 800 beds and more is slightly lower (33.9%) compared to 35.1% in medium and 36.6% in small hospitals. On the other hand, large hospitals invest more in IT projects (22.1%), compared to 21.8% in medium and 18.1% in small hospitals.
Bars number four to six from the left give an overview over the IT budget distribution across different sponsorships (n=200). Here we could identify differences in all budgeting areas. First, the part for IT operations represents almost half of the whole IT budget in private hospitals (47.3%) compared to 43.8% in public and 41.9% in non-profit hospitals. Second, the organizational part on the IT budget is much lower in private hospitals (30.1%) compared to 34.5% in public and 38.2% in non-profit hospitals. Finally, private hospitals invest a bigger share in IT projects (22.6%) compared to 21.7% from public and 19.9% from non-profit hospitals. T-tests could not reveal any significant differences in hospital size or sponsorship. This might result from the structure of the sample.

4.2 IT decision-making authority

The second question was related to the decision-making authority. Three types of decision-making authority were formulated in the questionnaire: the IT manager can only prepare but not make decisions, the IT manager is allowed to make decisions within a specific amount of budget and the IT manager may decide over the full amount of the IT budget (see Figure 2).
the full amount of the IT budget by their own. The percentage of IT managers which only prepare
decisions is almost the same across all hospitals (from 22.2% in public to 23.7% in private to 25.9% in non-public hospitals). Across hospital size, IT managers from large hospitals are more likely to be able to make decisions by their own (30.3% in large, 10.8% in medium and 5.0% in small hospitals) than in medium and small hospitals. This fact is also underpinned by a correlation between the freedom of IT budget decisions (decision-making authority index) and the number of beds (r=0.20; p=0.004; n=203; see Table 7). The decision making authority index is based on a three point scale: "prepare IT decisions" was mapped on a value of 1, "make decisions within a specific amount of budget" was mapped on a value of 2 and "make decisions within whole IT-budget" was mapped on a value of 3 (higher values represent higher decision authorities).

Another analysis of decision-making authority index and the different areas of IT budget revealed a positive correlation between the decision-making authority and IT projects (r=0.17; p=0.017; n=203). The more decision-making authority the higher the part of IT projects on the whole IT budget. One explanation is that IT managers with low budget responsibility have difficulties to convince other stakeholders of their ideas for IT projects. Another explanation is that IT managers which execute more IT projects receive more trust from the other stakeholders and therewith more authority for decision-making.

Another analysis of decision-making authority index and the different areas of IT budget revealed a positive correlation between the decision-making authority and IT projects (r=0.17; p=0.017; n=203). The more decision-making authority the higher the part of IT projects on the whole IT budget. One explanation is that IT managers with low budget responsibility have difficulties to convince other stakeholders of their ideas for IT projects. Another explanation is that IT managers which execute more IT projects receive more trust from the other stakeholders and therewith more authority for decision-making.

![Table 7. Correlations between decision making authority index (Source: sample data)](attachment:image)

Results of the t-test between hospital sponsorship across hospital size (see Table 8) disclose that differences in decision-making authority exist between big private hospitals and public (level of significance: 0.026) as well as non-profit (level of significance: 0.048) hospitals. The results need to be interpreted carefully as large public and non-profit hospitals are underweighted in the sample.

![Table 8. T-tests between hospital sponsorship across hospital size about decision-making authority (Source: sample data)](attachment:image)

4.3 IT decision domains

As previously described, we analyzed all IT decision domains across hospitals by classifying our sample in hospital sponsorship and size. The first IT decision domain we focused on is IT Strategy. Figure 3 shows that the fraction of the federal archetype increases and the fraction of IT duopoly decreases with hospital size. This can be explained by an increasing number of departments at larger hospitals. Decision processes for the IT strategy more often follow the archetype of an IT Monarchy in non-profit hospitals (34.2%) than in public (24.7%) and private (19.8%) hospitals. In public hospitals the most frequent archetype is federal, possibly because the share of large hospitals in public hospitals is higher than in private and non-profit ones, according to our sample data (Figure 3 and Table 5). Results for the decision domain IT Standards show that the most common archetype for IT standards is IT Monarchy (from 57.5% in small to 69.7% in big hospitals). This is not surprising, considering that decisions surrounding IT standards are often technically-driven, and do not primarily affect business process issues. In any case, almost one-fifth of the hospitals use a federal archetype in decisions on IT standards. The biggest share of the federal archetype can be found in private hospitals.
(23.5%), the smallest in non-profit hospitals (5.3%). Noticeable is the high share of IT duopoly in non-profit hospitals (15.8%) which is almost twice as high as in public hospitals (8.6%).

Next, we analyzed the decision domain IT Applications. In this decision domain, the archetypes are distributed very differently. IT Monarchy plays an unimportant role. The most mentioned archetype is federal. The fraction grows with the hospital size (42.5% in small, 58.5% in medium and 63.6% in large hospitals). This result shows that the clinical departments which use IT applications are mostly involved in decisions about these applications. In non-profit hospitals we identified a percentage of 18.4% and in private hospitals a percentage of 16% in which decisions on IT applications are made according to a Business Monarchy archetype — that means, without the involvement of IT decision makers and departments. The lower percentage of the federal archetype in non-profit hospitals is
derived from the high share of small and medium sized hospitals for this sponsorship type (see Table 5). In addition, the share of IT Monarchy in non-profit hospitals is much higher than in the other types of hospitals. One explanation might be that IT managers in non-profit hospitals place themselves near to medical and operating departments so they get more trust in selecting the best application for the requirements of their internal customers. The decision domain IT Infrastructure is dominated by the IT Monarchy archetype. The second important archetype is IT Duopoly. The federal archetype only plays a role in small hospitals (22.5%). The distribution of archetypes is highly similar across all sponsorship types. More than 50% of the decisions are made within a IT Monarchy governance type. These results demonstrate that IT infrastructure issues as well as IT standards are highly specified decisions of IT specialists in German hospitals.

The four main governance archetypes within the IT Investment decision area in German hospitals are IT Monarchy, Business Monarchy, IT Duopoly and Federal archetypes, with the last two archetypes being more dominant according to sponsorship and hospital size. The share of the IT Duopoly archetype is especially high in medium-sized (31.5%) and non-profit (31.6%) hospitals, whereas the share of the federal archetype is high in large (39.4%) and public (37.0%) hospitals. The results might be influenced by the share of large public hospitals in our sample data (24.7% compared to 15.8% of large private and 8.7% of large non-profit hospitals).

Our descriptive analysis on the IT Projects decision domain reveals that decisions on projects are mostly conducted in an IT Duopoly governance type. Just above 39.0% of the participants from larger hospitals confirm that an IT Duopoly governance is used for project decisions. A comparable picture describes the numbers derived from the survey data on small and medium sized hospitals where 32.5% and respectively 36.9% of participants indicate an IT Duopoly archetype for decisions on IT projects. Nevertheless, we see a relatively high fraction of the answer item “not applicable” (n/a), especially in medium (10.8%) and large (12.1%) as well as public (9.9%) and private (12.3%) hospitals. This indicates that the decision domain on IT projects does not exist in the mentioned sponsorship types and sizes of hospitals.

5 DISCUSSION

Based on different objectives and attributes between small and large as well as between private and non-private (public and non-profit) hospitals, we analyzed the IT governance approaches between hospital sizes and sponsorships. Overall, we concentrated our analyses on three topics: IT budget, IT decision-making authority and IT decision domains.

The relative distribution of IT budgets across German hospitals is dominated by IT budgets concerning IT operations. One explanation for this distribution could be that German hospitals deal with many legacy systems. In contrast, IT project-related budgeting which is invested to develop new and innovative IT solutions within the hospital, covers the smallest share. Although the partitioning of the IT budget differs between hospital size and sponsorship, these differences are not statistically significant.

In a next step, we identified a significant correlation between decision-making authority and the percentage of IT projects on the overall IT budget. We assume that IT managers invest mainly in IT projects. In other words, the more decision-making authority on IT budget, the more IT improvement through innovative IT project deliverables can be expected. Furthermore, with the help of t-tests we proved statistically significant differences between large and medium, as well as small hospitals in decision-making authority. In other words, the larger the hospital size measured in number of beds, the higher the decision-making authority of IT managers. We could also show that these significant differences only exist between private and non-private (public and non-profit) sponsorships.
We assume that private hospitals are more dedicated to increasing revenue and optimizing return on investment than hospitals under different sponsorship types based on findings of described similar studies. Our study revealed that IT managers from private hospitals try to support these objectives with a higher fraction of IT projects on the overall IT budget.

The third topic of the underlying study investigated the structures of IT decision domains in German hospitals. Our study revealed that in most hospitals a project-oriented specification of business needs for purchased or internally developed IT applications is not conducted in a systematic IT Governance approach. The high absence rate of a systematic IT Governance execution, especially in private and large hospitals in the decision domain IT Projects is very surprising as IT project-related budgeting is invested to develop novel IT solutions and drive innovation.

6 LIMITATIONS AND FURTHER RESEARCH

This study is not without its limitations. First, the study is limited by its data collection process and data set structure. The collected data represents a snapshot of reality and therefore conclusions on dynamics and timely progression cannot be derived. In the future, multiple and frequent data collection processes could lead to interesting findings over time. The data set structure is not representative along sponsorship and size segmentation. Second, the study only considers the perspective of chief information officers and IT managers in German hospitals, which might generate a bias on question items. Further analysis might be coupled with additional qualitative data collection, in order to create a deep and coherent understanding of these preliminary findings. In combination with further in-depth statistical analysis, the researchers plan to generate and test structural equation models to expose cause and affect chains in IT Governance in German hospitals and to identify the role of contingency factors in choosing the optimal IT Governance archetype. The generated findings could be used to discover similarities and differences to industry-related results and patterns discovered in comparable studies.

Abstract

The paradigm of the Internet of Services envisions trade on a global service-enabled internet. Companies, which participate in this new world of services, face the challenges of changing market conditions, new competitive threats, and new legal regulations. Service-oriented Architectures (SOA) provide a promising way to address some of these challenges at the level of the company’s IT infrastructure. In order to guideline an enterprise’s organization and IT and ensure smooth operations, governance frameworks have been established. More specifically, IT Governance and recently SOA Governance have been introduced. The basic structure of IT Governance frameworks is applicable to an SOA. However, they lack functionality or applicability concerning SOA-specific challenges. Current approaches, which focus on mere SOA Governance, lack framework scope and are mostly driven by individual companies. This issue aggravates taking into account the shift to an Internet of Services. We identify key issues and provide initial insights on building blocks for a Service Governance Framework which enables operations for companies in a moderated service network. We discuss service life cycle phases, stakeholder roles, and management processes taking into consideration existing frameworks such as ITIL and COBIT as well as industry-specific approaches from companies such as SAP, Oracle, and HP.

Keywords: Service Oriented Architecture, Framework, Service Governance, Governance Management Processes, Governance Roles, Internet of Services.
1 INTRODUCTION

The Internet of Services is thought to enable agile enterprises to reach out to a global market and focus on core competencies but also create global competition. It is extending today's internet to become service-enabled, i.e. facilitating the trade as well as execution of services. For businesses it is supposed to be the underlying global infrastructure which allows forming flexible and agile service networks to provide value-added services (Heuser, 2007). It is “a multitude of connected IT services, which are offered, bought, sold, used, repurposed, and composed by a worldwide network of service providers, consumers, aggregators, and brokers resulting in a new way of offering, using, and organizing IT supported functionality” (Villasante, 2009). Trends like this make companies face constantly changing market conditions, new competitive threats, and new legal regulations which have an impact on their IT (Barros & Dumas, 2006). The Service-oriented Architecture (SOA) paradigm provides a promising way to address these challenges at the level of the company’s IT infrastructure.

Diligent governance has been recognized in recent years as a major requirement for successful adaptation and operation IT, especially for large systems. Governance in general, be it political governance, Corporate or IT Governance, provides guidance for the definition of expectations and responsibilities as well as directions to assess the performance of organizations or projects. Governance elaborates guidelines and rules that need to be adopted and realized by the affected management processes and stakeholders. Service Governance must provide means to effectively exploit the capabilities of SOA in an Internet of Services.

For IT Governance, a number of existing frameworks provide structures, action scope, guidelines, and best practices. However, while the basic structure of IT Governance frameworks exceeds the needs of an SOA, they lack applicability concerning SOA-specific challenges, e.g. cross-company service deployment and third party service management. Current approaches, which centre on mere SOA Governance, lack framework scope and are mostly driven by individual companies. Hence, in order to meet governance requirements, existing frameworks need to be extended and/or refocused.

We analyze existing approaches with respect to their applicability to SOA scenarios and the Internet of Services in particular. In a first step, we blend both, COBIT and ITIL, to get a basic set of governance processes, tasks, as well as a related set of key performance indicators and controls based on mature frameworks. Then, we discuss the major elements of a Service Governance approach. We provide the theoretical fundamentals and initial keystones of a Service Governance Framework covering the service life cycle, involved roles, and management processes.

This research belongs to the design science paradigm (Hevner et al., 2004, March & Smith, 1995). It strives for developing a practically relevant artifact in form of a method framework for Service Governance in the Internet of Services. According to March and Smith (1995) and Hevner et al. (2004), (IT) artifacts are of four types: constructs, models, methods, and instantiations. Constructs are the vocabulary of a domain, a specialized language, and shared knowledge of a discipline or subdiscipline. Models are a set of propositions or statements expressing relationships among constructs. Methods are goal directed plans for manipulating constructs so that the solution statement model is realized. Instantiations (also implementations) operationalize constructs, models, and methods resulting in specific products.

The paper is organized as follows: In the subsequent section we elaborate on the fundamentals of an SOA as well as IT and SOA Governance. In Section 3, we outline necessary requirements for Service Governance by reviewing industry practice and provide building blocks for a Service Governance Framework. They include a frame for the service life cycle phase, stakeholder roles, and a management process cycle. The paper closes with a summarizing analysis of Service Governance for an Internet of Services realized through service marketplaces.
2 RELATED WORK

2.1 Service and Service-Oriented Architecture (SOA)

The SOA paradigm is a holistic approach towards the execution of business processes consisting of services within or across enterprise architectures. Structured adaptation is crucial to the success of a company’s SOA. As an architectural paradigm, SOA defines a number of mechanisms, principles, and conditions: All functions (e.g. business functions) are defined as services. Services can be regarded as “not storable and intangible goods which are constructed in cooperation with an external factor (usually the service consumer). Construction and consumption traditionally occur at the same time (uno-actu principle). Electronic services differ insofar as they are storable in a sense and their consumption, i.e. execution, does not necessarily involve concurrence” (Janiesch et al., 2008a). Services are designed to support reusability in different scenarios. In order to reuse, only a new parameterization is necessary without any change in its implementation. Service functionalities can be automatically discovered via service brokers or registries. They are centrally registered at a database which provides information about the services upon request. Services are self-describing. While interacting, services are loosely coupled. This means a mutual association via messages; dependencies are minimized to mere awareness. It facilitates a number of operations, e.g. their replacement by other services during runtime. Service operations always involve several parties. Services therefore adhere to a communications contract, a Service Level Agreement (SLA), defined by one or more service descriptions and related documents in order to regulate and control service execution. Services are autonomous concerning their logic. They are independent of other services, e.g. software modules, as well as resources such as databases. The realization of services follows the information hiding principle. Services are stateless. They minimize stored information regarding activities, i.e. state or context information concerning either execution or communication with other services is not saved. Services are completely independent of any platform, programming language or operating system. Their technical realization is transparent for service requestors and brokers. Services can be accessed by an invokable interface without any knowledge of its location. An important characteristic of services is their combinability. Services are designed to be assembled to form composite services, each consisting of several single or further composite services (Erl, 2005, Huhns & Singh, 2005).

Accordingly, an SOA is “an application architecture within which all functions are defined as independent services with well-defined invokable interfaces which can be called in defined sequences to form business processes” (Channabasavaiah et al., 2003).

In order to support and facilitate coordination and cooperation between service providers and service consumers, service brokers are established. These are registries known to all eligible providers and consumers. Providers register services by providing meta information such as name, functionalities, interfaces, etc. Consumers query a broker for a service needed – and if a service is found, the consumer and provider exchange interface specifications. If both sides agree to cooperate, a cooperation is established and concluded by an SLA (Huhns & Singh, 2005). Instead of merely being a broker, the platform host can evolve into a moderator who also supervises the delivery of services. In order to realize this vision and achieve this goal, a diligent governance concept is needed from the very beginning, to support the realization of these benefits.

2.2 IT and SOA Governance

The SOA paradigm offers advantages compared to common enterprise architectures such as an increased response rate to changing conditions or interoperability. However, these advantages entail new challenges such as the need for permanent monitoring and control of services – service guidance is required. By following specific guidelines in a top-down approach, an SOA is adopted, operated,
and continuously monitored and checked for adherence to regulations. Governance also ensures compliance, i.e., compliance to intra-company, normative, or legal standards (e.g., the Sarbanes Oxley Act, Basel II etc.).

For IT Governance, numerous frameworks have been specified, e.g., COBIT, ITIL, ValIT, ISO 20000, ISO 17799, etc. Basically, each of them focuses on a different aspect of a company’s IT. While the IT Infrastructure Library (ITIL), e.g., mainly deals with management and support process definitions (Office of Governance Commerce, 2007), the ISO 17799 standard primarily targets security management (International Organization for Standardization, 2006). When these approaches are compared, we see that they do not exclude but rather complement each other. In comparison, COBIT is a high-level governance and control framework, more tightly aligned with the business objectives of the organization than with operational issues (IT Governance Institute, 2007). As a matter of fact, all other frameworks class into COBIT. It has, so far, become a de facto standard for IT control globally, and its implementation increasingly gains interest.

Concerning SOA Governance, many software companies introduced their own definitions in whitepapers, often on behalf of own market interests (cf. Section 3.1). This resulted in the definition of a number of different approaches. Similarly, a number of definitions for SOA Governance can be found: “SOA Governance is a management structure including creational and administrative elements” (Fabini, 2007) or “SOA Governance is a set of solutions, policies and practices which enable companies to implement and manage an enterprise SOA” (Brauer & Kline, 2005).

It is difficult to give a common definition for SOA Governance as a number of different descriptions and understandings exist. The main objective is to define and introduce company-wide policies for the adoption and operation of an SOA as well as to introduce mechanisms controlling their enforcement (Fabini, 2007, Windley, 2006). According to several authors, the basic difference between SOA and common former enterprise architectures is the service life cycle (Bea Systems, 2006, Brauer & Kline, 2005, Software AG, 2005). There is a paradigm shift concerning software development (Johannsen & Goeken, 2007). Hence, a central issue of Service Governance is considered to be the service life cycle governance.

In most cases, an SOA requires the restructuring or adaptation of the company’s organizational structure. A SOA Center of Excellence as well as accompanying boards, consisting of management members and members from the different departments is recommended (Bieberstein et al., 2005b). In case of big companies, one central governance structure seems problematic – decentralized and coordinating as well as hierarchically structured governance positions are combined (Fabini, 2007). The deployment of an SOA Maturity Model is also recommended (Afshar, 2007, Johannsen & Goeken, 2007, Progress Software Corporation, 2006), measuring the maturation of a company’s SOA. Results of such an assessment provide information concerning the progress and success of the realization of SOA. This way they have impact on the governance policies – a control cycle is created.

Most of the authors agree that SOA Governance is a fundamental requirement for a trouble-free adaptation as well as for successful operation. Regulations and control are the central elements which are to be effectively implemented. In parts, SOA makes the same demands on governance as common systems, but to some extent it exceeds the regulative support IT governance can provide. Regarding value contribution or IT-business alignment, existing IT Governance frameworks (e.g., COBIT) provide sufficient support. However, if confronted, e.g., with cross-organizational aspects, the scope of IT Governance frameworks is exceeded. SOA Governance needs to provide the abilities to guarantee sufficient SOA adaptability and integrity as well as to check services concerning capability, security aspects, and strategic business alignment.
3 CURRENT ISSUES AND PROPOSALS FOR SERVICE GOVERNANCE

3.1 Existing SOA Governance Approaches in Industry

An inherent characteristic of SOA is that services are not bound to existent entities, such as, e.g., accounting applications. They can be provided, bought or sold and executed in third party applications or environments. Additionally, to a greater extent than previous enterprise architecture concepts, SOA facilitates inter-organizational deployment of software artifacts. Thus, a governance approach must focus on the adoption and operation of SOA as enterprise architecture in a company. It must provide guidelines and mechanisms to ensure the integrity of an SOA and its adaptability to business and general administration processes. It also must provide tools to support the monitoring and control of services concerning security issues and the alignment to business processes. The main goal is to achieve adherence of the SOA system to various specifications and standards, such as the Sarbanes Oxley Act, ISO norms or internal regulations.

Numerous perspectives of SOA Governance exist driven by individual companies. Hence, they are rather product-oriented. Thus, approaches to SOA Governance do not always comprise all of the above mentioned elements. It depends on requirements and existing structures of the particular cases, which of the elements are considered useful. But they all concur that the adequate implementation of SOA Governance in a company requires an extra approach as extension to IT Governance to address SOA challenges (Woolf, 2007).

The SOA Governance approach of SAP AG, e.g. consists of a guidelines framework and an organizational institution, the Process Integration Content (PIC) Council. The framework has three parts: modeling and implementation guidelines, a special review process performed by the PIC council (guidelines enforcement), and the continuous execution of manual and automated service tests (SAP AG, 2007). The process is model-driven with the support of an integrated modeling suite. The actual engineering and development process starts with the identification and structuring of functional requirements. They are scrutinized in a map which covers deployment units, process components, and business objects. The resulting integration scenario model defines the necessary interactions and results in a service orchestration. The resulting content is subject to a review process by architects and an approval by management. The PIC Council guarantees quality of process integration content by reviewing interfaces for semantic correctness, ensuring standard conformity, encouraging reuse, establishing enterprise-wide consolidation and improving the integration guidelines. The SAP AG approach implements the idea of the SOA Center of Excellence, defining a council as central element of SOA Governance. The design of individual services is also governed by an enterprise service design guide which promotes a business-driven view based on processes and scenarios. Thereby services are not to be designed isolated from each other and are meant to be reused (SAP AG, 2005). The guidelines include concepts of service design for SAP internal development, business analysts, system integrators, and independent software vendors. The procedure is three-stage and consists of indicator-based service discovery, service design and documentation. The methodology also distinguishes the three levels of design of single services, service systems design, and service-enabling of enterprise applications. It is centered on the notion of so-called design contexts which represent patterns for improving applications with services.

Similarly, a comprehensive examination of the scope of SOA Governance is given by Oracle, Inc. (Afshar, 2007). Oracle’s approach attempts to give an overview of the entire Governance domain. Starting from a generic point of view, Oracle Inc. identifies eight decision fields. Within each field, policies for key issues are to be defined, in order to assure the according requirements on SOA and their reliable realization. The approach combines these decision fields with an SOA adoption model and a comprehensive set of best practices. The following table gives a short overview:
<table>

Table 1. Key Aspects of SOA Governance Decision Fields

Apart from these approaches, many other companies propose proprietary models. We give an overview of the variety of the field in the following:

Brauer and Kline (2005) at HP define different components supporting the implementation and management of SOA. They provide a holistic controlling framework, emphasizing the integration of people (organization), processes, and technology.

Bieberstein et al. (2005a) of IBM propose an SOA Governance Model. They identify six governance processes and three steps for launching the SOA Governance Model. The SOA strategy and SOA objectives should be defined in a way that both business and IT units have a clear understanding of them. According to them, policies, defined by governance positions, form the basis for any decision. Their model is completed by a set of best practices. Bieberstein et al. (2005b) also describe an approach to guide an SOA successfully, emphasizing transformation of organizational structures and behavioral practices. They propose the Human Services Bus (HSB) as a new organizational institution, streamlining cross-department processes, thus optimally exploiting the SOA approach.

webMethods' (2006) SOA Governance approach consists of two parts: Architecture Governance and Service Life Cycle Governance, the latter is divided into design-time, run-time, and change-time governance. Architecture Governance comprises issues such as corporate technology standards, the definition of an SOA topology and determination of an SOA platform strategy. Service Life Cycle Governance focuses on the regulation of design etc. of services through according policies and enforcement mechanisms.

The approach by Software AG (2005) identifies maturity and governance levels. Besides this 6-level-maturity model they define an SOA service life cycle, incorporating services, related artifacts, and roles. They provide a 5-step SOA adaptation plan as well as a set of best practices.

Bea Systems, Inc. (2006) clearly emphasizes the importance of the service life cycle as the most critical requirement of a successful holistic SOA Governance approach. Central policy definition and enforcement, regulating the design, building, provisioning, and operation of services, affect the whole SOA referring to quality assurance, monitoring, and SLA management. The primary goals are reduced development costs and faster time-to-service. With the acquisition of Bea Systems, Inc. by Oracle, Inc. it is reasonable to assume that their approaches will merge.

This list of governance model proposals shows the diversity of approaches to SOA Governance. However, most of them show congruencies which can be generalized. For governance within the Internet of Services, an approach is needed that lies between the requirements of an SOA and the more
general governance of IT. Thus, Service Governance, as we understand it, is a form of IT Governance and is mainly driven by the Corporate Governance of the host. It subsumes several points from the current best practices of SOA Governance, e.g. comprises it considers cross-company issues of multiple parties. Also, SOA as enterprise architecture is addressed. However, in addition Service Governance comprises the consideration of cross-company legal aspects exceeding those of current SOA Governance approaches, i.e. contract management over country borders, country-specific laws for data transmission and protection, and laws concerning the fulfillment of online contracts. Being a cross-company approach the framework needs to consider the interests of all stakeholders of the platform. Both the interests of the host and customers have to be included. Preconditions to be fulfilled by suppliers also have to be formulated, and vice versa. In contrast, SOA and IT Governance approaches normally focus on the operation within a single organization, considering a single stakeholder.

3.2 Building Blocks of a Common Service Governance Framework: Service Life Cycle

As a balanced starting point, the IT Governance frameworks of CObIT and ITIL v3 can be used. This is not only because they provide insights from relatively unbiased organizations rather than individual enterprises, but because they are at both ends of the governance spectrum: strategic governance and IT management. CObIT focuses on strategically important tasks (i.e. main processes) and ITIL focuses on management tasks (i.e. support processes), which are often subject to outsourcing and, thus, the ideal blueprint for managed third-party processes (IT Governance Institute, 2007, Office of Governance Commerce, 2007). Figure 1 depicts existing processes which have been taken over as-is or in an abridged form to focus on the specific needs of a Service Governance Framework. Most of the time however, the governance processes need to be extended to cater for the specific needs in an Internet of Services.
All relevant governance processes from these frameworks can be grouped in a life cycle consisting of five phases: design, deployment, delivery, monitoring, and change (Janiesch et al., 2008b). In each of these phases, several processes constitute the Service Governance Framework. The design phase contains all sorts of strategic aspects of the use or operating of such a platform and traded services. Identifying requirements, development of services, as well as the selection of third-party services are components of the deployment phase. The delivery phase comprises all aspects of service and infrastructure operations. It is closely coupled with the monitoring phase as they are executed concurrently. The monitor phase contains all aspects of service and infrastructure monitoring. The change phase includes all processes and tasks needed to adjust and change the infrastructure and services traded.

Functionality within the Internet of Services is centered on the central service broker component. It cannot be found in current general IT Governance frameworks or in SOA Governance frameworks. Thus, this process is new. There is a need for future refinements of the framework as this first version is intended to show the scope of the Service Governance. While this scope will also be refined, the main focus for detailed development needs focus on the process of broker operations. This is of particular importance if – as mentioned above – services are not only brokered like tradable goods but also moderated in a value-added manner similar to product-service bundles (Schroeder, 2008).

3.3 Building Blocks of a Common Service Governance Framework: Management Processes

Services in an SOA are tightly linked to business processes. These are controlled, monitored, and improved by management and its processes. Generally, a management process is the process of planning and controlling the performance or execution of any type of activity, e.g. projects as well as business processes or workflows. It is a tool for managers to control existing business processes actively – sometimes also referred to as factual leadership. It can relate to the top management of an organization as well as to project management and risk management.

Commonly, the management process can consist of the following phases, mostly described as a circle (Burghardt, 2000) as depicted in the following Figure.

![Management and Business Processes](image)

**Figure 2. Management and Business Processes.**

The objective phase describes a desirable realistic state, defining the aim to be achieved. The planning phase identifies possible ways to achieve the goal. The realization phase triggers, e.g. organization, human resources management etc. During the control phase the degree of target achievement is measured. During each phase, communication and exchange of information between the involved parties is crucial. During the planning and realization phase the subordinate business processes are designed and implemented. During the control phase they are monitored and assessed and the need for change management is evaluated. This can lead to starting over again with the objective phase.

Concerning IT management, there are a number of frameworks that support process management, as e.g. COBIT or ITIL. COBIT provides supporting mechanisms on leadership or governance level, while ITIL targets management of software production in general, i.e. on business process level (Kamleiter...
& Langer, 2006). In case of SOA, a governance framework is of particular importance, as in an SOA the link between IT and business processes is closer than in previous enterprise architecture approaches.

3.4 Building Blocks of a Common Service Governance Framework: Roles

Weill and Ross (2004) stress the human involvement in IT Governance in their definition of IT Governance as they suggest to specify “the decision rights and accountability framework to encourage desirable behavior in the use of IT”. Consequently, as a further step starting from the guidelines for organization forms and responsibilities, a more concrete shaping of the necessary roles is given in this section.

In the Internet of Services, several main stakeholder roles have been identified: service provider, service brokers or platform hosts, and service consumers (Barros & Dumas, 2006). The following Figure gives an overview of the stakeholder roles. While the service consumer and the service provider are actual persons taking the specific stakeholder role, the service broker is a virtual entity, e.g. a marketplace, a piece of software. Nonetheless it is operated by actual persons who act as a platform host.

![Figure 2. General Role in the Internet of Services.](image)

The service provider stakeholder supports agencies that hold governance and operational responsibility for a service, including organizational structures and other business aspects, as well as systems and other implementation artifacts. The service provider represents the role of a development party, producing and publishing services ready for execution. Largely, they are the service owners, responsible for the service implementation as well as maintenance.

The service consumer finds services via the service broker and requests and invokes them. He is the customer in the market transaction. For aggregated services, providers can act as consumers to create value-added services.

The main role of a service broker is to provide service location and description information contained in a service registry. So far the broker role is mainly associated with maintaining registries. As the central information database, its actuality is crucial to the success of the whole SOA system. However, intermediaries can play additional roles, e.g. mutually providing themselves brokering services, load balancing functionalities or negotiation support services (Erl, 2005). With an increasing number of services, registries become more and more important. They serve as a central location for tracking and managing services. The reusability of services depends on registries as these provide a way to share services across organizational borders. As a moderating entity the scope of the host is extended since it also has to attend to run-time and change-time issues such as services, which is updated while being in use. They must not be interrupted during execution.

Gu and Lago (2007) also give an overview of typical service life cycle models, including roles and responsibilities, developed mainly by software companies. Bieberstein et al. (2005a) defines various organizational SOA specific roles which are needed within one or more of the stakeholder roles.
4 CHALLENGES OF A GOVERNANCE APPROACH FOR A SERVICE MARKETPLACE PLATFORM

The scope of this paper has been the examination of Service Governance starting from two perspectives – SOA and IT Governance. For IT Governance, there are existing frameworks that provide structures, action scope, guidelines, and best practices. As this research concluded, the basic structure of IT Governance frameworks is applicable to SOA. However, they lack functionality or applicability concerning SOA-specific challenges, i.e. cross-company service deployment. Hence, unchanged, these frameworks are not fully suitable. SOA Governance requires at least an enhancement. In fact, approaches that focus on mere SOA Governance, lacking framework scope, already exist. An overview has been presented above. Most of them represent generic approaches and are hence applicable for adoption.

The organizational aspect, often identified as one major decision field of SOA Governance, is an important issue. We investigated in detail the service life cycle, roles and responsibilities, and management processes. Common SOA-specific organizational as well as stakeholder roles were presented. Our focus on a specific form of Governance for Services in the open Internet of Services is future facing. Papazoglou and Georgakopoulos (2003) elaborate on service marketplaces as an existing occurrence of SOA and Janiesch et al. (2008c) present an infrastructure and web-based business model for a generic service marketplace. They argue that services will have the largest share in the future business value networks. Thus, services have to be transformed into tradable goods; service marketplaces are considered to be an adequate vehicle to do so.

This entails new challenges such as monitoring and billing techniques and cross-company legal issues which require an improved form of service (marketplace) governance. It shows that the particularities of a moderated SOA cannot easily be addressed and managed by a common IT or SOA Governance approach.

We developed an outline of a governance framework which can be used for a service marketplace incorporating the above described role concepts. While investigating existing frameworks for IT Governance, we learned that an SOA introduces challenges for traditional governance frameworks. In fact, in the case of an SOA marketplace approach, it is to assume that the regulatory demands exceed existing structures in governance frameworks. This Service Marketplace Governance is a form of IT Governance and is mainly driven by the agenda of the marketplace host or service broker/moderator. It is also an extension of SOA Governance and considers the conformance and regulatory needs of a service marketplace host. In four main points, it can be distinguished from the common SOA Governance approach:

It comprises a form of SOA Governance including an according policy framework. (It is considered a super class of the common SOA governance approach.)

It pays special attention to cross-company legal aspects, e.g. data protection/security. Additionally, the term Service (Marketplace) Governance comprises the consideration of contract management over country borders, country-specific laws for data transmission and protection, and laws concerning the fulfillment of online contracts (such as the Fernabsatzgesetz (Distance Selling Act) in Germany).

It covers different service monitoring aspects. Technically, there are a variety of possibilities to realize service or SLA monitoring: decentralized, centralized, or hybrid monitoring. However, centralized monitoring is considered inappropriate due to the large number of service providers and executors and the very large number of services being offered on the platform. Hence, a decentralized monitoring approach might be the better solution. This, however, comes with additional requirements for a Service Governance Framework.

It includes the interests of multiple parties, i.e. stakeholders. Operating a service marketplace platform involves much more stakeholders than common SOA approaches. SOA platforms incorporate at most
two parties: the platform host (which is the service provider, broker, moderator, and developer) and
the service consumer. Being a cross-company approach this framework considers the interests of all
stakeholders of the marketplace platform: Consumers, platform hosts or service brokers, and service
providers. Both the interests of the platform host (broker/moderator) and service consumer are
included. Preconditions to be fulfilled by the service provider are also formulated, and vice versa: A
marketplace governance approach defines policies with respect to service consumers regarding the
interests of platform hosts and service providers. In contrast, SOA and IT Governance approaches
normally focus on the operation within a single organization, considering a single stakeholder.

One way to address these challenges is to make extended use of certification of platform conform
behavior of service providers, executors, etc. A generally accepted way for service providers to show
their competence and compliance with certain standards is the certification of the service provider and
its organization, e.g. based on the well established ISO 9001 audit and certification for quality
management purposes.

The above assumes a governance approach for one (centralized) marketplace platform which acts as a
broker (or moderator) for service providers. This governance approach does not yet cover governance
of multi-broker architectures which have different brokers communicating and trading obeying certain
rules. In fact, however, it addresses complex requirements for controlling and directing an SOA
service marketplace and all of its services and stakeholders, common existing IT Governance
frameworks fail to cover.

TEACHING CASE

LEADING THE CHANGE - ERP IMPLEMENTATION AT KEDA

Abstract

While Enterprise Resource Planning (ERP) system demand in China has been steadily increasing, many of such implementation projects failed. Keda Industrial Co. Ltd (600986: Shanghai Stock Exchange), a manufacturer of large scale machinery in China, however, was one of the few that successfully deployed its ERP solution in 2005. In this case study, we document the ERP initiative of Keda from its conception to its deployment, study the factors that contributed to its success, and summarize Keda’s practices that substantiated the identified success factors.

Keywords: Enterprise Resource Planning
1 INTRODUCTION

According to a market study conducted by Gartner Research, ERP software demand in China increased by 29% in 2006. In fact, many enterprises in China have recognized the strategic importance of ERP in their rapid developments. Keda Industrial Co. Ltd. (600986: Shanghai Stock Exchange), a manufacturer of large scale machinery in China, was such a company. Keda produces and sells machinery for processing ceramics that are mainly used in construction. In August 2005, a mere five months after forming an implementation team, Keda successfully deployed SAP as their ERP solution. The project quickly paid off through lowered inventory and reduced operation and management costs. This success was all the more remarkable given the fact that an estimated 80% of ERP implementation efforts in China failed. Dr. Fan Zhu, the Vice General Manager of Keda, while utterly satisfied with the project outcome, could not help but wonder if the project success was the result of good practices that he could model future implementation projects after, or, just pure luck.

2 COMPANY OVERVIEW

Founded in 1992 by Lu Qin, with an initial capital of only 90 thousands Chinese Yuan (CNY), Keda began as a small manufacturer of ceramics machinery in Shunde of the Guangdong province. At that time, the ceramics machinery industry was dominated by European companies. By modeling its business after these market leaders, Keda enjoyed rapid growth in the local Chinese market in the mid-90’s and emerged as a major player in the industry, being recognized as one of the top 500 national machinery manufacturers in China, top 10 building materials machinery enterprises in China, among other acknowledgments and achievements. By early 2000’s, Keda had surpassed many competitors to become a world leader in building materials machinery, second only to SACMI of Italy (www.sacmi.com). Keda became a listed company on the Shanghai Stock Exchange in 2002, and in 2007, it reported a net profit of more than CNY 93 million, up from CNY 32 million in 2004.

Today, just 16 years since it was founded, Keda has more than 2000 employees and its product offering includes ceramics machinery, energy resource machinery, stone machinery, and building materials processing machinery. Keda also offers complete plant design and technical consulting services to ceramics and stone processing machinery. Due to the nature of its products, orders from Keda’s clientele typically involve high levels of customization and low volumes.

Keda’s business as a whole relies on several key business functions, such as research and development, purchase of raw materials and parts, inventory management, production that comprises of many assembly lines and workshops, logistics, and sales and marketing that connects the firm with its extensive customer base, which comprises mainly of construction materials providers from both the domestic and foreign markets. Each of these business units functioned autonomously, with little integration in between. This gave rise to a freewheeling corporate culture where non-standardized processes were adapted on the fly and issues were resolved in an ad hoc manner. With these, Keda continues its "pursuit of perfection" through "endless innovation" in the global market.

Innovation, in fact, has been Keda's emphasis. In terms of product innovation, Keda rolled out the first 3200 tons pressing machine in China in 1999. In 2005, three of the ten new machinery products were even considered world's first. Perhaps more remarkable was Keda's commitment to innovation for not just its products, but its business as a whole. In 2003, the company set up the national enterprise post-doctoral workstation, where post-doctoral scholars were invited to work. Their research areas included the business's supply chain management, human resource management, and so on. Keda also invested more than CNY 45 millions in setting up the ceramic engineering test center that was committed to research and development in state-of-the-art technologies. Through innovation, Keda established itself not just as a leader in market share and revenue, but also in product technology and management efficiency and effectiveness.
3 DRIVERS FOR ERP

Things, however, were not all good. The silo-based model was taking a toll on Keda’s business performance. Different business units often had duplicated tasks and data, resulting in redundancy, and in turn, heightened costs. Also, as there was little integration between departments, managers could not make timely and well-informed business decisions. This was especially taxing in the face of competitions from local and foreign companies, who challenged Keda in many fronts. To retain its leadership position and to continue growing its business, Keda needed to stay innovative with product development, business management and operation, and to be more informed about production, sales, and most importantly the customers when making decisions, or as Zhu put it,

“In managing the enterprise, our most important task is to provide the needed information for every decision maker every step of the way in the decision making process.”

An added external factor that also prompted for Keda’s ERP undertaking was pressure from Chinese government agencies. Recent years had seen China encouraging, and at times, pressuring for innovation in local enterprises through campaigns with explicit incentives to promote computerization in corporations. Keda’s ERP undertaking could be seen as a reaction to the government’s call.

A common challenge that enterprises like Keda face has to do with raw materials and parts. As mentioned above, Keda’s production is characterized by low volumes and high customization, which consequently lead to frequent and scattered demands for a large number, but not necessarily large quantity, of raw materials and parts. Some of these parts are common across different products, but most cannot be reused in different products. This makes purchasing decisions, or simply keeping track of the quantity purchased and used, difficult. This also has other repercussions, as Zhu explained,

“Before ERP deployment, due to the mess in material management, the cost of a product was unclear, and costing was based on experiences. It wasn’t clear how much profit or loss the sale of a product resulted in … and which part of the product or the production process contributed to that profit or loss. That made it difficult for us in pricing our products, too.”

Also observed was suboptimal utilization of resources and facilities. Reusable materials and parts were often scrapped; precious machine time of key facilities was often wasted idling. Zhu illustrated,

“For example, we had a key facility for production. We had someone time its usage in a week using a stopwatch. We were shocked when we learnt that it was only in production 24.6% of the time!”(Compared with over 90% utilization in a Japanese competitor)

Moreover, Keda’s rapid growth was not without consequences. For instance, competition from local and abroad prompted Keda to diversify its business and product lines. Keda’s commitment to R&D in turn resulted in a greatly expanded product offering. The single plant mode of production could no longer cope with the highly diversified business lines and production functions. This prompted Keda’s shift from single plant to multiple plants in 2004. By expanding its operation to multiple plants, it outgrew its existing Manufacturing Resource Planning (MRP II) system's capabilities. Keda's MRP II system at that time, CAPMS developed by Beijing Riamb Software IT Co. Ltd., did not support such multi-plant operations. Adding to the demise was the fact that Riamb ceased maintenance support for the system due to an internal restructuring of the software company. It seemed, to continue its success, Keda needed to rethink its IT, and it needed to do that quickly.

4 COMPUTERIZATION AT KEDA

Keda’s first take on computerization started in 2000. As a member of the IT department recalled,

“… there was no strategic goal. Others were doing it, so we decided to jump in as well. Since there was really no planning or even particular objectives, the IT projects were not
particularly effective in solving the company's problems, and the use of the systems at that time was less than satisfactory.”

Beijing Riamb’s suspension of support for the MRP system in 2003 did not help either. That was when Dr. Fan Zhu came on board as the head of the IT department. From an academic background, Zhu was familiar with the IT literature, and realized that success in an enterprise system project begins with clear objectives and expectations, and any computerization initiative would need to align constructively with the company’s strategic goals. In fact, one of the principal guidelines for enterprise system undertakings in the literature is to clarify strategic and organizational needs early (Davenport, 1998). Zhu explained the role of computerization in addressing such needs,

"Our goal is to be the world leader. Such goal cannot be attained by simply increasing labor hours. It requires a well established structure and system ... including computerization as a means. Computerization is an auxiliary tool that helps [Keda] to achieve its goals and develop its business."

What Zhu also realized was the fact that to harness the power of this tool, the computerization initiative had to be carefully planned, as a long-term disciplined plan was instrumental in any IT success (Feld & Stoddard, 2004). This multi-year plan would provide a detailed blueprint for systems adoption. With that in mind, he decisively ordered a halt to all ongoing IT projects. All resources and efforts were then put into working out a comprehensive and far-sighted five-year computerization plan. This plan would address the short term needs as well as the long term strategic goals, in order to propel Keda forward. In devising such a plan, Zhu had the help of Benjun Zhang, who has now become the head of the IT department.

"When working out the plan, we focused on how much investment was needed and in what kinds of systems, what our objectives are, what hindrances the company is facing, why we need computerization, and what problems we are targeting to solve." Zhang said.

One can easily imagine the complexities in working out such a plan. An assessment of status quo and a market analysis were first conducted. Existing problems were identified, and based on the business requirements collected from various levels of management, a set of objectives was set out. These objectives were then prioritized according to their urgency and how well they align with the company's strategic goals. Ranking high on Keda’s wish list was an integrated organization structure, breaking departmental boundaries, with streamlined data flows and business processes. Also considered crucial were increased management control, information availability, accuracy, and timeliness, by imposing standardized processes and procedures through systems adoption. Potential solutions for the requirements were considered as well. Throughout the plan, top management provided the high level direction, the long term vision, or as Zhang put it,

"... He (The Board Chairman) has a good vision ... wherever he is in the world, he wishes to be updated with the company's operation using a laptop computer, instead of relying on the reporting from the financial manager."

This planning effort lasted six months. The result was an encompassing plan that included the implementation projects for Enterprise Resource Planning (ERP), Product Data Management (PDM), Office Automation (OA), Manufacturing Execution System (MES), Customer Relationship Management (CRM), and Supply Chain Management (SCM) solutions, in phases. (See Exhibit 1.) This plan was directed towards a unifying platform on which all business applications run, uniting business units and promoting a centralized organization structure; a platform that was so often cited as a key ingredient in enterprise system success (Feld & Stoddard, 2004).

Also in the plan were detailed analysis of each project regarding its objectives, expected investments and benefits, feasibility in terms of factors such as staffing and technology, risks, and alternative solutions. According to the plan, the ERP implementation project was a priority, to be completed by the end of 2005, and had to go first. Time was critical.
5 CHOOSING A VENDOR

ERP strategy choice is crucial to project success but its importance is often underestimated (Holland & Light, 1999). One of the first choices Zhu had to make was between in-house development and third-party provider, and he felt that it was not a difficult choice. From the get-go, it was clear Keda would not be developing the system in-house. To begin with, time was not on Keda's side. Given the tight timeframe, partly due to Riamb ceasing maintenance support for the current MRP II system, building an in-house ERP solution that could easily take years was simply not an option. Moreover, ERP systems had been successfully adopted in many organizations in Keda's line of industry, rendering customizations needed and risk in packaged software minimal. Also, Keda derived its competitive advantages not from proprietary business processes, but from product innovation and price competitiveness. Hence there was little to lose adopting common existing solutions. Furthermore, there was a general lack of internal IT expertise at that time, but information technology was not perceived as a core competency of the company and accordingly, building a large team for such development was not favored. Instead, professional consultants and experiences vendors were to be leveraged, as Zhu explained,

"Enterprises need to be clear about their core businesses and competencies. For instance, we could have developed in-house our own ERP system, but that would not be very smart. Why reinvent the wheels when others have gone the same routes? Outside of our core business and competency, for anything we need, we prefer renting or buying existing solutions."

Keda thus went ahead and contacted twenty software vendors from both local and abroad. These included Kingdee, Lima, Tianxing, and several vendors for SAP, among others. These vendors were invited to visit Keda, and through these visits, they would briefly study the needs of the company, demonstrate how their software packages would satisfy those needs, share their past experiences, and discuss other implementation issues.

"The ERP project kicked off in August 2004. Vendor assessment was conducted. We invited both local and foreign software vendors to visit our company for detailed assessment ...
through these visits, we also aimed to let the middle and top management learn more about computerization and ERP in general.” Zhang recalled.

However, Zhu did not stop there. He decided to take on a more proactive role and, in turn, visited existing clients of these vendors. Zhang explained,

“We visited their existing clients, as we felt that only what we saw must be real. In these referrals, vendors would likely put forth their most successful cases, and through comparing the uses of their respective solutions in real production environments in the industry, we had a much better idea what suited us.”

In these visits, Keda gained insights about not only the vendors, but also possible complications in the implementation process; these insights proved valuable later in the implementation process, as they allowed Keda to avoid the same mistakes committed by others, as Zhu observed,

“After visiting several enterprises, we made an interesting observation: their IT departments were basically the only ones working on the ERP projects. They were churning out reports, workflows, etc, things we thought were outside the work scope of an IT department.”

Based on these encounters, Keda short-listed 9 vendors to respond to a Request for Proposal (RFP). This RFP specified the exact needs of the company and standardized the vendors’ responses thus allowing for comparisons of their products on the same ground, namely, how the particular modules of their packages would fill particular needs of the company. These 9 vendors presented their proposals in a three-day period. Zhu made sure senior management, including the director himself, was involved in this selection and negotiation process. After the presentations by the vendors, they would rate them according to how well the vendors’ solutions satisfy Keda’s needs and align with the management’s strategic goals. However, the reason for their involvement was much deeper, as Zhang explained,

“Through these presentations, we got a feel of what senior management was excited about. If he would not even attend these meetings, then his so-called support for the project remained superficial, and project implementation would be difficult. On the other hand, if they were interested, they would raise questions on the spot, after all, this is his enterprise and his 10-million yuan project.”

Finally in October 2004, SAP emerged as the winner. According to Zhu, SAP was chosen for various reasons. For one, SAP’s ERP solution was considered sophisticated and feature-rich. Specifically, unlike the company’s existing MRP solution CAPMS, SAP ERP was capable of supporting complex operational processes across multiple production plants. For another, being one of the industry leaders, continual and reliable support and maintenance could be expected. Moreover, with more than 35 years’ worth of experiences and more than 40,000 client implementations, SAP had a proven track record of successful ERP implementations. In particular, SAP was adopted by SACMI, a major competitor of Keda and the industry leader.

6 ASSEMBLING THE TEAM

“There were three main roles: the key users, the consultants, and the IT officers. The key users were at the core, consultants acted as coaches, and IT officers provided support, supporting the consultants and key users in their tasks. Success or failure hinged on the key users, since they dictated the future workflow. IT merely provided support; IT officers would not know how the production workflow should be,” said Zhang.

ERP is often regard as more about people than about systems, hence having the right people in the right roles is critical (Davenport, 1998). Zhu understood that, so with the ERP solution vendor on board, Zhu proceeded to painstakingly assemble the rest of the project team. Another external party, Digital China Management Systems Ltd., was recruited in a consulting role. Together with various stakeholders within Keda, such as the senior executives, key persons from all departments involved,
and all members of the IT department, the project team was officially formed in March 2005. In recruiting departmental representatives, Zhu made sure vital figures in the departments, like departmental managers or main operational staff who had thorough understanding of the operations and needs of the departments, were involved. He had an interesting philosophy, which illustrated his emphasis on user involvement as a key ERP critical success factor,

“In assembling the project team, we insisted that the top dogs of the various departments be involved. Also, we tried to pick those who were deemed indispensable by the departments. We relied on how vehemently departments opposed to the particular person's involvement in the ERP project to judge how indispensable he was.”

Zhu made sure every member had a clear idea of his role and responsibilities in the project, as he said,

"I think the definition and assignment of responsibilities were very important issues in the ERP implementation ... we had devoted a great effort on these issues throughout the process."

Exhibit 2: Keda’s ERP Project Team Structure (Source: Keda Industrial Co. Ltd.)

Exhibit 2 illustrates the team composition and assignment of responsibilities for Keda's ERP implementation project. In brief, top management of Keda would provide overall project direction and make critical decisions; overall project management would involve project managers from both Keda and Digital China; consulting support would be provided by personnel from Digital China; departmental representatives would oversee the business process redesign and system design aspects; the IT department would provide all necessary information technology support. In particular, each ERP system module was assigned an owner from the associated department, who was fully responsible for the workflows and operational details of that module. These key users ensured that system designs reflected business practices, and played a crucial role in training subsequent users in their respective departments. As illustrated by Zhang,

“Throughout the ERP implementation, we emphasized heavily on clear definitions of roles and responsibilities. They [Key users] were the core, consultants acted as coaches, and the IT department was in a supporting role. We could assist them technically but they were to determine how the system should function and what values it should create ... Obviously, the critical success factor lied with the key users.”
Besides clearly defining roles and assigning responsibilities, on a more tactical note, Zhu went to great length to ensure that the project team worked as an integral unit, as he believed that a determined team effort was not only beneficial but essential for project success. As Zhang recalled,

"... the arrangement was for the head of each module to work together at the IT department, with the marketing manager representing the marketing department, purchasing manager representing purchase department, etc ... at one point, their computers were moved to our office and we worked together as the ERP implementation was a crucial matter related to various business units."

This collocation scheme, which took place from March 8, 2005 to August 1, 2005, and from September 9, 2005 to January 4, 2006, is a further demonstration of the importance of user involvement and participation that is so commonly cited as a critical success factor in the literature (Holland & Light, 1999; Esteves & Pastor, 2000). The ERP effort was deemed important enough for all ERP team members to be physically working together. As a result, the departmental managers would only have time to work on departmental tasks after 5:00pm. Not surprisingly, this scheme was met with great resistance.

"There was a lot of resistance to this arrangement. For example, they said if they were to be working with the project team and be away from their offices for 5 months, and their departments continued to function normally, then they should probably all quit since that proved they were of no value to their departments," recalled Zhang.

Fortunately, management’s support was on Zhu’s side. After reporting to the director about the opposition, he worked with the director to devise an arrangement for reward and punishment in resolution of the issue. Since departmental managers had to work longer hours to keep their department afloat, they would be compensated with bonuses. On the other hand, if one were to be unsupportive of project work and miss project meetings, he would be assigned to serve at the canteen during lunch hours for a week!

"This arrangement was greatly effective as it somewhat frightened the staff, as no one wanted to be embarrassed. After all, it was the decision of senior management and if anyone really got punished this way, to serve at the cafeteria for a week, his career in Keda would be all but over," said Zhang.

7 IMPLEMENTING SAP

With these, the ERP implementation project in Keda went underway. Numerous changes were involved. The operations and workflow in many departments were modified and streamlined, and the organization structure also had to be adjusted, in order to accommodate the ERP system. In particular, as-is processes were to be studied and to-be processes were to be designed, and this was a responsibility given to the key users. According to Zhu, they would write the specific requirements for the system, specifying the inputs and outputs at various points for the particular modules they were responsible for, and the IT specialists would implement those requirements. Also falling on the shoulders of key users was data model specification, as explained by Zhang,

"Data was the main issue. The sheer amount of data was one issue, and the data model was another. We had to devise a data model to support all the operations and workflow, in order to minimize the disturbances after rollout. Since experiences in the operations were needed in this specification, we assigned this responsibility to the key users. Only they are most familiar with the operations and hence they should set the rules."

Much hard work was put into effectuating these changes, for instance, as Tian, the person-in-charge of the materials management (MM) module, recalled,
“Data preparation was the most difficult task. We spent a lot of time on stock taking and renumbering stock code so as to ensure data accuracy in the new system.”

With changes came disagreements, between different module owners, and between module owners and consultants. According to Tian, in resolving these differences, discussions among departmental representatives would first be held in seeking a compromise, and if no such compromise could be reached, the matters would escalate to the project management staff who would make the final call, balancing the way users wanted to work and the way the system was designed to work. Zhang added,

“The critical issue was balance; sometimes consultants would give certain advice but key users would advocate alternative proposals. Consensus could not be reached every time ... in those cases, project managers needed to make the decisions. In some cases, the IT department would have to submit a report analyzing the pros and cons of the proposals made by both parties in order to seek a decision from senior management ... As SAP ERP was a well-established system, in practice, in the absence of a consensus, we adopted the consultants' recommendations almost 100% of the time, since we were more inclined to adopt the model the system was originally designed for, and changes in the workflow and its management were to be expected.”

Implementation thus went on relatively smoothly, and speedily. Zhu again stressed,

“In managing changes, I deemed responsibility assignments the most important. There was no way the IT department alone could have achieved so much ... Take BOM [Bill of Materials] for example. We had over 30,000 products, if each was to have merely 3 levels, we would end up with 90,000 levels to specify; there was no way the IT department alone could do that.”

Also instrumental in managing these changes, as Zhu pointed out, was top management support, perhaps the most well-studied and central component of ERP critical success factor frameworks (Davenport, 1998; Holland & Light, 1999; Esteves & Pastor, 2000). Top management support is widely deemed essential for achieving project goals, and is manifested in managers’ involvement in the implementation process and commitment to allocating organization resources. Indeed, top management support was plenty throughout the implementation project. For instance, in 2005, the board chairman himself was present in five company meetings, four of which dealt with the progress and status of the computerization project. He was also present for some of the regular project meetings, blueprint design briefing, and the project launch ceremony. Zhu explained,

“... reactions of persons-in-charge of individual modules depended largely on the attitudes of the senior executives; the heads would not oppose to changes if top management had shown their determination.”

When asked about his success on securing top management support, Zhu offered his advice,

“You cannot let his [the director’s] support remain verbal, but to have it realize in actions. Firstly, he should be involved in the major events, milestones, and decisions making. Secondly, you should report all challenges and difficulties faced in the implementation process promptly, and not wait until the issues have already surfaced, so that you don’t appear passive.”

With the top management committed to the ERP project, the key users committed to the changes associated. In fact, the focus was then shifted to acclimating users to these changes. Besides involving them throughout the implementation process, staff training was also conducted, in parallel with system testing. Zhang explained on the training program,

“The first level of training was provided to selected key users by the consultants, the selected key users then in turn transfer their acquired knowledge and skills regarding system operations to other users. At the same time, selected key users were responsible for preparing operating manuals for all users.”
Moreover, according to Zhang, by conducting system training and system testing in parallel, not only was time saved, but users were also leveraged in identifying system issues. After all, the users of the system would be in the best positions to demonstrate how the system would function, or malfunction, in daily operations. Through testing, users also picked up skills in using the systems, as Zhang commented,

“Testing was training.”

8 GOING ONLINE

By August 2005, a mere five months after the project team was formed, Keda was ready for system deployment. Time for deployment was carefully chosen to mitigate risk and minimize business disruptions, as Zhang explained,

“All industry has its peak season and low season. For us, the months of August, September, and October were the low season and pressure on production would be lower. That was why we chose August as the rollout time.”

At this point, Zhu is faced with another strategic choice, this time a deployment one. While a phased implementation would be less risky, a “Big Bang” implementation offers full functionality right at cutover (Esteves & Pastor, 2000). To expedite the entire process, an aggressive Big Bang approach was adopted. Zhang explained,

“We did a rough assessment and did foresee the possible problems immediately after cutover, such as delay or even suspension of production. However, if we were to do a parallel rollout, it might take a month at least to stabilize, during which all data and work needed to be processed and done twice. Given the huge amount of data and the already heavy workload, parallel rollout was not viable and we went for a Big Bang approach.”

Work did not stop at cutover. Problems started to surface and they quickly translated into production delays. While busy fixing the technical problems and circumventing these delay issues, Zhu once again had the top management’s assurance:

“We notified the director himself before rollout about these possible delays in production, as the ERP rollout represented a fundamental change in how our staff operated. The director was extraordinarily supportive, and said that he could tolerate ERP-affected deliveries in the first year, during which ERP assumed top priority.”

User adoption was another issue. As most prominent ERP systems were originally developed with users in North America and Western Europe in mind, it was suggested that cultural complications might arise in the Chinese setting (Davison, 2002). In particular, opposition to technological changes might be especially pronounced in the Chinese context due to feared loss of status and discretion, new performance metric, and adaptation to something new (Zhang et al., 2003). According to Zhang, with the system online, workflow and operations dramatically changed, they faced a lot of challenges in human resource arrangement. Some workshops were unsupportive of the ERP initiative to say the least, since they did not view it as something the enterprise could not do without. In fact, resistance started to surface once again, as Zhang commented,

“When our ERP system first went online in 2005, some felt that work became more tedious. For example, materials for production now had to be checked in to and out from the warehouse before taking it to the production plant.”

He attributed users’ resistance to a power struggle brought about by the drastically changed business operations. Zhang explained,

“This resistance mainly stemmed from the redistribution of power following ERP rollout … Inventory management was decentralized and each workshop had its own inventory.
Following the ERP rollout, inventory management was centralized so that resources could be shared and better managed. On the third day after rollout, a workshop manager came to us and said that this centralization was wrong and he needed to set up his own inventory separately once again. Certainly, we said no since that would be in conflict with our ERP workflow. On the fourth day, he shut down the workshop, and the senior executives had no choice but to replace him.”

This replacement as a resolution was seen in another incident, as Zhang recalled, "We had new designs and new production orders every day, and these placed a lot of pressure on the purchase department and its manager. After one month, he could not cope anymore and decided to bypass the ERP system. Senior executives promptly replaced him.”

When asked about the rationale behind such responses, Zhang justified, “This is how things work in China; when a person is promoted to a new position, he has no conflict of interest with the new system, and is therefore willing to comply. Then everything else is easy, and can be solved by an increase in resources.”

Forced compliance worked well in this case. This apparent ease in change management stemmed from a country specific culture in the Chinese context, where organizational culture is imposed (Shanks et al., 2000). Authority, in this case the top management, was looked up to for direction. If top management demanded changes, they would be accepted. This demonstrated how country-specific culture could actually be exploited in attaining project success.

Forced compliance was of course not the only way Keda dealt with issues. For instance, after system rollout, some were not completely satisfied with system operations and interfaces, and requests for modifications to the system were reflected to the IT department. However, since the users were the original people who specified most of the system operations, Zhu was able to fend off these requests for the time being until system stabilized. He explained, “After system rollout, they [key users] found problems and demanded changes to the system. However, since they were the one who originally specified the workflow, the inputs, and the outputs, these shortcomings were their responsibilities. Yes, the system needed to be optimized, but that had to wait and they had to accept and adapt … Imagine if the IT department were to be responsible for specifying the requirements and system flows, then key users would demand endless changes, causing delays in the project. However, since they were responsible instead, they had no excuses.”

Within months, it was clear that the ERP implementation effort was a great success. Data accuracy, including that for production plan and inventory information, was estimated to have improved from 85% to 98%. Better data and information transparency and availability were also observed. “Information was much more transparent after system rollout, and tracing this information was much simpler through the system. This was in direct conflict of interest with some middle management. For instance, before ERP, it was very difficult to trace price paid for materials purchased, but after ERP, price analysis could be done conveniently. If price for a material was on a down trend, and your purchase price was getting higher, you have some explaining to do,” said Zhang.

These in turn allowed for improved market responsiveness, decreased level of stock, a significantly better product delivery time, and faster monthly financial reconciliation. The result was a dramatic decrease in operation and management cost, and improved efficiency, as Zhang illustrated, “In early 2005, we were struggling with our machine press production, and production delay was common. At that time, we were producing about 6 machine press per month, and that was under constant pressure from senior management. However, by March 2007, with
exactly the same facilities, we were producing over 30 per month. This dramatic improvement in production capacity is attributed to the information system in ERP.”

Due to improved dissemination of information, quality of decisions made was also improved, Zhang claimed,

“Before, he [the director] believed that orders from foreign markets would bring high profits, but after ERP rollout, through cost analysis, we realized that while a polishing machine sold for USD 50,000 higher, cost was CNY 400,000 higher! These orders did not bring high profits, and management shifted its focus from developing foreign markets to controlling costs.”

9 FUTURE OF ERP

Despite the success of the ERP implementation project, the initiative is part of a bigger computerization plan that would continue to satisfy the company’s information needs and improve the company’s productivity through better information management and dissemination for decision making. To fully capitalize on the centralized data and processes made possible by ERP, Keda remained committed to the computerization plan originally set out. Values were continuously created via disciplined new system additions and extensions. For instance, the Manufacturing Execution System, seamlessly integrated with ERP, tracked all manufacturing activities and provided real-time access to production progress and information.

“In the future, we would still be optimizing and extending on our ERP system, the ten modules and beyond. With the Manufacturing Execution System (MES) expected to roll out and be integrated with the existing ERP this year [2008], we foresee a much better monitored and managed production process. Besides improving resources and facilities utilization, we will also be able to tell exactly which stage of production each order is at, together with all other production details.”

ERP is an enabling technology. With ERP, Keda is strategically positioned to reap the benefits of computerization. ERP serves as the core on which systems, such as Customer Relationship Management, Business Intelligence, and Supply Chain Management, are built to enhance customer management, optimize decision making, and coordinate vendors respectively. To Keda, ERP is a beginning, rather than an end.

Abstract

CIOs and CEOs are confronted with the key question of choosing the right ERP software for their company. The evaluation process tends to be painstaking as the outcome usually affects the competitiveness and thus the future of the company itself. Packaged software has become so powerful in recent years that it fulfils the requirements of companies from different industries after a thorough customization process. Nevertheless, case studies and anecdotal evidence show that in many cases ERP implementation projects are demanding and results do not meet expectations. This leads to the question of whether and how ERP vendors are addressing the perceived problems of ERP users. Is there work in progress that will help facilitate the selection and implementation of ERP packaged software for users? Will there be tools available to adopt ERP modules to the specific business processes of a company and – taking into account that processes are likely to change over time – will there be mechanisms available to adapt the software to changing requirements (in the literature discussed as “agility”)? These are the questions that stimulated an in-depth study of the German-speaking ERP software market. In a qualitative study based on thirty interviews with ERP vendors we draw a picture of the value proposition of future ERP software.

Keywords: ERP systems, software development, requirements, IT value, packaged software.

1 INTRODUCTION AND LITERATURE REVIEW

Integrated business software (ERP systems) covers all relevant aspects of an enterprise (Davenport, 1998). “Business information systems can be either designed as custom applications or purchased as off-the-shelf standard solutions” (Scheer & Habermann 2000; Soh and Sia, 2005) (the latter is called “packaged ERP software” in this article.). According to the literature, today most companies turn to packaged software when looking for an enterprise solution (Schubert and Leimstoll 2004). Holland and Light recognized this trend almost 10 years ago when they said “companies are radically changing their information technology strategies by purchasing pre-packaged software instead of developing IT systems in-house” (Holland & Light, 1999).

Therefore many enterprises rely on external partners when it comes to business software. In recent years, researchers in the field of business software have investigated new architectural concepts and technologies for ERP systems including service-oriented architectures (SOA), Web services, XML and modularity. These are keywords which have been circulating for some years in the business software world. According to the experts, modern enterprise systems should be service-oriented, constructed in a modular form, and communicate via Web services. In addition the overwhelming variety of different interchange formats for business documents should be brought to an end by recognized XML standards (McGovern, Sims, Jain and Little, 2006; Yucesan, 2007). The question
which presents itself however, is much more far-ranging. Is a business solution sustainable if it does not fulfill the above mentioned requirements?

There are many systems in active use that are over six years old (Schmitt 2007; Winkelmann, Knackstedt and Vering, 2007) that follow few or none of the desired principles mentioned above. So for ERP vendors and ERP customers alike it is of reasonable interest to know about future challenges and opportunities. In small and medium-sized companies in particular, the introduction of a new system, or the migration of old to new platforms is accompanied by high costs in relation to turnover and, naturally, by associated risks (Scott & Vessey 2002; Winkelmann and Klose, 2008). The results of an SME study show that “the most important criterion used in selecting an information system is the best fit with current business procedures” (van Everdingen et al. 2000, p. 29). If a new system is needed, one should know exactly what it can do and how it will achieve this. A recent study confirms that “(...) companies often face the dilemma of whether to adapt to the software and radically change their business practices or modify the software to suit their specific needs.” (Dalal et al. 2004, p. 84)

Enterprise agility is understood as the ability of a company to adapt to new market requirements with the help of its ERP software and is a topic that has been discussed in academic literature in recent years (Gattiker et al. 2005; Sambamurthy et al. 2003). Concepts such as Service-oriented Architectures (SOA) (Liebhart 2007; Jankowska & Kurbel 2005) and Business Process Modelling (BPM) call loudest for research on flexible systems that can adapt themselves to user needs (Newcomer & Lomow 2005).

In order to be able to draw a picture of the state-of-the-art in ERP research we started our research process with a preliminary query of the EBSCO database using the search word “ERP”, “enterprise resource planning”, and “enterprise systems”. The search resulted into more than 40 articles of which 22 were interesting in the context of our project. Most of the papers stem from three special issues on ERP/enterprise systems (two in EJIS and one in CACM). Among the ones that we did not include were articles on performance measurement/cost-benefit analysis which are important topics for ERP but were not within the scope of our research. It is interesting to note that many authors underline the unvaried importance of enterprise systems for the competitiveness of companies and thus the importance of the topic for IS research. The following list contains an overview of the topics treated in the selected papers:

- ERP implementation: 10
- Process modelling: 3
- ERP system agility: 4
- ERP adoption: 2
- Miscellaneous (cultural aspects of ERP: 1, open source ERP systems: 1, ERP integration: 1)

The majority of articles deal with ERP implementations (Holland & Light 1999; Akkermans & van Helden 2002; Markus et al. 2000; Scott & Vessey 2002; Gosain et al. 2005; Biehl 2007). Two reports are on ERP implementation failures (Iacovou & Dexter 2005; Wei et al. 2005), two papers are specialized on upgrading ERP systems (Beatty & Williams 2006; Khoo & Robey 2007). There is a noticeably large number of case studies used in the articles to illustrate the findings. Process modelling (Scheer & Habermann 2000; Dalal et al. 2004; Delen et al. 2005) and ERP adoption (van Everdingen et al. 2000; Hwang 2005) focus on the need of the company to plan and adapt to the possibilities of the software system. The articles dealing with system agility show the need for flexible systems with regard to future requirements (Smith et al. 2003; van Oosterhout et al. 2006; Overby et al. 2006). It was interesting to see that none of the articles dealt with how or where companies operate their business software. The implicit assumption was that ERP software is operated by the user company itself. With the latest discussion of Application Service Providing (ASP), Software-as-a-Service (SaaS) as well as “on demand software” on our minds, we decided to also study the mode of operation (and thus the possibility for outsourcing) of future ERP systems.

With these considerations in mind the authors launched an investigation on the future requirements of packaged ERP systems. The underlying research question was the following:
What are future packaged ERP systems going to look like?

In order to answer this question, an empirical study of the ERP market in the German-speaking area of Europe was performed. We applied an explorative approach which used an empirical research method (interviews with ERP vendors) (Mayer 2004) in combination with an evaluation approach following Mühlfeld (1981) and Miles and Huberman (1994).

2 BACKGROUND OF THE EMPIRICAL STUDY

Since the study was geared at future requirements of packaged ERP software in the German-speaking market we chose an explorative research approach due to the unknown correlations that might affect our research objective. The study provides a structured overview of the different influential aspects such as technology or architecture and to reveal interdependencies among these components. We chose an empirical research method (Mayer 2004) because we wanted to collect knowledge from industry experts.

2.1 Research method

Mayer (2004, p. 30) suggests a general approach which starts with the development of a model. According to him five sources of information (theories, expert knowledge, common knowledge, literature and similar studies) are necessary to create a theoretical model which describes the research realm (the relevant part of reality). The next step includes the definition of all relevant concepts represented in the model followed by a dimensional analysis which deepens our understanding on a granular level. In the last step, the method of investigation needs to be selected (qualitative approach vs. quantitative approach). Since we intended to follow an explorative approach we selected a qualitative-oriented method. We created an interview guideline based on our theoretical model and evaluated the results.

2.2 Theoretical Model

The research was initialized by a preliminary query of the EBSCO database which gave us a general overview of relevant articles in the European Journal of Information Systems, Communications of the ACM and IEEE Software (mentioned above). In an initial workshop with an established ERP vendor and several other experts, key areas and relevant research questions were systematically identified. Areas of interest in the field of ERP systems such as business process modelling, SOA, Web Services and system architecture in general were discussed during the workshop.

The first version of the emerging theoretical model was based on practical experiences of the software vendor and the ERP experts who took part in the workshop. Architecture, technology and operations were identified as the initial three abstract model components. A consecutive literature analysis revealed that there are many publications which deal with architecture, technology and operations but there are additional studies which focus on market share and market development. We thus added the dimension “Market” to the model. The more detailed development of the model was performed by the authors based on existing ERP literature. In this phase we found a similar ERP study from 2007 with a focus on the user side with the title “Future development of packaged ERP-software” (Felley 2007) which provided us with valuable insights from the opposite perspective –the customer’s viewpoint.

The final result of this preparatory phase was a comprehensive multi-layer model which served as the basis for the development of the interview guideline (cf. Figure 1). The model includes all five sources mentioned by Mayer (2004, p. 30) (theories, expert knowledge, common knowledge, literature and similar studies).

The research questions for the analysis of requirements regarding ERP systems can be classified into aspects which contain conceptual and technical aspects as well as examined possible application
scenarios and market-relevant developments. The framework represents all the characteristics of an ERP system which the authors intended to study. In total, four aspects of an ERP system were defined:

- **Architecture**: This aspect contains the general concept, modelling as well as functional and integrative mechanisms.
- **Technology**: This aspect highlights necessary tools for internal operation and external integration (Volkoff et al. 2005).
- **Operation**: This aspect investigates the place of the software installation, maintenance and licence models.
- **Market**: This aspect includes the study of customers and competitors – the market environment which the commercial software provider faces.

![Figure 1: Theoretical model: the four main components of ERP systems](image)

### 2.3 Definition and Dimensional Analysis

In the next step we defined the relevant concepts of the theoretical model (Architecture, Technology, Operation and Market) followed by a dimensional analysis (Mayer 2004, p. 32) which describes the sub-categories of the main components in more detail (e.g. for Architecture: SOA, monolithic, client-server etc.). Due to limitations in space the sub-categories will not be described further in this paper.

### 2.4 Qualitative Research

In order to identify new patterns and correlations between the aspects of our theoretical model we followed an explorative research approach. Following Mayer (2004) we interviewed industry experts (*ERP software providers*) in the German ERP market. We conducted 32 interviews with company representatives in 8 different roles: 7 CEOs, 6 marketing directors, 6 product manager, 5 sales manager, 3 software development manager, 3 project manager, 1 business development manager and 1 key account manager.

Every interview was preserved in a written transcript. Afterwards all transcripts were analysed using recommended techniques by Mühlfeld (1981) and Miles and Huberman (1994).
2.5 The Interview Guideline

Questions for the four aspects of the model were summarized into an interview guideline. The outline of the questions can be found in table 1.1 and table 1.2. The interviews were conducted with representatives (experts) in each company. Every interview partner represents an expert “who provides in his defined area of expertise pure and repeatable knowledge.” (Mayer 2004, p. 40).

* Questions in bold will be discussed in the findings, in the following chapter

Table 1.1: The interview guideline, part 1

In the summer of 2007 the questions of the interview guideline were trialled in three pre-tests with selected ERP vendors in Germany and Switzerland in terms of completeness and length of the interviews and subsequently optimized regarding content and time-effectiveness. The questions were then used for the following interviews with selected ERP vendors. 17 interviews were conducted until December 2007, further 12 experts were interviewed in January and March. Overall, 130 ERP system vendors in Germany were invited for an interview of which 32 companies agreed to conduct an interview. This corresponds to a response rate of 24.6 %. All interviews were stored as written transcripts for later evaluation.

* Questions in bold will be discussed in the findings in the following chapter

### 2.6 Evaluation

The evaluation was based on an empirical content analysis (Kromrey 2002, p. 311). We applied the method suggested by Mühlfeld (1981, p. 334) to analyze the transcripts. First, every answer to the question was marked within the written text. In a second step, the answers were categorized according to a general scheme. After that the single pieces of information were combined logically so that similarities but also controversies could be discovered. The resulting text represented a first analysis from the interview guideline. In the next step it was enriched by selected citations expressed by the interview partners. In addition similar answers were summarized and evaluated based on the Conceptually Ordered Display approach by Miles and Huberman (1994). Instead of focusing on one interview we condensed the answers in a cross-case analysis. The results of these steps serve as the basis for the following discussion of the findings.

3 THE FUTURE PROMISE OF PACKAGED ERP SOFTWARE

Altogether, several important trends emerged from the interviews and the subsequent responses to the interview guideline. Due to the large amount of data (192 pages of transcript material – 6 per interview) this paper can only present some selected findings which we thought would be most interesting for an academic audience, namely (1) process orientation, (2) service orientation, (3) operational model, (4) market challenges, and (5) flexibility/agility. The complete study results can be found in (Frick 2008).

The following table contains information from the study referring to the bold questions in tables 1.1 and 1.2. The table shows the correlation between the available capabilities of process modelling and the discussed architectural and operational model of the vendors (table 2). The underlying assumption for the table is that both, the design and implementation of processes as well as service orientation enable a software package to be more flexible regarding changes (agility). The rows display the number of vendors who supply the user with ways of designing and implementing their individual processes into the software. This process goes beyond a mere customization of a packaged software solution. “Graphical processes” enable a dialogue between the implementation partner (the “consultant”) and the future user (the “business expert”). With the help of graphical workflow engines, consultant and business expert can discuss the detailed steps of a business process (with its events and ramifications). This can help to form a common understanding of how the software should finally work. Examples for these kinds of ERP extensions are event-driven supply chains (Scheer & Habermann 2000) or workflow modelling tools.

The second row displays the number of vendors who can use these graphical models to actually generate ERP source code from them. Industry standards (third row) refer to the availability of pre-defined processes which are implemented into the ERP system, e.g. a typical pricing model for retail. The last row contains the vendors who offer all three options. The columns on the other hand indicate the correlation of process modelling (rows) with the underlying technical architecture and the possible mode of operation. The table reads as follows: 8 vendors whose systems follow a fully service-oriented approach are also able to provide graphical process modelling tools. 6 of these have the possibility to generate code from the graphical models. The same comparison is also drawn with the possibilities in the mode of operation. 7 vendors who are able to offer their software as a service are also able to supply graphical process modelling.

Table 2: Service-oriented systems start to fulfil their potential by utilizing processes

In the following section we discuss the implications of the table together with the qualitative remarks of the company representatives.
3.1 Process Orientation: Graphical Design Support

The first requirement for continuous process support (Liebhart 2007, p. 91), the visualisation of processes, can be fulfilled by some of the vendors (cf. table 2.1). According to Delen et al. (2005, p. 107) “the synergistic combination of descriptive graphical models created using enterprise modelling methods (…) can deliver substantial results.” 50 % of the questioned software companies offer appropriate modelling possibilities, whether through connection of existing tools or by means of self-developed display methods. However, it will remain at the stage of visualization of business processes for the next few years. The next step, a coupling of process and application level in the framework of a process-driven code generation, is currently rarely implemented. Only 25 % of the vendors currently enable code generation from modelling. The offers range from workflow rules to whole class diagrams. The lack of support for automatic process transformation will not be enhanced. Complicated internal dependencies within an ERP system prevent building the needed program structure for supporting this feature. The software companies see no practical benefits in code generation, a procedure which, in their opinion, is simply impossible because of the internal dependence of an ERP system, as the following quote from a provider shows: “ERP systems are too complex to make business process modelling worthwhile.” (Frick 2008) Furthermore, there is little support concerning a standardized view of processes. Only 25 % of the vendors currently support process standards. Due to the need to provide fast and simple solutions for the customers it will be experience-based processes that are utilized in the future.

3.2 Service Orientation: The Concept of “Service” in ERP Systems

Services have established themselves as an important or even central building block in the system conception. 53 % of questioned vendors stated that they have integrated services into their system architecture, whether as integral service-oriented architecture (SOA) (28 %) or just as a SOA capability (25 %). Primarily, their benefit is gained from the possibility of offering functionalities externally. The reasons for this lie partly in differing definitions of SOA, which are internally seen as propagated by large producers such as SAP, IBM or Microsoft and therein make a standard architectural basis difficult. On the other hand, such a consistent new conception means a reprogramming or even new programming of many system components. The possibility of avoiding this expenditure and offering the required service by means of a service level agreement will be used more often in the coming years. Although it may sound strange, an interview partner expressed it as follows: “We can’t do SOA, we are SOA.”

3.3 Operational Model: Hosting Solutions for ERP Systems

Solutions on a rental basis have, since their hype at the end of the 1990s, found their way back into the customer’s awareness. SaaS has established itself as its own term for an operational model next to Application Service Providing (ASP) and will increasingly emerge as a possible solution from the software companies. Although SaaS is often equated with ASP, the differences between the earlier ASP (classical licence-based software is made available over the Internet to a customer) and SaaS (a software designed for Web use which serves several customers) are so clear that it can be defined as its own operational model. Although hosting solutions such as ASP (possible with 56.25 % of the products) or SaaS (possible with 31.25 % of the products) increasingly find their way into the offers of software companies, the in-house variant remains the main pillar of the product range. In addition, the technical possibility to host a system does not imply that vendors offer this service as operational functionality due to lack of customer trust. One vendor expressed the overall attitude towards hosting as operational model: “We provide in-house, ASP and SaaS but neither ASP nor SaaS are desired by customers.”
3.4 Market Challenges for the Future

For the future, 12 providers estimate an advanced consolidation as most likely. In the eyes of the questioned companies, the development of the market seems to clearly indicate a decrease in the number of providers. Exactly which group this will affect seems to be controversial. The niche suppliers are convinced that their excellence in their particular sector will protect them from great competition because cross-sector systems do not have the depth of functions which their customers need: “From our viewpoint the trend towards specialization in terms of sector-focus will continue further.” (vendor quote) 10 vendors forecast technological advancement as an influential factor for the market. Web-based architectures or fully modularized toolkits for building an ERP system are mentioned. Economical pressure by global players, in particular acquisitions by large providers like SAP or Oracle, is less eminent for the questioned vendors (7). So the statement concerning the ongoing consolidation does not necessarily imply a forceful buying strategy by global players that vendors are afraid of. Instead there is a general feeling that many vendors especially SMEs will perish during the process: “There won’t be several hundred vendors in five years time but only 20 to 30.” 5 vendors enhance this view by their comment towards a decreasing variety of systems in the market. Interestingly, there are only 5 system providers who focus on new operational models for differentiation despite the current obvious trend towards hosted solutions.

3.5 Flexibility of Processes and Services: Basis for Agile Enterprises

The already existing potential in Service Oriented Architectures (SOA) in conjunction with standardized process mapping (e.g. BPMN and BPEL) has, because of a lack of support from process modelling standards, not yet been exploited. A service orientation has already been implemented by 17 companies. In addition 13 of 17 vendors who use services in their system (internally and externally) do also have a graphical process representation. However, an orchestration of the services over and above the planning level is only possible to a very limited degree. Code generation is almost exclusively available for SOA based systems (7 of 8 vendors) so the infrastructure for combining processes with underlying services exists. Nevertheless the code which is currently produced is limited to specific code fragments (class diagrams, workflow rules, etc.).

The use of standards in process modelling is independent of the underlying architecture. Two vendors with a SOA and three with a SOA capability use industry standards. This means that the idea of a system which supports the ability to adapt to changed business processes will remain the exception in the coming years. The underlying architecture necessary to achieve such freedom and power of design would have to be component-oriented and also service-oriented up to current standards (Sprott 2000), so that the functionalities connected with the processes can, without any problem, be rearranged according to the restructuring carried out in the model. This will also help to meet increasing requirements regarding improved agility (Osterhout et al. 2006; Overby et al. 2006).

Based on these findings it is safe to assume that the graphical representation of processes will be more likely in combination with service-oriented vendors. The same conclusion is feasible for code generators that will be used within service-based scenarios. The architectural support for these tools on the other hand will be limited to a few vendors. The majority of vendors are not ready or able to rethink and rebuild their systems accordingly. When it comes to industry standards, service-oriented systems are more likely to include them. But without a common sense of well conceptualized and reusable process scenarios there will not be many systems in the future making use of standards.

4 CONCLUSIONS AND LIMITATIONS

Based on the results of our empirical study of the German speaking ERP market we discussed the aspects of process orientation, service orientation, operational model, market development, and
flexibility (agility) concerning future ERP software suites. We collected a large amount of data and decided to focus this paper on vendors whose systems are service-oriented and who offer hosting solutions for their ERP system. These vendors have, to some extent, already met the corresponding technological and organizational requirements for a flexible system that can cope with future technological and business-related challenges. However, in some areas there is still a clear need for development.

Process orientation is partly implemented in terms of a visual representation, it has not, however, come into its own yet as a standard organizational tool. Particularly in continuous process design and in the implementation of process standards there are still deficits requiring intensive further development. Modelling should not remain on the simple visual level but should, together with a service-oriented application system, allow for a reorganization of functions above the planning level. There are already corresponding approaches, although they are only used by a small proportion of the questioned companies. Additionally, there are standardized processes for cross-company process modelling for which implementation is lacking.

In the service-oriented areas, the necessary measures for a continuous application provision are to a large extent already implemented. Nevertheless, there are various aspects which still require further attention. SOA is still not clearly defined by all the companies questioned. However, the service idea is at least known of as a rough concept by all those questioned. Based on services, legacy systems can more easily be re-used, new modes of operations can be offered and acquisitions can be more easily integrated into the existing system. Nevertheless, a disciplined service administration is needed to ensure clarity, security etc., especially for large scale use.

Around one third of the companies see a progressive market consolidation happening in the future. This consolidation is likely to happen because of the growing pressure from global players such as SAP or Oracle who want to enter the SME market. Technological advancements as SOA and its possibility for simple application integration, or modern operational models as SaaS are contributing to the current market consolidation. Oracle alone acquired 41 companies within 48 months (Hill 2007). Some of the interviewees suggested a scenario in which some providers in the SME sector form so-called ERP clusters in order to arm themselves against the ever harder competition. For smaller ERP companies, it is reasonable to either secure a particular advantage in the market through niche excellence or to join forces and form a kind of “cluster” with other ERP companies in order to make a takeover unattractive: “It will be more important to link with others in the future.” (vendor quote) New technologies can even accelerate this process, as the expansion of Web services in the context of SOA has shown. One vendor summarized it: “As far the market goes, it’s: evolution not revolution!”

The paper presents selected aspects of a detailed analysis of the future requirements of ERP software in the German-speaking market based on an empirical study. We were confirmed in our belief that this topic still needs further research by the editors of the EJIS special issue on packaged software who stated: “In summary, we believe there is a need to theorize about packaged software and its place within the field of information system.” (Light & Sawyer 2007) Combining qualitative with quantitative research aspects, we shed light on the research question of what future packaged ERP systems are going to look like. Our research has several limitations. Firstly, the discussion is focused on the German-speaking area and it is possible the results may differ in other countries due to cultural implications (Soh et al. 2000; Davison 2002). Secondly – although the return rates were very favourable – this study is subject to the usual constraints regarding statistical representativeness. 32 interviews with vendors can only reflect a small portion of the complete universe of German-speaking ERP users and vendors.

Pattinson, Malcolm, School of Computer and Information Science, University of South Australia, 27 North Terrace, Adelaide 5000, South Australia, malcolm.pattinson@unisa.edu.au

Abstract

The research aims to address the existing theoretical gap in knowledge on antecedents to organisational adoption stage of the Enterprise Resource Planning (ERP) innovation process, and their relationship to performance of the firms. The predominant focus on investigating the implementation stage and its related issues has resulted in relatively limited understanding of the other stages of ERP innovation process. Additionally, little is known on how important critical success factors (CSFs) are to performance improvements of the firms. Grounded in innovation diffusion & IS Success theories, this study attempts to identify the antecedents critical to the success of the adoption stage of ERP innovation process and then examine their effect on organisational performance. Employing a mixed method research design for data collection and Structural Equation Modelling for analysis, the study empirically test a research model in order to develop an integrated, holistic framework for success of ERP innovation process. This research expects to contribute to the development of theory on innovation process by testing new antecedents to ERP adoption stage context as well as enhancing the understanding of CSFs’ role. The study will also provide recommendations for both the potential adopters and the vendors on successful uptake of ERP system.

Keywords: Adoption, Enterprise Resource Planning, Critical Success Factors, Firm Performance.
1 INTRODUCTION

Innovation is increasingly being hailed as the transformative engine that creates and shapes new economies of today’s networked world. The growth and survival of businesses is linked both to the creation of new products and services and to the adoption of novel ways of doing business whilst constantly improving the internal business processes, procedures, policies and business models (Damanpour & Schneider 2006). This ‘innovation pressure’ is thus translating into a tendency among firms to adopt information and communication technology / system (ICT/IS) innovations. One such technological innovation is the Enterprise Resource Planning (ERP) system.

With its hallmark enterprise-wide information sharing capabilities, ERP has gained popularity as the most rewarding information system of the 21st century (Davenport 2000). Paradoxically, the popularity of ERP does not seem solely to stem from its potential and promised benefits, but also partly comes from its notoriety for being complex to implement and various instances of its failed implementations (Ehie & Madsen 2005, Mabert et al. 2003). Reporting accurate information on ERP failures might be difficult if not impossible. However, it is generally believed that an estimated 60-70% of ERP projects, either fail to implement successfully or face various obstacles during implementation (Harvard 2007, Leung 2008). While such estimates seem very alarming, the lack of clear understanding on how ERP systems can be implemented successfully is still vague, thus adding to the burgeoning problem.

ERP projects fail due to a variety of reasons. Some of those reasons are: the complexity of the implementation process, misfit between ERP and organisational business processes, lack of availability of skilled human capital, cross-functional coordination issues, inappropriate planning and project management and incompetent consultants (Kim & Lee & Gosain 2005). All these reasons seem to embody one common theme: that is a sound understanding of the innovation process is essential in order to realise success in ERP projects (Laukkonen & Sarpola & Hallikainen 2007). This realisation has led to extant research, in terms of both the volume and diversity, on ERP related themes such as CSFs to ERP implementation, change management, cultural issues, trends and perspectives, use, maintenance and cross border implementations etc. (Moon 2007).

Despite the proliferation of studies on ERP, the research examining the organisational innovation process of ERP is still at a preliminary stage (Mabert et al. 2003) whereas the research on the adoption stage of the process is scant. The organisational innovation process is the combination of various stages or phases ‘along the temporal dimensions of their anticipated sequence’ (Rogers 2003, Zaltman & Duncan & Holbek 1973 p.52). Suffering from a lack of consensus on a globally accepted subdivision and nomenclature for the stages of an innovation process, the theorists have commonly identified these stages as initiation, matching, adoption, implementation, use and retirement of innovations (Kwon & Zmud 1987, Rogers 2003). The literature review indicates that the major thrust of the research on ERP has concentrated on the implementation phase generally and CSFs to ERP implementation in particular (Esteves & Bohorquez 2007, Moon 2007). This trend has resulted in a relatively limited understanding of the other stages of ERP innovation process such as adoption, use and retirement (Kamhawi 2008). Perhaps, the peculiar focus on investigating ERP implementation process is either the outcome of a sense of urgency among the researchers to find a ‘mantra for success’ to curb or to slow down the failures of ERP implementations, or it may be due to the reason that implementation, in ERP research context, is being treated as an inclusive process combining initiation, adoption, implementation and use. Regardless of the reason, it is crucial to avoid this “one size fit all” approach and any conceptual overlap between implementation and other stages of the ERP innovation process. This avoidance is vital, since understanding of each stage will enable the firms to proactively seek relevant solutions for achieving success at each specific stage of the ERP innovation process. Without diagnosing every stage of the ERP innovation process specifically, it seems unlikely that sound solutions to problems in ERP projects can be developed and its failures can be reduced or eliminated (Peslak & Subramanian & Clayton 2008). Equally important is the fact that the literature on ERP implementation is characterised by inconsistent, inconclusive findings and it lacks maturity (Ngai
& Law & Wat 2008). Therefore, there is a need for a fine-grained and well-structured approach to research in ERP context (Finney & Corbett 2007).

The adoption stage is the decision making stage in an innovation process (Rogers 2003, p.420). This is a very important stage as the ERP adoption decision entails huge monetary and resource commitments. An incorrect adoption decision could ‘well jeopardise the very existence of the organisation’. A well grasped understanding of CSFs relating to the adoption stage can help firms to achieve savings in costs, time and reduce the risk of failures by creating a more ideal environment and adequately preparing themselves (Verville et al. 2005). Furthermore, the identification of CSFs specific to every stage of the innovation process is of paramount essentiality, as each stage has different focus, priorities, stakeholders and performance metrics. With a very limited research on CSFs to ERP adoption stage, this study addresses these gaps in knowledge by investigating the factors critical to the success of adoption stage.

Though the significance of CSFs is recognised, little is known about whether the impact of CSFs is limited to the success of the relevant stage alone or does it extends beyond that, influencing the performance of firms in long run. Therefore, the study investigates the relationship between CSFs to adoption stage of ERP and their performance impacts on firms. An investigation of this relationship is vital in order to understand the real impact of CSFs (Nicolaou 2004).

Finally, literature presents a strong case for examining factors specific to the adoption of complex ICT/IS innovations, as the conventional factors presented by classical innovation diffusion theories (e.g. Rogers 2003) may not prove to be strong predictors to understand the innovation process of complex technologies (Hong & Zhu 2006). As such, the study fulfils this gap by testing factors specific to ERP adoption in particular and complex ICT/IS in general.

In the context of the literature gaps discussed above, this study investigates the following questions:

- What are the antecedents critical to successful adoption of ERP?
- What is the impact of successful adoption of ERP on the firm performance?
- What are the effects of CSFs for adoption of ERP on performance of firms?

This paper is organised as follows. First, in Section 2, a review of the literature pertaining to ERP adoption, implementation problems, CSFs and performance impacts is presented. In Section 3, the theoretical foundation of the study is discussed. Next, a theoretical framework identifying antecedents and their structural relationship is proposed in Section 4, followed by a discussion of methodology in Section 5. Finally, the implications and limitations of the research are discussed in Section 6.

2 LITERATURE REVIEW

2.1 ERP: significance and implementation problems

ERP, a term coined by the Gartner Group in the early 1990s, is a commercially available off-the-shelf software system, which embeds best business practices (Cotteleer & Bendoly 2006, Mabert et al. 2003). ERP offers extended functionalities to support critical business processes in many functional areas throughout the whole enterprise as compared to its specific-purpose predecessor systems such as Material Resource Planning (MRP) and Manufacturing Resource Planning (MRP-II) system of 1960 and 1970 respectively (Mabert et al. 2003). SAP, Oracle, Baan, PeopleSoft, JD Edwards, Technology One and MS Dynamics NAV are some of the well-known ERP systems.

ERP enables process and information integration across all functional domains of an organisation. It is defined as the customisable, modular structured software system that embeds best business practices and seeks to automate, standardise and integrate the key business & management processes and information using a common database and IT architecture; and provide real time information flow (Mabert & Soni & Venkataramana 2003).
The investment in ERP entails a variety of tangible and intangible benefits. Shang and Seddon (2000) and Basoglu, Daim and Kerimoglu (2007) list some of the benefits: (a) operational as in: reduced operating costs, accurate demand forecasts; (b) managerial as in: improved decision making and better resource management; (c) strategic as in: greater support for business alliances, building business innovations and cost leadership; (d) IT infrastructure as in: building business flexibility; reducing ICT costs; and (e) organisational benefits as in: supporting organisational change, facilitating better communication, business learning and empowerment. Historically, however, the implementation of ERP was carried out to replace fragmented, multiple, difficult and costly to use & maintain legacy systems – a transition that was neither easy nor quick.

Basoglu et al. (2007) cited figures from a Standish Group report on ERP implementation, note that ERP projects are, on an average, 178% over budget, take 2.5 times longer than intended to implement; and deliver only 30% of the promised benefits. Supporting this line of argument, several other researchers have reported a number of failed ERP projects with some of the projects involving multinational firms, including Boeing, Siemens, Panasonic, NAB Australia, AeroGroup, Dell, FoxMeyer, Whirlpool, and Dow Chemical (Ferguson, 2004, Karim & Somers & Bhattacherjee 2007). On the contrary, several ERP projects have been implemented successfully or have resulted in a number of benefits to adopting organisations too. Some examples are: IBM Storage system which achieved a reduction in shipment time for replacement parts from 22 days to 3 days, and Par Industries which reaped delivery performance improvement from 60% to 95% with a lead time to customers reducing from 6 to 2 days (Ehie et al. 2005).

The foregoing discussion highlights the opportunities and risks associated with adoption of ERP systems. Indeed, a failed ERP project could entail a potential disaster to the survival of the adopting organisation.

2.2 Critical Success Factors (CSFs)

The concept of critical success factors was originated in 1960s and it gradually gained practical acceptance in 1970s when it was used for the design of a management control system (Leidecker & Bruno, 1984). Since then, it has been variedly used across different disciplines such as organisation behaviour, business, management, marketing and information technology / systems. Also named as strategic factors, key success factors, key result areas and pulse points; the CSFs have been widely conceptualised as the ‘few key areas where things must go right’ for the firms to achieve competitive performance and profitability (Leidecker & Bruno 1984 p.23, Rockart 1979). Hofer and Schendel (cited in Leidecker & Bruno 1984) proposed a deterministic view of the concept and described CSFs as those areas, which can be influenced by management decisions to achieve competitiveness – a view that seemed limited in conceptual utility and sounded too simplistic. However, Leidecker and Bruno (1984, p.24) took a more comprehensive and deeply insightful approach in defining the concept of CSFs as “those characteristics, conditions or variables that when properly sustained, maintained, or managed can have a significant impact on the success of a firm competing in a particular industry.” This view and definition are shared and adopted as fundamental concepts in the present study.

The determination of CSFs is vital to organisations, to constantly and sufficiently focus on activities in already identified key areas or in identifying key areas for achieving the performance improvements. CSFs have been classified in a variety of ways such as strategic, tactical, internal / firm specific, external / industry specific, technological / innovation related and environmental (Finney & Corbett 2007, Leidecker & Bruno 1984). Given that the success of the ERP projects has been widely termed as ‘a moving target’ (Karim et.al. 2007), the identification of CSFs has attracted considerable literary interest. The CSFs are assumed to provide a positive, beneficial effect on the outcome, and thus knowing greater number of CSFs pertaining to a specific innovation process has been considered as critical to success of the process (Karim et.al. 2007). Despite the fact that conceptually CSFs are the areas that are linked to performance impacts on the firms, there seems to be a very significant gap in the literature in understanding the true role of CSFs on the firms studied. Generally, previous studies
investigating CSFs seemed to conceptualise them as an independent object relevant to a certain process, without investigating how critical the related CSF is to performance improvements. This situation warrants immediate attention and requires further examination of the role of CSFs in their interactive effect on performance improvements of the firms.

2.3 Adoption & Performance impacts of ERP

Referred to as a go no-go decision point, adoption is a key stage in the innovation process (Rogers 2003, p. 423) and has been extensively investigated in innovation diffusion literature. It has, however, received little attention in ERP literature as a bulk of studies have focused on investigating the implementation process of ERP (Esteves et al. 2007).

The literature points that assessment of benefits and risks of ERP has remained of strategic interest to the adopting organisations. Achieving operational efficiencies such as improvements in productivity, optimising inventory and data integration capabilities are some of the prime benefits being sought by ERP adopters (Kamhawi 2008). In investigating adoption motives, Raymond and Uwizeyemungu (2007) conclude in their study of Canadian Small & Medium enterprises (SMEs), that the firms with significant organisational capacities, commercial dependence on major customers and tendency of bringing innovative products are internally predisposed to ERP adoption, whereas those firms which are focused on networking and partnerships with other firms are externally pre-disposed towards adoption of ERP. Unfavourably disposed firms are profiled as having less conducive environmental, organisational and technological tendencies towards the adoption of ERP.

Extending the investigation on motives of adoption, Kamhawi (2008) finds that gaining strategic management and decision making capabilities are the main themes influencing ERP adoption decision, whereas startup costs and availability of resources are the main challenges to adoption of ERP. The findings indeed confirm the standpoint of Huang and Palvia’s (2001) study in which they highlight the differences in challenges faced by SMEs in adopting ERP, in developing and developed countries. Huang and Palvia (2001) find that the SMEs in developing countries face various cultural, economic and infrastructure challenges to adoption of ERP in contrast to their developed countries counterparts. However, Buonanno et al. (2005) contradict this position and conclude that SMEs do not regard financial constraints as the impediment to ERP adoption, but consider organisational and structural factors as the main influencing reasons thereof.

In an attempt to explore CSFs to ERP adoption, Deep, Guttridge, Dani and Burns (2008) suggest various factors across four key activities: plan, identify, evaluate and select. These factors are core team formation, review of requirement planning, ranking of needs / priorities, list of available resources, software and vendor short list criteria, arranging workshop and demonstration for end-users and customer site visits. Interestingly, Elbertsen, Benders and Nijssen (2006) discover that firms having less knowledgeable people / IT managers, who consider ERP as a complex and incompatible system, exhibit greater receptiveness to ERP marketing efforts and tend to adopt ERP more. The findings point to the opportunities available to ERP vendors for marketing customisable or best-of-breed systems. They also draw attention to the need for ERP vendors to review their marketing approach and step up efforts to target both well informed and less informed potential adopters.

Given the considerable investment of time, money and resources in ERP projects, the researchers have looked at the performance impacts of ERP in a post adoption scenario. Conducting a survey of Hong Kong based firms, Law and Ngai (2007) find that user satisfaction of ERP and business process improvement positively impact the organisational performance. They claim positive empirical relationship between the strategic intent behind the adoption of ERP and organisational performance. Velcu’s (2007) study reinforces the above findings, as the study reveals that firms driven by technologically-led motives versus business-led motives, perceive differently towards benefits of adopting ERP. Poston and Grabski’s (2001) longitudinal study of pre versus post implementation present mixed financial benefits to the ERP adopters. Hunton, Lippincott and Reck (2003) argue that a decline in financial performance of non-adopters relative to adopters should be anticipated and
studied, as adopting firms may not necessarily exhibit financial gains immediately for a number of reasons.

Among the studies measuring the non-financial impacts of ERP, O’Leary (2004), using data from companies which had opted for Oracle’s ERP, identifies several tangible and intangible benefits of ERP implementation. Considering ERP’s multi-directional impact, McAfee (2002) observes significant operational performance improvements in the pre versus post ERP implementation contexts. Supporting these findings, Cotteleer and Bendoly (2006) discover significant performance improvements in order fulfilment lead times in the near-term, as well as over an extended period following the deployment of an ERP system.

Interestingly, the time lag has been seen as quite important in assessing ERP performance outcomes. Although the ‘normal’ time lag has been found to be approximately three or more years, Matolcsy, Booth and Wieder (2005) report sustained operational efficiencies and overall improved liquidity for adopting firms after the second year of implementation. Similarly, Nicolaou’s (2004) study supports this view of early impacts on performance and found that ERP implementing firms realised performance impacts (ROI improvements) in their 2nd year after implementation.

Urging further empirical studies that consider implementation factors and their linkage to performance impacts, Nicolaou (2004) concludes that implementation factors such as vendor selection, implementation goals, scope and time on ERP implementation efforts are significant in affecting a firm’s realisation of performance impacts.

3 THEORETICAL BACKGROUND

3.1 Diffusion of Innovation

Over the past 50 years, innovation scholars have produced a number of theoretical models, terminologies, typologies and nomenclature, to explain the concept and the process of innovation (see for review: Kwon et al. 1987, Rogers 2003, Zaltman et al. 1973). To attribute this situation to the cosmopolitan characteristics of innovation or to the bandwagon effect of innovation is a matter of debate which is beyond the scope of this study, however, the resultant literature certainly seem to be converging towards a ‘core set of theoretical models’ (Kamal 2006). Supporting this line of argument, a review of various theoretical models indicates that the innovation process have been explained through four core processes: generation, diffusion, adoption / implementation and retirement / obsolescence. These core processes have further been divided into sub-processes such as initiation, matching, assimilation, use, and infusion to provide deeper insights into the various stages of the innovation process. Diffusion of innovation (Rogers 2003), IS Implementation Model (Kwon et al. 1987), Technology Acceptance model (Davis 1989), Innovation adoption and implementation Model (Gullivan 2001), Theory of Reasoned Action (Ajzen & Fishbein 1975) and Theory of Planned Behaviour (Ajzen 1985) are some of the core models of innovation (Cited in Kamal 2006). The linear, sequential and formulaic approach adopted by these models has attracted criticism (Bayer & Melone 1988) as well as validation in multiple studies across different disciplines (Damanpour et al. 2006, Molla & Licker 2005).

Rogers (2003) has described innovation process from individual as well as organisational lenses, explaining several attributes that influence the process. According to Rogers (2003, p.420), the organisation innovation process is a sequential combination of five stages, which is made up of a two-stage initiation sub-process, namely agenda-setting and matching; and a three-stage implementation sub-process, namely redefining/restructuring, clarifying and routinising. Rogers’ (2003) innovation models have been tested in cross-disciplinary contexts and many scholars have presented updates, extensions and revisions to this model. Rogers’ (2003) model has also been termed as being too formulaic and lacking in realism (Bayer and Melone 1988). Given the scope of this study, however,
the authors employ Rogers’ (2003) stage-based organisational innovation model as it lends well with the objective of the study.

3.2 IS Implementation Model

Consistent with Rogers’ approach, Kwon and Zmud (1987, p.233) proposed a multi-stage model of IS implementation, theorising that organisational innovation follows six stages, namely initiation, adoption, adaptation (development/installation), acceptance, use and incorporation. Extending Rogers’ (2003, p. 392) five-stage organisational model, the IS implementation model emphasises that four assessments: acceptance, usage, performance and satisfaction, should be incorporated into the innovation process model, as these assessments form the basis for implementation success. Since, the IS implementation model has been widely tested and has proved robust in explaining the organisational innovation process of information systems, this model serves as a framework in the present study.

3.3 IS Success Model

Delone and McLean (1992), in their famous IS success model, posited that system quality and information quality jointly and severally affect use and user satisfaction which, in turn, result in individual impact and subsequent organisational impacts. Further research into this model, however, had led to the addition of dimensions such as service quality, intention to use and Net benefits (replacing organisation impact construct) (Delone and McLean 2004).

4 RESEARCH HYPOTHESES AND MODEL

This study uses a synthesis of three models described above to test attributes critical to the adoption of ERP and their effect on firm performance. Consistent with broad category of attributes identified in these theories, the research uses environmental, technological / innovation related, organisational and IS Success related factors to create a hypothetical model, which is shown graphically in Figure 1.

1) Perceived Information quality
Information quality refers to measures of IS output, and has been measured in a variety of ways, e.g.: accuracy, output precision, output reliability, information timeliness, information relevance to decisions, completeness, format, understand-ability etc. (Delone & McLean 2004; Nelson & Todd 2005). Information quality has been found to relate positively to user satisfaction (Nelson & Todd 2005), so that ERP information quality would appear to be critical to adoption success of the system. Further, ERP systems are generally recognised as providing reliable, accurate and timely information. It is thus argued that ERP’s perceived information quality is a positive contributing factor to adoption decision, and the following hypothesis is developed:

**H1: ERP’s ability to provide information quality positively influences the successful adoption.**

2) Perceived System quality
DeLone and McLean (2004) found system quality to be one of the most important enablers of IS success, in their meta-analysis of the IS literature. Systems quality has been measured in a variety of ways, e.g. convenience of access, integration capabilities, reliability, ease of learning, resource utilisation, investment utilisation, flexibility of system, response time and usefulness of specific function etc. (Delone & McLean 2004; Nelson & Todd 2005). It has been seen as an important factor for ERP implementation and was positively associated with user satisfaction (Nelson & Todd 2005). ERP systems are believed to provide integration, flexibility, and optimum resource utilisation – and thus provide high system quality. It is therefore argued that ERP’s perceived system quality capabilities will be an important factor to adoption and its success thus develop the following hypothesis:

**H2: ERP’s ability to provide system quality positively influences the successful adoption.**
3) Organisational Readiness
Organisational readiness has been defined as “the ability of a firm to successfully adopt, use, and benefit from information technologies” (Fathian & Akhavan & Hoorali 2008). Prior studies have used a variety of measures to investigate readiness, e.g. awareness of benefits and risks of innovation; availability of human resources skills and capabilities; availability of technological, business and financial resources, commitment and support by top management, fit between innovation and organisational structure as well goals and values of organisation (Fathian et al. 2008; Molla & Licker 2005). Grounded in structural contingency theory of fit, Khazanchi (2005) believes that assessment of ‘readiness’ for an organisation to adopt a certain technology is an important criterion for successful implementation and performance impact. Researchers often posit that top management attitudes to change have significant influence on adoption outcomes (Wu & Mahajan & Balasubramanian 2003). Organisational readiness positively impacts adoption of technological innovations (Molla & Licker 2005). An ERP adoption introduces enterprise-wide change. Hence it is expected that the internal organisational preparedness will be critical to adoption success and therefore it is hypothesised:

**H3: Organisational readiness positively influences the successful adoption.**

4) Environmental Assessment
Chi, Jones, Lederer, Li, Newkirk, and Sethi (2005) note that: “an environmental assessment evaluates external information and identifies business needs, objectives, external opportunities, and threats”. Though environmental assessment has been measured using many indicators, it broadly encompasses: hostility, dynamics and heterogeneity of environment (Newkirk & Lederer 2006). These authors note that environmental hostility includes unpredictability of competitors’ market activities; legal, political or economic constraints; price / product quality competition; labour scarcity; and Product / service differentiation. By contrast, they argue that, environmental heterogeneity includes diversity in production and marketing methods; in customer buying behaviours; in the nature of competition; and in product line. Finally, growth opportunities, change in production/service technologies, rate of innovation, product / technology changes etc. indicate environmental dynamics. Competitive pressure, normative pressure and customer power have been found to positively impact adoption of technologies (Wu et al. 2003).

A dynamic, heterogeneous and hostile business environment may affect stability of demand, put strains on supply, generate a disloyal customer base; and result in fluctuating economic outcomes. Thus, a system that predicts, coordinates and forecasts market trends will enable the organisation to react swiftly and efficiently to market changes (Wu et al. 2003). ERP systems, with their flexible and integrative architecture, seamless data flow and real-time global connectivity features have the capacity to help forecast demands and supply variations, support sound decision-making, efficient utilisation of resources and achieve competitive advantage. It is therefore postulated:

**H4: An Environmental assessment characterised by environmental hostility, dynamism and heterogeneity positively influences the successful adoption.**

5) Perceived Strategic Value (PSV)
Information systems form the key strategic assets of an organisation’s asset portfolio. Thus their adoption is motivated by “business justification and strategic value” which the new systems are seen as bringing to the firm (Subramanian & Nosek 1993). Subramanian and Nosek (1993) pioneered the concept of perceived strategic value and presented three factors: operational support, managerial productivity and strategic decision aid, to measure perceived strategic value. Amit and Zott (2001) found four key factors of strategic value in e-business context: transaction efficiency, complementarities, lock-in and novelty. Grandon and Pearson (2004) concluded a positive relationship between PSV and adoption. ERP involves a huge monetary and resource commitment and promises benefits in operational, managerial and organisational domains. It is considered a tool for achieving operational efficiency and competitive advantage, thus it is argued that a positive assessment of ERP’s perceived strategic value would contribute to successful adoption of ERP. Thus the following hypothesis is developed:

**H5: Higher Perceived Strategic Value of ERP positively influences the successful adoption.**
6) Adoption, Implementation Success and Firm Performance

Success of ERP adoption is dependent on combination of various factors. A clearly defined vision and mission, the top management support and leadership, the detailed evaluation and selection process of ERP vendor and a detailed cost benefit analysis of the ERP project are the foundation stones for the success of ERP project at implementation stage and post-implementation performance of the organisation. This study adopts these items to measure the adoption of ERP and its success. Literature suggests that the implementation success have been measured in variety of ways, such as ERP project success, performance of ERP etc. Implementation in this study has been measured in terms of project success using four items: completion on time, within budget, as per expectations and level of user satisfaction with the ERP. It is argued that performance should be measured as the outcome of adoption and implementation of ERP, in order to understand the impact of ERP in post adoption and implementation context. Hence firm performance has been measured by two underlying latent variables: competitive advantage and overall performance of the firm. Dehning & Stratopoulos (2002) suggest “a company achieves competitive advantage by implementing a value creating strategy that is not being implemented by competing firms.” The adoption of strategic information systems such as ERP have been linked to achieving capabilities such as agility in offering innovative products and services, effective leveraging of resources, raising entry barriers for new competitors, achieving increased bargaining power with suppliers and customers and changing the dynamics of competition (Bhatt & Grover 2005). As such a ten-item measure as proposed by Teo and Pian (2004) has been adopted to tap into competitive advantage gained by the organisations in post ERP context. Overall performance of the firm is measured by seven item measure to check the impact of ERP on customer service, productivity and sales growth of the adopting organisation. Based on foregoing discussion, we argue,

H6: Adoption success positively influences implementation success.
H7: Adoption success positively influences firm performance.
H8: Implementation success mediates the relationship between adoption success and firm performance.
H9: Perceived information quality, perceived system quality, organisational readiness, environmental assessment and perceived strategic value have positive relationship with firm performance.

Figure 1. Preliminary Research Model

5 RESEARCH METHODOLOGY

This research project is designed to empirically test and validate the hypothetical structural model presented in Figure 1. The study employs a mixed method approach in data collection. The quantitative data will be gathered through a cross sectional survey and be used to identify the influence of various organisational, technological / ERP related, environmental and IS Success related variables on the adoption stage and their effect on the performance outcomes of the firms studied. It will be followed by semi-structured interviews with respondents in five firms to supplement and cross-validate the findings of the survey and probe further insights into the issues. Given the complex nature
of ERP adoption and implementation process, the choice of mix-method approach suits the objectives of this study as it will allow the testing of the hypothesised relationship among various factors as well as explore in greater depth the process by which the relationship among these factors occurred (Tashakkori & Teddlie 2003). The data collected through the cross-sectional survey is expected to provide greater external validity and generalisability of results, and afford an opportunity to analyse the collected data using a robust statistical tool. Considering that the conceptual model of this study is grounded in theory, takes a confirmatory approach to test the various hypothesised relationships a priori and includes relationship between multiple latent and measured variables, Structural Equation Modelling (SEM) is the most appropriate approach to be used for analysing data.

The population for the study is the Australian organisations that have implemented ERP systems. The sample frame has been identified using “Fairfax Business Research's MarketBase” companies database which includes decision-maker & company contact information, ERP software details and financial data of the company. Consistent with the prior research into ICT innovations and given the focus of this study, the target respondent group is senior managers for example: Chief Executive Officer, Chief Technology Officer, Chief Information Officer, Project Managers and business managers with dedicated involvement in the adoption and implementation of ERP in their respective organisations. This set of group is chosen as they fit the criteria of: (a) knowledge ability concerning the content of the enquiry and (b) ability to generalise patterns of behaviour after summarising either observed or expected organisation relations (Wu et al. 2003).

All latent variables / factors shown in the model (See Fig. 1 above) are being measured through multiple item scales, which are expected to provide a stronger construct validity. Wherever possible, measurement items which have been operationalised and tested in previous empirical studies have been re-used, which will increase the comparability and reliability of the results. All the items in the survey are being measured using a five-point Likert-type scale with response alternatives ranging from strongly disagree to strongly agree.

A two-phase pilot test of the survey instrument have been conducted, with fifteen academics and nine ERP practitioners / professionals respectively. The feedback has been incorporated into the survey instrument and where necessary modifications have been made to suit the context of the present study.

The web or Internet based surveys are seen as a convenient platform in achieving higher response rates due to their ease of use, low cost and greater interactivity (Dillman 2007). As such the survey questionnaire has been replicated into its web-based version and is available at www.surveymonkey.com. A link to the online questionnaire has been provided in the covering letter. Respondents are given the choice either to respond in hardcopy or online. To avoid duplication, an identifier number has been allocated to each respondent.

Data analysis will be carried out using a two-step approach: (a) assessing the measurement model; and (b) analysing the structural model for adequacy of data representation. The measurement model will be tested for validity and reliability properties. Construct validity will be assessed by convergent and discriminant validity, using confirmatory factor analysis (CFA).

6 CONCLUSION

This study intends to propose a new systematic direction to research on CSFs on innovation process of complex technologies in general and ERP in particular. By adopting a structured and an integrated approach, it is believed that the shortcomings of traditional CSF oriented studies could be overcome. The question, how important critical success factors are, requires an in-depth examination of the interactive effect of CSFs beyond the particular innovation process, and to further understand the role of CSFs in the spirit of the concept.

The findings are expected to have several important academic as well as practical implications which include: a) improving our understanding of the adoption stage of ERP through identification of key
attributes to the process. This would help firms to study their conditions against a set of identified CSFs, which is expected to improve their chances of eliminating or reducing the risk of failure or improving the chances of success of their ERP projects (Ngai et al. 2008), b) testing of a new combination of CSFs to ERP adoption, will shed light on the complex interaction and effect of these variables on the performance outcome, c) identifying new factors that could improve the predictive power of diffusion theories in explaining the uptake of complex technologies including ERP, d) providing a better understanding of whether CSFs role is limited in influencing the outcome of relevant stage in an innovation process or it goes beyond in influencing the performance of the firms as well, e) helping ERP vendors to understand the needs of potential ERP adopters, and thus formulate their marketing and product development activities to increase their market share and f) laying the foundation of a new theoretical framework of ‘successful adoption’ of ERP.

While unique in its design and perspective, the study has several limitations as well. Firstly, it only examines a limited number of antecedents pertaining to ERP adoption stage. As such there is a need for future research in testing more factors in getting an agreeable set of CSFs. Secondly, due to its geographical focus in Australian context, the utility of study’s findings in the cross-border and cross-cultural ERP projects context would be limited. Finally, the study provides a snap shot understanding of the adoption stage, and thus do not takes into account the dynamic nature of changes in effect of CSFs to improvements in performance and on the innovation process generally.

Abstract

How do emotions affect telemedicine adoption and usage for critical-care episodes? We report on early findings from a grounded theory approach in a multiple-case study of critical care tele-pediatrics (research in progress). Thus far our findings suggest that specialists believe that generalist clinicians at remote “spoke” hospitals are anxious and fearful when performing in a high stress crisis situation involving an acutely ill or gravely injured child, leading to tunneling of attention (overlooking important clinical details). The specialists at tertiary care “hub” hospitals feel they are able to keep an emotional distance from the situation and they also report feeling less anxious because they have had extensive training for these acute care situations. Both emotional distance and higher skill level seem to help the specialists to take in more clinically-relevant information and use this to guide the generalists. The generalists’ fear of negative evaluation by the specialists, or embarrassment in front of other clinicians, may have some impact on their decision to use tele-pediatrics, but does not seem to be a salient concern during critical care episodes. These findings suggest that emotions do play a role in telemedicine use and possibly also in other forms of technology-mediated inter-organizational collaboration.

Keywords: telemedicine, anxiety, stress, emotion

1 INTRODUCTION

The emotional side of technology-mediated inter-organizational collaboration has received little attention in the IS literature. Studies in other fields (reviewed below) find that stress leads to anxiety which in some situations will impede learning and in other situations improve learning. Stress may also increase or decrease the likelihood that individuals will seek knowledge from others. Under the stress of extreme time pressure people seek less information and performance degrades.

In critical-care pediatrics a child’s life hangs in the balance. A stressful situation such as this can elicit emotions such as fear or anxiety among clinicians who are not trained in pediatric critical care. Telemedicine can connect these clinicians to critical-care specialists located in tertiary-care teaching hospitals. In this paper we focus on the specialists who use telemedicine to provide assistance to physicians located elsewhere who are caring for acutely ill or critically injured infants and children (critical care tele-pediatrics). We report on early findings from case studies of two “hub” hospitals that provide pediatric critical-care consultation services via telemedicine. Conversations with pediatric intensivists (pediatricians who received additional post-residency certification in pediatric critical care) reveal that fear, anxiety and other emotions do apparently play important roles in both the acceptance and ongoing use of telemedicine in this domain.
This paper is organized as follows: We discuss prior research addressing the influence of stress on learning, information seeking, decision-making and collaboration. We describe our methodology, then discuss how the “fear factor” played out among several stakeholder groups – specialist experts at hub hospitals, generalist physicians and other clinicians at spoke hospitals, and hospital administrators. We discuss these findings and suggest opportunities for further research on the role of emotions in computer-mediated inter-organizational collaboration under time pressure.

2 EFFECTS OF STRESS, ANXIETY AND FEAR ON LEARNING

Human stress is a physiologic and emotional response to a stimulus (the stressor) (Gaillard, 2001). We experience stress and related emotions as follows: A triggering event or stimulus (such as a loud noise) precipitates an immediate pre-attentional orienting reflex (Rohrbaugh, 1984). Next the brain attends to key features of the precipitating event and matches them to past experiences, evoking a previously learned response. A state of arousal, initially experienced as uncomfortable, is subsequently experienced as a more refined emotional cognition. Unexpected stressors cause individuals to focus on their own emotional response, and less on the stressor itself. (Chajut and Algom, 2003; Zohar and Brandt, 2002). When a stimulus is perceived as threatening, the individual is more likely to use selective attention (Baddeley, 1972), attending to a subset of available information. “Under stress, attention appears to channel or tunnel, reducing focus on peripheral information and tasks and centralizing focus on main tasks … tunneling of attention can result in either enhanced performance or reduced performance, depending on the nature of the task and the situation. … When peripheral cues are irrelevant to task completion the ability to tune them out is likely to improve performance. On the other hand, when these peripheral cues are related to the task and their incorporation would otherwise facilitate success on the task, performance suffers when they are unattended” (Staal, 2004, p. 31).

Also, when anxiety impedes one’s ability to process relevant information, this itself can increase stress. Thus, anxiety is both a response to stress and a cause of it.

Through attentional processes a negative feeling is experienced, and through cognitive processes it is interpreted as an emotion such as anxiety or fear. Psychologists place situational anxiety and fear on a continuum; not separate emotions but different manifestations of the same emotional state. Anxiety affects one’s ability to learn new material or to apply previously-learned knowledge (Taris and Feij, 2004; Warr and Downing, 2000), but (consistent with the tunneling-of-attention findings above) the nature of that impact varies. One theory proposes that anxiety leads employees to seek help from people who they believe possess useful knowledge or skills. Lower performing employees reportedly engage in such interpersonal help seeking more than high-performing employees (Warr and Downing, 2000) and individuals are less likely to seek help if they fear learning bad news (Sheikh, 1998).

Time pressure is a stressor that can affect both emotions and performance. Novices benefit from being provided meta-information that describes the accuracy, timeliness and completeness of specific data sets (Fisher, et al, 2003), but in real life such meta-information is often not available (Ballou and Pazer, 1995; Cuppiello, et al., 2003). Under extreme time pressure decision makers may seek or process less information (Pearson and Clair, 1989) and perform worse (Entin and Srfaty; 1990; Van Galen and van Huygevoort, 2000; and Wickens, et al. 1991). Extensive training and rehearsal improves one’s ability to work effectively under high time pressure (Sniezek, et al., 2002) and to attend to the appropriate cues (Lerch and Harter, 2001). The theory of recognition primed decision making posits that when confronted with a new situation, an individual quickly assesses its key features, then recalls a similar previous situation and responds in ways similar to how he acted previously (Lipshitz, et al., 2001). Under time pressure, novices tend to focus on a single comparative situation and set of behaviors, even though a better outcome might be attained by altering the course of action to better meet the unique needs of the current situation (Flin, et al., 1997). Experts are better able to match salient features of a situation against appropriate prior experiences, while novices are more likely to focus on the wrong aspects (Kaempf, et al., 1996; Klein, 1993; Lipshitz, 2001).
While much research has studied the effects of prolonged exposure to chronic stress, we focus in this paper on technology mediated collaboration under acute (situational) stress.

3 TELE-PEDIATRICS

In the US and elsewhere there is a shortage of pediatric intensivists (doctors with advanced post-residency certification in critical-care pediatrics). Indeed, this field is young; following the establishment of pediatric intensive care units in several influential hospitals in the sixties and seventies, the first post-residency fellowship programs in pediatric critical care were offered in the eighties by hospitals in Toronto, Philadelphia, Washington DC, Baltimore, Boston, Dallas and Detroit (Epstein and Brill, 2005; Randolph, et al., 2004). As of 2009, 49 US hospitals offer pediatric critical care fellowship programs to just 116 candidates, according to the National Resident Matching Program (www.nrmp.org). Most fellowship programs admit just one or two fellows per year, and once their training is completed, most pediatric intensivists remain in urban centers; only 3% practice in rural areas. This is a problem since about 21% of U.S. children live in rural areas (Heath, 2008).

Fortunately it is a rare occurrence for physicians (especially in rural locations) to see critically-ill children; common conditions such as ear infections or minor injuries are far more likely. Unfortunately, when a child suffering an acute illness or critical injury is brought in, rural clinicians may not have all the necessary skills to care for them. At a community hospital a critically ill child might be seen by emergency room clinicians who are accustomed to treating adults, or by pediatricians who have little experience providing acute emergency care. The child may require immediate attention and stabilization before being transferred to a pediatric emergency department or intensive care unit at another hospital. So, some clinicians turn to specialists at teaching hospitals for help. Traditionally, that help is provided via brief telephone consultations, but today a few teaching hospitals offer telemedicine-based consultation services. Consistent with Thrall (2007) we define telemedicine as “the delivery of health care services over a distance.” In the current paper we focus on telemedicine-supported real-time consultations by experts working online to assist physicians located elsewhere, to care for acutely ill or critically injured infants and children (i.e., critical care tele-pediatrics).

Telemedicine is not new (early applications of it began in the 1960’s) and its scope is broad. Some telemedicine applications entail store-and-forward transmission of video, still images, documents, and graphical data while others utilize real time video conferencing. Numerous studies have led to a consensus among physicians that telemedicine services are safe and efficacious (Hersh, et al., 2001; Taylor, 2005) across a broad range of medical specialties. The top ten telemedicine domains (per the Telemedicine Information Exchange, which tracks more than 200 active programs worldwide) are: mental health, cardiology, dermatology, pediatrics, radiology, home health, orthopedics, neurology, oncology, and general surgery (Tulu, et al. 2007). While pediatrics is included in the above list, critical-care tele-pediatrics is not widespread. Fewer than six “hub” hospitals currently provide this service in North America, and the number of participating “spoke” hospitals is also quite low. One reason (as noted above) might be that the number of critical-care episodes is not very high and thus critical care tele-pediatrics is just not yet high enough on the priority list for health care administrators. Another reason might be that the supply of specially trained pediatric intensivists is not yet high enough to support this activity. Or, there may not be enough champions promoting this innovation. To date, studies in tele-pediatrics have largely focused on evaluating the technologies and establishing the appropriate networked applications for diagnosing and caring for infants and children (Marcin and Ellis, 2004; McConnochie, et al., 2006; Mehta, et al., 2001; Sable, et al., 1999).

Prior research hints that fear and anxiety may impact telemedicine use. For instance, a state hospital physician reportedly participated in telemedicine consultations in order to avoid dangerous exposure to patients with certain conditions (Paul and McDaniel, 2004, p. 200): “Would you like to get in the ambulance or the life-flight helicopter with somebody with a very contagious disease?” Yet, the impact of emotions on telemedicine use is largely unexplored.
Our research was conducted at two tertiary-care teaching hospitals that provide critical-care tele pediatric services. Our purpose is to explore the emotional side of tele-pediatrics. Little is known about the role that emotions play in influencing the behavior of the specialists and generalists on either side of the urgent telemedicine consultation. Thus, our research questions:

- Do emotions influence whether tele-pediatrics is used for critical care consultations?
- How do emotions influence what happens during these consultations?

4 METHODOLOGY

Our research is part of a larger study of telemedicine challenges in several clinical domains. In this paper we draw insights from interviews of 60 to 90 minutes each, conducted with three specialists in pediatric critical care (hereafter “intensivists”) at two teaching hospitals (UrbanHub and RuralHub). We interviewed one of the three pediatric intensivists on staff at RuralHub and two of the pediatric intensivists on staff at UrbanHub. We also conducted interviews with several administrators and other clinicians at each institution, to learn about other telemedicine services and to explore business, legal, technical and other challenges associated with them.

This study is ongoing and we are using an inductive, grounded theory approach, the constant-comparative analysis, and snowball sampling (Stake, 1995; Strauss and Corbin, 1998). Our open-ended interviews explore challenges and issues in pediatric critical care in general and in offering tele-pediatric consultation services. Interviews are recorded and interviewers also take field notes. In the first phase we interviewed specialists at two hub hospitals, and in spring 2009 interviews are being conducted with generalists at participating spoke hospitals. After interviews are professionally transcribed, we review them and add corrections and contextual notes to the transcripts. All members of the research team then code the transcripts, using four forms of coding: 1) Factual coding captures key events and facts (such as the cost of telemedicine equipment and number of pediatric intensivists on staff). Facts and viewpoints obtained in interviews are triangulated against information available in publicly available documents such as web pages, presentation materials, planning reports, news accounts and journal publications. 2) Comparative coding captures findings that are or are not consistent with previously-identified themes from earlier rounds. Our initial comparative coding entailed comparing interview segments with themes identified in earlier telemedicine studies conducted by two of the authors (such as the influence tactics of a telemedicine champion and concerns about licensure, credentialing, and reimbursement), and with findings identified in our literature review of other telemedicine studies. 3) Open coding captures new themes or sub-themes revealed in the interviews (such as in this study a theme about clinician fear which we had not anticipated). 4) Interpretation examines the relationships among themes and sub-themes to reveal the significance of events, actions or viewpoints (Stake 1995).

After each researcher separately codes the transcripts we meet to identify areas of overlap or difference in the coded themes and consolidate them into broader themes or break them out into narrower sub-themes. Each author then revisits the transcripts again with these themes and sub-themes in mind to substantiate or refute them and to identify additional informants and research sites.

In this paper we offer preliminary evidence of how stress, fear, anxiety, and telemedicine usage play out in the context of critical care pediatrics. In this research in progress the themes thus far reflect three experts’ views about critical care tele-pediatrics, but do not yet directly reflect the generalists’ views (although we expect to be able to discuss their perspective at the ECIS meeting in June 2009).

We next provide a brief background of the two hospitals and their critical care tele-pediatric services.

4.1 Case 1: UrbanHub

UrbanHub is a division of a well known urban teaching hospital. UrbanHub’s 14-bed pediatric critical care unit is considered a leader in this specialty, with intense competition for spots in its pediatric...
critical care fellowship program. The parent hospital has experimented with telemedicine in a variety of clinical areas, a few of which – such as its tele-stroke service – are now well established.

In the late nineties the UrbanHub pediatric critical care unit launched a grant-funded pilot test of tele-pediatrics with an affiliated suburban hospital. A video camera was set up in a treatment room at the spoke hospital’s emergency department. From the pediatric critical care unit at UrbanHub a consulting physician could closely examine the patient, see clinical information provided on various monitors, and observe the clinicians at work. More recently UrbanHub began offering the service to another suburban hospital and (thanks to private funding from a donor with ties to Puerto Rico) to a hospital in rural Puerto Rico. The department head would like to expand the service but reports that a financially viable business model for doing so has not yet been established.

4.2 Case 2: RuralHub

RuralHub, in a state with a very rural population, is the only tertiary care teaching hospital in its state. Its catchment area covers about one million people. Most residents of this state live in towns with populations less than 2500, and its mountainous terrain makes travel to RuralHub time-consuming and challenging, especially in winter.

In 1994 RuralHub had launched a tele-pathology pilot study, involving two remote hospitals. In the nineties pathology was the largest telemedicine user, followed by vascular surgery and nephrology. Some path-breaking telemedicine examples included remote endoscopy exams and a few instances in which telemedicine was used during live surgical procedures. Pediatrics was not a regular user of telemedicine for physician-to-physician consultations at that time. RuralHub began its critical care tele-pediatrics program in the early years of this decade. A RuralHub pediatrician had trained at the prominent UrbanHub pediatric critical care program in 1998, just as UrbanHub was starting to use telemedicine in this domain. When this physician returned to RuralHub after completing his fellowship, he began to offer tele-pediatric consultation services (funded by a federal grant) and to build a department of pediatric critical care, which now has three intensivists.

Before launching a telemedicine service the intensivists visited ten rural emergency departments to help them learn how to comply with new guidelines for pediatric critical care and advanced life support. The field of pediatric critical care was evolving rapidly, however, so there was still a concern that rural clinicians’ skills might erode in comparison with best practices in just a few years. The RuralHub intensivists reported that since pediatric emergencies are rare, rural clinicians who underwent training might nevertheless be poorly prepared to provide critical care when needed. Motivated by these concerns, more federal funding was sought to set up a pilot test of a critical care pediatric telemedicine service involving ten rural emergency departments. As was the case at UrbanHub, intensivists provided 24/7 coverage. This pilot test demonstrated the feasibility of using telemedicine for critical care consultations to rural clinicians, and the RuralHub pediatric team continues to offer this service, even though they are not yet being reimbursed for their consultations.

5 EMOTIONS AND CRITICAL CARE TELE-PEDIATRICS

The three specialists at the hub hospitals were unanimous in the belief that clinicians at spoke hospitals are eager to transfer critically-ill children to tertiary-care facilities, because they are anxious about caring for these patients. A RuralHub intensivist discusses this:

“*These are low frequency, high morbidity events. ...The level of comfort can become extremely low for someone who doesn’t see children very often and is presented with a tiny baby with serious health problems; it’s very difficult for them. ...The goal for that provider is to make this problem go away as fast as you possibly can. So they don’t hesitate to call us... None of the pediatricians, zero, want to take care of these children; they want them gone. Emergency department physicians feel the same way, because they don’t have the technology to care for these children. ... When physicians, nurses, respiratory therapists on the other end are clearly scared to death and we walk them through how to*
do absolutely everything and the transport team comes and the kid leaves, they are so happy with the service that we have given them”

Another hub doctor presumed that a physician at a spoke hospital was anxious out of concern about being observed by the experts in the new telemedicine consultation service:

“It took us a while for the person there [at the spoke hospital] to rely on us and feel confident...(It) is a very sensitive relationship. At first, physicians are afraid we are seeing what they are doing wrong; they are concerned about that. Like, ‘Oh my God, these guys are going to see us, we’re not doing well.’ So we have to overcome this barrier. Once they feel that we are friends and that we’re working together and we’re partners (then it is fine). The new person over there is now learning gradually. She prefers to call us over the phone more than talk with telemedicine. We tell her, ‘Turn [the video camera] on.’ She says, ‘Oh no it’s just a quick question on the phone.’ [Laughs] It takes some time.”

Before telemedicine, anxious clinicians at spoke hospitals in the rural state would place a telephone call to request that a critically ill or injured child be transferred to RuralHub, and the intensivist would attempt to determine whether the patient was stable enough for the transfer to take place. However, the intensivist found it difficult to offer advice based on clinicians’ verbal descriptions of what was going on. Being able to see the child, the various monitor displays, and the clinicians at work via video is a huge plus, in his view. He described one particularly vivid case:

“I turn on the telemedicine and can see them doing chest compressions on this kid. I say, ‘You need to slow down a little bit and push harder, make the chest move more.’ Then I see they have a breathing tube in and they’re squeezing the bag and I say ‘Slow down, squeeze harder and longer.’ I could see the cardigram and monitors and can make recommendations. ‘You put the breathing tube way down too far in the lung.’ That happens all the time because they are anxious and they push it in too far. I say ‘Pull the endotrachial tube back and you will ventilate better.’ I could see the patient had a type of lung injury called non-cardiac pulmonary edema. I could tell the respiratory therapist, who had not had experience using ventilators with children in the past 15 or 20 years, exactly what dials to push on the ventilators and what settings to do exactly what we wanted. I told them the resuscitation drugs and the doses to use, because they may remember what drugs to use but they can’t remember how to use them or how much to use. The child was placed on mechanical ventilation (and transferred to RuralHub). I sent the transport team out and directly supervised them; they talk to me over telemedicine, I told them exactly what to do.”

A RuralHub intensivist felt he was able to “see the big picture” better than clinicians at the spokes:

“...When they’re intubating, everyone’s field of vision focuses down, very, very narrowly on the procedure they’re doing. I can sit up there, move the camera around, pan in and out and I can say, ‘You know something? The level of oxygen in his blood has dropped to a very dangerous level and you need to stop doing what you’re doing right now and fix that and then try your intubation again.’ They don’t hear the alarms and they don’t see the stuff because they’re busy doing other things. And there is just the question of familiarity. I do this for a living; it doesn’t scare me anymore. And we can provide that sort of experience and expertise.”

An UrbanHub intensivist also commented on his ability to retain some emotional distance:

“We have our remote control from here that we can use to control three cameras that they have over there. We can see all the monitoring equipment, see the patient, see the x-rays, see the EKG’s and all the other stuff that we need. … We supervise them, and move the camera wherever we want … The system surprised us, how well it works. We really can see a lot. … We could see the pupils of the patient’s eyes. Clinicians on the ground … are so stressed caring for the children that they don’t pay attention to things that we can see since we are less emotionally involved. We can see what is happening on the whole … We can point out that a valve is not functioning too well. For example, a cardiac arrhythmia case: the ventilator connected to the child was not working so well; oxygen was not coming. Even before they had time to get that information on the monitor, even before alarms went off we could see that the chest was not moving well and we could tell them what was wrong. Another
time, they were trying to intubate but the child was nauseous and about to vomit. There again they are so anxious trying to maintain the airways to make the kid breathe. If you say, ‘Hey wait a minute, turn the kid to the side’ to avoid aspirating. It’s amazing sometimes by not being over there (we can be more effective). …We really can see a lot. The clinicians on the ground, in the field are so stressed caring for the children that they don’t pay attention to things that we can see, since we are less emotionally involved. We can see what is happening on the whole at that point.”

One hub intensivist states that what the spoke clinician needs is “having another set of eyes consulting them, helping them to make the decisions.” Another expert offers a similar comment about the importance of his role in reassuring the spoke clinicians that they are making the right decisions. In the interview, we asked whether there were circumstances in which he might say to a clinician at the spoke, “You are doing the right thing.” He replied: “There is a lot of that. ‘Yes, I agree absolutely with what you’re doing.’ These are the – yes, yes, yes – ‘I suggest doing this and you’ve already done that – we’ll send a transport team out.’”

Sometimes the clinicians at the spokes just need assurance that a specialist is present. In one episode a specialist suggested that the two doctors work together: “I said ‘You know, why don’t we observe this kid together, give him a couple of nebs (nebulizers) one after the other and let’s observe him in twenty minutes again. We’ll see how the kid responds.”

Many spoke hospital clinicians want to transfer patients immediately; however this can be risky. A Boston physician contrasts what might have happened had the transfer details been done over the phone versus the actual outcome in which they were able to use full video:

“…[without video] it would be a description over the phone. ‘We have this 17 years old that’s doing fine, having some mild headaches, having a little fever, we don’t know what it’s going to involve and want to transfer the kid. We have called the ambulance.’ I said, ‘wait a minute, let me look at the kid. We need a critical care ambulance, we need a critical care doctor, we need her to be ready for the transfer. …If she had been transferred without us seeing her it could be a disaster en route. The old fashioned way that most of the hospitals do over the phone, they never described her as sick as she was; when we looked at her and said, ‘This is a sick patient, we cannot put her on the ambulance and just send her, especially now during the traffic hours. We have to stabilize her over there as well.’ And as we are talking, within 10 minutes the patient collapsed over there. So at least they were prepared.”

Thus, the specialists that we interviewed at two hub hospitals contended that a) spoke clinicians are more anxious than experts because they don’t have the same level of skill; b) some spoke clinicians are, at least initially, anxious about being observed by hub experts; c) hub pediatric intensivists feel that when they use telemedicine they achieve a degree of emotional distance that allows them to take in more relevant information and thus more effectively guide and reassure the generalists.

6 DISCUSSION

From interviews with pediatric intensivists at two “hub” hospitals we uncovered evidence about the influence of emotions on telemedicine adoption and use. Anxiety – whether about using a new technology or out of fear of being exposed as incompetent – apparently led some clinicians to choose a more familiar technology, the telephone, when requesting help from hub specialists. This illustrates the familiar pattern of anxiety impeding new system adoption. Yet, some spoke clinicians did use telemedicine when confronted with critical care cases for which they had little prior experience and inadequate skills, and the specialists who provided help believe that their guidance helped the spoke clinicians provide better care under extreme stress.

We further learned that the intensivists believed that telemedicine extended their expert capacity to take in a great variety of clinical information and to focus on important details that escaped the attention of anxious clinicians at the spokes (because presumably stress caused tunneling of the spoke clinicians’ attention). Telemedicine also allowed the experts to achieve some emotional distance; they reported feeling less emotionally involved and better able to see the “big picture,” remain calm and
effectively guide the spoke clinicians. These early findings suggest that while stress can cause tunneling of attention for those clinicians who have less specialized and/or less practiced skills, the combination of emotional distance and high-level expertise allows medical experts to take note of important clinical details. This is an important finding that warrants further investigation in other time-pressed clinical situations (such as trauma care, ambulance care, and complex surgical care). Most observers contend that telemedicine provides the “next best” alternative to having an expert physically present in the room to guide the less-expert clinician. However, our finding about emotional distance suggests a more intriguing possibility. The experts that we interviewed indicated that telemedicine gave them a degree of emotional distance that they found beneficial, suggesting that in some circumstances telemedicine might be seen as superior to face-to-face consultation.

It is important to note that all physicians are trained to perform under stress in a variety of clinical situations. However (as mentioned in the introduction to this paper) pediatric critical-care situations are rare occurrences. Thus, even during their internships and residencies, pediatricians or emergency physicians may get few opportunities to learn how to provide effective care in these situations. Post-residency, clinicians at remote spoke hospitals will get especially few opportunities to participate in critical-care events involving young children, and also most of these remote hospitals do not have pediatric intensivists (with their higher level of post-residency training) on staff and available to coach other clinicians in these specialized techniques. With fewer than 120 physicians entering pediatric critical care fellowships each year, this situation is likely to persist for quite some time. While the numbers of board-certified intensivists on staff at tertiary-care centers and perhaps at suburban hospitals will gradually increase, there will continue to be a physicians with this specialized skill set at rural hospitals and clinics. And, with pressure to control costs and with the low frequency of pediatric critical-care episodes, most hospital administrators will choose to allocate scarce resources elsewhere.

Thus, when a critically ill or injured child does arrive at a rural clinic or hospital, the attending clinicians may not have all the knowledge and skills necessary to provide the best possible care and this shortcoming may increase their experience of stress, anxiety, and/or fear. Our interviews revealed that telemedicine can be helpful in these situations. The intensivists that we interviewed explained that specific system capabilities -- such as real-time video transmission and the ability to remotely control video cameras -- were important technical features that helped to reveal important clinical information to them and improved their ability to guide the clinicians at the spokes.

Because pediatric critical-care episodes are rare occurrences, the skills, knowledge, and confidence of even well trained clinicians will tend to erode due to lack of practice. To combat this issue, experts at the hub hospitals offered refresher training (sometimes delivered via the telemedicine tools) to help generalists keep their skills current. One specialist at UrbanHub felt that these training sessions actually reduced the number of requests for telemedicine system for consultations, because (he believed) the spoke clinicians now feel better prepared to handle pediatric emergencies and thus don’t feel as anxious when these emergencies arise.

In our study clinical experts freely shared their knowledge via telemedicine consultations, with little concern that this activity would reduce their power or professional standing. Physicians in a teaching hospital are, of course, expected to teach, and a telemedicine consultation is a form of education. Nevertheless, it was interesting to observe this apparent beneficence, since in contrast, some prior knowledge management studies (e.g., Cabrera and Cabrera, 2002) report that business experts sometimes decline to contribute to knowledge repositories, presumably out of anxiety or fear (of losing status or being deemed expendable). This finding also deserves further exploration to uncover specific aspects of hospitals’ work climates and incentive schemes that facilitate “unselfish” knowledge sharing. Perhaps organizations in other industries can draw some important knowledge management lessons from health care.
LIMITATIONS AND CONCLUSIONS

As a research in progress, to date our findings are based primarily on interviews with three key informants at two hub hospitals (interviews with other administrative and technical employees provided valuable background information but did not speak to this particular issue). In spring 2009 we are scheduled to interview clinicians at the spoke hospitals that these two hub hospitals serve. Until then, we will not be in a position to speculate as to whether generalists really were motivated to request telemedicine consultations out of fear/anxiety versus out of a dispassionate assessment of the skills that are missing from their repertoire, or some other reason. One vignette hinted that some spoke clinicians preferred to use a less transparent communication technology (the telephone) compared with video-conferencing, which might put this clinician’s mistakes in full view, causing embarrassment or further stress. A hub specialist believes that once trust is established, such concerns will fade into the background. This view is consistent with Dunn and Schweitzer’s (2005) behavioral experiments in which they find that emotions do not influence trusting behaviors when the trustee is someone familiar. Other studies have explored issues surrounding emotions, affect, and trust (e.g., Williams 2001, Weber, Malhotra, and Nurninghan 2005).

Our study findings thus far only hint at circumstances that may impede the use of telemedicine for pediatric critical care, and further study is needed to attain a clearer picture of the facts that impede or encourage adoption by the spoke clinicians. Also, our informants thus far have not brought up any instances when they felt that telemedicine impeded their ability to provide care or had adverse effects, but that does not mean that we can conclude that there have been no problems. Nor at this time are we able to conform whether the infrequent occurrence of critical care episodes is strongly or weakly related to participants’ experience of anxiety or fear, although the comments that we heard from our three informants at the two teaching hospitals were strikingly similar. At the June ECIS meeting we should be able to speak to these issues. Further in-depth interviews are needed to tease out a clearer picture of both positive and negative aspects of telemedicine use under time pressure.

Early findings from our research in progress point to fascinating issues concerning how emotions affect technology-mediated collaboration across organizational boundaries in risky, time-pressed situations. Several vignettes reveal specialists’ beliefs that fear motivates generalists to seek their help. However, we cannot as yet say whether and how specific features of the technology artifact affected this collaboration. In learning that hub specialists believe that generalists are motivated to participate in telemedicine services because of fear or anxiety about their ability to provide the best care to the critically-ill young patients in their charge, we wondered what actually goes on in the generalist’s mind. We do not know if these participants would feel more or less comfortable if the specialist were in the room with them. We do know that most rural hospitals will not have this choice (if they want their clinicians to have access to the guidance of specialists during critical-care episodes, they will need to use telemedicine).

At one of the hub hospitals that we visited, an administrator stressed the importance of having their hospital personnel regularly test the system and its network connectivity in order to ensure that spoke clinicians will be able to use the system when it is most needed. This individual observed that while clinicians are accustomed to employing a great variety of improvisational skills when providing medical care, many clinicians are taken aback when confronted with a piece of video conferencing equipment that is not operating correctly. It may just be a matter of noticing that a plug has come loose or a setting changed, but the clinicians will not know what to do to get the system working correctly. Clearly, while some clinicians are comfortable with a variety of information and communication technologies, others are less so. If they perceive that telemedicine is their only avenue available to get the expert guidance they need, then perhaps they will embrace it even if they normally shy away from using leading-edge technologies. In that case it can be helpful to have nearby technical support personnel on call, and it also may be helpful to give the hub specialist control over the cameras, able to zoom in and out on his/her own. Our reasoning here is that the hub specialist is under less stress
during a critical-care consultation and may be in a better position to perform these tasks than if the harried clinicians at the spoke site are expected to do this.

Our interviews revealed that the experts value their ability to use remote video to take in many more clinical details than are available in telephone consultations, as well as their ability to control the video from their end. This, combined with the findings about emotional distance suggests that system trust (trusting beliefs about ICT applications) interacts with emotions in ICT-enabled collaboration. In future studies we suggest exploring how emotions such as anxiety and fear interact with organizational trust, interpersonal trust, and system trust. For example, further research is needed to investigate specific technical features used by clinicians on both sides of telemedicine consultations (for chronic versus urgent care), and to closely compare how experts coach novices when using ICT versus in face-to-face situations.

This study explored specialists’ views on the effect of fear/anxiety on telemedicine usage in a single high-stress domain (critical-care pediatrics), characterized by infrequent episodes and extreme time pressure. Our interviewees emphasized that critical-care episodes occur infrequently in pediatrics, and that ongoing training is thus necessary to ensure that spoke clinicians will initiate telemedicine consultations in those situations when the hub experts can be most helpful. Further research is needed in order to determine whether these findings about emotional aspects of ICT-enabled collaboration would apply in other high-stress domains in which infrequent episodes and time pressure are at play, and to tease out the separate and interacting influences of frequency, time pressure and risk.

These are early days for critical-care telemedicine, especially in pediatrics; we are eager to learn more about this promising use of information and communications technologies to bring needed expertise to underserved populations in this and other clinical domains.

8 ACKNOWLEDGEMENTS

We gratefully acknowledge the assistance of the unnamed individuals who we interviewed at RuralHub and UrbanHub, who took time out of their busy clinical schedule to share their thoughts. We thank also the McDowell Research Center of the University of North Carolina at Greensboro, who provided funding that partially supported this study, and Bentley University which provided additional financial support.

Abstract

Recently, there has been a growing trend towards consumer-based healthcare in which consumers are increasingly becoming partners in their own care. One way of accomplishing this is to provide consumers with access to their health records through the use of Personal Health Record (PHR) systems. In spite of their potential benefits, recent research has shown that PHRs are not yet popular or well known to consumers. The overall objective of this research is to investigate the influences of various personal, behavioral, and environmental factors on the adoption and use of PHR systems by Canadian consumers. Drawing on both the information systems and behavioral healthcare literatures such a model is developed and presented. The proposed model will be validated using a longitudinal design over a period of 16 months involving patients from two local clinics. The study participants will be introduced to an existing PHR system at those clinics. The system will subsequently be made available for their potential use. Users will be surveyed at various points in time regarding their perceptions about the system utilizing both close-ended and open-ended questions. Collected data will be analyzed using structure equation modeling and qualitative data analysis techniques.

1. INTRODUCTION

Two important trends can be observed in the Canadian healthcare system (Urowitz et al. 2008): the advent of e-Health giving rise to a more important role for information technologies in healthcare (Eysenbach 2001; Tan 2005); and a shift towards consumer-based healthcare (Eysenbach and Diepgen 2001; Runy 2000) where patients are considered as partners in their own care process (Urowitz et al. 2008). For example, today’s educated and computer literate baby boomers who make up almost one in every three Canadians (Folker 2007) are facing health-related conditions as they age and are increasingly seeking health-related information from various sources including the Internet (Bliemel and Hassanein 2007). Providing access to personal health information through innovative technologies could potentially reduce the cost and complexity of healthcare delivery through efficient use of resources in the healthcare system (Raghupathi and Tan 2002). One such innovative technology is the use of Personal Health Record (PHR) Systems.

A PHR can take various forms including a stand-alone application or an Internet-based system (Endsley et al. 2006). PHRs are created, owned, updated, and controlled by an individual and/or others authorized by her/him. They contain a summary of a consumer’s lifelong health information such as allergies, home monitoring data (e.g. blood pressure), medications, laboratory test results, conditions suffered, treatments given, vaccinations, etc (Thomas 2006). Numerous benefits have been suggested for consumers utilizing PHRs. For example, they can access a wide range of reliable and credible health information leveraging this access to increase their understanding of their health condition and to be active participants in their own care (Cimino et al. 2002; Moehr and Grant 2000; Ueckert et al. 2002). PHRs put consumers in control of their own health information by allowing them to update their records either manually or by automated polling of information from visited care facilities (e.g. hospitals, physician offices) (Tang et al. 2006). By leveraging the control and access provided by PHRs, consumers could become empowered to better manage their health (Tang et al. 2006). For example, they could in collaboration with their physicians, detect disease in the early stages by observing trends in their health status (e.g. changes in blood pressure). They can also consult with their physicians on any usual conditions observed in their health records. Moreover, the system can alert people when their health records show such unusual conditions or exceptions (Tang et al. 2006) (e.g. a conflict between newly prescribed medications and previously or currently used ones). It is important to note that PHR consumers are not necessarily dealing with immediate medical concerns and can be ill or healthy.

PHR systems are also suggested to be beneficial for patients with chronic diseases (Heubusch 2007). Chronic diseases are often characterized by long latency requiring patients to be continuously aware of their condition in an ongoing collaboration with their caregivers (Folker 2007; Heubusch 2007). PHRs can facilitate patient-physician communications in an efficient manner through changing such communications from episodic encounters to continuous interaction (Tang et al. 2006). Furthermore, self-management activities and active patient participation in the care process are major parts of a successful chronic disease management program (Lankton and St. Luis 2005). A PHR system can facilitate such a high level of patient engagement (Tang et al. 2006).

In spite of all the aforementioned potential benefits for PHRs, recent research has shown that they are not yet popular with or well known to consumers (Sittig 2002; Cronin 2006). Very few studies have covered the reasons responsible for the lack of PHRs’ popularity. Existing studies have mostly concentrated on overviews to clarify the characteristics and functionalities of PHRs (Abrahamsen 2007; Atkinson et al. 2007; Brown 2007; Cronin 2006; Kim and Johnson 2002; Lafky et al. 2006; Sittig 2002; Tang et al. 2006; Thomas 2006; Yee and Trockman 2006). The few studies performed on the adoption of PHRs were for the most part not empirical in nature (Denton 2001; Iakovidis 1998; Jones 1999; Lafky and Horan 2008; Winkelman et al. 2005). These studies have put forth numerous factors that bring about the lack of PHR popularity. Of particular interest, Tang et al. (2006) suggest...
that behavioral factors may impact PHRs’ adoption, yet the role of such factors was not empirically tested. Hence there is a need for additional research in this area.

By developing and validating a model that explains the behavioral/social factors influencing consumers’ adoption and use of Internet-based PHR systems, this study pursues the following objectives: (i) to identify the behavioral/social factors influencing PHR system adoption and use among the consumers; (ii) to investigate the impact of individual characteristics (perceived health status, age, sex, Internet experience and education) on relationships in the model.

This paper is organized as follows: the proposed research model is presented in section 2 along with theoretical background and hypotheses. Details of the proposed research methodology are presented in section 3. Finally, the potential contributions of this research are discussed in section 4. Throughout this paper the words consumer, individual and patient are used interchangeably unless otherwise specified.

2. THEORETICAL BACKGROUND AND RESEARCH MODEL

Social Cognitive Theory (SCT) (Bandura 1986) will form the basic framework for conceptualizing a research model for this study. SCT explains human behavior as an interaction between behavioral, environmental and personal factors. SCT has been widely employed in the IS literature with demonstrated validity (e.g. Chan and Lu 2004). Specifically, this theory is a widely accepted model for explaining individual behavior in the IS area (e.g. Compeau and Higgins 1995). SCT states that a person takes an action that has personal cognition in a social environment (Bandura 1986). This notion fits well into the context of this study since individuals need to make a decision to adopt a PHR system for managing a healthy life while interacting with the medical environment through the system. The proposed model in this study (Figure 1) builds on the above SCT categories while incorporating related constructs from both the IS and healthcare literatures. The underlying theories for the proposed model are examined below.

Since PHR systems are information systems, IS-related constructs are incorporated in the proposed model. The Unified Theory of Acceptance and Use of Technology (UTAUT) aims to explain user intentions to use a new computer technology and subsequent usage behavior (Venkatesh et al. 2003). This theory was developed through a review and consolidation of the constructs of eight theories that were previously employed in the literature to explain usage behavior regarding a new computer technology. The eight underlying theories include Technology Acceptance Model (TAM) (Davis 1989), Theory of Reasoned Action (TRA) (Fishbein and Ajzen 1975), Theory of Planned Behavior (TPB) (Ajzen 1985), Motivational Model (Davis et al. 1992), combined TPB and TAM (Taylor and Todd 1995), model of personal computer utilization (Thompson et al. 1991), innovation diffusion theory (Rogers 1995) and social cognitive theory extended to personal computer usage (Compeau and Higgins 1995). UTAUT holds that three key constructs, namely performance expectancy, effort expectancy, and social influence are direct determinants of usage intention (Venkatesh et. al. 2003). Moreover, gender, age, experience, and voluntariness of use are shown to moderate the effect of the three key constructs on usage intention (Venkatesh et. al. 2003).

Due to the healthcare context of PHRs, there is also a need to consider relevant theories from the healthcare literature. Lee et al. (2007) argue that the design of PHR systems should be informed by the Health Belief Model (Janz and Becker 1984). The Health Belief Model seeks to identify antecedents for an individual’s health behaviors which include activities undertaken by the individual for the purpose of preventing or detecting disease (Rosenstock 1966). It asserts that the likelihood of a person taking a preventive healthcare action is the outcome of his/her perceived health threat as well as the benefits/costs associated with engaging in that action. These variables are in turn influenced by demographical, social and psychological cues (Janz and Becker 1984; Jayanti and Burns 1998; Rosenstock 1966). Using PHR systems is similar to such behaviors since such systems are intended to help consumers maintain a healthy life. Hence, it is reasonable to consider using PHRs as a preventive healthcare behavior. Consequently, constructs such as subjective health knowledge and health
consciousness are added to the model from the healthcare literature and hypothesized to have a direct impact on behavioral intention. Additionally, inter-relationships between the aforementioned constructs from both the IS and healthcare literatures are incorporated in the model as appropriate. The relationships between the constructs in the model shown in Figure 1 are explained below in detail.

The main objective of this study is to identify the behavioral/social factors influencing PHR system adoption (intention to use) and usage (actual use) among consumers. Based on Fishbein and Ajzen’s (1975) definition, intention to use, in this paper, is a measure of the strength of an individual’s intention to use a PHR system as a preventive health care behavior. On the other hand, actual use is a measure of the frequency and extent of using a PHR system by users (Venkatesh et al. 2003). Prior research has shown a strong correlation between behavioral intention and actual system use (Venkatesh and Davis 2000; Venkatesh et al. 2003). Thus, we hypothesize that:

**H1:** Stronger consumer intentions to use a PHR system will positively influence her/his future usage of such a system.

**Facilitating conditions** is defined as the degree to which an individual believes that organizational and technical support is provided for using a system, and has been shown to be a direct determinant of system usage (Venkatesh et al. 2003). Within a healthcare setting, caregiver support has been suggested to have a positive impact on consumers using PHRs (Johnson and Singal 2006; Tang et al. 2006). Caregiver support is incorporated as part of the facilitating conditions in the proposed model as described in the methodology section. Therefore, the following is hypothesized:

**H2:** Facilitating conditions will have a positive influence on an individual’s actual usage of PHR systems.

**Social influence** is defined as “the degree to which an individual perceives that important others believe he/she should use the new system”, and it has been shown to be a major determinant of behavioral intention to use new technologies (Compeau and Higgins 1995; Venkatesh et al. 2003). Moreover, Janz and Becker (1984) have shown the positive impact of social influence on intentions to

![Figure 1. Proposed research model](image-url)
perform preventive healthcare behavior. Since it has been argued here that using PHR systems is a form of preventive healthcare behavior, the following is hypothesized.

**H3:** Social influence will have a positive influence on an individual’s intentions to use PHR systems.

**Effort expectancy** is defined as the degree of effort an individual believes is required for using an information system, and has been shown to negatively impact an individual’s intention to use new technologies (Thompson et al. 1991; Venkatesh et al. 2003; Wilson and Lankton 2004). In a preventive healthcare context, Janz and Becker (1984) acknowledged the impact of difficulty of taking a preventive healthcare action as a barrier to performing that specific action. Such difficulty is similar to the concept of effort expectancy. Therefore, the following is hypothesized:

**H4:** A higher effort expectancy associated with using PHR systems will negatively influence an individual’s intention to use such systems.

**Performance expectancy** is defined as the degree to which an individual believes that using an information system will help him/her attain benefits in his/her job (similar to health benefits attained through using a PHR system). Performance expectancy has been shown to be a determinant of behavioral intention to use technology (Davis 1989; Venkatesh et al. 2003). On the other hand, Jayanti and Burns (1998) have acknowledged the positive impact of the degree of ease associated with performing a preventive healthcare behavior on individual’s likeliness of performing such behaviors. Moreover, the belief of important others supporting a particular behavior has also been shown to impact an individual’s assessment of outcomes associated with that behavior (Compeau and Higgins 1995). Finally, effort expectancy has been shown to be a direct determinant of performance expectancy (Venkatesh 2000). Similarly, Davis (1993) has shown the relationship between perceived ease of use and perceived usefulness of an information system which are similar to effort expectancy and performance expectancy in the proposed model (Venkatesh et al. 2003). Thus, we hypothesize that:

**H5:** A higher performance expectancy associated with using PHR systems will positively influence an individual’s intention to use such systems.

**H6:** Social influence will have a positive impact on an individual’s performance expectancy in using PHR systems.

**H7:** A higher effort expectancy associated with using PHR systems will negatively influence an individual’s performance expectancy associated with using such systems.

Computer **self-efficacy** refers to an individual’s belief of having the capability to use computers (Compeau and Higgins 1995). This definition can be extended to the belief of having the capability to use an Internet application such as a PHR system. It has been shown that belief of important others supporting the use of technology, positively impacts an individual’s self-efficacy regarding such usage (Compeau and Higgins 1995). Moreover, self-efficacy has been shown to also have an effect on perceived ease of use which is incorporated here as effort expectancy. Individuals with higher levels of self-efficacy will perceive the system as being easier to use (Venkatesh 2000). Finally, self-efficacy was shown to have an impact on performance related outcome expectations regarding the use of a computer system (Compeau and Higgins 1995). This latter construct is incorporated in the proposed model as performance expectancy, thus, we hypothesize the following:

**H8:** Social influence will have a positive impact on an individual’s self-efficacy regarding the use of a PHR system.

**H9:** A higher level of an individual’s self-efficacy regarding the use of PHR systems will negatively influence his/her effort expectancy in using such systems.

**H10:** A higher level of an individual’s self-efficacy regarding the use of PHR systems will positively influence her/his performance expectancy in using such systems.
Subjective health knowledge is defined as an individual’s storehouse of healthcare information (Jayanti and Burns 1998), and has been shown to have a positive effect on individuals’ likelihood of performing preventive healthcare behavior (Boechner et al. 1990). Subjective measures for health knowledge are well established in the literature, and they cover general health information rather than information about specific symptoms and cures. Moreover, Jayanti and Burns (1998) argue that subjective health knowledge has a positive impact on an individual’s assessment of positive outcomes related to performing a preventive healthcare behavior. Therefore, we hypothesize that:

H11: A higher subjective health knowledge level possessed by an individual will positively influence his/her intention to use PHR systems.

H12: A higher subjective health knowledge level possessed by an individual will positively influence her/his performance expectancy associated with using PHR systems.

Health consciousness is defined as “the degree to which health concerns are integrated into a person’s daily activities” (Jayanti and Burns 1998). Prior research has shown that individuals who are health conscious are much more likely to engage in a preventive health care activity (Jayanti and Burns 1998; Kraft and Goodell, 1993; Rosenstock, 1966). Since in this research using PHR systems is considered to be a health care behavior, it is expected that individuals who are more health conscious will exhibit higher intentions to use PHR systems. Moreover, Janz and Becker (1984) showed a positive influence of social influence on health consciousness. Therefore, we hypothesize that:

H13: Individuals with a higher level of health consciousness will exhibit a greater level of intention to use PHR systems.

H14: Social influence will have a positive influence on an individual’s level of health consciousness.

3. RESEARCH METHODOLOGY

Research setting: The research model presented above will be empirically validated through a longitudinal field study involving patients using an actual Internet-based PHR system. Performing a longitudinal study will allow the investigation of factors as they evolve during the active process of adoption decision-making (Venkatesh et al 2003). The study will be conducted at two local clinics, namely Stonechurch Family Health Centre1 and the McMaster Family Medicine2, located in Hamilton, Ontario, Canada with almost 35,000 registered patients. There are currently 27 physicians, 60 residents and 30 nurses, nurse practitioners, and allied health professionals practicing at these clinics. MyOSCAR3 is an Internet-based PHR system associated with the above clinics which incorporates typical PHR functionalities including communication with healthcare team, requesting copies of records, prescription renewals, appointment requests, access to reliable health information, etc. There are currently 100 users registered with this PHR system which will be used to conduct this research. Prior to testing the hypothesized relationships, and in order to refine/enrich the proposed model, the concerns and experiences of a subset of the current users of the PHR system will be investigated through conducting two focus group sessions with 5-8 participants. Each session will be lead by a facilitator and a recorder will be available in order to capture all the responses (Basch 1987). Collected data will be analyzed in order to identify particular patterns, themes or concerns which are mentioned repeatedly by the respondents (Bender and Ewbank 1994). NVivo will be used as the software tool for analyzing the data (Richards 1999). Mingers (2001) suggests that research results will be richer and more reliable if different research methods from different paradigms are mixed together.

Pilot study: Prior to conducting the actual study, a pilot study involving 30 new users of the PHR system under study will be performed. The pilot will also have a longitudinal design which will be

---

1 http://stonechurchclinic.ca/
2 http://fammedmcmaster.ca/
3 http://www.myoscar.org
conducted over a period of two weeks. At the beginning, instructions on using various features of the system will be provided to the participants using a short online video. Then, participants will be asked to fill out a survey containing the model measures as well as questions about demographics and perceived health status. Two weeks later, log files of the PHR system will be examined to measure actual usage through objective measures based on frequency and extent of system use. Participants will be encouraged to use the system by asking them to complete specific tasks simulating realistic scenarios encountered by typical users during the pilot study to ensure the collection of enough data to achieve the objectives of the pilot study. Results from the pilot study will be used to: conduct a qualitative analysis based on the open-ended questions and to refine the model; measurement scales for the model constructs will be assessed and refined; and any potential technical issues or problems with procedures will be identified and resolved.

Main study: Prior to starting this research study, a research ethics protocol will be prepared and submitted to the McMaster Research Ethics Board which is the body responsible for reviewing and approving all research studies involving human subjects at McMaster University. This protocol will include a consent form that all participants will be asked to sign prior to joining the research study. The consent form will provide potential participants with information regarding the objectives, nature as well as any potential risks of the study. It will also explain the measures put in place to ensure confidentiality of subjects' collected information and the option to drop out of the study anytime at their will.

Data collection for the actual study will be performed at two points in time over a 16-month period. At the beginning of the study participants will be provided with a short online video tutorial on how to use various features of the PHR system. Then, a survey will be conducted to gather measurement scales for the model factors except for actual use and facilitating conditions which should be measured after users have actually experienced using the system. Individual characteristics (demographics, details of previous computer and Internet use as well as perceived health status) will also be collected at this point. Data collected at this point will be used to validate a model for antecedents of behavioral intention to use PHR systems. Sixteen months later at the end of the study, actual system usage will be measured by analyzing the log files of the system. In addition, subjects will be asked to respond to a survey instrument measuring facilitating conditions. Data collected at this point will be matched to previously collected data and used to validate the full model (including both behavioral intention and actual use). Moreover, perceived health status will be measured again in order to investigate the existence of any meaningful change in this construct before and after using the PHR system. Based on prior research experience in the abovementioned clinics, a 16-month period was chosen to allow for sufficient patient-caregiver encounters thus providing participants with motivation to use the PHR system. The time period between measurement of model constructs and actual use will also allow the establishment of temporal sequencing thus avoiding common method bias (Compeau et al. 1999).

Measurement instruments: In order to ensure content validity, measurement scales for constructs in the proposed model will be selected from extant literature, and will be slightly adapted to reflect the context of this study. Measures that require considerable change will be re-developed following the guidelines suggested by Moore and Benbasat (1991). Intention to use will be measured using the 3-item scale by Venkatesh et al. (2003). Other constructs will be measured as follows: performance expectancy using the 7-item scale by Compeau and Higgins (1995); effort expectancy using the 4-item scale by Moore and Benbasat (1991); self-efficacy using the 10-item scale from Compeau and Higgins (1995); social influence using the 4-item scale from Thompson et al. (1991); health consciousness using the 6-item scale from Jayanti and Burns (1998); subjective health knowledge using the 5-item scale from Jayanti and Burns (1998). Finally, a formative construct will be devised for facilitating conditions to capture both concepts of technical support (Thompson et al. 1991) and caregiver support (Paswan and Young 2002) relying on both IS and healthcare literatures. Measurement scales for this construct will be developed following the three stages of item creation, scale development and instrument testing suggested by Moore and Benbasat (1991) while considering guidelines on specifying formative constructs by Petter et al. (2007). Perceived health status will be measured using
the 2-item scale from Kaplan and Baron-Epel (2003). A subjective measure for health status is employed as an individual’s perception of his/her health status is likely to influence his/her adoption and use of a health service like PHR system (Ware et al. 1981).

Qualitative analysis: Participants will also be asked to respond to open-ended questions relating to their concerns and experience with using the PHR at the two points of data collection in this study. Subjects’ responses to open-ended questions will be analyzed using NVivo in order to enhance the robustness of results as well as to strengthen the findings through triangulation (Benbasat et al. 1987). Triangulation involves validating the results by combining a range of methods (Tashakkori and Teddlie 1998).

Model validation: Structural Equation Modeling (SEM) will be used to validate the proposed model. SEM allows the analysis and investigation of unobservable variables that are indirectly measured from observable variables (Chin 1998). In particular Partial Least Squares (PLS) will be used as it is applicable to both exploratory and confirmatory research which is appropriate for this study and as it supports having both reflective and formative constructs in the model (Chin et al. 2003; Gefen et al. 2000). Further, PLS gives optimum prediction accuracy because of its prediction orientation (Fornell and Cha 1994). The measurement model in PLS will be assessed in terms of item loadings, internal consistency and discriminant validity (Gefen et al. 2000) using SmartPLS4 software.

Impact of individual characteristics: In order to investigate the impact of individual characteristics on PHR system usage, various statistical techniques will be employed. First, Chow’s (1960) test will be used to investigate whether the validated model varies for individuals with various perceived health statuses. To this end, subjects will be divided into two groups of well and un-well people based on their responses to the perceived health status scale. One PLS model will then be developed for each group and corresponding path coefficients will be compared across the two models using Chow’s test to identify any significant variations (Chin 2000). The same approach will be used to compare PLS models for males and females. Second, the impact of age, education level and frequency of Internet use will be examined by creating a series of control models. To this end, for each of the aforementioned variables, one construct will be added to the model and additional paths will be created from the new construct (e.g. age) to all the existing constructs. Then, variance explained for the constructs in the original model and the controlled models will be compared. Finally, we will examine other possible relationships which are not hypothesized, through a saturated model analysis (Chin et al. 2003). In addition, any possible interaction effects between independent variables will be examined using PLS as suggested by Gefen et al. (2000).

Sample: The sample size for validating the model in PLS is determined by the maximum of 10 times the number of paths leading to a construct and 10 times the number of items for the most complex construct (Chin et al. 2003). Self-efficacy is measured using the most number of items (10) in the proposed model resulting in a minimum required sample size of 100. Performing the Chow test will require twice as many subjects (200) since the models should be tested for the two groups separately (Ghilagaber 2004). To allow for possible spoiled surveys 300 participants will be recruited. Previous research experience in the clinics indicates a 50% initial response rate. Considering the longitudinal nature of the study and the fact that questionnaires will be sent out at two points in time, it is reasonable to expect that part of the subjects might drop out of the study. Assuming a 50% dropout rate, there is a need for initially targeting 1200 adult registered members of the clinics in order to ensure having 300 participants throughout the study. Invitations to participate in the actual study will be sent by regular mail to a randomly selected sample of 1200 adult patients and followed up with reminder phone calls. Approached members of the clinic will be incented to participate through opportunities to win prizes. In order to assess non-response bias, respondents and non-respondents of the both surveys will be compared, based on demographic information (Compeau et al. 1999).

4. POTENTIAL CONTRIBUTIONS

Personal health record systems have the potential for helping consumers to take over more of their own care, thus reducing the burden on the healthcare system. But it is essential to improve the adoption rates of such systems if they are to have an impact on patient care. Behavioral issues have been identified as major inhibitors to adoption of PHR systems by consumers. Thus, there is a special need to focus on consumer behavioral factors influencing intention to use health information systems in general and personal health record systems in particular. While there is a plethora of research discussing adoption models for information systems in general, only a few studies have focused on the adoption of information systems in healthcare settings. The proposed study attempts to address this gap by seeking to develop and validate a theoretical model explaining the factors influencing an individual’s intention to use personal health record systems as a preventive health care behavior. Although this research is being carried out in a Canadian context, it is highly relevant for other developed countries that have similar demographic and healthcare system characteristics.

From an academic perspective, results of this research will contribute to the IS and e-Health literatures by developing an adoption model specific to PHR systems. It is hoped that this research will attract the attention of researchers to further develop and test constructs and models applicable to consumer intention to use personal health records and other health information systems as a preventive healthcare behavior.

Practitioners will also gain a better understanding of consumer preferences through this work, resulting in practical guidelines for PHR systems’ development, promotion and use. Results from this research can help direct attention to the most influencing adoption factors while proposing solutions that mitigate consumer resistance. Such solutions will enhance the PHR benefits for consumers and the healthcare system. Technology providers will benefit by informing the design of their proposed systems based on these results. This, in turn, will lead to higher rates of adoption and success of the Internet-based personal health records. Health care providers will also benefit from the results of this research by being able to deliver a higher quality level of care at a lower cost and complexity by involving patients in their own care through PHR systems. Given the growing importance of consumer-centered healthcare and e-health, adoption studies of this nature are both timely and relevant.

Abstract: The purpose of this paper is to explore attitudes towards IT among various categories of health care staff; health care professions. We will identify problem areas that may be the reasons for why different attitudes among different professions at a healthcare organisation exist, and subsequently we will analyse how this may have impact on how to make sense of IT use. The research question is: What factors may explain differences regarding attitudes to IT among different professions in a health care organisation? The paper reports from a particular study of the “NU” healthcare organisation in west Sweden. The results reveal two main problem areas: i) the infrastructural and; ii) the socio-organisational. These are discussed as analytical implications for bridging the gaps between different professions in health care organisations.

1 INTRODUCTION

As modern information technologies (IT) now offer new possibilities for improving almost every aspect of health care, their implementation is a highly relevant and fast accelerating process. The initiatives themselves vary greatly from scattered single projects of various ICT solutions to large national programmes. The domain has been studied intensively during the last decades. The studies have been conducted in several ways and from different perspectives. Many researchers have used empirical approaches to analyse how IT can support standardisation and flexibility (Hanseth, 1996), work practice and coordination (Lundberg, 2000), IT and gender (Wilson & Howcroft, 2000) and adoption in context (Chiasson & Davidson, 2004; Cho et al, 2008). All these studies address the issue of IT and its design and use in a medical work context. For instance, Heath & Luff (2000) present several examples where seemingly innovative and reliable systems have failed when introduced into specific and critical organisational contexts, such as health care work. In much of these examples the system in question does not necessary cause severe problems, but it is simply “under-used” or rather. They call for further examples that actually take the serious account of detailed user studies attempting to exploit the fundamentals of and attitudes towards new technology, in order to find implications for re-design or adopt them. Wilson & Howcroft (2000) highlights another aspect when they point out that IT use is more or less closely related to socio-cultural perspectives such as gender, roles, and the individual competence level. The results of their studies show that health care workers associate
information systems and information technology to effectiveness and control, which is perceived as being in conflict to the traditional values of healthcare: care and humanity. In Chiasson & Davidson (2004) they discuss the use of IS theory in understanding IT adoption in health care. They call for a deeper consideration of the actual context of health care settings in order to explore new challenges for both the health care industry (practitioners) as well as to develop new IS theories (researchers).

We argue that research aiming to understand people’s assumptions, attitudes, and knowledge is of special interest when discussing change in organisations, especially when change is caused by IT. Many varying factors contribute to the understandings of attitudes towards IT in health care. Many of the factors concern the flexibility of the systems and whether they were 'fit for purpose', along with the confidence and experience of the actual IT users. We believe that attitudes of practitioners are a significant factor in the acceptance and efficiency of use of IT in practice. There is a clear correlation between people’s mental frames and their technology use. Previous research indicates that during conditions where the technological frames of key persons and divergent stakeholder groups, such as managers, technical experts and users, differ a lot the result can be even more complex and cause problems and conflicts related to IT design and use (Orlikowski & Gash, 1994; Constantinides & Barrett, 2006).

In this paper we take this previous research seriously. Treated as purely technical in nature, IT issues in health care should gravitate towards a more soft and people-oriented approach. Point of care delivery is vital for the success of any application in the clinical healthcare environment. We aim to explore attitudes towards IT among various categories of health care staff; health care professions. We will identify problem areas that may be the reasons for why different attitudes among different professions at a healthcare organisation exist, and subsequently we will analyse how this may have impact on how to understand and use IT. The research questions is: What factors may explain differences regarding attitudes to IT among different professions in a health care organisation? The paper reports from a particular study of the “NU” healthcare organisation in west Sweden. By attitudes we mean peoples assumptions and expectations that relate to their understanding and use of IT. We assume that these are tightly related to the knowledge and experiences developed during IT implementation and adaptation processes. This is based on assumptions used for instance in theories developed by Henfridsson (1999). Orlikowski & Gash (1994) use the concept ‘technological frames’ when they analyse different attitudes towards technology. They say that individuals create mental models and expectations about their future use of IT in work organisations. Here we will identify the gap that may exist in between the different models of the technological aim and how this gap may be bridged.

2 RESEARCH METHOD

We have used ethnographic methods as a means to study contexts where the organisation of human interaction and computer support is apparent. Ethnography is a collection of methods for collecting and analysing data from empirical settings. According to Hammersley & Atkinson (1995) the importance of attitudes is obvious, which means that we try to understand and make sense of actors and activities in the organisation under study.

Our research was conducted as an ethnographic study of a health care organisation in Sweden, the NU Health Care. The NU health care is divided into five hospitals in different cities, two of the hospitals are complete with emergency departments and the other is classified as local area hospitals. The study took place in two of the five sites of the highly distributed organisation. In order to get a
coherent understanding of the work conditions and the people's attitudes to IT we strove for a broad representation from various key professionals from both the emergency department and the IT department. All together we interviewed 20 persons that represented the operational as well as management categories at both departments. Their professions were ranging from doctors, nurses, secretaries, management, IT co-ordinators, supporters to ambulance drivers. As mentioned earlier, the two sites we studied were located in two towns. Here we can suppose that there exist different cultures that have developed over the years. However, this perspective addressing a more geographical and cultural aspect we have not been into so deeply.

We applied semi-structured interviews. Some questions were adjusted in order to capture the specific conditions of the different interviewee categories. The questions were grouped under headings such as current work activities, attitudes to IT, the fusion and integration of the organisations into “NU”. The interviews lasted for 45 to 75 minutes each and were all recorded. Except the interviewer we were at least one more to take notes and comments during the interview session. In our study the informants were interviewed in their real work place and wore their actual working clothes. A consequence of this may be that the attitudes recorded in the interviews are rather expressed in a role-playing game, from a perspective of what they should say rather than what they in fact like to say.

By using qualitative analysis to the empirical data, many researchers see the potential for informing appropriate lessons learned for improving the design and use of IT. (e.g. Hughes, Randall, and Shapiro, 1992). In our analysis we try to be constructive in the situations where we found a “gap” between different technological frames among the different professions. In this analysis we did not necessarily see typical design issues but rather analytical findings that may have impact on the design as well as use and adaptation of IT in the organisation. Before the analysis took place we read the material several times. We interpreted the data through continuous discussions. At the same time it was possible to reflect upon the situation recorded and this is of special importance in long, qualitative interviews, according to McCracken (1988).

3 ATTITUDES TO INFORMATION TECHNOLOGY

There are several perspectives that relate to people's attitudes to technology, on the one hand the perspective that relates to the individual and on the other hand the one that relates to social processes within the organisation. To be able to interact with technology people have to make sense of it, and in this sense-making process, they develop particular assumptions, expectations, and knowledge of the technology, which then effect their actions toward it. While these interpretations become taken-for-granted and are rarely brought to the surface and reflected on, they nevertheless remain significant in influencing how actors in organisations think about and act toward technology, (Orlikowski & Gash, 1994). Further, Orlikowski & Gash (1994) suggests a conceptual framework when studying people’s underlying assumptions, expectations, attitudes, knowledge and experiences of technology. These interpretations of technology, technological frames, are central to how people interact with technology. The framework consists of three categories that can be applied on empirical data to characterise the result.

- **Nature of Technology** – refers to people’s images of the technology and their understanding of its capabilities and functionality.
- **Technology Strategy** – refers to people's views of why their organization acquired and implemented the technology. It includes their understanding of the motivation or vision behind the adoption decision and its likely value to the organization.
• Technology in use – refers to people's understanding of how the technology will be used on
a day-to-day basis and the likely or actual conditions and consequences associated with such
use.

These conceptual models or technological frames are essential when the individual interpret and
understand his and others actions toward information and communication technology. It is however
important to emphasise that these interpretations have a distinct social dimension. They appear,
develop and change in interaction with the information technology as well as with other people.

A sociologist who has great influence on the understanding of how people relate to information
technology is Karl Weick. Weick (1995) consider that sensemaking can start with someone noticing
something different in the organisation. There are several barriers to make these assumptions public
and accepted, although one ought to consider that the problem is obvious. It may be something very
complex and therefore difficult to understand. Orlikowski & Gash (1994) refer to the same
phenomenon when they argue that pre-understanding play an important role under these
circumstances.

Henfridsson (1999) has been studying sensemaking in organisations related to adaptation of IT. He
proposes that Karl Weicks (1995) sensemaking perspective is especially useful in order to understand
IT-adaptation in a micro-perspective. Henfridsson has been studying the process, which an
organisation transits when IT first is introduced and until the technology is a part of people's taken-for-
granted conceptions. He also defines three elements of this transitional process, between the phase
associated with ambiguity about an IT-artefact and the following phase of common-sensible use of the
same IT-artefact. The elements are referred to as “enactments” and can be described as identity-
construction, self-fulfilling prophecies, and organisational defences. In our study Orlikowski and Gash
may help us in understanding the different attitudes from the perspective of an individual professional
 technological frame. The categories that they are suggesting can make it possible to obtain a clear
picture of an actual condition in the process of IT-adaptation.

4 RESEARCH SITE: THE “NU” HEALTH CARE ORGANISATION

The study was conducted in the NU health care in Sweden. The NU health care is divided in five
hospitals in different cities, two of the hospitals are complete with emergency departments and the
other is classified as local area hospitals. In the below sector the organisational structure, that faced the
reality when the study was conducted, is described. At this time there was although a very unstable
situation characterised by organisational changes. This comes from political turbulence as well as from
constant threats about economical reductions for the health care sector in general, but most important
was however the discussion that dealt with the question of closing one of the emergency departments
in the NU health care.

4.1 The IT-department

There are three people sharing the role of IT-manager, one of those are also responsible for the IT-
strategy within the NU healthcare and is also a doctor. As an IT-strategist he also participates in the
regional IT-managing group, which are supervising the IT-director and have the primary responsibility
for IT in the region. There is also an IT advisory team that function as a link between the health care
management and the IT managers, in this team both practitioners and IT-people is taking part.
4.2 The emergency department

The emergency department is divided in two departments; each of them located on different hospitals in different cities. The two departments have one common manager. There are several section managers on each department responsible for scheduling, personnel businesses among other things. The emergency department has a medical department, a surgeon department and an emergency department for children, ears and gynaecology and during the nights and weekends. In the clinic nurses, assistant nurses, doctors and medical secretaries works. Every department has their own IT-coordinator that function as the primary support to the personnel.

4.3 The information in the healthcare system

The information flow in the healthcare sector is complex. It can be divided into three categories. There is the information that is protected by the law of secrecy, the so-called medical records where patient information is collected in archives. The information includes individual information, diagnoses and treatments for every contact that the person has had with the department. The information system also includes an administrative information volume, for example messages from the personnel department, protocols, and notes from meetings among other things.

When it comes to information that aim to support medical treatments, documents are created by one individual that has the expert knowledge within the specific area. This information is then used in a variety of different documents and is part of many different document-flows. Either the document is used as it is or it is read and rewritten. This duplicating of information involves many risks. When the document is distributed throughout the organisation, it is difficult to determine what version is the most recent. It is impossible to know how many who has interpreted and rewritten the information, and therefore it is hard to know if the original message is changed. As expressed by one of the IT-coordinators:

“The information handling in the healthcare is extremely complex. There is a need of one solid group of people who really understand how systems is constructed in order to describe the handling of information in the health care properly and to deliver the specification to the people who are going to develop this. I do not think we have ever succeeded with it...we must develop solutions that generates something useful for the people that are making the beds and are helping the patients on the health department. If we cannot do this soon, then they won't understand why we buy a computer and put it in the expedition. ...We have a long way to go, the health care need to mobilize a huge knowledge to be able to do the descriptions that is needed.

5 SENSE-MAKING OF IT IN THE “NU” HEALTHCARE

The ethnographic study has provided an understanding of the sensemaking of IT in the organisation. There are large differences between different groups of professions, though within one profession the sense making has shown to be relatively homogeneous. From our empirical material we have tried to crystallise the different approaches to IT, put them together in groups and identify the contrasts between them. To explain the different approaches to IT we have derived two comprehensive categories that are argued to constitute the essential problem areas: infrastructure and socio-organisational problems.
5.1 Infrastructural problem areas

In the infrastructural processes the present systemic conditions can be seen as a main problem. We found three subcategories, which we decided to name activity-adapted functionality, communication and integration between systems together with co-ordination of initiatives.

5.1.1 Activity adapted functionality

In the NU health care they have only started the work with descriptions of work processes and routines. This work has been started to avoid creating IT solutions with weak coupling to the organisational activities.

The reason is that some people in the organisation have realised the importance of considering the IT infrastructure to support organisational activities. The IT technicians often see as their speciality to secure the technical specifications and other requirements on the IT equipment. People in the NU-organisation are concerned with that IT have proper functions to help them in their daily work. But they are not always aware of the need for functions to cooperate. Different professions here think in different ways. The knowledge about the activities within different areas in the organisation, co-ordination between departments and the technical knowledge do not always walk hand in hand.

People who order new systems need knowledge about organisational needs. When ordering new systems the discussion easily drifts to first of all specify the equipment and its details. The staff in the healthcare is enthusiastic, but at the same time disappointed or dissatisfied. The management often is perceived as alienated from the need of IT support in different areas in the organisation. For example when an Intranet is created there is a risk that management sees and compare this to an information site on the Internet and the references become incorrect.

There is also a problem consisting of communication, where management is not aware of the complexity of managing information. If IT should satisfy the requirements of different work activities in the organisation, a different approach to is needed. The ambition could be to go from standardisation to methods which are characterised by de-central requirements and co-ordination.

5.1.2 Communication and integration between user levels and system levels

The vision is to have access to the patient’s records wherever the patient is located. The vision is also that the systems are open and able to communicate with each other. From a user level perspective the routines are almost the opposite today:

“We are too bad in describing our requirements in the NU health care. Often it is too urgent, the clinics miss the long term thinking about IT support. We are often too late...”

People within the IT profession at “NU” needs to participate in an earlier phase in the requirement process. Both the IT department and the clinical departments need to get together and come to an understanding about functions in a desired system. It could then be easier to formulate the requirements before looking for suitable systems. There is a great amount of work going on at the IT department on standardisation of the technical platform and the products in use. They also try to standardise the user interfaces on the screens.

But from a system level perspective, there is another gap as well. How should the systems exchange information? Today there is a lack of knowledge about principles of standardisation. They are quite unaware of that the standardisation often has an impact on making a choice of a system and that it could be crucial in creating suitable systems- and communication solutions. The integration
between systems is almost non-existent. For example the system for patient case books is completely separated from the system for patient administration, which handles notices to appointments, next visits, diagnoses, registrations and so on. At one clinic they use three different systems to complete the patient care documentation. The systems have to be activated at the same time because some of the information in one of the systems must be manually registered in another system. The work of harmonisation of systems in the NU health are is going on, but is often met with suspicion.

“The Västra Götaland region wanted that system [Melior], we, used to work with the old system was not asked, as usual.”

When choosing a system it is important to analyse what the system should support and if there is need of a system which allow integration between systems in a smart way.

Most of the patient’s records are paper-based today. Though there is an objective that all records should be computer-based in 2002. Medical records are handled separately by each clinic, and each clinics have separate records for each patient they have treated. If the patient is coming to a new clinic it is impossible for them to see if and what medicine is previously prescribed. The consequence is that much time in spent looking for old records in archives at the different clinics or records are freighted by taxi between different hospitals.

“It should be possible to fill in the forms of X-ray referrals, laboratories referrals etc at the computer. It is bad that it is not possible today. At Huddinge, where I have worked before, the possibility existed already in 1979. It is badly managed by the management. Therefore there are no uniformed systems. It will be difficult for us because we need all three systems. It will probably change very much.”

5.1.3 Co-ordination of ideas, initiatives and projects

The results show that there is an optimistic attitude to the future possibilities with IT, both at the operative and the management level. Some different initiatives have already begun, which could be seen as embryos to a positive work towards changes. There is a tendency to invest money and resources on many different small IT-related projects.

In the organisation there are many fruitful ideas about systems for more efficient administration. Workings groups exist within clinics at both NÄL and Uddevalla to co-ordinate the work when new jointly systems are introduced. As an example a project with development of an Intranet could be mentioned. The Intranet should be created and implemented to give the users access to information in an easy and efficient way. The ambition is also to emanate from an original document, and use this original document in different document flows. The aim of the Intranet project is furthermore to develop the infrastructure of the information processing. It is clearly expressed that the Intranet project should not affect and changes local work practice. When each small project is carried out with its own budget the effect is that the advantages of co-ordination is missed. The way that the systems will communicate is also missed when small projects are carried out without co-ordination with each other. Often a more overall project is missed. It is the integration and communication between systems, which are very important when the systems should be used in an efficient way. Other consequences of small projects can also be that small information islands are created, from which information is distributed. The very same information can be created in different places and the risk for an uncontrolled information overload without co-ordination is obvious. No common information sources are created.
5.2 Socio-organisational problem areas

Problems due to the practical use of IT appear continually. We refer to these problems as a socio-organisational problem area. These are extremely intertwined with and in a sense derived from the infrastructural ones, but here we outline particular categories such as lack of communication, the dialogue about IT, attitudes to their daily IT use, about uncertainty and differences.

5.2.1 Lack in communication – the dialogue about IT

The results show an obvious lack in the communication between different groups and professions within the organisation. In the empirical study there are many examples on this phenomenon. Regarding the NU health care IT vision the personnel has lack of knowledge. All of the personnel told that they did not know anything about the IT vision. The conclusion is that the IT vision is not anchored in the organisation and that there is an obvious lack in communication between the different groups.

The dialogue concerning user and systems requirements has shown to be problematic. The health care personnel consider themselves as bad in describing their requirements. The reason is not fully clear. But the mental pictures of what to focus in the choice of system are different in different groups. For example has the health care personnel more knowledge about which functions the system has to have. The IT personnel are instead focussed on which communication standard is required. Today the health care personnel come up with ideas. These ideas are also rather incomplete due to the technical requirements. One reason to the problematic situation is that the technical competence is coming in too late in the process of describing the requirements. The following example also shows the difficulties in communication between the IT personnel and the health care personnel. The language used within the IT community is rather technical and that will cause problems.

“It is very difficult for me to really explain in the project administration group, what we are able to create in this project, and to have them to understand this theoretical discussion and give them a chance to really say yes or no. They really understand the activities in the health care, but… the project has interpreted the clinic requirements to a computerised solution and the project administration group is going to take a decision to the amount of resources to create this solution. This implies a lot of things; there are always risks with development projects. It is heavy principles they have to decide on, because it is there principles we have to build upon later on in different IT systems. But when the project administration group says yes, I cannot clearly feel that they have understood what I have told them.

There is a prevalent uncertainty among the IT personnel and the management level at the clinics in decision processes, where IT personnel have knowledge which is hard to communicate to them who are going to make the final decisions.

“Unfortunately we don’t have this, we should need this, we not always agree with the catwalk… so we have talked loosely about this. But it is still so new…”

“[It is] much dependent on whom you are talking with up there [at the IT department]. If I talk to someone it is away with the fingers, do anything at all. If I talk to someone else it is yes, you can do this… I don’t really know which leg to stand on.”
5.2.2 Attitudes in the daily IT use

The functionality in the systems is not always adapted to the clinic’s routines, which influence the attitudes to IT in a negative way. The knowledge about the systems functionality is therefore important. Regarding signing documentation in the patient’s electronic case books the consequence sometimes could be that one have to sign what others have documented. It is perceived as risky because it is possible to have the responsibility for something one has not being involved in. The consequence will be that they not document as much as before.

An essential problem in the daily use of the system is the lack of education in using the documentation system. For example at a clinic in Gothenburg were some of the personnel dedicated for some weeks only to support the use of the system, which was seen as a prerequisite to handle the documentation in a satisfying way.

In spite of these problems with the system the personnel is very positive to the system. In a few years they think it will work very well. The system only has to be more adapted to the clinics’ routines and the personnel need education in using the system.

“If we had good systems and if they worked we could dedicate more time to the nursing work.”

“I see very good possibilities with IT but nothing is happen or it goes to slowly and there are many problems…”

The clinics’ personnel want a better co-operation, and they wish that they could call the IT department and have support instead of having a service order number.

“I stumble against many problems every day, which is due to the users lack of knowledge.”

Amongst the health care personnel there is a negative attitude towards IT, which tends to be caused of fear to changes and to the overall technology. The IT personnel are also aware of this, which the following citation shows:

“… I have also encouraged everyone to use the computers and the Internet to learn and exercise. So the use of hotmail is absolutely OK. Otherwise they will be kept away from the computer if the only are allowed to do certain things. Then they get more exercise to use the keyboard an so on.”

The health care personnel see the functions closed to the work activities, which could be computerised. The attitude to IT is much troubling and there are many problems with IT, but if it works it will possibly be good.

“I think we can use this much more than we are doing today. But we need education and information about this. I feel that if one is not trained or interested from the very beginning it is difficult to dare. One does not go into the system then.”

The prevailing situation is that there is a kind of negative resignation towards IT. The development is too slowly as it takes too much time etc. The health care personnel also feel that they are bad in handling computers:

“The majority of us are women and have low interest of computers. We see them mostly as type writers. Our computer technicians have not come to their advantage. Probably we could solve many of the problems but we have no time to learn. I see good possibilities with IT but nothing is happened or the process is going too slowly and there are much problems…”

“As a section leader I see the computerised system as a huge problem. We are going to have a
new salary system at the new year, Palett, so we hope it could be better. The old system was miserable, what should take one hour takes a whole day. Now we are doing the salary reports manually so that the salaries will be paid in time before Christmas. It has been hard to log in to the systems.”

5.2.3 Uncertainty and differences

Individuals could perceive differences between events going on and events which told to happen (Weick, 1995). It can be exemplified of when a clinic should choose a system. A clinic had a wish of a specific system adapted to their activities. The IT co-ordinator perceived that the choice of system been something else and not the system they wish to have. Even if the IT co-ordinator in this situation tried to convince himself that it really was the original wish of system they still were searching for, the result was not what was thought. He interpreted the situation as a gap between how it was and how it should be. He tried to make sense of IT based on the intentions of the system, his knowledge and experience about the health care activities and the presumption he had.

The personnel then discovered that the system was not that integrated as expected and they experienced interruptions in their routines. It can arise situations hard to interpret which comprehend unstructured problems, there both the goals and the means are problematic and unclear (Henfridsson, 1999). Weick (1995) means that there is no need for more information when overwhelmed of ambiguity. Instead there is need for appraisals, priorities and clarity of preferences.

One more expressive example relates to the development of an Intranet, which was conducted as a project with a reference group. The reference group is composed of user representatives from five different clinics. Though it is a relatively small group of users. The situation is risky in that it can be more confused and that more interpretations can be added if more information is spread to the individuals in an organisation (Henfridsson, 1999). An IT co-ordinator expressed it as:

“It is tremendously hard for the average user to understand a theoretical discussion of how an Intranet will work and how we had planned the information handling, when the user cannot see the practical solution in front of him/her. And I would say that it gives no more than creating more question marks, therefore we have chosen to work with a reference group of users instead.”

It is problematic if the IT co-ordinators would like to change the configuration of the computers at the clinics. Even if they have the education to do this, and if they have a storage from old computers, they are not allowed to mount the storage without the approval from the IT department. At the same time is the IT department only responsible for the equipment until the wall socket at the clinic. The consequence will be that the personnel feel watched over. There is also a scanning program at each computer, which every time when the computer is stated, reads the configuration of the computer and detect if any new programs have been installed. The personnel is also monitored in their use the Internet. The IT department have the possibility to see which pages the personnel are looking at and for how long time they are connected to the Internet.

6 DISCUSSION

An analysis of the attitudes towards IT with respect to the three dimensions of technological frames (Orlikowski & Gash, 1994) starts with the fairly obvious reflection that the meaning of technology is perceived differently by the two professions: IT- and health care personnel. The technical education and competence of the IT-personnel results in a more imaginative and change oriented attitude. At the
same time, this profession shows a tendency to underestimate the potential problems related to changes in work practice brought on by the use of new systems. In that sense, IT staff can be argued to have primitive view of what Orlikowski and Gash refers to as technology use.

Work at the emergency health care unit is highly complex and involves processes where a large number of people, often under great stress and time pressure, shall co-ordinate their respective tasks into a well-oiled machinery. Even the smallest disturbance or flaw might result in serious consequences for the patients. In light of this, it is perhaps not surprising that the staff mobilizes an organizational defence (Henfridsson, 1999) as a reaction to plans of new systems and applications in the clinic.

The strategy of technology refers to the way an individual or a group of people understands the purpose or the agenda behind the implementation and use of information technology. Wilson and Howcroft (2000) argues that healthcare operatives tends to perceive IT in general as having the primary purpose of monitoring, controlling and rationalizing work. This is in clear conflict with the traditional ideals of nursing, caring and healing, and can consequently result in a rejection of new technology. Subsequently they explain this conflict between technological and professional ideal as being rooted in traditional gender-roles, with nursing and caring as female attributes whereas control and rationality are traditionally male. This gender aspect probably gives an important contribution to the analysis of the case study, but other aspects can offer equally powerful contributions.

As pointed out by Goffman (1969) people tend to adopt different roles when presenting themselves in public life. It cannot be ruled out that the critical attitudes towards new IT systems found in this study has other origins but the ones conveniently afforded by the professional role of a stereotypical nurse or doctor. Perhaps it is easier and more socially accepted to use such a line of argumentation instead of expressing for instance a fear of change and a reluctance to abandon familiar work practices. Furthermore it is worth noticing that this technological strategy ("the vision") is not expressed among IT-personnel. Instead they tend to emphasize efficiency, professionalism and "keeping up with scientific progress". Technology is viewed as having a large potential with respect to increasing the quality of healthcare professionalism. The fact that healthcare operatives still view IT as primarily an instrument of control can be interpreted as a lack of confidence in IT staff as legitimate authorities in the area of healthcare.

Dissonance with respect to how the work practice is perceived and understood could have a negative impact on performance. This study shows that health care operatives are a fairly homogeneous community engaged in a process of common sensemaking with respect to their technological frames. This is so, inspite the fact that the community contains a number of different professions and specialities that needs to communicate and co-ordinate their activities. The study also shows how the IT-staff has arrived at different, yet shared, understanding of technology. This group expresses a somewhat uncritical and unproblematic attitude towards IT, which does not make sense for the end-users in operative healthcare.

The operatives report problems and calls for action regarding the complex processes of information management. IT professionals design 'solutions' aiming at addressing these issues, that in turn is perceived as not appreciating the nature of existing work practices, and consequently run a high risk of being rejected. This fundamental conflict creates a gap that calls for organisational changes in order to be bridged.

In this context it is important to point out that healthcare operatives should not be perceived as being totally hostile towards all technological change. Healthcare in general and emergency healthcare
in particular is constantly invoked in adaptation of new technology. New machines, instrument, and methods of treatment is reforming and revolutionizing work practices all the time. These innovations are however originating from sources that healthcare operative perceives as legitimate professional authorities, hence national or international medical specialists and or new government legislation.

This could contribute to that some of the suspiciousness connected to implementation of new IT systems is replaced with positive expectations and faith, something that dramatically would open for individual and collective sensemaking. In this sense, it is all about giving the IT systems "a fair chance" and consequently end up with faster adaptation, where members of the organization are tolerant and hospitable (Ciborra, 1999), overseeing initial problems related to IT. Such processes should be seen as benign, when they result in improvements with regard to the quality of healthcare, but there is also an evident risk of prolonging the lifetime of less successful ventures. Both scepticism towards IT and positive expectations regarding other care-technologies run the risk of becoming self fulfilling prophecies (Henfridsson, 1999).

What makes the situation somewhat hopeful for the future is the fact that healthcare sector have long traditions of coping with situations where people of different professions (assistants, nurses and doctors) and different area of expertise (medicine, surgery, pathology etc.) manages to integrate their efforts into an efficient operation. The challenge at hand is consequently to involve also IT-specialists and administrators.

Addressing the socio-organisational aspects we believe that a strong candidate as a possible future link between health care professions and IT profession is the IT-co-ordinators. At present their situation is problematic, especially since their profession is fairly new to the organisation, and has not yet positioned itself in relation to other professional groups. The sensemaking of their environment and themselves has not converged to a situation where all stakeholders agree on what part they will be playing. Apart from IT-co-ordinators, also the operative managers might play an important role. Having the benefit of being legitimate authorities in both camps, this category of people could hopefully catalyze a fruitful dialogue that will result in a shared culture with positive attitudes towards sound IT interventions.

The analysis highlights the infrastructural aspects as important aspects of understanding the way people in NU-healthcare relate to IT. The results can be understood as contradicting paradox, where calls for flexible systems that are well rooted in work practice is in conflict with the demands for co-ordination, efficiency and standardisation. It is highly problematic to run large-scale bottom up projects, and at the same time impossible for top down initiatives to gain sufficient momentum, because of organisational defence mechanism (Henfridsson, 1999).

Some changes in the healthcare sector, such as implementation of new apparatus or methods of treatment, are local and situated to one or a few specialist clinics. Other systems (Melior, Adapt etc.) relate to information management (patient records, process reports etc.) and concern the entire organisation. This type of exhaustive systems are difficult to adapt to micro-level requirements, and are to a large extent designed in a way that makes integration with other systems very difficult, (Lundberg, 2000; Hanseth, 1996). Also Lundberg (2000) passes the ball back to designers and system-vendors for the healthcare sector, when arguing that the paradigm of designing generic systems must be replaced a paradigm of designing work oriented infrastructures. Existing systems should be cultivated into supporting a given work practice. This does not imply a conservation of existing routines, but rather that innovation and change should evolve from a close co-operation between designers, IT-professionals and healthcare operatives, making sure that common sensemaking is
aligned with an optimal use, meaning and strategy for information technology. This may call for a profession-oriented infrastructure rather?

7 CONCLUSION

The aim of this study was to explore problem areas concerning different attitudes to IT in health care. The conclusions are derived mainly from the ethnographic study but some theoretical discussions have also been developed. Two main problem areas were found: the infrastructural and the socio-organisational. We have argued for a dialectic approach, which means that we consider both the individual as well as the social processes that build up the attitudes to IT. We found reasons for the differences that include lack of co-ordination between professional groups, human communication problems, and hindrances in systems integration and low level of knowledge and understanding in the daily IT aim and use. Here we have tried to be constructive and find mechanisms that may trigger the social processes between people with different attitudes. The adaptation process will be extremely important as a stage for these processes to take place. We believe that open up the dialogue and reason about the technological aim may foster attitudes that make a better understanding and use of IT in the “NU” health care organisation as well as in similar organisations.

Abstract

With the global spending of more than US$4.1 trillion in 2007, healthcare has been one of the largest industries worldwide. To better plan and develop the healthcare system, an effective way is to leverage on the advancement of information technology (IT). However, despite of many attempts in the computerization and automation of healthcare services, most of the healthcare information systems failed to deliver in the era of rising expectations. With respect to this aspect, this study focuses on the success stories of a private-owned hospital in Singapore. We illustrate our lessons learned from this hospital, the Alexandra Hospital, which has successfully innovated a healthcare system setting and making a benchmark standard for the Singapore healthcare industry. By conceptualizing on the generation of innovative capability process, this study complements the scarce innovation literature in the service industry. Theoretical and practical contributions were shared and documented in this paper.

Key Words: Information Technology in Healthcare, Innovation in Services, Innovative Capabilities and Case Study
1 INTRODUCTION

Healthcare is the single-largest industry worldwide with a total spending of more than US$4.1 trillion (World Health Organization, 2007b). In which, the U.S. healthcare expenditures alone make up 14% of its GDP, and this figure is projected to rise to over 16% ($2.3 trillion) by 2010 (Plunkett Research, 2003). Recognizing the massive size and continuing growth of this industry along with its potential of transforming societal health-and-wellness quality, the Singapore’s Ministry of Health sets the mission to develop the world’s most cost-effective healthcare system to help keep Singaporeans, the country’s key resources, in an ideal state of health (World Health Organization, 2007a).

One of the most prominent ways to improve the healthcare system is to leverage on the advancement of information technology (IT). Healthcare experts, policymakers, payers and consumers find that computerization and automation of health records and processes could critically transform the scenarios of healthcare industry (Dwivedi et al., 2007). Though much in-depth studies had been done to improve the healthcare information system, yet it fails to rise on the occasion.

In view of rapid changes and uncertainty in the healthcare industry, it is crucial, practical and interesting to investigate how organizations can innovate and stay competitive in such a volatile environment. From expert’s opinion, organizations could shape the future of their industry through innovative changes (Lawson & Samson, 2001). The problem is that, an acceptable, comprehensive and systematic framework towards successful innovation is difficult to come by. This means that, an ideal and systematic framework of innovation has yet existed (Lawson & Samson, 2001). The scarcity of studies on innovative change in the servicing industries (Amble & Palombarini, 1998, Aranda & Molina-Fernandez, 2002, Martin & Horne, 1993) has motivated to focus on this subject. In this study, we intend to bridge the research gap by conceptualizing the generation of innovation services and innovative capabilities to illustrate lessons learned from a private hospital that has successfully designed and injected an innovative philosophy into its healthcare system-a service firm.

The other parts of this paper are structured as follows. First, a review is presented on the background of innovation services with innovative capabilities before an outline of our research methodology which is coupled with a description of the Alexandra Hospital’s case study. Second, the findings and discussion on the generation of innovative capability processes are listed in detail. Finally, the theoretical and managerial contributions are put in place.

2 LITERATURE REVIEW

2.1 Innovation in services

Despite the growing awareness that innovation is not confined to technical processes and products alone, contemporary research on innovative activities is still largely focused on technical innovations in the manufacturing sectors (Gallouj & Weinstein, 1997, Koch & Strotmann, 2008, Tether, 2003). Until recently, researchers began to recognize that there are differences in the nature of innovation in services in comparison to manufacturing. Probably, the two most prominent characteristics of services compared to manufacturing are: intangibility and interactive aspects of services. The reasons may be that firstly services tend not to have an independent physical existence and also service innovations can be invisible. Secondly, as services are interactive, they are often being co-produced by the providers and users acting together” (Tether, 2003). For these reasons, it is interesting to explore how innovation can be specifically carried out in the services sector of a hospital setting in this study.

Three schools of thoughts have emerged so far in the services innovation. The first school of thought advocates supplier-dominated innovation and suggests that services innovation is largely dependent on adopting externally developed technologies in facilitating the provision of new services and/or...
enhancing the productivity of their services (e.g. den Hertog, 2000, Pavitt, 1984). Services are often considered to be “laggards” in terms of innovation and dominated by the technology provided by suppliers (Pavitt, 1984). More recently, some researchers began to suggest that service innovation might be beyond pure technological innovation. Beginning with the “interactive model” suggested by Kline & Rosenberg (1986), the second school of thought on service innovation emphasizes the differences between services and products, and suggests that services are far from dull providers of standard activities, but are instead dynamic and fluid, constantly changing to meet customer requirements, and achieving them through creative combinations of hard (e.g., equipment, computer software, etc.) and soft (human skills, knowledge, etc.) technologies (e.g. Camacho & Rodriguez, 2008, Gallouj & Weinstein, 1997, Kline & Rosenberg, 1986, Sundbo & Gallouj, 2000). This perspective of innovation in services strongly emphasizes interaction with users and is believed to be particularly relevant for a knowledge-intensive business services (KIBS), such as consultancy. The third school of thought sees competition and innovation as related processes, which are themselves related to the scope for strategic positioning (e.g. Tether, 2003). It further suggests positioning and innovation through creative combinations of hard and soft technologies. While this perspective accepts that the adoption of technologies can be hugely significant for service development, it also considers that adoption is rarely as passive or as dependent as the supplier-dominated view (Tether, 2003). With the basic knowledge on these schools of thought fundamental to services innovation, it provides us a clearer notion to further explore them from a hospital perspective. Most interestingly, in this case, we examine the services innovation in the process of adopting a new workflow and information system in a hospital setting. To further extend the background understanding of this study, we look into IT innovation literature.

2.2 Information technology innovation

Information technology (IT) innovation has been extensively studied by researchers in the Information Systems (IS). Early studies on IT innovation from IS perspective have been focused on the impacts of perceived technology characteristics on adoption of technology. Relying on the theories of innovation diffusion, key perceived technology characteristics have been identified, such as perceived complexity, relative advantage, compatibility, etc (e.g. Rogers 1995, Moore & Benbasat, 1991). More recently, scholars suggest that the fit between technology and the task might significantly influence the success of technology adoption (e.g. Goodhue & Thompson, 1995, Zigurs & Buckland, 1998). On the matter of the main stream philosophy, IT innovation has also been recognized as a process of movement, i.e., transforming inventions into usable forms and use in practice (King et al. 1994). Holding fast to the same belief, we examine the service innovation of this healthcare case study from a process perspective.

By adopting a Health Information Systems (HIS), we could most probably share some similar concepts and situations in normal IS adoption. Nevertheless, the adoption could be quite different from the generic IS approach, given its specific purposes in serving the healthcare practice. For example, Heeks’s (2005) “design-reality gap” conceptual model has highlighted HIS implementation challenges. Hence, it would be interesting to find out the generation of innovative capabilities introduced by AH hospital. Especially, in the case of AH, the extent of its innovation does not only evolve around the technology, but also include the change in its hospital workflow and structure. This has added the creditability to this case study.

2.3 Innovative capabilities

The concept of innovative capabilities refers to a firm’s ability to develop new products, services and/or markets through aligning strategic innovative behaviors and processes to achieve the usual and novel solution (Wang & Ahmed, 2007). In general, there are two types of innovative capabilities: incremental and radical innovative capabilities (Dewar & Dutton, 1986). Incremental innovative
capability is defined as the capability to generate innovation in a progressing manner, which refines and reinforces existing products and services (Subramaniam & Youndt, 2005). Radical innovative capability is the capability to significantly generate and transform existing products and services (Subramaniam & Youndt, 2005). Fundamentally, the distinction between incremental and radical innovative capabilities lies in the ability to draw organization knowledge (Subramaniam & Youndt, 2005). Such capabilities are particularly associated with the ability to enhance a firm’s performance (D’Este, 2002, Deeds et al., 1999), evolution and survival in the light of external competition and change (Deeds et al., 1999, Lazonick & Prencipe, 2005).

To innovate, it would require the recognition of the new, unfamiliar capabilities of IT for rethinking business processes instead of its familiar ones (Whitman, 1996). Unfortunately, most organizations often do not provide sufficient supportive resources for individuals who are prone to IT innovations (Wu, 2003). Thus, it would be interesting to study an organization which provides supportive resources to innovate. In this study, we intend to increase the understanding of AH’s IT innovation by unveiling its processes and capabilities. Supposedly, the more innovative a firm is, the more it possesses the capability to search for sustained competitive advantage (Wang & Ahmed, 2007).

To innovate, an organization has to have the ability to develop new products, services and/or markets with continual and incremental learning and experimenting from inside and outside of the organization (Aranda & Molina-Fernandez, 2002). Teece, et al. (1997) identified learning, reconfiguration and coordination/integration as the key processes in dynamic capabilities. In this case, learning refers to the ability to acquire, assimilate, transform and exploit existing knowledge to integrate and generate new knowledge (Aranda & Molina-Fernandez, 2002, Teece et al., 1997). It is acknowledged that knowledge and transfer of learning is of utmost importance for the implementation of system innovation (Metcalf, 1995)

Integration and coordination have been viewed as important elements that facilitate the deployment of resource reconfiguration. Such two elements could specify how different resources are integrated to create new ways of performing new sets of activities, for example, by transforming the existing resources into new potential resources that could correspond to volatile environments (Teece et al., 1997).

In this study, we aim to explore the process of innovative capabilities development and its deployment in resetting a new healthcare industry model (including structure and IT systems). In view of our research interests, our study builds on the innovative services and capability conceptualization and commonalities identification derived from the case study.

3 METHODOLOGY

We chose a case study approach to investigate our research interest, as it provides the opportunity for the researchers to explore contemporary events in the case company (Winter, 2003) with the empirical inquiry research on “how” and “why” questions (Lazonick & Prencipe, 2005). The main interest of this study is to discover how a service firm- Alexandra hospital (AH) innovates in a volatile environment to set a new healthcare industry model for Singapore.

In addition, the scarcity of research in this phenomenon (Amble & Palombarini, 1998, Aranda & Molina-Fernandez, 2002, Martin & Horne, 1993) has further substantiated the choice of research method in this study. In particular, an interpretive case study is an appropriate means of empirical inquiry (Lazonick & Prencipe, 2005) when the phenomena to be studied are complex and not easily separated from its original context (Yin, 1994). Thus, drawing from interpretive perspective, a process model of innovative capabilities development will be presented. This study will use the rich insights available in the case by examining the major events (narrative as instance) of the entire innovative response process in the volatile hospital environment.
One of the most dynamic Singaporean hospitals- AH was invited to participate in this study. This case study is particularly appropriate for the purpose of our study because it is cited by the Singapore Health Minister as the piloting prototyping center, which leads and sets the future standards of the Singapore Healthcare industry. In particular, the case study focuses on how innovative they are in deploying resources and capabilities in response to the government challenge to formulate a new explanatory model for the Singapore Healthcare industry.

This case study was conducted over a period of six months with the total of 19 face-to-face interviews with nine distinct interviewees, who were nominated by the Director of Operations according to their expertise and relevance to this case study. In addition, due to the size of the hospital and its limited resources, no more than ten staff were allocated to handle matters relating to all its IS projects. At the period of change, employees were bound with multiple tasks in their daily routine. Tasked with heavy workload, our informants were still willing to sacrifice their valuable time over the lunch or even after office hours with us over the interviews, demonstrating their passion for this project. Most interviews were tape-recorded and transcribed, with photos and additional notes taken to collect the best possible events of the case. Each interview session lasted between 1.5 to 3 hours, with informants ranging from nurses, IT specialists, doctors and top-management personnel having an average working experience of three years. We adopted a practical way of understanding textual data that was suggested by Klein & Myers (1999), i.e., via personal visits, emails and phone contacts to foster relationships among researchers and key informants. By doing so, it enables us to understand their rich depictions (Yin, 1994) underlining the meanings of their expressions (Hirschheim et al., 1991) so as to discover the core-case information that is necessary for the comprehending, analyzing and evaluating of the case study (Klein & Myers, 1999). To ensure the quality of data collected, we triangulated the data collected with other resources including empirical observations, follow-up email clarifications, along with about 230 MB softcopy documentations and archive records.

4  CASE STUDY

4.1  Case background

Alexandra Hospital (AH) was first established in 1938 as a British Military Hospital in Singapore. In 2000, AH had undergone a restructure and became a member of the National Healthcare Group (NHG), which is one of the two healthcare clusters in Singapore today. Since then, it has undertaken many initiatives to upgrade its major facilities with the desire to become the Mayo Clinic of Asia complimenting with the objective to provide patients with the hassle-free experience.

As one of the smallest hospitals in Singapore and a lack of government supports, AH was limited to use its scarce resources wisely to achieve its aim towards the upgrading of healthcare service standards in Singapore. That is to offer a better, faster, cheaper and safer-care service to patients on top of developing new business processes, and exploring innovative technologies. Ultimately, they decided to set up a new healthcare standard in Singapore by moving towards a Hassle-Free, patient-centric hospital to be located in the Northern Singapore in 2009.

4.2  Planning and preparation for an innovative breakthrough

To achieve the Hassle-Free Hospital vision, AH referred to the two best practices of US-Japanese Medicine/Healthcare systems (the Mayo Clinics (United States of America) and the Kameda Medical Centre hospitals (Japan)) to realize this vision. In addition, AH staff were sent to visit the Toyota plant in Japan and its workshop in Singapore to study how to transfer the learning into the hospital via the approach of thinking out-of-the-box mindset. Coupling with the impressive Japanese ‘Kaizen’ (continuous improvement) philosophy, a management team member:

“It worked for Toyota cars, so why not for patients at hospitals?”
Motivated with the inspiration of ‘Kaizen’ initiative of the Japanese, AH management team has to nurture the interest of the relevant stakeholders for their intellectual and emotional buy-in before kicking off a series of ‘Kaizen’ activities. Knowing that the change would bring tremendous impact to the hospital, creatively, the management team capitalises on its choice of having a passionate and committed IT personnel to spearhead the change. Through her social network and personal relations in the hospital on top of a supportive medical doctor husband, they managed to bridge the ideas and interests over informal social discussions and gatherings. News spread with the growth of interest and eventually the casual talks and gatherings were supported and attended by more specialised staff forming into an action-oriented team. Such a carefully crafted and planned management initiative has eventually and successfully nurtured the interest and cultivated the need for change in the hospital with minimum hassle.

Following the change, there are improvements whether significance or not were encouraged by the Director of Operation with the aim to save resources, time and add value to patients. According to a senior top-management:

“We believe in taking small steps in rapid succession approach, where we test new technology and deploy them if suitable”

Complementing the knowledge learned through the ‘Kaizen Flow’ (refers to Figure 1) initiated by the AH operational team with a small number of volunteered staff, including medical doctors and nurses, to participate in the change, the management incorporated the patients ‘wish list’ into the system. The initiative kicked off with scrutinizing the traditional work processes to identify bottlenecks, reviewing the existing patient-care processes and also re-examine patient services via the exploitation of technologies.

To further support the innovative change, all management staff including the operation team were assigned with a mobile phone and relocated to an office with no designated seats to encourage dynamic interactions, responsive and attentive management practices.

With the belief that innovation does not lie in the hands of the top-management, weekly system review session is organized to welcome suggestions from all levels. According to the Director of Projects in Operations:

“The contribution is from everyone because the process flow and the initiated changes have to happen on the ground then we (the management) help to “systematize” the components or the requirements.”

The hospital is filled with synergy to innovate. It is not uncommon to detect members of the management team gathering first-hand-on-site problems from the ground staff to understand the practicality and the feasibility of the change. Since then, the process of identifying and solving problems remains part and parcel of everyday work, more importantly, the project specialist 1 claimed:

“We feel that we should not get a system that changes our workflow. So we started to review our processes and request for an integrated IT system that can support us.”
On-going trainings were provided to staff to increase their awareness of the undergoing projects in relation to future changes to the hospital performances. In addition, the Andon board \(^1^\) is used to notify the new changes and act as a means to justify the improvements and benefits of the newly introduced workflows and healthcare system to staff.

### 4.3 Articulating and integrating resources

A series of continual learning and experimenting activities were carried out by the AH management to identify the necessary improvements before sourcing for further resources to accomplishing the task. The Chief Operating Officer alleged:

“We will continue to source for relevant technology in the market for our new facility, which will be ready in 2009”

To offer a more efficient and effective safer-care service to patients, an internal operational team was set up to examine the workflow of emergency-ward patients at the triage. After the review, three potential areas of improvement were identified— the physical layout of the department, the business workflow and the need for an integrated healthcare information system. The proposed improvements were then readily agreed by the management as prompt attention to emergency-department patients is vital and immediate change is targeted to upgrade its conditions and services.

After several intensive meetings on costs-and-benefits analysis, the management decided to invite external collaborators for strategic partnerships in improving the department physical layout, business workflow and the healthcare information systems. The assistant director of operations explained:

“We are a small hospital. So for some of the things we implemented, cost is important, as we don’t have the financial arm to bring in the big software players…”

To initiate the innovation, AH proposed the idea of setting up its integrated healthcare information system as a business case for a Singapore polytechnic college to take up as an assignment topic.

“To be able to solve an actual business problem is a precious opportunity for those polytechnic students…” Explained the Assistant director of operations

Through the ‘kaizen’ management approach and the workflow process review under the guidance of the head of emergency department, the physical layout of the emergency ward was innovatively improved over a short period of time by the internal operational team in ensuring that the point-to-point stations are positioned for the convenience of patients. After due considerations, AH made a bold and historical move to revamp the triage system by allocating a senior doctor (experience doctor), instead of deploying a junior doctor (trainee medical officer) to serve as the first point of contact with patients in the initial consultation process. Within the 90-day commission period, AH surprisingly received an endorsement for IS prototype from the Singapore polytechnic college regarding the newly improved workflow.

To put the IS prototype provided by the Singapore polytechnic college into practice, AH extended their partnerships with some other industry partners to pilot and test use various advanced technologies in its process of transforming into a hassle-free hospital. Along the exploration journey, Frontline Solutions (FS) Corporation implemented the prototype and played the role of system integrator to merge all the medical records and information, currently stored in various databases into a central-integrated-database system, on top of customizing information for efficient delivery across multiple devices. This collaboration has indeed created a win-win scenario for both parties. While AH benefits

---

\(^1^\) Japanese name for a visual production-control device (usually a lighted overhead display) that continuously shows changing status of the production line and sounds alerts if a problem is imminent (Business dictionary.com, 2008)
from the integrated healthcare system, FS Corporation enjoyed the privilege of advertising its success story with reference to AH experience. Based on the synergy and creativity manifested by AH staff, an innovative healthcare system is successfully designed from scratch.

4.4 Paving to the innovative hassle-free hospital service model

Taking a bold move to improve the workflows and innovatively develop a better system and workflow process from scratch is an achievement and a great leap forward for AH. The entire innovation service transformation was a great success: 1) AH has tremendously improved patients’ satisfaction, but also successfully expedited patient flow by 400% (from 22 to 70 patients attended per hour), 2) Reduced patient waiting time by 50%, and 3) The newly designed system can genuinely contributed to the recording and retention of patients’ medical history via the paperless administration in supporting the go-green campaign. By so doing, AH boosted its brand-name in the hospital industry by ranking consistently number one in the Ministry of Health Patient Satisfaction Surveys from 2004 to 2007.

5 DISCUSSION

Basing on the AH organization-wide innovation effort, a definition of a high-performing innovation organization suggested by Lawson & Samson (2001), we developed a process model of innovative capabilities development in a hospital-service settings, as showed in Figure 2. As suggested by our model, the development of innovative capabilities is a complex-helix process in articulating and integrating organizational learning and knowledge with tactical partnership and coordination to technologies, processes, services via organizational intelligence, strategic integration and operational articulation. In other words, the capability to innovate is developed through the capability to integrate and to articulate internal and external knowledge, resources and expertise to develop a new standard of products/services through aligning organizational intelligence to create a novel solution.

The conceptualization of strategic integration refers to critical managerial decision process in identifying, modifying and improving the internal and external resources. Operational articulation accounts for the operational activities of a firm in reconfiguring hospital standard, building stability, efficiency and profitability including the reduction costs, risks, and the achievement of economic of scale. Organizational intelligence is known as the capability to deal, process, interpret, manipulate and access information to resolve complicated problems/issues in a purposeful, goal-directed manner so that an organization can increase its potential to adapt and operate strategically (Glynn, 1996, Lawson & Samson, 2001). In other words, organizational intelligence refers to the capability for an organization to harness its preserved knowledge from different problems/issues, then deepen the knowledge through learning and further legitimize its perceived value according to its goal. AH focuses its initiative by learning from foreign hospitals in US and Japan and among its employees through the ‘kaizen flow’ which allows it to build the capability to identify new avenues for investigation and to innovate (Burgelman & Maidique, 1988).

Given that this model was inductively derived from the AH case study data, we present in a way how the existing literature corroborates with the model and how the model enriches our present understanding of innovative capabilities process model.
Figure 2: Process model of innovative capabilities development derived from the AH case study.

Figure 2 suggests that the process begins with an innovative aim to build a hassle-free hospital by providing faster, cheaper and safer-care services to patients. Such an idea was initiated by the top management since AH became a member of the NHG. To address the initiative, the hospital articulated knowledge from various sources by integrating information and expertise from both internal and external sources (Aranda & Molina-Fernandez, 2002) and transforming them into hospital-embedded knowledge or ‘organizational intelligence’. This is in line with previous research which suggests that a firm can develop superior capabilities through learning mechanisms, including continual experimentation, and the analysis of small mistakes (Eisenhardt & Martin, 2000). The ability of a hospital to integrate and articulate knowledge gained externally through the benchmarking of others’ best practices and technological opportunities coupled with the incorporation of its internal capabilities is critical to the success of an innovative change (Cohen & Levinthal, 1990; Anderson & Ejermo, 2005).

5.1 The evolution of capability to articulate in the process model of innovative capabilities development

The ability to articulate knowledge plays a critical role in innovation process (Andersson & Ejermo, 2005). Capability to articulate is generated from a series of continual learning and experimenting activities on new healthcare information technologies. These activities were identified by exploring how AH can transform its technology and process experiments to set a new standard in the healthcare industry. From the internal trial-and-error practices, the hospital devoted continual efforts to examine potential mismatches between the work processes and patients expectations. In addition, different experimentation methods were used to explore, investigate and collect stakeholders’ feedbacks for articulation purposes before formulating appropriate requests into a business project.

The next phase suggests that the innovative capability processes are involved to find out how continual experimenting and learning activities can evolve in response to feedback and stimuli from the external environment (for example, government and patients). Such external involvement is inevitable, especially, in the volatile industry, where government and practitioners are trying to explore and set right the blurring healthcare IT structure (including standard and systems). To innovate, hospitals ought to conduct operational articulation that identifies discrepancies or gaps for modifications and improvements from trial-and-error processes (Winter, 2003). The innovative achievement in reducing patient waiting time by 50 percent demonstrated that the capability to articulate is crucial for new ideas and knowledge to emerge.

5.2 The evolution of capability to integrate in the process model of innovative capabilities development

Innovative capability refers to a firm’s ability to integrate and reconfigure resources within (Eisenhardt & Martin, 2000), and outside the firm (Eisenhardt & Martin, 2000; Wang and Ahmed, 2007) for a novel idea. The development of innovation capability for AH hospital is achieved from the integration of resources and technologies, both internally and externally (Aranda & Molina-Fernandez, 2002). AH leverages on its internal resource integration via the coordination of cross functional team members (operational team member, doctors, nurses, top management, and patients) to draft AS-IS problems and TO-BE statements (refer to Figure 1) AH’s Kaizen flow to articulate lessons learned from experimental activities undertaken in the redesigning of the emergency ward workflow. Thus, the soft technologies such as knowledge, skills and expertise from members of the AH’s cross functional teams were critical for innovation in services to integrate and create streamlined business processes.
The notion that innovative capability is embedded in distinct ways of tactical partnership and coordination helps to explain how and why process and technological changes can have tremendous impact and influence on a firm’s services. This capability enables firms to select, develop exchange relationships with units and/or individuals beyond the traditional organization boundaries, such as networks and alliances of customers, suppliers, competitors and other non-market participants which are the key source of innovations (von Hipple, 1988; Hagedoorn & Duysters, 2004) to improve its services. Besides, the existing literature also suggested that the user-producer partnership and coordination would be fruitful for creating a complex and new-to-market innovation (Koch & Strotmann, 2008).

Not surprisingly, as evident in the case, AH demonstrated its capability to integrate knowledge and expertise from tactical partnership. In the initial stage, AH first partnered with a local polytechnic to develop a prototype healthcare information system that is articulated through experimenting continuous learning by the operation team members. After the test-run of the prototype to enrich the innovation process, AH invites other professional industry partners (e.g. FS Corporation) to take part in its success model. Thus, to innovation, a hospital ought to conduct strategic industry partnership that could integrate and leverage internal and external expertise, knowledge and technology (Teece, et al., 1997; Hagedoorn & Duysters, 2004) as evident in the case. All in all, conscientious and strategic integration planning not only tactically positions AH to innovate, but also benefit its partners to creating a win-win scenario.

6 CONCLUSIONS

The purpose of our paper is to conceptualize the generation of innovative capability from innovative services literature. A service innovation goes beyond pure technological innovation to a creative combination of hard and soft technologies and processes innovation. As evident in AH case, innovative capability development in service industry includes innovative workflow and system improvement. By drawing on the AH case study, we have developed an innovative capability model that depicts innovation as a complex process, whereby an organization’s key resources are decomposed into strategic integration and operational articulation that are reconfigured iteratively during the process of capability development.

The innovative capability development model in this paper has significant implications for researchers and practitioners. Previous studies contributed to the understanding of innovative capability as a subset of dynamic capability but not much information was provided as to how innovative capabilities can be developed and achieved. Our model proposes and clarifies that there are certain activities and processes involved in achieving innovative capability. This study contributes to providing some answers in responding to the lack of innovation studies in service firms (Amble & Palombarini, 1998, Aranda & Molina-Fernandez, 2002, Martin & Horne, 1993) and also serving the basis for further investigations.

In addition, this model proposes a process model that describes and analyzes the ways how innovative capabilities are implemented and managed during the innovation of healthcare IT in the hospital backdrop with the aim of setting a new standard for the healthcare industry in Singapore. This innovative development process model presented in this paper is grounded on the activities and processes revealed in the case study. Aspects of this model could be generalized into other cases of dynamic and volatile environments. However, more empirical work is necessary to test the applicability of the model in other settings.

For the practitioner perspectives, this study provides useful insights into the ways to manage innovation capability in order to design and create new industry standards. Taking the initiative to innovate itself into a hassle-free hospital, the AH case underscores the needs for hospital management to understand the concept of innovative capability as well as the approaches to build innovative capability by using organizational intelligence to cross reference with the strategic integration and
operational articulation processes. This study suggests that hospital management could adopt a more systematic innovation process by focusing more on soft technologies while handling services related challenges.

Abstract

It has been argued that the promising benefits of Enterprise Systems (ES) implementations are overshadowed by their high failure rate. One of the commonly cited reasons for ES implementation failures is the end-user’s unwillingness to adopt or use systems. Considering that the appropriate management of expectations may play an important role in forming positive behavior toward newly implemented systems, this study examines the effect of outcome expectations on the system use activity in the mandatory-use context of information systems (IS) from the perspectives of Social Cognitive Theory and Coping Theory. Structural equation model analysis using LISREL 8.7 provides significant support for the proposed relationships. The empirical results suggest that outcome expectations and user satisfaction have positive effects on system use activity conceptualized by immersion, reinvention, and learning. Theoretical and practical implications of the study shed some light on how to improve system use activity in the mandatory-use context of IS.

Keywords: Outcome expectations, IS use activity, Social Cognitive Theory, Coping Theory.
1 INTRODUCTION

Although enterprise-wide information systems (IS) such as Enterprise Systems (ES) have received massive investment and have promised major strategic benefits, they have suffered from a high failure rate and difficulties in realizing the anticipated performance. The factors involved in ES failures are not limited to technical issues, but include various causes arising from the interactions among people, task, environment, and technology.

One of the commonly cited reasons for ES implementation failures is the end-user’s unwillingness to adopt or use systems. Despite the successfully developed system, the lack of positive user acceptance can lead to simple rote use rather than sophisticated system use, leading to dissatisfaction in the organization as the expected performance gained by the system’s introduction is not realized.

The introduction of new information technology (IT) generates numerous expected and unexpected consequences in the user’s environment. As these consequences are subjectively interpreted and understood by users, they respond in a variety of ways to the new system. According to the Coping Theory, the individual appraises what he/she can do to cope with disruptive events based on the potential consequences of events with subjective value, and then performs different cognitive and behavioral efforts (Lazarus and Folkman, 1984). This means that the user’s efforts to achieve the expected benefits or cope with the feared changes of the IT implementation depend on the user’s appraisal of the expected consequences of a variety of events which are induced by IT changes. Bandura (1986) also suggests that outcome expectations are a significant cognitive factor for individuals to control their behavior. Similarly, Thompson et al. (1991) proposed that the long-term consequences are important and effective factors related to new IT usage. Particularly, Chau (1996) showed that the long-term consequences (e.g., increasing the flexibility to change jobs, increasing the opportunities for more meaningful work, enhancing the user’s prestige among colleagues or professional peers) play a more important role in an individual’s IT acceptance by directing the individual’s focus on future benefits rather than short-term consequences (e.g., usefulness). In addition, successful system implementations are more closely related to successful management of user expectations than to user involvement or management support, and expectation management is considered highly important in determining the user’s attitude toward IT acceptance from the initial stage of system development through to the adaptation stage (Hoffer et al., 1999). These study results imply that inappropriate management of expectations may have a negative impact on successful system implementation by failing to meet expectations, despite the intention for a positive system contribution to the organization.

Prior IS research on the new IT adoption has been conducted in the context of voluntary adoption of the new IT by users and either the usage or the intention to use is exploited as a dependent variable. However, most of the current enterprise-wide IS are used in non-voluntary contexts where users must use the system to perform their jobs. Therefore, debate has continued over whether usage or intention to use is an appropriate surrogate variable for actual system use behavior (Rawstorne et al., 1998, 2000). Moreover, the concept of frequency or duration used as a surrogate of system usage does not appear to be appropriate in a mandatory context. Therefore, some researchers suggest that a new concept as a dependent variable should be considered instead of the concept of intention to use or simple system usage (Barki et al., 2007; Burton-Jones and Straub, 2006).

This study aims to understand the role of outcome expectations for successful IS use and suggest a new surrogate variable for system use, based on the Social Cognitive Theory (SCT) and the Coping Theory. The study is conducted with two research objectives. First, from the IS acceptance perspective, we examine how outcome expectations affect the IS use activity of the organization members. Second, we suggest and examine a new outcome variable describing the actual acceptance behavior of the user in the mandatory-use contexts.
2 THEORETICAL BACKGROUND

2.1 Social cognitive theory (SCT)

According to SCT, environmental influences such as social pressures or unique situations, cognitive affects and other personal factors, including personality and behavior, are reciprocally determined as interacting determinants that influence each other. This relationship is characterized by “triadic reciprocal determinism” (Bandura, 1986). It is not that the individual simply reacts to the environment events, but that the individual acts for positively creating and changing his/her environments. Furthermore, individual cognition and the way of changing his/her environment are affected by either positive or negative feedback from behavior; that is, the determined behavior influences the individual’s cognitive process and environment. While SCT can approach many dimensions, this research is particularly concerned with the role of outcome expectations that form and control individual behavior. Outcome expectation that reflects expectations about the level of consequences from their behavior has been considered a significant factor predicting future behavior. While individuals are more likely to engage in behavior with expected favorable or positive consequences, outcome expectations affect their behaviors by letting them avoid expected behaviors that result in negative consequences. Therefore, outcome expectation is considered to play an important role in explaining individual behaviors in the IS research from the SCT perspective (Compeau and Higgins, 1995). Expectations about the net benefits of future IS use are continuously modified based on the IS use that is experienced, and modified expectations change the level of IS use, which further changes the perceptions of the IS performance again. Several recent studies have reported that outcome expectations affect such dependent variables as computer use, knowledge sharing, and user’s organizational commitment (e.g., Stone and Henry, 2003). These research results imply that outcome expectation is a very important cognitive factor to control the user’s behavior. Thus, outcome expectation that controls behavior in the SCT frame can play an important role in predicting and explaining the acceptance behavior of various users in the IS use context.

2.2 Coping theory

Lazarus and Folkman (1984, p.141) defined coping as “the cognitive and behavioral efforts exerted to manage specific external and/or internal demands that are appraised as taxing or exceeding the resources of the person.” It deals with the adaptation acts that the individual performs in response to stimulation or disruptive events and circumstances in his/her environment. That is, the individual either adapts to the subjective meaning of the event or makes coping efforts to seek additional information and evidence for the purpose of changing or avoiding the situation (Lazarus and Folkman, 1984). Individuals apply two subordinate processes (appraisal and coping efforts) to cope with the disruptive events (Lazarus and Folkman, 1984). First, the individual evaluates the potential consequences of an event (primary appraisal and secondary appraisal). The individual evaluates specific events in relation to his/her welfare, i.e., whether it is related to him/her or it is beneficial and positive to him/her. While the primary appraisal focuses on the events that give some kind of meaning to the individual, the secondary appraisal evaluates available social and personal resources required to cope with the events and considers available behavioral options (Lazarus and Folkman, 1984). Second, the individual makes problem-focused coping and emotion-focused coping efforts to deal with the situation (Lazarus and Folkman, 1984). The former aims to solve the problem (e.g., disruptive issue) by changing the environmental pressures, barriers, and resources or by changing oneself (e.g., learning new skills or procedures and finding new channel of satisfaction). The latter aims to reduce or manage the negative emotional distress. It doesn’t change the situation itself, but changes one’s perception of the situation (Lazarus and Folkman, 1984). The kind of efforts that the individual makes depends on how the given situation is appraised.
In an IS research drawing on the Coping Theory, Beaudry and Pinsonneault (2005, p.496) introduced adaptation as a similar concept with coping and defined it as “the cognitive and behavioral efforts exerted by users to manage specific consequences associated with a significant IT event that occurs in their work environment.” The user assesses the expected consequences of the IT event and how the changes affect himself/herself and his/her work at the stage of primary appraisal, so that the user will be aware of the opportunity or threat about the potential consequences of the significant IT event (Beaudry and Pinsonneault, 2005). Such potential consequences are a very similar concept to the long- and short-term consequences of Thompson et al. (1991) and to the outcome expectations of Compeau and Higgins (1995). For instance, if a user evaluates the fitness between work and IS to be high, the changing of the new IS would be recognized as an opportunity, otherwise it would be recognized as a threat. Based on such primary appraisal, the user appraises how much he/she modifies work, controls himself/herself with the new environment (Lazarus and Folkman, 1984), and controls the characteristics and functions of new IT at the stage of secondary appraisal (Beaudry and Pinsonneault, 2005). After such cognitive appraisal, the user makes emotion- and problem-focused adaptation that is similar to the coping efforts of the Coping Theory. Problem-focused adaptation aims at dealing with the issues of IT changes directly by adapting oneself, work, and technology (Rice and Rogers, 1980). Self-adaptation involves adjusting one’s habits, learning new skills, and adjusting commitment to the work to meet the requirements of the technology. Adapting the work changes procedures and routines, and adapting the technology changes functions and features. Emotion-focused adaptation aims at changing one’s perception of the consequences of the newly introduced IT or reducing emotional distress. Emotion-focused adaptation is oriented toward avoiding reality though self-deception or psychologically minimizing negative consequences, selective attention, and positive comparison to other users (Beaudry and Pinsonneault, 2005). It is especially emphasized that the user’s adaptation efforts depend on the user’s appraisal. In other words, the user’s adaptation efforts are changed by cognitive evaluation of the IT event (i.e., the awareness and expectation of potential consequences). Thus, the Coping Theory indicates that outcome expectation plays a significant role in explaining the behaviors of various users in the IS environment.

2.3 Conceptualization of system use activity

It has been argued that predicting behavior based on intention is inappropriate in a mandatory-use environment (Rawstorne et al. 1998, 2000). The link between intention and behavior only applies when the behavior is under volitional control of the person (Fishbein and Ajzen, 1980). That is, the connection between behavioral intention and actual behavior lacks consistency in mandatory contexts.

The mandatory IS use environment means that the user has no choice but to use the system to perform his/her work, so that prior measurement of system usage based on voluntary contexts is inappropriate. The effectiveness of technology usage is decided by the organizations’ aims and objectives in mandatory contexts (Adamson and Shine, 2003). Thus, simple usage behavior of IS may be inappropriate as an indicator of success for the system implementation. The behavior of the user is more complicated than simple IT use in the organizational setting (Adamson and Shine, 2003). Thus, we propose positive “system use activity” related to IS use as a surrogate variable for new IS acceptance instead of intention to use or mechanical use behavior under the premise of mandatory environment. We conceptualize system use activity into three dimensions based on the studies of Burton-Jones and Straub (2006) and Barki et al. (2007): user’s immersion, reinvention, and learning.

First, Burton-Jones and Straub (2006) proposed that system usage is an activity among a user, a system, and a task, and they defined the individual user’s level of system usage as the extent of his/her employment of one or more features of a system to perform a task. To measure the activity between the user and the system in their research, they adopted focused immersion, which is among the five dimensions in the cognitive absorption construct by Agarwal and Karahanna’s (2000). Immersion means the extent to which the individual can set aside other concerns related to their ability to focus on
and perform the specific task required. The user’s immersion activity related to system use activity can be defined as the extent to which the user concentrates on the task while using the system.

Second, Barki et al. (2007) conceptualized IS use-related activity based on task-technology fit and activity theory. IS use-related activity was classified into three behaviors: technology interaction behavior, task-technology adaptation behavior, and individual adaptation behavior. They empirically verified the effects of these activities on the individual and organizational benefits. Among them, task-technology adaptation behavior includes all behaviors like modifying or changing IT and determining how it will be used in the organization. This concept is based on Rice and Rogers’ (1980) notion of reinvention, which reflects the extent to which an adopter changes an innovation following its original development. That is, reinvention can be measured as the amount of effort the IS user puts into the enhancement of the fit between the task and the system to improve his/her performance.

Third, individual adaptation behaviors suggested by Barki et al. (2007) represent behavioral changes that the individual makes to himself/herself in order to adapt to IT. Such self-modification behaviors include learning activity and interaction between individuals and the IT system (Beaudry and Pinsonneault, 2005). Information acquisition activities reflect the coping strategy of users to reduce uncertainties in their work. As users learn how to use the new IT, they can apply new ways to perform their tasks and exchange information with each other. Barki et al. (2007) categorized individual adaptation behaviors into communication behaviors (interactions with other users or IS professionals to exchange information about an IT) and independent exploration behaviors (information search behaviors undertaken independently to improve one’s knowledge and mastery of an IT). So learning can be defined as the degree to which users communicate with each other and search for information in order to improve their knowledge and IT skill.

3 RESEARCH MODEL AND HYPOTHESES

The research model is shown in figure 1, which is based on previously discussed research motivation and theoretical background. We here discuss the conceptual background about the hypotheses in the research model.

![Figure 1. Research model.](image)

According to Bhattacherjee (2001), the comparison evaluation between expectation and system performance is a continuous process, so users’ expectation can change while using a system. Szajna and Scamell (1993) suggested that unrealistically high or low user expectations change into realistic levels, and that low expectations are associated with low satisfaction of users based on the Cognitive

Proceedings ECIS 2009
Dissonance Theory (CDT; Festinger, 1957). According to CDT, when cognitive dissonance occurs, the perceived performance is assimilated toward the initial expectation. It has been reported that consumers’ expectation based on CDT has a positive influence on perceived product performance in marketing research (Szymanski and Henard, 2001). Kim et al. (2004) suggested that the user’s high expectation highly assesses system performance in IS research. Hence, we hypothesize the following:

H1a: Outcome expectations-performance has a positive effect on perceived system quality.
H1b: Outcome expectations-performance has a positive effect on perceived information quality.
H2a: Outcome expectations-personal has a positive effect on perceived system quality.
H2b: Outcome expectations-personal has a positive effect on perceived information quality.

Outcome expectation is considered an important cognitive factor in determining individual behavior, according to SCT (Bandura, 1986). Individuals do not simply respond to the environment, but behave positively to create and change it. Similarly, when the user primarily assesses the expected personal and professional consequences of a newly-introduced IT event in the organization as an opportunity, he/she recognizes and exercises control over the situation, and makes problem-focused adaptation efforts (Beaudry and Pinsonneault, 2005). That is, the user tries to increase his/her knowledge of and improve on his/her ability in using the system and makes additional efforts to communicate with other users in order to seize opportunities offered by IT changes. This behavior consequently modifies prior work procedures and even changes the function of the system (Beaudry and Pinsonneault, 2005).

Thompson et al. (1991) also suggested that perceived consequences, which are composed of three dimensions (complexity, job fit, and long-term consequences of use), strongly influence the degree of computer utilization. The most valuable effect proved to be job fit, which is defined as an individual’s belief that the system enhances his/her job performance. Compeau and Higgins (1995) also reported that outcome expectation has a significant impact on usage by demonstrating that both outcome expectations-performance and outcome expectations-personal affect usage. An individual’s experience, environment, and use behavior affect his/her cognitive factor as suggested by SCT, which then feeds into one’s behavior again by forming a feedback mechanism. Hence, we hypothesize the following:

H3: Outcome expectations-performance has a positive effect on system use activity.
H4: Outcome expectations-personal has a positive effect on system use activity.

The IS success model suggested by DeLone and McLean (1992) and Rai et al. (2002) reported that user satisfaction is affected by the quality of system and information. It was also verified that IS performance is positively associated with user satisfaction. According to Roca et al. (2006), system quality and information quality have positive effects on satisfaction of Web and e-learning users in which perceived system performance is measured in terms of quality. An empirical study on Web-based decision support systems also verified that system quality and information quality have significant impacts on decision-making satisfaction (Bharatia and Chaudhury, 2004). Incidentally, this relationship has already been proved in many studies in the IS field including the IS success model. Hence, we hypothesize the following:

H5: Perceived system quality has a positive effect on user satisfaction.
H6: Perceived information quality has a positive effect on user satisfaction.

Individual user satisfaction with IS use reflects a status of either positive (satisfied) or negative (dissatisfied) feeling (Bhattacharjee, 2001). It can be an impression of delight or disappointment often derived from a comparison of perceived IS performance and its expectation (Bhattacharjee, 2001). It has been widely recognized that an affect associated with a user (e.g., finding delightful about the system) is a significant factor for system use behaviors (Compeau and Higgins, 1995) and that an individual’s feeling for particular behaviors significantly influences that behaviors (Bandura, 1986). According to a study on innovation acceptance of system developers (Chau, 1996), although system developers are mandated to use the innovation (as the adaptation decision about the software development tool is made at an organizational level), whether or not the user enjoys using it (i.e., satisfaction with the innovation) plays a critically important role in productivity. When the
introduction of new system forces users to change tasks, techniques, attitude, and efforts, user satisfaction can play an important role as a way to reduce the resistance of the users, particularly when the system is closely associated with the users’ work (Melone, 1990). We can infer that the user who is satisfied with system use may spontaneously apply the system to his/her work to achieve benefits provided by the new system. In doing so, he/she will exert great effort to learn the new system, modify his/her work procedures, and concentrate on the task during system usage, thereby reducing the negative aspects of the new system. Hence, we hypothesize the following:

H7: User satisfaction has a positive effect on system use activity.

4 RESEARCH METHODOLOGY

We performed a questionnaire survey at the individual level. The data used to test this research model were collected from ERP system users who use the system to perform their organizational tasks. We selected ERP system users because they are supposed to use the system in the mandatory context. Four hundred questionnaires were distributed by mail and 225 responses were received. After the exclusion of 17 incomplete responses, 208 usable respondents were analyzed in the study. The validated questions used to make measurements in this study were mainly adopted from the relevant literature whenever possible and were modified for adjustment to the current research context. All items were measured using a seven-point, Likert-type scale with answers ranging from strongly disagree to strongly agree. The instrument was reviewed by three IS researchers and feedback results were strongly disagree to agree. The instrument was reviewed by three IS researchers and feedback results were reflected in the question items. Measurement instrument used in this study is shown in table 1.

5 DATA ANALYSIS AND RESULTS

5.1 Confirmatory factor analysis

First, we checked the unidimensionality of each construct to test the convergent validity. Following proposed methodological procedure, we conducted revisions on the measurement model by removing one at a time, those items which shared a high degree of residual variance with other items. The measurement model showed a suitable fitness level after removing five items (PFO4, SYQ1, IFQ1, LEN1, and USF4). The normed $\chi^2/n$ to degree of freedom was 1.532, which was a good fit as it was below the desired maximum cut-off of 3.0. The root mean square error of approximation (RMSEA) also showed a good fit at 0.051, which was below the maximum desired cut-off of 0.06. The root mean square residual (RMR) was 0.044, which was lower than the desired maximum cut-off of 0.05 (Hair et al., 1998). The goodness-of-fit index (GFI) was 0.849, which was above the recommended threshold of 0.8 (Hair et al., 1998). The other fit indices were also satisfactory: comparative fit index (CFI)=0.989, normed fit index (NFI)=0.972, and non-normed fit index (NNFI)=0.987. Thus, we concluded that the measurement model had adequate overall fitness.

As shown in table 2, most standardized path loadings were greater than 0.7 and significant ($t$-value > 1.96) with only one exception: PFO5. Composite reliability (CR) and the Cronbach’s $\alpha$ for all constructs were larger than 0.7. All the average variance extracted (AVE) for each factor exceeded 0.5. Thus, the constructs used in this study had convergent validity.
Next, we accessed the discriminant validity. As shown in table 3, the square root of AVE for each construct exceeded the correlations between the construct and other constructs. Hence, the constructs used in this study had discriminant validity. In addition, we examined common method bias (CMB) using Herman’s single factor test (Podsakoff et al., 2003). A significant difference in the $\chi^2$ statistic of the original ($\chi^2=534.6, \text{df}=349$) and single factor model ($\chi^2=3814.4, \text{df}=377$) revealed that this research was not affected by CMB.

Table 3. Results of discriminant validity testing.

5.2 Second-order confirmatory factor analysis

System use activity consists of immersion, reinvention, and learning activity. Thus, the second-order factor, system use activity, was assumed to be indirectly measured through the lower-order factors. The results of second-order confirmatory factor analysis showed a satisfactory fit level (Normed $\chi^2=1.671$, RMR=0.025, GFI=0.943, NFI=0.984). Therefore, the first-order factors and the second-order factor were verified to have strong relations. We carried out item parceling by averaging the first-order factors to measure the latent variable of system use activity, the second-order factor, in the structural model.

5.3 Hypothesis testing

The test of hypotheses using the structural model was performed with LISREL 8.7. We first evaluated the goodness of fit indices. Considering the overall fit indices ($\chi^2/\text{df}=2.07$, GFI=0.846, CFI=0.977, and NFI=0.960), we concluded that the research model provided a good model fit to the data. The standardized path coefficients for the research model are presented in figure 2. All three variables (outcome expectations-performance, outcome expectations-personal, and user satisfaction) were significantly related to system use activity and explained 72.7% of the variance in system use activity: outcome expectations-performance ($\beta=0.125$, p<0.05), outcome expectations-personal ($\beta=0.457$, p<0.01), and user satisfaction ($\beta=0.434$, p<0.01). Outcome expectations-performance and outcome expectations-personal showed significant relationships with perceived system performance (system quality and information quality) and explained 44.1% and 47.3% of the variance respectively: outcome expectations-performance ($\beta=0.338$, p<0.01; $\beta=0.453$, p<0.01) and outcome expectations-
personal ($\beta=0.447$, $p<0.01$; $\beta=0.360$, $p<0.01$). Perceived system performance had a significant relationship with user satisfaction and explained 61.8% of the variance in user satisfaction: system quality ($\beta=0.466$, $p<0.01$) and information quality ($\beta=0.457$, $p<0.01$). These results supported all hypotheses.

Figure 2. Results of research model (*$p<0.05$; **$p<0.01$; One-tail test).

6 DISCUSSION AND IMPLICATIONS

The study results suggested that as the user uses the system, both the expected usefulness related with job (outcome expectations-performance) and personally expected usefulness (outcome expectations-personal; e.g., recognizing my competence, accomplishment, or obtaining a promotion) have a significant effect on positive system use activity of users. In contrary to Compeau and Higgins (1995) who reported that outcome expectations-performance has a more significant impact on computer usage than outcome expectations-personal, this study showed that improving job performance through IS may not be a strong motivation for IS use on the individual level in the mandatory-use context. Rather, in this context, a good assessment of outcome expectations-personal like image as a constant driving force is an important factor in positive system activity beyond a simplistic view of system use such as the amount or frequency of IS use. Similar to the present study result, Tampoe (1993) suggested personal growth as a knowledge worker’s motivation, and argued that, in particular, professional and personal accomplishments are seen to be the driving force of ongoing motivation. Two types of outcome expectations and user satisfaction explained 70.5% of the variance in system use activity. This might imply that the user assesses the potential consequences derived from IT changes as an opportunity. This translates to positive system use activity (e.g., concentrating on the job, efforts to fit between task and system, and efforts to understand the system activity) as users try to cope with these kinds of challenge in terms of the Coping Theory. The results of this research also supported the importance of user satisfaction as a way to reduce the resistance of the user, when the system is closely associated with the user’s work. The cognitive process from user’s outcome expectations to positive system use activity shows that the user’s high expectations induce a high evaluation of perceived system performance (system quality and information quality), which is consistent with CDT. In addition, the results of this research supported those of existing IS research showing that perceived system quality and information quality have a significant effect on user satisfaction with system use.
The findings of the present study have several implications for theory and practice. From the theoretical perspective, first, we developed a theoretical model to explain the effect of outcome expectations on IS use activity of organization members. This proposed theoretical model provides an understanding of the role of outcome expectations for successful IS adaptation, especially outcome expectations-personal as intrinsic motivation in the perspective of expectancy management. In addition, the suggested research model can present the cognitive process from outcome expectations to positive IS use activity through the IS success factors (system quality, information quality, and user satisfaction). Second, this research proposed a new variable composed of three dimensions (immersion, reinvention, and learning) as a surrogate variable of system use or intention to use in mandatory IS use context. This may reflect a user’s actual system acceptance behavior in the condition when the introduced system use is decided by management. Most of the existing IS studies suffer limitations in representing various responses of users as they have focused the user’s system acceptance behavior simply on the system use or the intention to use without considering the IS use environment (voluntary or non-voluntary environment). Thus, the research results facilitate an understanding of the varied responses and behavior of users in IS acceptance studies by suggesting a new dependent variable. Third, the study finding implies that user satisfaction and positive system use behavior are significant factors in individual impact to achieve the goals of introducing a new system in an organization. Igbaria and Tan (1997) suggested that user satisfaction is a more important factor in individual impact than system usage and the influence of user satisfaction on an individual’s performance is partially mediated by system usage. A satisfied user shows a high-level of system use activity because he/she does not simply use the system, but tries hard to use it better. Eventually, the user shows a high-level individual performance.

From the practical perspective, the study results support two findings. First, the results represent how outcome expectations enforce the system use activity of users in the perspective of expectancy management. Szajna and Scamell (1993) showed that expectation can change as a user uses an IS, i.e., the user can have realistic expectations and form a positive user attitude about the newly introduced IS while performing appropriate expectations management. In other words, positive system use activity can be reinforced, thereby supporting successful implementation of the system through the user’s positive employment of the system and appropriate expectations management. This is required for systematic evaluation and reward systems. Systematic evaluation and reward are the easiest ways for the management to inform the members of the organization of worthwhile activities and perceived results from these activities. The management should focus on preparing a systematic plan to properly manage job performance and expectancy at the individual level. Second, outcome expectations-personal is enhanced when an individual’s colleagues encourage system use. A user will expect, among other things, that his/her behavior will be recognized and will please other members of the organization (Compeau and Higgins, 1995). The results of Compeau and Higgins’s (1995) study show that a user’s image can be enhanced as the user follows his/her colleagues’ requirements or recommendations to develop the initiative to use the system. Consequently, when the user has opportunities to discuss aspects of the IS changes with his/her colleagues, it may lead to positive system use activity. Thus, the management should be interested in creating a friendly job atmosphere that is conducive to discourses regarding IT changes among members of the organization.

Abstract

Online discussion forum, which plays an important role in online criticism, provides useful information such as online commentaries generated by other users. The paper uses regulatory focus theory to explain how online commentaries are processed differently depending on the user’s information processing style and how each self-regulatory mode moderates the impact of online commentaries on one’s overall evaluation of information. The study produces three major findings: (1) Promotion-focused users are more likely to distort online information than prevention-focused users do, (2) With hedonic information, information distortion will be stronger for promotion-focused users as compared to prevention-focused users, (3) With utilitarian information, information distortion will be stronger for prevention-focused people as compared to promotion-focused users. These finding have implications for online discussion forums in terms of how to manage users effectively and also how to prevent unintended criticism.

Keywords: online discussion forum, online commentary, regulatory focus, bias information processing

1 INTRODUCTION

Online discussion forums are widely available computer-supported communication technologies that facilitate virtual interaction on the Internet. Online discussion forums are open, internet-based forums that anyone can join to discuss topics of mutual interest (Desanctis, Fayard, Roach, and Jiang, 2003). By supporting extensive online interactions to complement conventional debating, online discussion forums can effectively enrich the process of acquiring, sharing and exchanging knowledge among users, thereby improving learning performance and outcomes (Leidner, Jarvenpaa, 1995). In online discussion forums such as internet news sites or online communities, we commonly face with online commentaries generated by others. Using these commentaries, online discussion forums can be a many-to-many communication space where users can post a new topic and reply to an existing one (Cunha and Orlikowski, 2008). According to “2008 Online Journalism Award” by Online News Association, large online discussion forum sites such as Beliefnet.com, Chron.com, and NYTimes.com were selected for their effective management of online commentary. As evidenced by such examples, the importance of online commentaries is on the rise recently. Although there is a great deal of research investigating the impact of online discussion forums on organizational change (Cunha and Orlikowski, 2008), intention of participation (Yang, Li, Tan, and Teo, 2008), learning (Thomas, 2002), and corporate reputation (Clack, 2001; Park and Lee, 2007), there has been no systematic
assessment of online commentaries’ role in framing users’ information processing and experiences of bias processing.

In light of this, we propose that online commentary has a crucial impact on users’ information processing, and also that there are psychological differences in the characteristics of such process. This study will specify the role of online commentary, and it will also test this empirically. It seeks to answer following questions: (1) Is there any information distortion behaviour depending on the direction of online commentaries (positive vs. negative)? (2) What kinds of differences are there for information distortion by users’ motivational orientation? (3) Does the characteristic of information affects these biased information processing?

In what follows, we first consider some previous research on information distortion and selective exposure to information, particularly those studies examining the people’s psychological information processing. We then describe the setting of our research study and the methods we use to connect these cognitive processing to the context of online discussion forums. We next discuss the information processing style of users in terms of regulatory focus, which we identified as a moderator for the valence of online commentaries and informational characteristics. We also discuss our finding that user’s information distortion by online commentaries was induced differently depending on users’ motivational orientation and informational characteristics. We conclude the paper by examining the research implications of the impact of online commentaries to the information processing during information adoption by the user.

2 THEORETICAL BACKGROUND AND HYPOTHESES

2.1 Information distortion and selective exposure to information in online discussion forums

As noted earlier, we expected that users of online discussion forum may distort their preference toward information by adopting online commentaries. It is widely known that after a decision is made, people distort information in favor of the chosen alternative in order to reduce cognitive dissonance (Elliot and Devine, 1994; Fazio and Cooper, 1983). In online discussion forum, users may seek online commentaries that confirm their choice and depreciated encountered commentaries that oppose it. Investing these phenomena, we lift up online commentaries to the surface of theoretical context.

Information distortion is defined as a change in the forms, meaning and/or availability of information (O’Reilly, 1978; Huber, 1982). Larson and King (1996) mentioned that tendency to suppress or alter ‘bad news’, or to exaggerate and circulated ‘good news’. Also, systemic filtering of unfavourable information is referred to information distortion. More specific, three types of information distortion are identified. One type of information distortion occurs when the sender does not intend to distort information but, because of an inadvertent change in form, meaning and/or availability, information becomes inaccurate. This type of distortion is referred to as unintentional distortion. Information distortion can also be malicious in nature. Departments or individuals who do not get along may distort information to mislead or satisfy their own objectives at the expense of the other party. This type of information distortion is referred to as malicious intentional distortion. A third type of information distortion occurs when information is intentionally distorted, either for the benefit of the receiver or for the benefit of both the sender and the receiving party. This third type of distortion is referred to as well-meaning intentional distortion. Users in online discussion forums may have this third type of information distortion. They are likely to find online commentaries for benefit of them to reduce cognitive dissonance. What might cause users to distort information in online discussion forum? To answer this question, we examined the effects of valence of online commentary (positive or negative) on users’ selective exposure to information.
People often systematically prefer information that is consistent with their beliefs, attitudes, or decisions and, in contrast, neglect inconsistent information. This phenomenon is called selective exposure to information, and online discussion forum users are likely to select information which their preference matches with online commentary. A great deal of empirical research on selective exposure to information has been conducted in the context of dissonance theory (Festinger, 1957; Frey, 1986; Jonas, Schulz-Hardt, Frey, and Thelen, 2001). Dissonance theory suggests that subsequent to having made a decision, decision makers experience cognitive dissonance because of the salient negative aspects of the selected alternative and the salient positive aspects of the rejected alternative. One prominent means of reducing dissonance is selective exposure to consistent information (Festinger, 1957). Previous research has revealed that such biased information-search processes occur in different contexts, including attitudes (Lundgren and Prislin, 1998), self-serving conclusions (Frey, 1981; Holton and Pyszczynski, 1989), and online news (Best, Chmielewski, and Krueger, 2005). Most important to the focus of the online discussion forums, biased information processing has also been consistently observed following individual and group decisions (Jonas, Schulz-Hardt, Frey, and Thelen, 2001; Schulz-Hardt, Jochims, and Frey 2002). In the context of online discussion forums, we expected that selective exposure to information has also been consistently observed between positive-framed online commentaries and negative-framed online commentaries. Moreover, we proposed that the valence of online commentary (positive vs. negative) can affect users’ information preference, and these effects can be moderated by users’ motivational orientation and informational characteristics.

2.2 Regulatory focus theory and informational characteristics

For the past few decades, many researches in IS has been focused on users’ motivational factor which can explain their information processing in many contexts (Gill, 1996; Couger, Zawacki, Oppermann, 1979; Burton, Chen, and Grover, 1992). In this research, we focused on online discussion forum users’ information processing style, specifically motivational orientation factor: self-regulatory. Regulatory focus theory (Higgins, 1997) offers an insight into this motivational difference of informational processors. Regulatory focus posits two motivational orientations: a promotion focus and a prevention focus. Promotion-focused people emphasize aspirations and achievements and focus on the presence and absence of positive outcomes. Prevention-focused people are concerned with responsibilities and safety and focus on the presence and absence of negative outcomes (Shah, Higgins, and Friedman, 1998). In accord, Idson, Liberman, and Higgins (2000) found that promotion-focused people exhibited greater “eagerness” in working toward a gain than guarding against a nongain, while prevention-focused people displayed greater “vigilance” in preventing a loss than working toward a nonloss. In this regard, in online discussion forums, promotion-focused users display greater eagerness in striving toward a positive outcome (positive online commentaries) than away from its absence (negative online commentaries). Further, consistent with these users’ desire to secure hits and avoid misses, positive online commentaries in online discussion forums allows for an inclusion of consistent original information. In contrast, prevention-focused users are concerned about negative outcome (negative online commentaries) more intensely than they are concerned with its absence. They focus on identifying correct rejections and on avoiding incorrect “hits.” Considered in this framework, we address that these motivational differences can induce different bias information processing and selective exposure to information in online discussion forums.

As evidenced by their endorsement of multiple alternatives and placing lower weight on prior choices in making future decisions, promotion-focused users should display a lower tendency to allow their evaluation of one information to bias the other information’s evaluation. In contrast, based on their tendency to entertain fewer hypotheses and to place greater weight on prior choices when making future decisions, prevention-focused users should allow their evaluation of negative information to influence their evaluation of the other. Thus, we expect that the tendency of prevention-focused users to allow their rating of online commentaries to affect the overall information’s rating is due to the possibility that they have a greater preference for consistency than do promotion-focused users. Preference for consistency (PFC), the “desire to be and to be seen as consistent” (Guadagno, Asher,
Demaine, and Cialdini, 2001), leads users with a higher PFC to weight previous expectations or choices more when engaged in subsequent decisions. Further, low-PFC users seen open and oriented to the new, in ways that are relatively unconstrained by the established (Cialdini, Trost, and Newsom, 1995). Related to regulatory focus, Higgins (1996) suggests that prevention-focused users' tendency to narrow alternatives “raise the intriguing possibility that self-consistency motivation is linked to the prevention focus of self-regulation.” So, we expect differences in PFC associated with different regulatory foci to manifest different level of information distortion in online discussion forums by online commentaries.

**H1:** Promotion-focused users are more likely to distort online information than prevention-focused users.

In line with consumer behaviour literature that distinguishes between utilitarian and hedonic products (Hirschman and Holbrook, 1982) and applying literature to IS context (Heijden, 2004), we can classify these types of information in online discussion forums. There are two kinds of information in online discussion forums: utilitarian information and hedonic information. Consistent with previous research in informational characteristic, we use the term “utilitarian information” to refer to the functional, instrumental, practical benefits of informational characteristic, and we use the term “hedonic information” to refer to its aesthetic, experiential, and enjoyment-related information (Batra and Ahtola, 1990; Chitturi, Raghunathan, and Mahajan, 2007; Dhar and Wertenbroch, 2000). In the context of online discussion forums, for example, the economic theme and health information can be utilitarian information, whereas aesthetic appeal from entertainment news. The consumer behaviour literature demonstrates that what specifically determines intention to consume depends on the utilitarian or hedonic nature of the product (Babin, Darden, and Griffin, 1994; Holt, 1995). We develop a parallel argument that what shapes information distortion is dependent on the utilitarian or hedonic nature of information in online discussion forums.

There is converging evidence that the types of goals people to be fulfilled by the utilitarian dimension of a product are different form those they seek from the hedonic dimension (Chernev, 2004). Specifically, whereas people expect the fulfilment of prevention goals on the utilitarian dimension, they expect the fulfilment of promotion goals on the hedonic dimension (Chitturi, Raghunathan, and Mahajan, 2007). According to the regulatory focus theory, prevention goals are those that ought to be met, such as “behaving in a safe and secure manner” and “being responsible.” Fulfillment of prevention goals in the context of online discussion forums eliminates or significantly reduces the probability of painful information such as negative online commentaries, thus making overall evaluation of information that results form fulfilment of prevention goals. For example, in the case of economic news information, prevention goals might be served by its useful features or helpful online commentaries. Conversely, promotion goals are those that a person aspires to meet, such as “fun or enjoyable information.” Fulfillment of promotion goals in the hedonic information such as entertainment news significantly increases the probability of a pleasurable experience, thus enabling users to distort information that result from the adoption of online commentaries. Therefore, following hypotheses are proposed that the different level of information distortion depending on informational characteristic (hedonic vs. utilitarian) and users’ regulatory focus (prevention vs. promotion). Also, the proposed conceptual framework in Figure 1 captures the relationship among hedonic versus utilitarian information, the impact of online commentaries, and users’ regulatory focus, respectively.

**H2:** In case of hedonic information, information distortion will be stronger for promotion-focused users as compared to prevention-focused users.

**H3:** In case of utilitarian information, information distortion will be stronger for prevention-focused people as compared to promotion-focused users.
3 RESEARCH DESIGN AND METHOD

3.1 Design, Subjects, Experimental System, and Procedure

The present study uses a $2 \times 2 \times 2$ between-subjects experiment manipulating regulatory focus (promotion vs. prevention), valence of online commentaries (positive vs. negative), and information characteristic (utilitarian vs. hedonic). Two hundred seven college students participated in the study voluntarily. Their average age is 21.8 and 54.2% is male. Most of the subjects had participated in online discussion forum such as beliefnet.com or NY Times.com. Subjects were randomly assigned to each of the cells in the factorial design, and they participated in different experimental conditions in a single session. The original information used in the experiment were two news manipulating information characteristic. Consistent with previous researches, utilitarian information contains useful and helpful reports about economic phenomenon. In contrast, hedonic information contains interesting and exciting reports about entertainment gossip. For the experiment, eight-independent virtual online discussion forum sites were constructed for each condition. The online discussion forum sites contained both original news information and the set of online commentaries. This experimental system encapsulates the attributes of a real online discussion forums sites. In an experiment, the subjects followed instructions that address a scenario manipulating different regulatory foci. Then original news information was provided to each group, and measured their evaluation about news. After measuring prior evaluation, subjects received online commentaries together with original news information, and measure their evaluation again. Subsequently, the subjects gave an answer questions about preference for consistency, manipulation checks, in regular sequence.

3.2 Independent Variables

3.2.1 Information characteristics (Utilitarian vs. Hedonic)

Based on the news information from a real online discussion forum, six candidates for news information were collected. To increase face validity, twelve subjects participated in a pre-test that checks whether this information was perceived in the appropriated dichotomy (utilitarian vs. hedonic). In the main experiment, relatively different news information was used. Utilitarian information was manipulated with instrumental and functional topic such as economic news, whereas hedonic information provide fun, pleasure, and excite topic such as entertainment gossip. This relative hedonic or utilitarian nature of information is consistent with prior research (Batra and Ahtola, 1990; Dhar and Wertenbroch, 2000). Each online news contained an attribute of information such as instrumental or
pleasure topics, and the length of information was set at fifteen lines. The length of each news information was controlled to avoid the effects of information quantity, and to focus on the effects of information characteristic. Also, original news information provided neutral opinion to focus on the effects of the valence of online commentaries.

3.2.2 The valence of online commentaries (Positive vs. Negative)

Before manipulating the valence of online commentaries, forty candidates for online commentaries were collected from a real online discussion forum. Each online commentaries’ length was 2 lines and consist of 40 words. A focus group interview organized with ten people who frequently use online discussion forum was performed. In the FGI, subjects were asked the degree of strength that how much online commentaries agree to original news or not. After the FGI, we calculated strength of online commentaries with nine-point scale (where -4 = extremely opposite, 0 = neutral, and 4 = extremely agree), and among same strength-commentaries, finally five positive online commentaries and five negative online commentaries were selected. The positive valence of online commentaries was organized with seven positive commentaries and three negative commentaries, and negative valence of online commentaries was organized vice versa. Figure 2 shows example of experimental online discussion forum screen.

3.2.3 Regulatory Focus (Prevention vs. Promotion)

To manipulate regulatory focus, we provide a role-play for subjects in the introductory session. This manipulation is very much like that of situational regulatory focus in past studies (Jain, Lindsey, Agrawal, and Maheswaran, 2007; Shah, Higgins, and Friedman, 1998). Regulatory focus was manipulated first by requiring subjects to unscramble six jumbled words that were actually names of commonly used cosmetic brands. Prevention condition subjects were informed: “Each incorrectly unscrambled name loses you 2 point. If you do not get a name wrong, you won’t lose 2 points. Your goal is to lose as few points as possible by minimizing the number of names you get wrong. For every brand name that you wrong, you will lose 2 point. For every brand name that you don’t get wrong, you won’t lose 2 point.” In contrast, promotion condition subjects were informed: “Each correctly unscrambled name gains you 2 points. If you do not get a name correct, you will not gain 2 points. Your goal is to gain as many points as possible by minimizing the number of names you get right. For every brand name that you get right, you will win 2 points. For every brand name that you do not get right, you won’t win 2 points.” Due to the dichotomized regulatory focus, prevention-focused subjects processed the information both original news and online commentaries more carefully via their concern about the presence of negative online commentaries, but promotion-focused subjects processed the information both original news and online commentaries more carefully via their concern for positive online commentaries. This is consistent with regulatory focus theory.

3.3 Control Variables and Dependent Variable

Control variables: Experimental systems should consider other effects such as the characteristics of subjects and exogenous stimuli on all matters. It could be affected by the tendency of reliance on online commentaries, general attitude toward the online discussion forum. To focus our independent variables and increase internal validity, the following methods were employed to control confounding effects on evaluation of information. First, the characteristics of subjects comprising individual differences such as online searching styles and personality were controlled by allotting subjects to each condition at random. Second, this present experiment used imaginary online discussion forums’ names. If we consider the online discussion forums’ reputation, many compounding effects are revealed. An online discussion forum which has a strong reputation may tempt users, and they only regard the reputational cue as serious. In this case, since the online discussion forums’ role (i.e. informational role) cannot work, the work retailer is probably unsuitable. Finally, prior knowledge
about original news information, the degree of reliance on online commentaries was measured by survey items in experiments, and they were used as control variables in an ANOVA analysis.

**Dependent variable:** Preference change toward information used in dependent variable (Russo, Medvec, and Meloy, 1996). It indicates the level of information distortion, and was measured by the difference between before and after the evaluation of information. First, participants indicated their evaluation of online news on three scales anchored ‘favorable/unfavorable,’ ‘good/bad,’ and ‘desirable/undesirable.’ And then, participants were asked their evaluation on both online news and according online commentaries. Preference change toward information was developed by subtracting next evaluation to prior evaluation.

### Oil and Gasoline

In 1999, the price of oil hovered around $18 a barrel. In July 2008, it reached a peak of $147 a barrel. In the months that followed, as fears of a global recession grew, prices plunged to the $75 a barrel range, a roller coaster ride that left both producers and consumers confused and wrung out. Prices were still far higher than they had been a few years earlier, but oil-producing countries that had reshaped their economies around the huge influx of revenues faced a suddenly altered landscape. Many factors contributed to the long buildup between 1999 and 2008, including the relentless growth of the economies of China and India and widespread instability in oil-producing regions, including Iraq and Nigeria’s delta region. The triple-digit oil prices that followed appeared to redraw the economic and political map of the world, challenging some old notions of power. Oil-rich nations made enjoying historic gains and opportunities, while major importers—including China and India, home to a third of the world’s population—confronted rising economic and social costs.

**Figure 2.** The experimental online discussion forum site (example of utilitarian information and the negative online commentaries condition)
4 RESEARCH RESULTS

4.1 Manipulation Checks

To check the manipulation of informational characteristic, we used the perceived measure adopted from prior research (Batra and Ahtola, 1990). Informational characteristic was measured using four seven-point semantic differential scales (the utilitarian component by the items useful/useless, and beneficial/harmful; the hedonic component by the items pleasant/unpleasant, and nice/awful). The ANOVA analysis indicated that there are significant differences between the utilitarian information condition and the hedonic information condition [for utilitarian component measure, M=4.68 vs. 2.41, F(1,206)=167.295, and for hedonic component measure, M=5.31 vs. 1.91, F(1,206)=370.69]. The subjects also checked two items designed to check neutrality of original news information (“This online news is neutral,” and “This online news contained both support arguments and counter argument.”). The ANOVA results show that the neutrality of original news information was also successfully manipulated [M(utilitarian information)=3.80 vs. M(hedonic information)=3.24, p>0.1]. Then, as a check on the valence of online commentaries, we measured two items: “the online commentaries about this online news are mainly supportive/opposite (reversed coding).” Using this method, the valence of online commentaries was manipulated successfully [for utilitarian news information, M(positive commentaries)=4.68 vs. M(negative commentaries)=2.41, F(1,206)=167.295; for hedonic news information, M(positive commentaries)=5.31 vs. M(negative commentaries)=1.91, F(1,206)=370.69]. Finally, the efficacy of the regulatory focus manipulation was assessed by asking subjects to indicate the “extent to which you focused on scoring more points when playing the brand name quiz” and “the extent to which you focused on not losing any points when playing the brand name quiz.” The ANOVA tests confirmed that promotion-focused (prevention-focused) subjects concentrated more on winning (not losing) points [M(promotion/score more)=5.09, M(promotion/not loss)=4.50, F(1,206)=6.96; M(prevention/score more)=3.39, M(prevention/not loss)=4.93, F(1,206)=53.05]. Thus, the manipulations were successful.

4.2 Hypothesis Testing

The preference change toward information (Cronbach’s Alpha = 0.84) was calculated as a difference between after and before evaluation for information (where -3 indicated “strongly disagree,” 0 indicated “neutral,” and 3 indicated “strongly agree”). Table 3 presents the mean and standard deviation of dependent measures for each cell. The dependent measures were analyzed in a series of 2 (Informational characteristic) × 2 (The valence of online commentaries) × 2 (Regulatory focus) ANCOVA. The ANCOVA results are in Table 4. The covariate variables were not significant. So, exogenous factors were controlled successfully.

Proceedings ECIS 2009
The analysis indicated the presence of a significant main effect of users’ regulatory focus \[F(1,206)=5.323, p<0.05\]. It means that promotion-focused users more distort information than prevention-focused users. As suggested earlier in this paper, the preference for consistency (PFC) of users can affect their bias information processing. To validate and understand the underlying mechanism of plausible explanations, simple regressions are conducted both promotion-focused users and prevention-focused users. Consistent with the expected regulatory focus-PFC relationship, analysis revealed that, promotion-focused subjects are likely to distort information with no effect of PFC on preference change \[t(1,101)=0.515, \beta =0.051, p>0.1\]. In contrast, prevention-focused led subjects to less distort information with marginal significant effect of PFC on preference change \[t(1,104)=1.673, \beta =0.163, p<0.1\]. Therefore, Hypothesis 1 was accepted.

Also, there is a significant main effect of the valence of online commentaries \[F(1,206)=5.711, p<0.05\]. It means that users in online discussion forum are affected their attitude toward information by online commentaries generated by other users, and form their preference based on these online commentaries. The set of positive-direction online commentaries lift up users’ evaluation on information, but the set of negative-direction online commentaries reduce users’ evaluation on information irrespective of informational characteristics.

![Figure 5. Three-way Interaction for preference change toward information](image)

We further explored the different effects of the manipulation of users’ regulatory focus and the valence of online commentaries under hedonic and utilitarian information conditions. Theses analyses were possible because the three-way interaction effect of informational characteristic \( \times \) regulatory focus \( \times \) the valence of online commentaries was significant \[F(1,206)=4.178, p<0.05\]. For hedonic information, promotion-focused subjects showed greater tendency that change their preference by
positive and negative online commentaries \[F(1,101)=7.652, p<0.01\]. But, for prevention-focused subjects, there are no significant preference change depending on the valence of online commentaries \[F(1,104)=0.290, p>0.1\]. These results support our predictions that information distortion can be stronger for promotion-focused users than for prevention-focused users in case of hedonic information (see Figure 5 on the left). Accordingly, Hypothesis 2 was accepted.

Under utilitarian information, in contrast, prevention-focused subjects showed greater change of preference by the direction of online commentaries \[F(1,104)=7.24, p<0.01\]. For promotion-focused subjects, there are also marginal preference change \[F(1,101)=2.58, p<0.1\]. But, their information distortion is less strong compared with that of prevention-focused subjects (see Figure 5 on the right). Such results might be interpreted as suggesting the difference pattern of information distortion in utilitarian information depending on users’ self-regulatory. Specifically, information can be stronger for prevention-focused users than promotion-focused users in case of utilitarian information. Thus, Hypothesis 3 was accepted.

5 CONCLUSION AND LIMITATIONS

The online discussion forum has increasingly been recognized as a useful space that facilitates virtual interaction and forms online criticism. We focused on the question of users’ information preferences change due to specific direction of online commentaries in order to investigate the influence of users’ motivational orientation and the informational characteristics in online discussion forums. The empirical results indicated that the informational characteristic and the valence of online commentaries were important because they change the preference to the given information, and these patterns were different depending on users’ regulatory focus. The primary insights that this research provides are as follows: (1) Overall, promotion-focused users distort their preference more than prevention-focused users do when adopting online commentaries, (2) Information that meets or exceeds users’ hedonic needs and fulfills promotion goals enhance users’ information distortion, and (3) Information that meets or exceeds users’ utilitarian needs and fulfills prevention goals enhance users’ information distortion in online discussion forums. Furthermore, the research finds that the online commentaries have significant impact on users’ preference change to information. For the two decomposed concepts of the regulatory focus, promotion-focused users react more to the valence of online commentaries in case of providing hedonic information. In contrast, prevention-focused users are more sensitive to the valence of online commentaries when utilitarian information is presented. We establish a causal asymmetric link between framing and focus that connects information distortion of utilitarian information and hedonic information. Furthermore, we identify the process underlying this different information distortion. The higher PFC associated with prevention-focus induces little preference change to information. But, the lower PFC associated with promotion-focus allows for more preference change to information. PFC may also play a role in information distortion phenomenon occurring in online discussion forum such as the prevention-focused users prefer to the status quo and the notion that promotion-focused users entertain multiple hypotheses.

For theoretical contribution, building on the work of Yang, Li, Tan, and Teo (2007), Cunha and Orlikowski (2008), we proposed that sophisticated information processing in online discussion forums. Our examination of the information distortion in online discussion forum by online commentary has implications for the online communicational and educational literature in that it provides evidence for users’ biased information processing. To the best of our knowledge, this is the first study to demonstrate such a correspondence among informational characteristics (hedonic vs. utilitarian), the valence of online commentaries (positive vs. negative), and users’ regulatory focus (prevention vs. promotion). The research findings would have significant implications for managers in online discussion forums. Practically, this study’s major results emphasize the importance of proper management of online commentaries. Because of negative aspects of unintended online criticism, managers and users are often compelled to process among various attributes of information. Since online commentaries are differently processed depending on users’ motivational orientation, managers
can use this result strategically as a new channel that provides a bridge between users and online information providers.

The present study has several limitations. First, the reputation of the forum itself was not considered. Since users did not have a holistic valuation of the reputation of the online discussion forums, the effect of online discussions’ reputation could be explained by additional study. Second, in this study, the quantity of online commentaries was fixed to avoid unintended effects. It could be possible that the quantity of online commentaries act as a signal for the popularity of the information. Further research considering this issue should be conducted. Finally, regulatory focus was manipulated by differing situational role-playing. Individual’s regulatory focus can be either situational or chronic. From this point of view, users’ chronic regulatory focus needs to be considered in the future study. In spite of these limitations, the result described in this study shows that online news and related online commentaries need to monitor closely the extremely negative or defamatory postings in their online discussion forums in order to minimize possible spillover of negative sentiments from online discussion forum users to others, and also provides a rationale for online discussion forums to offer venue for online public discussions.

Proceedings ECIS 2009
THE APPLICATION OF A PHENOMENOLOGICAL FRAMEWORK TO ASSESS USER EXPERIENCE WITH MUSEUM TECHNOLOGIES

Pallud, Jessie, CESAG Research Center, EM Strasbourg Business School, 61 Avenue de la Forêt Noire, 67085 Strasbourg Cedex, France, jessie.pallud@em-strasbourg.eu

Abstract

Providing visitors with a valuable experience of the past has become a crucial mission for cultural heritage institutions. The experience of the past is one where visitors understand the museum’s communications about the meaning of artefacts and where visitors undertake an active role in interpretation and reflection on the past. Several studies promote technologies as a good way for museums to reenergize their relationships with their visitors. But even as some research has concentrated more and more on visitor experiences, this work has neither particularly stressed on visitors’ experience of the past nor on their evaluation of museum technologies with respect to their potential for engendering a better experience of the past.

Monod and Klein (2005) elaborated a phenomenological framework with six criteria to evaluate IT used in the cultural heritage. Since it has not been empirically “validated” yet, the objective of this paper is to employ these criteria with samples of users of museum technologies and in the process determine whether these criteria can be met by IT.

Our field study indicates that technologies available in museums positively contribute to an experience of the past.

Keywords: Museum technologies, evaluation, experience, phenomenology, Heidegger, historicity.
1 INTRODUCTION

Museum studies in a wide range of journals have noticed individuals having an increased interest in the past in general (Liew 2005), and more specifically in heritage sites (Poria et al. 2006). The principal motivations for heritage site visits are the desire to connect with one’s heritage and the desire to learn more about history (Poria et al. 2006). According to Kimmelman (2001), “we go to museums to remind ourselves [about] who we are”. There are many benefits that visitors gain from heritage sites, from connections with the past and identity finding (Chronis 2005) to a “nostalgic bonding” linked to the recollection of things belonging to the past (Holbrook and Schindler 1994). The past is a valuable experience because of its civilizing effects and the extent to which it becomes a highly personal experience for the participant. It is one where visitors understand the museum’s communication about the meaning of artifacts and where they undertake an active role in interpretation and reflection on the past.

Consequently, providing visitors with a valuable experience of the past has become a crucial mission for cultural heritage institutions. Technologies have been presented as the panacea to enhancing visitor experience. Indeed, numerous studies promote technologies as a reasonable way for museums to reenergize their relationships with their visitors (Fopp 1997; Messham-Muir 2005; Vom Lehn and Heath 2005). For instance, virtual reality technologies can represent “items which have not survived, creatures which are extinct, the visions of great men which were never realized or even the imagination of artists and thinkers” (Fopp 1997, p. 146). By displaying events from the past, virtual reality helps people relive historical events in their mind. Furthermore, the “first-person perspective” (Lok 2004, p.50) enables visitors to feel more concerned by what they see and so to project themselves in history. Hybrid environments or mixed reality simulators, devices that enable visitors to look at real and virtual objects in the same time (Lok 2004; Sparacino 2004), reduce the distance between past and present objects by allowing visitors to directly compare objects belonging to two different eras. More common museum technologies like audioguides, interactive and multimedia kiosks generally provide historical background and tutorial aids to visitors.

However, even while some prior research has focused on visitor experience, there has been neither a particular stress on visitor experience of the past nor on an evaluation of the technologies that are proposed to enhance better experience of the past. In effect, museum professionals have few guidelines on how to assess visitor experience, particularly in the context of IT use (Institute of Museum and Library Services 2006; Pujol Tost and Economou 2007).

Monod and Klein (2005) have proposed a phenomenological framework to evaluate IT used in the cultural heritage. Nonetheless, this framework has not been empirically tested and the criteria have not been operationalized with subjects. Therefore, this research aims at examining these phenomenological concepts. The subsequent research questions that guide this study are the following:

1. To what extent do museum technologies contribute to an experience of the past? More precisely, to what extent does IT meet the criteria proposed by Monod and Klein (2005) and convey a phenomenological experience to visitors?

2 THE EVALUATION OF VISITOR EXPERIENCE

Researchers from different disciplines have developed a wide variety of frameworks to study visitor needs and to provide directions to museums (Anderson 2004; Kotler and Kotler 2000). It is noteworthy that these frameworks have remained conceptual since they have not been empirically tested within museums or with visitors. Furthermore, they do not explicitly address the role of technologies in museums. For instance, the marketing researchers Kotler and Kotler (2000), propose
three dimensions on which museum professionals should focus in order to improve visitor experience. They are: (1) the variety of visitor experiences, (2) the level and depth of visitor experiences and (3) the design and orchestration of visitor experiences. While Kotler and Kotler (2000) principally identify operational levers to enhance visitor experience, Anderson’s framework (2004) points out the organizational functions of museums serving as a foundation to develop a visitor perspective. More precisely, Anderson (2004) suggests four domains on which museums should rely in order to be visitor oriented: 1) governance, 2) institutional priorities, 3) management strategies and 4) communication style.

Certainly, a number of empirical frameworks do address visitor experience and some examine visitor experience with technologies (Falk and Dierking 1992; Peacock and Brownbill 2007). But even while these studies do focus on visitor experience, there has been neither a particular stress on visitor experience of the past nor on an evaluation of the technologies that are thought to lead to a better experience of the past for visitors. Additionally, museum professionals have few guidelines on how to assess visitor experience, particularly in the context of IT use (Institute of Museum and Library Services 2006; Pujol Tost and Economou 2007). According to a recent report,

“[Museums] would like information, training, and guidance on how to better assess user needs, including methods of collecting information about the characteristics of users, how they use an institution’s technology and digitization services and products, and for what purpose.” (IMLS, 2006, p.124)

Information systems evaluation is an important research stream for the IS discipline and it has given rise to several frameworks, such as the IS Success Model (Delone and McLean 1992; Delone and McLean 2003) and the Task-Technology Fit (Goodhue and Thompson 1995). This issue has also been addressed in several IS journals and in special issues (e.g., Irani and Fitzgerald 2002). For instance, Delone and McLean (1992) elaborated the IS Success Model in order to determine the factors that play a role in IS success. This model was refined in 2003 to include other variables and new linkages that appear to be important in the assessment of IS. Recently, Petter et al. (2008) in their meta-analytical review of the IS Success Model highlighted the fact that this research model has mainly been applied to utilitarian contexts.

“[M]what still remains to be discovered is if the D&M model is appropriate for hedonic IS. Some of the dimensions may no longer be relevant or may need to be measured differently for gaming, social networking, or other types of IS used for enjoyment.” (Petter et al. 2008, p. 258)

Consequently, prior research dealing with evaluation has mainly focused on a utilitarian perspective of IS evaluation, that is trying to determinate how IS can increase organizational or individual performance. Appropriate for this utilitarian context, users are often represented by managers or employees.

What is different about the cultural heritage context, however, is that IT users are best compared to visitors but visitor performance does not appear to be as important as in company settings. Rather, enhancing user experience by providing entertainment, education, and a good experience of the past are the crucial targets for museums. According to the well-known museologist Sola (1997), “a museum should assist people to understand the experience of the past. In its mutual relationship with its users, it should find in past experience the wisdom necessary for the present and the future” (Boylan 2002). Moreover, museum technologies tend to serve hedonic purposes. Therefore, the evaluation of IS deployed in cultural heritage institutions should be done in accordance with these cultural objectives.

Some researchers who have paid attention to hedonic information systems (Van der Heijden 2004; Wakefield and Whitten 2006) show that they require specific criteria for their evaluation. For instance, Van der Heijden (2004) highlight the fact that enjoyment and ease of use are more relevant in the
assessment of hedonic technologies. The Human-Computer Interaction subfield has also devoted part of its research attention to hedonic systems. User reactions, such as cognitive and affective reactions, have been conjointly analyzed to better evaluate the efficiency of information systems (Sun and Zhang 2006).

Even if cultural heritage research focuses more on visitor experience, there is neither a particular stress on visitors’ experience of the past nor on evaluations of the technologies with respect to their potential for engendering this better experience of the past. Furthermore, Monod and Klein (2005) explain that the frameworks that exist to evaluate IT in cultural heritage are mainly driven by technological determinism. Indeed, these models generally postulate that the implementation of IS in museums will positively impact visitor satisfaction and experience even while there is little verification of whether these technologies really achieve their goal (Monod and Klein 2005). In the next section we present a framework that addresses many of these gaps by evaluating user experience with IT from a phenomenological point of view.

3 THE VALUE OF PHENOMENOLOGY IN STUDYING VISITOR EXPERIENCE: INTRODUCTION OF THE CONCEPTUAL FRAMEWORK

3.1 Phenomenology: How this Philosophy Particularly Fits Museums

Phenomenology is the “science of phenomena” (Heidegger 1962, p.50). This is also a philosophical movement that appeared in the first half of the 20th century (Spiegelberg 1975). It focuses on the experiences of individuals. Indeed, it aims at studying “phenomena as consciously experienced” (Spiegelberg 1975, p. 3). This philosophical underpinning was initiated by Husserl (1936) and his student Heidegger (1962). They encouraged researchers and philosophers to turn “to the things themselves”. People should turn themselves “to the world as it is already experienced” (Ilharco 2002, p. 304). Other philosophers like Merleau-Ponty and Sartre also nurtured phenomenology through the concepts of self and embodiment (Smith 2003). While these other philosophers are important in the development of the philosophy of phenomenology, our research follows Heidegger’s view as it was developed in his book Being and Time (1962).

Phenomenology aims at studying individual experiences. Heidegger (1962) contended that human beings need action and praxis with objects (i.e., to engage with them) in order to feel closer to these things (Smith 2003). Therefore, individuals cannot see an object or imagine it in order to understand it because it is only a “representational form of intentionality” (Smith 2003). This argument leads to conclusion that being able to touch things or to manipulate them contributes to a better experience and to better interpretation.

As indicated in the title of his book, Heidegger (1962) addresses the question of time and its relation to being. Heidegger asserted that time has an ontological function since it constitutes being (Dastur 1993). Indeed, “we are temporal beings not because we exist in time but because time is really what composes our beings” (Dastur 1993, p. 301). Temporal beings are open because individuals are always turned towards the future and the past, and their self-meaning is not fixed (Lyotard 1992).

Additionally, it seems that history plays a role in people’s existence as it can shape their present and future (Monod and Klein 2005). In effect, historical objects represent remains of the past and consequently, they give to people their historical dimension. It is thanks to these remains that individuals know that something before them existed (Heidegger 1962). However, these historical objects have a secondary historicity; they are historical because they belonged to a past humanity and were created by historical beings (Lyotard 1992).
In that Heidegger’s phenomenology puts a special emphasis on time (history), human existence and experience seem to be perfectly appropriate to the study of cultural heritage institutions, whose goals are to display past heritage and focus on visitor experiences.

3.2  Phenomenological Framework: Presentation of the Criteria

Based on Heidegger’s concept of historicity, Monod and Klein (2005) elaborated a framework to evaluate technologies of cultural heritage institutions. The framework aims to determine whether technologies, by meeting user requirements, have interpretive characteristics, and whether IT contributes to a good experience of past. In their original framework, the authors included eight criteria: re-enactment, embodiment, context, self-projection, possibilities of being, historical self, inquiring being, and universality in uniqueness. These criteria were reduced to six in a more recent version, and the framework now focuses on context, embodiment, self-projection, re-enactment, possibilities of being, and historicity. These criteria are defined in greater detail hereafter.

- **Context**

  The first criterion proposed by Monod and Klein (2005) to provide IT users with a phenomenological experience is context. According to Monod and Klein (2005), context is represented by the shared values, overarching values and beliefs that contribute to meaning-making experiences. Indeed, without cultural and historical context it is difficult for individuals to have a comprehensive understanding of their personal history and of history in general. It is very frequently true that in cultural heritage sites, visitors do not understand the purpose of an object or even realize its historical importance. Indeed, Schärer (1996) contends that information provided within museums is generally more structural (some general indications) than cultural (information on the earlier context of use).

- **Re-enactment**

  Re-enactment is the second criterion identified by Monod and Klein (2005). “Re-enact” in a literal sense means to “perform again” or “to go through a second time” (The American Heritage Dictionary of the English Language 2000). Collingwood (1946), who studied philosophy of history and devoted a lot of his research to re-enactment issues, argues that the work of historians should be seen as an imaginative reconstruction. Indeed, re-enactment was first set forth as an important capability for historians since these scholars need to relive historical events in their mind in order to interpret history and to better convey it to people (Collingwood 1946). Consequently, re-enactment can be viewed as a methodology to produce historical knowledge (Nielsen 1981). It is noteworthy that this possibility of reenactment should also be at visitors’ disposal in order to enhance their experience of the past (Monod and Klein 2005). Indeed, if visitors can relive historical events in their mind, they will be projected into the past and are more likely to understand historical personalities, for instance, or way of life in the past.

- **Embodiment**

  The third dimension deemed to be important for IT user experience is embodiment. Embodiment is a notion that was developed principally by Merleau-Ponty (1962). The Cambridge Dictionary of Philosophy (1999) gives this definition of embodiment. It is “the bodily aspects of human subjectivity. Embodiment is not a concept that pertains to the body grasped as a physiological entity. Rather it pertains to the phenomenal body and to the role it plays in our object-directed experiences.”

  Mingers (2001) also examined the concept of embodiment and its implications for IS research. According to Mingers (2001), embodiment resides in the fact that “our basic attitude is always (except in pure contemplation) one of doing, acting, having some aim in mind, having some concern” (p. 108). His explanation sheds more light on the definition of The Cambridge Dictionary of Philosophy. From this observation we can conclude that embodiment designates the sensory experiences that an individual may have with objects encountered in the world.

- **Self-projection**
Monod and Klein (2005) proposed self-projection as a fourth criterion. Self-projection works by allowing one to put oneself mentally in the shoes of historical characters and by imagining what one could and would have done in another’s situation. This type of self-projection has both cognitive and emotional aspects. The cognitive aspects are linked to the deliberations that lead to decisions and actions actually taken whereas the affective aspects are related to emotions such as love, anger, surprise, joy, etc.

- **Possibilities of being**

Possibility of being is the fifth phenomenological criterion. According to Monod and Klein (2005), a phenomenological experience helps people realizing the constraints that have been created by the past and the impacts on their present life. This leads to the realization that the present could have been different, too, had the past been different. Reflecting on alternative pasts, individuals come to realize how the present could have been different, too. Monod and Klein (2005) argue that cultural heritage sites, and more precisely historical characters, represent an important vehicle for inspiring this process.

- **Historicity**

The last criterion, historicity, is the most conceptual and existential dimension. Historicity refers to the understanding that we are fundamentally historical beings and that the meaning of our action and of our existence, is linked to history. In Being and Time, Heidegger (1962) devotes the entire section “The Vulgar Understanding of History and the Occurrence of Da-Sein” to define history properly. Heidegger insists that the term “history” should be distinguished from the term “past” in that history represents the influence and consequences of past on the present and the future: “Thus history does not so much mean the ‘past’ in the sense of what is past, but the derivation from it” (Heidegger 1962, p. 347). Heidegger also uses words such as “move, rise, fall, connection, change and transformation” to designate history (p. 347). These words capture the dynamic nature of history. It is noted that history is a specific component of human beings, or “Dasein,” since it constitutes our lives. Therefore, to capture history in a meaningful way, we argue that individuals need to be confronted with a dynamic representation of history by understanding the influence of past events on their personal existence.

Even though not grounded in a phenomenological framework, other studies validate the importance of these six phenomenological criteria for IT users’ experience. For instance, Pujol Tost and Economou (2007) surveyed visitors of the Ename Museum (Belgium) about their favorite rooms and devices at the end of their museum visit. The applications that were designated by visitors correspond to the ones that were able to convey context, empathy, interactivity, and sensations. More precisely, Pujol Tost and Economou (2007) found that context is one of visitors’ most important expectations. Moreover, empathy contributes to visitor engagement and satisfaction. The dimensions of interactivity and sensations (described by the participants as the possibility to touch) also led to better learning.

Hence, the phenomenological criteria developed and identified by Monod and Klein (2005) appear to be of great importance to visitor experience. As Monod and Klein (2005) have not verified their framework in the field, the present research will extend their work empirically through a field study with museum visitors.

### 4 METHODOLOGY

We distributed questionnaires to visitors of a French museum, hence employing a field study methodology. This field study aimed at empirically examining the extent to which museum visitors believe the phenomenological concepts are being facilitated by the museum technologies. Even while we are utilizing a quantitative methodology, this study does not ground itself in positivism. We do not test a research model with a set of hypothesis, but rather view the questionnaires as an opportunity to obtain more qualitative data. Moreover, Mingers (2003) asserts that “the tendency to link quantitative
methods with a natural science (positivist) approach, and qualitative methods with a social science (interpretive) approach” corresponds to a “crude dichotomy” (p. 236). The questionnaire methodology was also more convenient to implement at our field study because visitors did not have much time to spend in interviewing.

4.1 Presentation of the Site

The research site was the National City of History of Immigration (NCHI), a public museum located in Paris, France. This museum, inaugurated in October 2007, deals with the history of immigration, tracing back its evolution in France from the nineteenth century to the present. NCHI exhibitions also show how immigration has contributed in shaping French society. In research conducted before the opening of NCHI, potential visitors expressed strong expectations about historicity and an experience of the past. As an illustration, Poli et al. (2007) showed that potential visitors expected that NCHI would: 1) deepen their knowledge about history of immigration, 2) offer new perspectives on their personal history, 3) contribute to identity building and 4) explain the consequences of immigration on the world of today.

In addition to dealing with history, this museum uses modern media to communicate with its public. NCHI is equipped with common museum tools such as televisions, RFID audioguides, but also more recent technologies such as computers, Webcam, and interactive kiosks with both audio and video content. Overall, NCHI appeared to be an adequate setting for examining the historical and phenomenological concepts, as well as to evaluate the contribution of IT to an experience of the past.

Furthermore, the choice of a history museum can be justified by the following reasons. First, we did not want to study types of museums that were highly specialized to the point of idiosyncrasy, as, for example, science museums which generally include a lot of technological equipment and hands-on activities. In such a case, we believed that perceptions of authenticity and historicity would be more difficult to measure; they could also be biased in such an environment. Furthermore, this type of museum appears less appropriate to apply the phenomenological criteria, which are related to the history of Being. We also deliberately eliminated art museums since they generally offer less technology to their markets. Actually, after visiting several art museums in the Paris locale, our region of residence, we realized that this type of museum was less equipped with technologies. Finally, the choice of the historical setting was instrumental for conducting good research since we were able to obtain a broad license to conduct our field study at the National Center of History of Immigration.

4.2 Set of Scales to Measure the Phenomenological Criteria

Based on the literature review and the phenomenological framework, we developed scales for each phenomenological concept. We followed advice for scale development (Lewis et al. 2005; Moore and Benbasat 1991; Straub et al. 2004). Generally, three steps are suggested for construct development: 1) review the literature to determine the content domain of the constructs, 2) formulate the items for each construct and 3) test the psychometric properties of the scales.

The literature was employed as a rigorous benchmark to evaluate the content of our scales. In the final analysis, we retained three sentences per concept. After defining the domain of our constructs and developing the scales, we pre-tested the scales with a group of college students, after which we refined some sentences. A few months later, a pilot study was also conducted with twenty visitors at NCHI. Visitor comments were taken into account and we modified some sentences for a second time in order to fit better the research context.

4.3 Sampling and Selection

We used the following procedure for surveying NCHI visitors. The researcher was positioned at the museum entrance where visitors borrow the audioguides in order to induce participation by the
maximum of persons. This positioning was strategic because visitors had to return to this desk at the end of their visit to return the audioguides. We took advantage of this time to gather visitor feedback regarding their interaction with the museum technologies. Finally, we collected 111 questionnaires over a period of one and a half months.

4.4 Data Analysis

The descriptive statistics of the sample were computed using SPSS 12.0. To conduct the analyses, we had to delete questionnaires that were unusable because of too many unanswered questions. Hence, we collected 111 questionnaires but our final sample was 106 questionnaires.

The descriptive statistics indicate a higher proportion of females than men, with 66% women and 34% men. This result is not surprising, however, because French statistics on museum attendance also report a higher percentage of women in museums (Cardona and Lacroix 2007). The mean age was 39, with a population aged between 18 to 74 years-old.

We analyzed visitor responses in order to establish the psychometric properties of the constructs. Five out of the six developed scales demonstrate good psychometrics properties, as indicated in Table 1. Except for self-projection with a Cronbach’s alpha slightly lower than 0.70, the other scales range from the acceptable 0.735 to 0.889. However, Nunally (1967) considers that the 0.6 level is acceptable for exploratory research.

Data analysis also helps in determining the role of IT in visitor experience of the past. We asked NCHI participants to rate their experience with the museum equipment using Likert scales. Since NCHI offers several types of technologies, we decided to survey the museum equipment globally. Hence, we cannot assert which technology contributes the most to the phenomenological criteria.

The mean of each phenomenological construct is reported in Table 2. We also provide a ranking of these constructs from the one that is the best reached through IT to the one that is the less achieved.

5 DISCUSSION AND CONCLUSION

Unexpectedly, it is self-projection that is the criterion that best describes the NCHI technologies. This means that the visitors who used the set of technologies found that these devices helped in projecting themselves into the shoes of the characters. More precisely, 13.2% visitors strongly agree with the fact that IT improves their self-projection, 34% visitors agree and 28.3% slightly agree with this assertion. Visitors likewise felt empathy for the different portraits of immigrants displayed at NCHI through the videos and interactive kiosks. IS research has already shown that IS can provoke emotional reactions (Messham-Muir 2005; Sun and Zhang 2006), such as flow (Koufaris 2002; Skadberg and Kimmel 2004) and enjoyment (Lin and Gregor 2006; Van der Heijden 2004). However, affective behavior like self-projection (or empathy) has been lightly studied in the context of IT use.

Embodiment comes second. Actually the sensory experience offered at NCHI was quite highly rated. Most of the devices convey visual materials (videos, pictures and texts), the audioguides and the TVs diffuse audio content, while the interactive kiosks give an opportunity to have a physical interaction. The visitors cannot really touch the museum artifacts, but very few objects are exhibited in this museum since the scenography relies on IT. Therefore, the possibility to touch is offered through computers and kiosk. Smell and tastes were the two missing senses but it seems that visitors appreciated the variety of sensory experiences. Visitors also agree with the fact that the technologies allow them to relive the historical events in their minds. The mean value for this construct is 5.35 and the levels of satisfaction are the following: 42.3% slightly agree, 27.9% agree and 9.6% visitors strongly agree that NCHI technologies contribute to re-enactment.

Context appears as the fourth construct achieved by the NCHI technologies. Surprisingly, we would have thought that context would be the easier criterion to be met by the NCHI technologies. Tellingly, one of the chief roles of Information Systems is to transmit information to users. But our empirical results contradict this assertion. Nonetheless, the results also indicate that visitors were not entirely satisfied with the cultural and historical background presented by the technologies. These findings support prior research that points out the lack of understanding and context presentation in museums (Hooper-Greenhill 2000; Schärer 1996).

When we scrutinize the ratings in Table 2, we clearly see that the most advanced (and conceptual) criteria, namely possibilities of being and historicity, are also the ones that are the most difficult to reconstitute with IT for museum visitors. Historicity is last in the minds of the visitors, but in the philosophical literature it also represents the ultimate step towards a phenomenological experience. Pointedly, 34.4% visitors are neutral and 30.1% disagree with the statements that NCHI technologies contribute to historicity. Therefore, roughly 65% visitors think that NCHI technologies do not convey a sense of historicity.

NCHI provides several technologies to its visitors, but the types of IT implemented do not provide an entire satisfactory experience of the past. More advanced technologies such as 3D or virtual reality systems are an option to address this lack. It may also be that technologies cannot replace the physical objects displayed in the museums and this explains why visitors have difficulties feeling historicity. The IT role should be to support the visit, enhance the appreciation of the artifacts, but not to enclose...
visitors in a virtual world (Ciolfi and Bannon, 2002). What is clear in the potential use of IT in museums is that technologies that support all the criteria, like those suggested in Monod and Klein’s (2005) framework, are rare. Furthermore, since few technologies have all the characteristics described in the phenomenological framework, museums need to combine multiple devices in order to meet the overall objective of full coverage of the criteria (Monod et al., 2006).

Several researchers have already pointed out the potential of phenomenology for user-driven research and information systems in general (Boland 1985; Introna and Ilharco 2004; Mingers 2001; Monod and Klein 2005). This study confirms this assertion of prior research by showing how phenomenology presents a viable perspective for assessing visitor experience with museum technologies.

Museums represent distinctive institutions and the technologies they provide to visitors generally aim at presenting history, creating reflection, enhancing knowledge and entertaining. Consequently, we decided to rely on Monod and Klein’s (2005) phenomenological conceptualization, a framework which proposes a set of criteria relevant for assessing e-heritage systems. But, even though we rely on this new framework for IS evaluation, links can be created to existing scales. For instance, the criterion “context” can be related to the IS variable “information quality”. Information quality includes notions such as “relevance, understandability, completeness and accuracy” (Petter et al. 2008, p. 239) and it represents a strong predictor of user satisfaction. Our results indicate that context provided by IT is an important factor in hedonic context as well. Therefore, this research can contribute to the evaluation of other hedonic systems (Van der Heijden 2004) and in future research our phenomenological items could be merged or inserted into existing scales that serve for the evaluation of hedonic information systems.

Abstract

This article summarizes the results of 25 expert interviews, regarding the value potential and challenges of the Service-oriented Architecture (SoA) paradigm for users and software vendors.

On the user side, the SoA value potential most often mentioned by experts was agility, followed by process optimization. Cost reduction, through a more efficient development, or consolidation of redundant IS landscapes are also seen as a value potential. In contrast to the literature, reuse of services seems not that significant and is highly debated among the experts. In order to realize the value potentials, users have to overcome certain challenges. Here, the experts mention the financing of the investments, the setting up of a proper governance and the creation of a common understanding of the SoA paradigm as biggest hurdles.

For the software vendors, experts mention that SoA-based solutions create new market opportunities as lock-in-effects are lowered and offerings can be easier enhanced by third-party services. Regarding cost, there is potential to harmonize existing product portfolios or integrate acquisitions more easily. Development cost reduction is less evident at the current stage of adoption. It is assumed that lower lock-in effects also lead to increased competition, which could become a major challenge especially for established vendors.

Keywords: Service oriented Architecture (SOA), Business value of IT, Empirical study, Economics of IS
1 INTRODUCTION

IT departments are currently facing the challenge of determining whether they should adopt Service-oriented Architectures (SoA) as their key architecture paradigm. One reason why they are struggling with that decision is that it is still unclear whether SoA-based solutions can actually deliver the many promised value potentials. The basic idea behind the SoA paradigm is the support of business processes by IT systems consisting of services. Those services are clearly encapsulated, and loosely coupled entities, which deliver a defined business functionality. (Erl 2008, p. 290ff), (Papazoglou & van den Heuvel 2007, p. 389). The SoA concept itself is technology-independent; however, SoA is mostly seen in direct correlation with the Web-Service technology and associated standards.

A first analysis shows that the main research into SoA is focused on technical integration questions, as well as on the design and management of services (Kaczmarek & Wece 2008, Tab. 7, p. 56). So far there is a lack of independent and reliable studies on the actual value of SoA (Vitharran 2007 et al., p.7 f.). Whereas a large set of statements regarding the value potentials for SoA can be found in literature, correct theoretical deductions of the value arguments are very rare. In fact, most of the potentials are only non-revisable claims described at a very generic level. This lack of clear evidence leads to a critical discussion of SoA value in practice (e.g. Graegert (2007)).

The target of our research is to analyze which of the many SoA value potentials discussed in literature can be actually realized in practice. We do not aim for a complete return-on-investment or business case consideration, since such an analysis has to be case-specific (for a full framework to determine the RoI of SoA we refer to Beimborn & Joachim & Weitzel (2007)). The goal is rather to deliver more detailed findings for the value side of the equation, which is usually much harder to determine than the costs. We assume, that the costs for a SoA-based implementation can be quantified using classical IT cost estimation techniques, therefore we focus on the quantification of the benefits. In differentiation to the work of vom Brocke & Sonnenberg & Thomas (2008) who investigate the impact of SoA from a process perspective, we approach the question of SoA value from the perspective of added value of SoA to the entire enterprise. The underlying value concept is the economic value in terms of the EBIT impact, which focuses on the quantifiable effects in terms of revenue increase or cost reduction for the whole company. Effects that contribute only indirect to these two quantitative value drivers are considered as "qualitative" value.

It is important to distinguish two types of companies that can benefit from this value: On one hand, there is the rather small group of software vendors, meaning companies who develop software based on SoA in order to sell it. On the other hand, there are the companies who use these SoA-based software products or develop their own individual solutions while applying the concept (further on named "users"). As there are many similarities in the actual usage (e.g. both groups try to reuse services while developing a system) but also different motivations for the use of SoA, we incorporated both views in our study and try to gain an additional explanatory value from comparing the two sides.

Based on a literature analysis, an explorative expert-study was conducted from end of May till beginning of August 2008. A broad focus was chosen in order to determine as many relevant potentials as possible. After a short introduction into the methodology, this article summarizes the major results of the literature review and 25 expert interviews. Chapter 3 shows the categorization of value potentials based on the literature review. The next chapter then presents the results of the expert interviews by showing the order of mentions and describing the categories of SoA value potentials in more detail. Wherever possible, supporting examples from the interviews are shown. To emphasize that realizing the SoA value potentials requires significant effort, a paragraph on the challenges facing users and software vendors deducted from the expert interviews completes this chapter.

Due to the qualitative method used here, the results are not fully representative. Therefore, the article concludes with a critical discussion of the results and the prospect for the further research opportunities aiming for fully representative answers.
2 METHODOLOGY

Our overall research, targeted to identify the SoA value potentials observable in practice, is structured in three major steps: 1. State-of-the-Art analysis (literature review), 2. Qualitative survey (expert interviews) and qualitative evaluation, 3. Quantitative empirical survey (planned for early 2009).

This article summarizes the first and second step with a focus on the qualitative survey. The expert interviews followed an explorative approach, in order to determine a broad spectrum of value potentials. Semi-structured expert interviews were chosen, as they are a frequently used and well-suited method for this purpose (Denzin & Lincoln 2000, p.653). In this context, an expert is defined as a person, who possesses special knowledge on the subject. This knowledge results from a day-to-day occupation with the concept of SoA in practice. It has been rumoured that Europe, or Germany in particular, would be lagging behind in SoA adoption; however, we have not found any scientific evidence to support that claim. We therefore assumed that the geographical location had no influence on the realization of SoA value potentials. In light of this, the survey was limited to the German-speaking regions for reasons of cost and practicability. The interviews were mainly conducted by phone. As Sturges and Hanrahan (2004) have shown, there are no significant differences between a telephone and a face-to-face interview regarding the quality of the gathered data.

The interviews were targeted at 4 groups (users, software vendors, IT providers and IT consultants), and the structure was based on a modularized interview guideline. In addition to 10 core questions, which were identical for all the groups, a specific set of questions was formulated for each individual group. Note that IT consultants and IT providers were only asked about the SoA value potential for users and software vendors, as they are seen as unable to profit directly from SoA itself. Vendors were asked for the impact of SoA in their own business as well as for the value on the user side. Although statements of vendor representatives bear the risk of being biased for marketing reasons, their opinion on the user value was considered relevant, as they usually have insight in several SoA projects and can therefore provide information which is more representative. The experts were chosen based on internet research and contacted via mail or telephone. The expert status was guaranteed by choosing individuals who were either known through multiple contributions to practical oriented SoA conferences and/or were engaged in several specific SoA implementation projects. 28 experts were contacted and 25 agreed to participate in an interview. The interview sample included eight users, six IT consultants, six software vendors, five IT providers. The users came from five different industries (banking, insurance, telecommunications, retail and logistics). This supported the broad explorative focus of the approach and ensured the diversity needed to create meaningful results. The interviews were recorded digitally before being transcribed. In 10 of the 25 interviews a recording was not possible, either because the interviewee declined to be recorded (six times) or due to technical problems (four times). In these cases a protocol was made on the basis of notes that were taken during the interview (Yin 2002, p. 92). The evaluation was performed according to the methodology of qualitative content analysis according to Mayring (2000).

3 "SOA VALUE" IN THE LITERATURE

An analysis of 20 literature sources revealed 145 text passages describing SoA value potentials. These potentials were extracted by paraphrasing before being aggregated into 16 categories (see Table 1). Although some sources stated different arguments belonging to the same category, they were counted as 1 nomination only. SoA value potentials mentioned only once among all sources were grouped into the category "other". The literature analysis considered the major English books on SoA (including scientific and practical oriented literature), as well as papers from leading IS conferences (01/2000-
05/2008) and IS journals\(^1\) matching the keywords "SoA" and "value"/"benefits". It has been interesting to note that there are only a few sources dedicated to the question of SoA value. Most sources are limited to a small list of potentials with a short explanation of each, however, no explicit discussion or logical deviation can be found. The number of mentions per source differs between three and 16 potentials. Only three of the analyzed sources ((Erl 2008), (Krafzig & Banke & Slama 2007), (Müller & Viering & Riempp 2007)) discuss the subject in a broad manner over several pages. Note that, the method of the qualitative analysis assigns statements to a certain category based on defined rules. This ensures that every category contains at least one clearly defined and therefore distinctive core argument, which minimizes overlaps. However, we found in our explorative analysis that there are dependencies between the categories (e.g. reuse can be seen as facilitator for agility). In our further research, we aim to examine possible dependencies more deeply (rf. chapter 4.1 for first approaches).

</table>

As there was a very limited discussion of value potentials for the software vendors, this aspect was not included in Table 1. However, it should be mentioned that one source named two main advantages, while discussing the impact of modularization, standardization and loose coupling on the software value chain. Firstly, it enables vendors to outsource the development of services thereby creating new ways of collaborative software development. Secondly, by integrating third party services from niche players, the existing offers from large vendors can be enhanced, leading to a restructuring of the value chain (Messerschmitt & Szyperski 2003, p. 172 ff.).

Concerning the challenges of realizing value by applying SoA, the situation was similar to the question of vendor potentials; explicit literature sources were very rare. Only three challenges could be found consistently in more than one publication: the issues related to governance, complexity and

\(^1\) Note that no relevant articles were found in journals, this is in line with a recently published overview on SoA value papers from Beimborn & Joachim & Weitzel (2008)
financing. Governance is about adapting the organization and the processes in order to efficiently manage a SoA. Doing this right was mentioned by 11 sources as a major hurdle to leveraging the SoA value potentials. (A good overview on the aspects of governance can be found in (Bieberstein 2006)).

The challenge of complexity, mentioned twice, addresses the problem that the fine granularity and distribution of services require significant additional effort in the design phase as well as in the run phase, compared to monolithic systems. Two sources state the challenge of financing the investment in SoA, however with little detail. All other challenges were technology related (e.g. limited data throughput performance of SoA-based solutions). As they were only mentioned sporadically and described very heterogeneously, they were aggregated in one category "Technology issues" (seven mentions). Several sources refer to "success factors", which could be interpreted as the logical counterpart of challenges. However, they are mostly generic to IT projects and not SoA specific, therefore they could not be related to the question of SoA value and are not considered in our study.

It is interesting to note that several of the examined sources on the topic have at least one chapter on SoA benefits (e.g. "Advantages and Motivation" in (Krafzig & Banke & Slama 2007) chapter 11). However, apart from (Erl 2008) none of these sources have an explicit chapter on "challenges" and most work merely addresses the issues implicitly while describing how to implement SoA. This observation, in combination with the fact that several books have very positive titles such as "Succeeding with SoA" (Brown 2007) while only one subtitle (McGovern & Jain & Little 2006) speaks of "Challenges", strengthens the hypothesis that there is a lack of critical and profound discussion of the actual value of the SoA paradigm.

4 RESULTS FROM THE INTERVIEWS REGARDING VALUE POTENTIALS AND CHALLENGES OF THE SOA PARADIGM

The following paragraph shows the main results from the expert interviews concerning the question of what kind of value potentials users and software vendors can draw from applying the SoA concept. It will conclude with a discussion of the challenges which complicate the realization of those potentials. Regarding the current hype about SoA and the marketing activities of software vendors and consultants, it is important to mention that all the experts’ arguments were critically reviewed. The experts were consistently asked to provide examples during the interviews. Most of the interviewees (21/25) could base their argumentation on personal practical experience. Many of them were also clear about the fact that the value of some potentials is hard to quantify or to measure - which is why the value discussed here is only "potential" or "expected" value rather than actually "realized".

4.1 Value potential for users of SoA based software systems

Table 2 provides an overview of the interview results sorted by the number of positive mentions of the SoA value potentials for users in the expert interviews. The rightmost column indicates whether the experts’ opinion was homogenous or not on this potential. Potentials marked with a "+" were not doubted among the experts and based on several arguments and at least one specific example. If there were no specific examples and many weak arguments, the potential was marked with "+/-". A "-" shows that the potential was debated among experts and there were even some critical voices negating this potential. As you can see in table 1, the categories were grouped by two dimensions: a) the type of value they are providing according to our value model: revenue, cost (logically split into business- and IT-related cost) and qualitative effects; b) the "layer of impact" which classifies the layer of the company the value is created in. The layer structure follows the model of Österle (1995), who states that the design of information systems has impact on the strategic layer, the process layer, and IT layer of a company. This structure helped to minimize redundancies (e.g. all potentials with a effect on IT-cost have to consist of mutually exclusive arguments) and allow to explain dependencies between categories, which mainly exist between layers (e.g. reuse on the IT-layer can be seen as a precondition for agility on the strategy layer). Due to space limitations, only those potentials mentioned by more than 10 experts will be discussed in the following.
All interviewed experts mention the improved agility of an enterprise as a SoA value potential. The arguments and examples thereby are centred around two main aspects: The first aspect is speed: agility is expressed by a faster adoption of the IT to business changes (measured by a reduction of the so called "time-to-market" of change requests). Several experts report a significant reduction of the implementation time of new requirements. Four interviewees (three consultants and one user from the industry) mention the telecom industry as a good example in this context. The introduction time of new tariff models, can be reduced by applying the SoA concepts. Starting with the completed concept in product management to the actual positioning in the market, a time saving of between 20% and 50% is stated by three experts, compared to the old architecture. Two interview partners phrase the advantage: "We came down from a question of months to a question of weeks". In this case the effect can be explained by the decoupling of customer centric from network- and infrastructure-related systems by applying the concepts of SoA. Following this, a new product, e.g. a so called bundle-offering, is maintained on only one system and can be changed independently of the complex systems administering the telecom network infrastructure. The second aspect of agility besides speed is an increased flexibility in IT systems. Most interview partners explain this increased ability to change, by the architectural separation of dynamic logic (process) from the static logic (service). The dynamic logic is more likely to be subject to changes and can be adapted more easily. Although agility can be separated into the two aspects mentioned it was contained as one category. As agility can be seen as an overarching term for several aspects, according to the definition of Yusuf et al. (1999): "Agility is the successful exploration of competitive bases (speed, flexibility, innovation pro-activity, quality and profitability)". During the interviews most interview partners did not differentiate between the terms agility, speed and flexibility and even used them synonymously.

The majority of experts agree that reuse is a value potential of SoA (20/25), however, there are also very critical voices. Two interview partners express their concerns that the design of reusable services is very difficult and they never saw a real value from reuse in practice. Especially in the early phases

---

2 This and all following citations are translated from the German transcript into English.
of SoA maturity, it would be very difficult to achieve a consensus on the functionality among the stakeholders, as there is no experience about how a reusable service would look like. Another expert points out that reuse is not a new subject in computer science. He claims that earlier approaches - like modularization or object orientation – did not fulfil the expectations of high reuse either. There are also limitations among those experts who were positive regarding reuse. Four experts state that reuse exists and is a value potential, but it is limited and can only be achieved after a long period of SoA experience. They explain that there are only a few services in an enterprise that can be reused frequently (e.g. services for the management of customer or product data, or basic services like printing or calendaring). Three experts cite analyses that measured a reuse factor (i.e. average reuse-of one service in different contexts in the same period of time) between 1 and 2. One software vendor reports on his customer, an Austrian bank, which measured a reuse factor of 1.3. An IT-consultant cites an internal analysis measuring a reuse-factor of 1.5 among several companies. One user states that, in his company, a few services were frequently reused (up to 14 times), however, the majority, and therefore also the average, had a reuse factor below 2. Contrastingly, there are interview partners who strongly believe in reuse. An IT provider reported the development of a new core banking system able to be finished ahead of the planned time because many services (approx. 10 %) could be reused. He states the example of a service for transfers which is reused for the web portal as well as for the ATM and the teller application. Two interview partners from the user side point out the business value of reuse in this context: Reusing an existing service allows standardizing functionality; for every process using the same proven business logic is applied enterprise wide. One reason for the obviously contradicting opinions about reuse might be the variety of interpretation of the concept. Most experts understand reuse to be the usage of the same service in multiple processes at the same time ("multiple usage"). Others also mean the reuse of one service in a different context at another time, which means that the service is "used again" but only by one user. Another group of experts describes a "reuse" of legacy systems by encapsulating existing functionality and providing it via a Service interface. This approach allows the prolongation of existing systems’ lifecycles by using their functionality in new processes with new user interfaces. Some experts also phrase this value potential explicitly as "prolonged usage" instead of "reuse".

The vast majority of experts (17/25) report that process optimization in particular is the main motivation for users wanting to adopt SoA. Especially vendors and consultants report that there is a strong demand among their customers to integrate and automate process flows, especially across line of business or even enterprise boundaries. SoA is seen as the best basis for Business Process Management (BPM) systems, as it allows the process-oriented integration of IT systems, leading to a more automated IT support of processes. The value can be measured by known process key performance indicators, e.g. shorter cycle times or reduction of required manpower. One user reports that process optimization was the only reason why the insurance company he works for adopted SoA. By automation of a claims settlement process across several silo systems, the cost could be cut to 1/50 of the old manual process. It is obvious that not the full amount of this savings potential can be assigned to the SoA-based IT solution, however the interviewee pointed out that SoA was a necessary precondition to realizing this value, as other attempts to realize the potentials failed before. It is also worth mentioning that according to three experts, SoA is especially valuable when it comes to the harmonization and standardization of processes in a globally acting enterprise.

17 experts state the value of facilitation of software development driven by the standardization of interfaces which leads to less mapping efforts. Standardization of tools and methods for model-driven development reduces coding. However, there are, as yet, no concrete examples or data points available for this potential and some experts are uncertain whether this potential could be actually captured.

The potential of IT-landscape consolidation is directly tangible in the context of systems operation. Implementing a certain functionality only once in a IT-landscape is a core concept of SoA and allows

---

3 Note that this category does not include efficiency effects from reuse as reuse is a category of its own.
the identification of redundancies. Two interview partners point out that this value potential can already be leveraged by the mere introduction of SoA Management tools, such as the development of a domain map, without actually implementing SoA at a technological level.

The subject of improved information quality and availability addresses the typical "Master-Data Management" questions. Through consolidation of customer data in a central service, for example, the integrity and consistent availability of that information within the enterprise is improved.

The increased IT/Business Alignment is debated, which is partly due to the different interpretations of that term. If a better IT/Business Alignment is defined as a better fitting of IT solutions to the business problems, the majority of experts agree. This is explained by the process orientation of SoA, which leads to a business proximity. Some experts interpret the IT/Business Alignment as the cooperation between IT and business departments. The picture regarding this interpretation is more unclear. Some experts state that SoA enables IT to make architecture questions more understandable for people outside the IT department and creates "a common language". However, some users also state that there has been no improvement in IT/Business cooperation through the introduction of SoA; on the contrary, the already existing problems only became more obvious.

The idea of creating new functionality via SoA is valued more in practice than in literature. Interestingly it is not so much about providing functionality as a service externally, but rather about offering new products by integrating third party services, or even building up new business models on that idea. One consultant reports the case of a retail company that integrated the Web-Services of a bank in order to offer the customer a loan at the point of sale. Two other experts name the Hypoport AG as an example of an SoA based business model. Hypoport acts on the technological basis of a SoA platform as a broker for financial services. (For a more detailed description of Hypoport’s business model see (Hypoport 2008)). These examples could also been realized in a different way. However, the SoA paradigm and the underlying technology ease the integration and make it cheaper. This lowers the integration hurdles and new, collaborative business models become more attractive.

Concerning the value potentials on the strategy and process layer, it can be stated that most potentials identified in the literature analysis can be realized in practice. Regarding the SoA value potentials on the IT layer, the discussion is much more controversial. The majority of IT related potentials are marked with a "+/−" or "−" in table 2, meaning that their validity is low in average.

4.2 Value potential for software vendors

Four different value potentials were identified for software vendors among eight interviewees (Consisting of the six vendors and two consultants).

All vendors, in particular smaller ones, state that the standardization allows them to integrate in existing product landscapes from other vendors more easily (Two already leveraged this potential). It is also easier to sell software as a service (SaaS) when software is based on SoA principles. These two arguments were summarized in the value potential category of new market opportunities.

Most experts (5/8) also agree that an integration of acquisitions, or already existing heterogeneous portfolios, is much easier when software is based on SoA principles. The standardized interfaces and clear capsulation eases the combination of different products to an integrated solution and helps to reduce redundancies. Two vendors have already actually realized specific value from this potential.

Vendors can also enhance their product offerings by integrating third party services. This results in a more complete and therefore more attractive product for the customer. Based on capsulation and standardization this enhancement can be done quickly and the vendor does not need to invest in the development of the new functionality himself. Some experts also claim that the capsulation leads to the effect that software offerings could be more modularized (i.e. sold in smaller pieces), which allows vendors to offer customers a more individual product instead of a big "all-in-one"-solution. This could attract new customers that are interested only in a dedicated part of the existing solution. Specific
statements concerning revenue or cost effects of this potential could not be garnered from the interviews. However the arguments were consistent among all experts and therefore the validity is "+".

**Table 3 Ranking of SoA value potentials for software vendors according to expert interviews**

Two of the six software vendors also explained that they had realized a facilitation of software development through SoA. Others said it was too early to measure that, but they would also expect benefits in this area, one expert however was sceptical. Therefore this potential was marked with "+/-".

Comparing the results from the qualitative analysis of the vendor potentials and the results from the user side, only the SoA value potential "facilitation of software development" can be found on both sides. The judgement on this potential is consistent, as both groups expect an improvement, whereas there are only few proof-points yet. It is interesting to see that reuse was not mentioned as value argument from the vendors themselves. This supports the hypothesis from the user side that this value potential is – at least to the current stage of adoption – very hard to realize. Although the consequences are different, the basic arguments for SoA value are the same, as they relate to the same core aspects of SoA (especially capsulation and interface standardization). Overall, one can summarize that according to the number of mentions on the vendor side SoA value is seen to be more about creating new opportunities (in terms of revenue) than improving efficiency (in terms of reducing cost). This pattern could also be identified on the users' side. The matching results of the analysis confirm the value of comparing both views. However, due to the small number of statements on the vendor side, a more comprehensive and structured data gathering is needed to derive further results.

4.3 Challenges for vendors and users in realizing the potential values of the SoA concept

During the interviews, it became quite clear that SoA does not only bring new value to a company, it also introduces new challenges, or at least different ones than typical challenges of new IT technologies. Table 4 gives an overview of the challenges related to the concept of SoA, identified during the interviews from the user perspective. As the discussion of challenges was less controversial then the one on value potentials, all statements can be seen equally valid and therefore no validity was assigned. Some of the statements were not directly focused on the question of value realization, but on the question of challenges with SoA adoption in general. However, it is obvious that a challenge hindering a company to adopt SoA is a challenge to get value out of SoA too.

According to the experts, the most important challenge is the question of financing of the investment.

---

4 Note that the stated "Impact Layers" differ from the user side. As the model of Österle (1995) does not apply for software vendors, we assign the identified potentials to the steps of the software business value chain which consists in our definition (based on Messerschmitt & Szyperski 2003) of 8 steps: 1) "Research", 2) "Product Development", 3) "Documentation", 4) "Marketing and Sales", 5) "Consulting", 6) "Implementation", 7) "User Instruction", 8) "Maintenance".

5 Related to SoA means in this context, that the challenge has its root cause in one of the core aspects of SoA according to our definition in chapter 1 ("process orientation", "loose coupling", "capsulation", "(Interface) standardization"). Statements on general project challenges that are not SoA specific (e.g. "Find a strong project manager") were not included in the analysis.
In the past, the different systems could easily be assigned to one owner on the business side. Only a rather small part of shared applications were financed by a collective budget. SoA incurs a much bigger part of collective infrastructure. In addition, the services (especially when there is reuse) do not have explicit owners anymore either. The SoA enablement of legacy software, as well as the infrastructure investments, requires significant investment and it is, as yet, unclear in many companies how this cost should be divided among different stakeholders.

Table 4 Challenges for users in realizing the potential values of the SoA concept

Another big challenge to realizing SoA value is the set up of a proper business case because of the long-term nature of the value: As most of the potentials are only expected in the long run, and therefore are hard to calculate, it is difficult to show a credible calculation proving the investment is worth it. According to the experts, many companies that have so far adopted SoA did it because they "believed" in it, rather than having a solid business case calculation. It is obvious that if nobody really thought about the specific potentials upfront it is hard to capture the value afterwards.

As already explained in chapter 1, the adaptation of the organization to SoA is difficult, 11 experts mention aspects concerning this challenge, which were categorized by the term "governance".

As one can see from the issues described with the definition of the value from IT/Business Alignment or reuse (rf. chapter 4.1), there is still much uncertainty about what SoA actually is. The experts report that this effect results in a significant effort for a company to define what is actually meant by the term SoA, and to align all people, especially on the business side, with one common view. This is why 10 experts name "comprehension" as a big challenge in realizing value from SoA.

Although integration is eased by common syntactic standards, there is still the issue of missing semantic standards. Until there is a common semantic model available, integration will still require project effort, and the IT world is far away from "plug-and-play" scenarios. Compared to the issues before, this challenge seems rather small, as it is mentioned only a few times. The same is true for the design of a service or sourcing a service out of the box from a software vendor. Regarding technological issues like security and performance, there are also voices that explicitly do not see them as issue anymore. Software vendors in particular claim that nowadays the issues regarding technology have been solved, and most scenarios can be supported via SoA securely and with high performance. Interestingly "complexity", a challenge identified in literature, was not mentioned in the interviews, in contrary nine experts claim that SoA helps the users to manage complexity better (rf. Table 2).

Regarding the software vendors, data about challenges could not be collected. In the interviews the vendor experts were quite reluctant to talk about challenges for themselves. Although the results were guaranteed to be anonymous, they might have been afraid of undermining their reputation as leading SoA vendors by talking about these issues in public. This hypothesis of hidden agenda in positive marketing is supported by another phenomenon that occurred during the interviews. Regarding the question "What is your unique and differentiating value proposition in the SoA market?", five out of six vendors answered that their solution is the only one that would offer the complete range of tools. Whereas four out of eight users asked for vendor strategy answered that they would source a best of breed solution, as no vendor could deliver a full tool portfolio. Despite this lack of data, it is possible
to logically derive some hypotheses from the results on the user side: Apart from the question of internal accounting, the challenges are assumed to be the same for vendors and users of software based on the SoA paradigm. It is imaginable that the vendors also are facing the challenge of justifying the architecture shift in their products economically. They might have struggled in adapting their governance in order to manage a service rather than a product portfolio. And it seems possible that they are also struggling with missing semantics, technology and the difficulties of service design. Creating new market possibilities for one vendor because of standardization, and therefore lower integration hurdles, means a direct threat for those vendors that have profited from a lock-in effect so far. The big, established vendors in particular could face increasing competition when it becomes easier for niche players to integrate and enhance existing applications with their services.

5 CONCLUSION AND FURTHER RESEARCH

Summarizing the results discussed, it can be stated that the SoA value potentials postulated in literature are, at least partly, evident in practice. On the user side, the value potentials "process optimization" and "agility" seem to be most evident in the current phase of the SoA adoption process. Nevertheless, some of the value potentials remain highly debated. Generally, our interview series identified more value potentials on the user than on the vendor side. On the user side, the provable potentials are mainly found on the strategy and process layer, IT (cost) potentials are less evident. This matches the results from the vendors, where the value arguments were centered around new revenue opportunities instead of development cost reduction. The experts pointed out that the majority of the promised SoA value potentials, especially those regarding cost reductions on the IT side, are only achievable in the long run. As the current experience horizon with SoA is too short for most users, those value potentials are still only "expected".

As the expert interviews were not designed to gather specific and comparable data points about the absolute economic impact of the potentials, it is hard to bring them into a relation. It is imaginable that the economically quantifiable and measurable benefits from process optimization might be bigger than the potential from facilitation of software development, although both can be seen as equivalently important potentials according to table 2. Concerning this question, a broad empirical study could deliver further insights.

It also became transparent that most value potentials of the SoA concept can only be realized with significant investments in infrastructure and service enablement of applications. In addition, governance questions have to be solved and a common understanding about SoA in the respective company has to be achieved to make the realization of value possible. The discussion with the experts showed that it is very hard to generalize the value of SoA. Therefore there is no generic answer and every user company and software vendor has to do its own calculation concerning the individual profitability of a SoA adoption. It strongly depends on the individual usage scenario, such as the industry or the functional context which the architecture is used in. Based on the interviews, we developed first hypothesis on such influence factors, which will be tested in further research.

We are currently working on an even more detailed structure of the SoA value potentials, allowing to identify dependencies and to derive clearly defined and representative indicators to measure the potentials. As the study presented here was not designed to be a representative analysis, a quantitative empirical study evaluating such indicators could be a promising field for further research. We hope that the proposed categorization of value potentials and challenges is a first step towards a more precise and fact-based value argumentation in the controversial discussion about the value of SoA.

6 ACKNOWLEDGEMENT

We would like to thank the anonymous reviewers and Helge Buckow for their many useful suggestions on our research. Thomas Widjaja’s research is supported by a research grant from the FAZIT-Stiftung.

Abstract

Service-Oriented Architecture (SOA) has gained focus as a driver for bridging and aligning business
and IT-oriented views in information system development. The critical aspect of successful SOA is
aligning technology and business; without proper alignment, the full potential of SOA will not be
achieved. The current academic literature includes only few empirical studies on business-IT align-
ment aspects related to SOA adoption. In this exploratory study we explore factors influencing suc-
cessful SOA implementation. We interview IT and business people from nine organisations appearing
as SOA forerunners in Finland. Our findings indicate that successful SOA adoption is affected by sev-
eral factors varying from organisation culture to processes and methods, communication and technol-
ogy. The findings form a basis for future SOA research and a set of guidelines for practitioners.
1 INTRODUCTION

Aligning information technology (IT) with business, i.e. “applying IT in an appropriate and timely way, in harmony with business strategies, goals and needs” (Luftman & McLean 2004, p. 90) has been the main objective of IT executives for years (Luftman & McLean 2004, Luftman & Kempaiah 2008). This is not surprising as IT has been considered as a means of gaining competitive advantage – if used appropriately (c.f. Ragowsky & Gefen 2008; Yoon & Carter 2007). However, as Luftman & Kempaiah (2007) argue, achieving appropriate alignment is not straightforward but involves consideration of interrelated components such as communication, value, governance, partnership, scope and architecture and skills.

Business-IT alignment has often been seen as a strategic asset (Bergeron et al. 2004; Peppard & Breu 2003; Cumps et al. 2007). Under these circumstances, it is evidently interpreted as a duty and as an obligation by IT executives (Silva et al. 2007). Alignment is consequently every day business for organisations (Cumps et al. 2006). Because of dissimilar strategies, processes, practices and cultures alignment is perceived as the unique, inimitable competence of an organisation where learning from others and exploiting their experiences, models or practices is difficult. As Silva et al. (2007) pointed out, this emergent phenomenon indicates that different alignment models and methods are not necessarily known by IT executives.

However, service-oriented architecture (SOA) has gained a lot of interest lately (c.f. Ren & Lyytinen 2008; Baskerville et al. 2005) since service oriented organisations and SOA are seen as revolutionising methods for managing information and streamlining operations (Vitharana et al. 2007). Yet SOA architecture itself seldom provides significant benefits. Baskerville et al. (2005) stated that SOA is a means for attaining organisational agility. In other words, SOA development is a continuous process where business-IT alignment needs to be invariably ensured. In their words: “SOA is only one ingredient in a recipe for a much larger meal” (ibid.). Although SOA is usually perceived as technical component (Antikainen et al. 2009), other non-technical stakeholder groups also have to be involved for successful business-IT alignment. This necessitates shared knowledge and mutual understanding about the dimensions of alignment between IT unit and business department (Beimborn et al. 2007). Achieving this kind of reciprocal understanding is difficult indeed. Silva et al. (2007; see also Ciborra 1997) even showed that there is no mutual understanding about the alignment concept between IT executives and IS researchers.

Understanding business-IT alignment in organisations is our focus. We try to identify the main factors influencing SOA development from the business-IT alignment viewpoint. Understanding these factors provides a basis for further research and theory building, and helps researchers to articulate their findings to (IT) executives and practitioners in SOA development initiatives. The data for the case study on SOA development and deployment was derived through twelve interviews conducted in nine large organisations. Next we take a tour of related business-IT alignment research from several perspectives. Then we present our research methods and the findings. The paper ends with discussion and concluding chapters.

2 RELATED RESEARCH AND THEORETICAL BACKGROUND

Business-IT alignment has been defined as the degree to which the mission, objectives and plans articulated in business strategy are shared and supported by IT strategy (Reich & Benbasat 1996). Henderson and Venkatraman (1993) follow this by stating that alignment is the degree of fit and integration among business strategy, IT strategy, business infrastructure, and IT infrastructure. These definitions claim that alignment is static. Campbell (2005) took a different approach by defining alignment as business and IT working together to reach a common goal. Yet this approach does not explicitly point out the strategic aspect of alignment. Chan and Reich (2007) identified several dimensions of alignment apparent in the IS literature: strategic and intellectual dimensions, structural dimensions,
informal structure, social dimension and cultural dimension. These dimensions emphasise the need for alignment on several levels: organisational, system, project and individual and cognitive. Alignment is correspondingly a multidimensional subject ranging from strategies to practices, from processes to activities bridging business to IT, and vice versa.

Business-IT alignment has been studied extensively in the IS literature. Some recent studies discuss the strategic level of alignment (Bergeron et al. 2004; Griffiths & Finlay 2004), the evolution of strategic alignment (Peppard & Breu 2003), business process alignment (Cragg et al. 2007; Beimborn et al. 2007), cultural aspects of alignment (Silvius 2008, Bieberstain et al. 2005), aligning users, organisations and IT goals (Singh et al. 2008), the role of informal networks (Haried & Ramamurthy 2006), measuring the success of alignment (Denford & Chan 2007) and several models and methods (e.g. Mueller et al. 2007; Griffiths & Finlay 2004; Chen 2007; Dertzi 2008; Klose et al. 2007; Henderson & Venkatraman 1993). Yet these studies do not correspond with the call by Chan & Reich (2007) to examine the practical processes of alignment; i.e. how alignment really takes place, what factors frame it, and how managers may benefit from these studies.

Different factors of alignment have been studied. Henderson and Venkatraman (1993) argued that an organisation’s external fit is influenced by IT scope and system characteristics (reliability, flexibility and IT governance), and internal fit by the IS architecture, IS processes and skills required to manage and operate information systems. Chan and Reich (2007) reviewed the challenges in attaining alignment as being related to knowledge (unknown corporate strategy, lack of awareness or belief of the value of alignment, lack of industry or business knowledge), related to locus of control or the status of IT, and related to organisational change (see also Ciborra 1997). An influential study by Sabherwal & Chan (2001) discussed the dynamics of alignment. Although they identified several factors and challenges, their focus was rather on organisation level issues and not on the process or operation level factors. In fact, this kind of focus on theoretical issues is common in the IS literature (Gutierrez et al. 2008). Baskerville et al. (2005) took analysis to the SOA context. They identified the challenges of alignment as application integration, value reconfiguration, value preservation and meagre use of agile development approaches.

Individual factors influencing business-IT alignment have also been examined. The role of management and their commitment and involvement has been recognised as a key factor for successful alignment (e.g. Cumps et al. 2007; Henderson & Venkatraman 1993; Brown & Magill 1994; Benson et al. 2004; Earl 1989; Kean 1993). Yet management’s involvement is not enough. Communication and knowledge sharing have also been identified (e.g. Reich & Benbasat 2000; Chan et al. 2006; Luftman et al. 1999; Campbell 2005; Sledgianowski and Luftman 2005). These studies usually emphasise a close relationship and continuous cooperation between business departments and IT unit. The influence of IS architecture, its governance and technology, and social skills have also been acknowledged (c.f. Henderson & Venkatraman 1992; Brown & Magill 1994, Luftman 2000) in addition to the ability to justify up-front ICT investments as they inevitably have an impact on alignment (Cumps et al. 2006; Mueller et al. 2007).

SOA has been considered as a means for alignment although it has been approached widely, ranging from technical solution and implementation methods to enterprise architecture and IT governance tools (Lyytinen & Rens 2008). Legner and Heutschi (2007) argued that SOA adoption can most beneficially be targeted as standardised integration infrastructure, for decoupling application domains, or for flexible user/business process integration. Yoon and Carter (2007) perceive SOA as IT strategy, where it requires extremely high levels of business-IT alignment to achieve benefits. Other key factors to successful SOA implementations include SOA registries, governance, effective pilot projects, top management support, trust among business units, personnel training and change management (ibid.). Chen’s (2007) BITAM-SOA framework attempts to consider all these aspects by combining SOA, engineering alignment methods, enterprise architecture, and business performance management. She suggested that the impact of SOA adoption can be divided into three different factors: communication, architecture and governance, each being a critical success factor for alignment. Alignment via architecture is influenced by architectural adaptivity, misalignment detection, misalignment prevention,
enterprise modelling, and integration (of workflow management application portfolio management). Alignment via governance necessitates regulatory compliance. Alignment via communication stresses management asking for support and implemented vision.

The studies merely focusing on SOA success do not provide adequate results that would explain how business-IT alignment is realised in SOA development. From a technological perspective, a successful SOA project may not fulfil the business objectives while still being successful in technical excellence. In such a situation, proper alignment is not achieved. Bridging the business-IT gap requires 1) a structured view of a business that facilitates its strategic and operational analysis and is a familiar representation to IT professionals, 2) a rigorous method to translate this structured business view to the appropriate (service-oriented) IT layer, and 3) new build and runtime technologies suited to the new IT layer (Cherbakov et al. 2005). Shiskov et al. (2006) argued that adequate business-application alignment can be achieved only if the initial business model is a valid reflection of the real world, and provides a suitable basis for future models. As bridging the gap between business and IT is not trivial, both the architecture style and development approach should facilitate the alignment. Particularly the architecture approach emphasises the importance of service-orientation in establishing enterprise-wide perspectives on organisational resources (Nuffel 2007). This way SOA adoption improves architectural agility, which further positively impacts on IT’s abilities to align with the changing business environment. Shiskov et al. (2007) summarised three properties for desirable SOA development. First, application architecture must allow the usage of SOA infrastructure, second, ‘loose coupling’ should be enforced and third, application architecture must fit within the business context. This is in line with Klose et al. (2007) and Yoon and Carter (2007), who supplemented the list by the need for systematic identification of IS functions to be implemented as SOA services.

## 3 RESEARCH METHOD

This case study is based on a set of semi-structured theme interviews, where the interviewees’ interpretations of different SOA related issues were discussed. The questions were developed by the authors according to their interests. After a pilot interview in an organisation, unclear or incorrectly understood questions (3 out of 20) were reformulated. The results from the pilot interview were not included in the study. Four groups of questions were used. First, background information about the interviewee, his/her organisation, and the project where SOA was applied was gathered. The second set focused on the expectations and challenges to SOA adaptation in general. The third set was about a certain SOA adoption project, while the last set was about business process modelling and its role in SOA projects.

Table 1. Interviewees and their background

We decided to focus on multiple organisations instead of one. This approach was believed to provide a broader understanding of the phenomenon and more generalisable results. Potential organisations for
The study were identified according to their public presentations in several national practitioner-oriented SOA conferences where they presented themselves as having a significant amount of SOA experience. SOA consultation houses and tool vendors were excluded as we wanted to avoid their market speech, and tool and supplier dependence. After potential organisations (12) were identified, they were contacted for two sets of interviews: one from the business side, the other from the IT side. This follows the suggestion by Silva et al. (2007) that in order to gain insights both stakeholder groups need to be involved. Unfortunately not all organisations responded or granted two interviews. The set of organisations, persons interviewed and their backgrounds are presented in Table 1.

Each interview followed the same order of questions, which were sent in advance to the interviewees by email. The interviews, each lasting 60 to 90 minutes, were audio recorded and transcribed. Data analysis was conducted according to the principles of grounded theory methodology (Urquhart 2001). First, without collaborating with any of the other four members of the research team, each researcher made preliminary coding using varying coding schemes. The coding process continued until theoretical saturation of the data was considered to have been achieved. Next, the researchers held two workshops where the results of the first round of analysis were discussed and refined into a final result set containing harmonised presentation of the previous results. Finally, the final outcome was reflected against the findings of a literature review and the sample data to ensure the validity of study.

4 FINDINGS

The analysis of empirical data revealed 11 factors related to the business-IT alignment of SOA development. These are discussed in detail.

Organisation culture

Organisation culture has various impacts on the business alignment of SOA development. For example, when business and IT had traditionally operated in a close cooperation, SOA development seemed to be better aligned with IT objectives (as expected) than in organisations where such cooperation was not a part of organisational culture. A developer manager described this as follows: "Traditionally we have had strong IT and business. They have never been that much separated... In our organisation business-IT collaboration is happening on a daily basis."

Furthermore, business unit oriented organisational structures had an inhibiting influence on the realisation of business-IT alignment in SOA development. The existence of business silos facilitates a culture where individual business units have to take ownership of specific data, processes and even IT systems. In such situations services, data sharing and open interfaces are not favoured. This was believed to be due to the fear of losing power and influence within the organisation. A CIO from the same finance industry organisation also described their successful SOA process as an outcome of good business-IT alignment. Yet he emphasised organisation culture, not only good alignment. "Our way of working has been on a common good basis for a long time. Our organisation structure also supports it. We have organisation wide services like finance, human resources, Internet services and customer interface services."

As each service unit was producing services to others, the transformation to SOA thinking was minimal.

Another problematic area was data confidentiality. A public sector interviewee demonstrated that business unit people consider the data in their IT systems to be so confidential that it could not be exposed even within the organisation. "[Data confidentiality was] the biggest problems. It was caused by change resistance... For example, a few people from [unit X] had realised that the data in their systems was secret and valuable that it could not be shared with others."

---

1 The questions were the same for both business and IT personnel.
2 Translations from original Finnish data by the authors.
A similar phenomenon was also identified on the IT side. Openness and the sharing of data and IT services were perceived to decrease the importance of the IT unit making them “replaceable”. The same interviewee continued that “in the IT department the valuable asset was the technology. They felt that along with more open communication environment, their power would be taken away... For some, for this reason, information sharing is really difficult.” [I1]

Competences

The skills needed in the design phase, such as business process modelling and service design, were considered particularly important for SOA application development. This was underlined, especially in the business process oriented projects. An architect argued for the importance of the business process modelling in SOA development for all participants. However, he emphasised that this was critical for business people as it is the main competence they bring into the project. “They [business people] should be totally unaware of the technical aspects related to information systems but they should have an understanding of processes and process development in general.” [I11].

Yet business process modelling is not only the business people’s responsibility. A director from a public sector organisation described the shift in thinking that “in the past, it was good enough that the one who made the specification got something out of it. Now, the IT must focus on business services and understanding processes.” [I10] This view, shared with the other interviewees, points out that the focus in SOA development should be on understanding business services and processes. According to the interviewees’ experiences, putting focus on services and processes is not easily achieved.

Service identification and finding the right level of service granularity were identified in several case organisations. Service design was recognised by many organisations to be one of the most challenging parts in SOA development process. Several interviewees stated that understanding the essence of business services, what they really are, and then finding a suitable balance between abstraction, modularity and reusability required skills and knowledge beyond what the organisation currently had. The need for technical, domain specific skills was pointed out by several IT side interviewees. This is in line with Shiskov et al. (2006).

SOA teams

Multidisciplinary teams, with members from both IT and business domains, were seen as crucial for SOA development. In all cases it was common that the main role of SOA team was to endorse cooperation between business and IT, and furthermore to act as a centralised steering body for the organisation’s SOA development projects.

“An SOA team was established. It had a few people from business and few people from IT. The business people were working in positions where they were able to gain a holistic view to the customers. They had the capabilities to think what services would be needed.” [I6].

Following Baskerville et al. (2005), SOA development is rather a means than an end. Such thinking as acknowledged governance of SOA compatibility was seen to be a part of the SOA team’s responsibilities:

“There were participants from business units, the CIO’s office and the IT. The purpose was to establish SOA policies and practices. There we looked at things from the exploiter point of view... That way we started to develop our SOA platform and the governance process.” [I5]

Business driven SOA development

It seems that the business driven SOA projects yield better business-IT alignment than other projects. The fundamental difference between the approaches was that the requirements were based on real business cases in business driven projects, while in non-business driven projects the requirements typically originate from a technical viewpoint without clear links to business objectives. Business driven projects were using a process-oriented development approach with intensive use of business
process modelling for capturing functional requirements. Interestingly, this led to a heightened awareness of SOA in general in comparison to IT driven projects.

**Governance**

In the five case organisations, SOA development was directed by defined policies and practices. This improved the quality of the SOA implementation by enabling a better fit with business needs. Yet SOA governance was not initially considered but necessitated some degree of adoption and use. Moreover, SOA applications had to be business critical. This implies that the role of SOA governance is emphasised in an organisation where SOA is used in applications that have a direct impact on the organisation’s business. There SOA is needed as a value adding component that can be further invested in.

The following quotes emphasise SOA governance in the organisational context:

“[Now] we [IT] can challenge business to start thinking things in a new way... Now we get all development needs from the business units to our [IT] headquarters, where we [the business solutions team] analyse them before any development takes place.” [I2]

“[It was hard to set up a governance infrastructure. The job is still ongoing, but we have already taken some parts into production... Governance with a wider scope, when [service] reuse will happen, services will be located and everything running smoothly [that’s still to happen]” [I7]

**Business stakeholder participation**

Having a common forum for business and IT people is an important factor in achieving business-IT alignment through SOA development. In addition to organisation level SOA teams, business domain stakeholder participation in SOA development was also identified as a key factor, having a positive influence on alignment on the project team level. Business domain knowledge and expertise in certain business cases and business requirements were considered beneficial for SOA development projects. Further, although business process modelling was used to specify and illustrate the project’s business requirements, business people had an important role in interpreting and clarifying the models to the IT developers.

“We have business people participating in development projects. Those who can do business process modelling, their role is really important because they can interpret and read these kinds of generic models.” [I6]

Moreover, business stakeholder participation had a positive influence on project execution and outcome as both change management and exception management were jointly handled. For example, an IT architect from finance industry explained the benefits of having business people participating in the development project: "Business has their own developers, who are creating these processes. After they have finished their work, the focus shifts to the IT side. These business people are still taking part in project implementation, and monitoring it as members of a steering group, and, if necessary, giving support to the project team.” [I7]

**Common language**

Mutual understanding between business and IT people is achieved through continuous communication. SOA provided several means for this. First, SOA terminology and concepts formed a basis for IT people to comprehend the current system architecture and articulate it through common language.

“The greatest benefit of SOA has been that our own understanding of how things should be done is improved. Our [IT] vision has been improved, and our competence to communicate with business about IT as a dynamic enabler has been gently enhanced.” [I2]

However, the business people disagreed. They did not consider that SOA had improved their communication capabilities or increased understanding about the systems and architecture, because "every-
body has heard about SOA. To really understand what it means, that’s difficult because it gets so tech-
nical so fast” [13]

These quotations indicate that SOA is mostly a technical concept. To understand SOA terminology
requires an in-depth understanding of the technical concepts. This implies that SOA, as a software
architectural style, does not provide an adequate base for business-IT communication.

Second, using business process modelling was seen to be useful in gaining a common understanding
of the business requirements. An ICT architect described how business process models contributed
business-IT cooperation: “A common language was established when process flow diagrams were
walked through together [with business people]” [14].

Third, business process models were also seen to be useful in validating the implementation of the
development project. The concepts and terminology provided a common language for business and IT.
Process-oriented design approach, combined with SOA development, thus seems to be able to enable
an appropriate environment for business-IT alignment.

However, there was a major problem in communication. Business people and IT people have a ten-
dency to conceive of the concept of service differently: both groups comprehend service from their
own perspectives. “The problem is that in business, we have difficulties to identify what is really a
service. The level of abstraction is either too high or too low. Even in our IT unit they are not able to
identify services properly or to support business units in identifying services. IT people focus too much
on technical details.” [16]

This gap is because of the ambiguity of the terminology. From the business process viewpoint the
service is simply a business service. Similarly, from the technical perspective, the same service is per-
ceived as a technical, application-level service.

Strategy

Strategy level alignment was identified in only two interviews with the IT people, the business people
did not address it at all. This may be because the development projects were still only discrete applica-
tions or aggregates of applications rather than organisation-wide systems. Yet SOA was recognised as
a long-term business plan, valuable for IT development. Knowledge about business strategy was seen
as a useful input for designing reusable services and architectures that would fit future business needs
without major re-implementation efforts. Two architects explained their problems when evaluating
whether to develop reusable services.

“It [potential for service reuse] should be interpreted from the business perspective. To be able to do
it, business should have a future vision that reaches far enough” [14].

Enterprise architecture framework

The utilisation of enterprise architecture framework was considered to improve business-IT alignment.
With the framework, IT’s capability to involve business people in systems development was in-
creased. On the other hand, business people were able to gain a better awareness of the organisation
architecture and of SOA in the system architecture landscape at large. However, enterprise architecture
frameworks originated from IT as “we, in the IT unit, came the conclusion that we need a [language]
for communicating to the business side people what sort of development process we should have in
order to identify architectural requirements from the business point of view” [111]. “Even in practice,
the business people may like the report [that describes what systems are related to certain business
processes]… We get onto the right level in the discussion faster… The idea was that modelling is done
so that IT and business are already aligned there in the models.” [112]

Rapid development tools

Baskerville et al. (2005) argued for agile development methods in SOA development. Our findings
concur, and indicate that the utilisation of such methods for SOA development enabled faster delivery
cycles by increasing development efficiency and enabling agility in adjusting to changes in requirements.

**Process automation**

The process engines technology was scarcely used in the production of SOA services. They were only used for process automation purposes, yielding additional business value for the existing SOA implementation. The biggest challenges in process engine utilisation were claimed to be immature tools and technologies, and interoperability issues.

5 DISCUSSION

In this paper, we explored the potential and realised benefits of SOA utilisation in an organisational context. The interviews with key SOA people provided us with an understanding of the factors essential for SOA development for achieving business objectives. We categorise eleven factors into the 4 themes, discussed in below.

**Organisational culture and human resources.** Resistance to change and siloed organisation structures are creating barriers to SOA utilisation (c.f. Bieberstein et al. 2005). This impedes the achievement of alignment objectives. Yet, by creating common ground and shared understanding, it is possible to overcome cultural barriers. A close relationship with business and IT was found to be an indicator for a positive organisational culture. This positive atmosphere is essential for fruitful business-IT alignment. To achieve it, the importance of continuous communication between IT and business needs to be acknowledged, as this has been one of the main reasons for numerous project failures (e.g. Chen 2007). The solution is to have an SOA team, composing of members from IT and from business domains, and to use shared models and terminologies. Business process modelling and service identification contribute to organisations’ capabilities to develop business process driven SOA projects.

**Processes and methodologies.** Business driven SOA projects seemed to yield better results in terms of business-IT alignment than IT driven projects. We believe this is because business driven SOA projects meet mutual needs better. There business process modelling is used as a means to capture functional requirements. Yet translating the models into application layer artefacts is very difficult. Although it is claimed that business process modelling is suitable for both IT and business users, current modelling notations are still too complex to be efficiently used by average business users. To correctly comprehend the models, business stakeholder participation is needed throughout the SOA projects in order to achieve the business goals. Business stakeholders may contribute to this by interpreting and clarifying the models for the IT developers, participation in the project’s change management and exception control, and ensuring the congruence of SOA implementation in the long run. This emphasises the importance of accommodating SOA development with pre-defined rules and policies, which further improve the quality of the SOA implementation and enable better alignment with business needs in a sustainable manner.

**Communication and artefacts.** The importance of communication for business-IT alignment has been identified (e.g. Reich & Benbasat 2000; Chan et al. 2006; Luftman et al. 1999; Campbell 2005; Sledgianowski and Luftman 2005). Our findings show that earlier findings are also applicable in SOA development. The greatest difference is with SOA terminology, which is comprehensible only to people with a technical background. It can thus be argued that SOA is a technical concept requiring an in-depth understanding. This implies that SOA, as a software architectural style, does not provide a feasible terminology for business-IT communication.

Another significant finding is the tendency to comprehend services differently. This could be explained by the duality of the service concept. Although the concepts and process model terminology offer a basis for a common language between business and IT, they value strategies differently. While business people do not seem to evaluate SOA implementation from the business strategic viewpoint,
IT people perceive it to be valuable as a basis for technical advancement. The business strategy knowledge is thus a useful input for service and architecture design.

**Technology.** Lyytinen and Ren (2008) and Baskerville et al. (2005) discuss the importance of rapid development methods for SOA development. Our findings confirm this. The methods shorten delivery cycles and increase development efficiency, thus enabling a better fit with changing requirements.

These factors influence SOA development from the business-IT alignment viewpoint. Their identification provides us with a better understanding of the complex nature of SOA development. Although many of the findings are already recognised in the literature, the factors provide a complete, practically oriented approach to business-IT alignment. In other words, we try to respond to Chan & Reich’s (2007) call for **practical** studies on how alignment really takes place, what factors frame it, and how managers may benefit from these studies. Researchers may utilise our findings as follows. First, the factors provide a basis for understanding different factors and their causalities regarding successful SOA development. Second, this study complements earlier studies by producing empirical evidence on the phenomena. Third, new research themes are introduced to the landscape of service-oriented systems research e.g. Kontogiannis (2007). Practitioners and managers may benefit from the list of factors by using it as a checklist in their SOA initiatives. By so doing, practitioners may be able to increase the business value obtained from SOA utilisation. Therefore, we suggest that managers should evaluate their current SOA development environment in the light of our results.

The study has several limitations. First, the small number of organisations and interviews is an obvious limitation. Having more organisations would have enabled better generalisations of the results. Second, although we collected the data using key informants at each organisation, a wider set of stakeholders might have provided additional insights to the research theme. Third, only one person per organisation was interviewed in most cases. Taking these weaknesses into consideration, we argue that we have been able to gain an in-depth understanding of the phenomenon in general. We acknowledge that the findings do not provide an exhaustive or widely generalisable explanation for SOA development, but, following the tradition of qualitative and exploratory research, we hope such a defect is pardonable. All in all, we believe that these findings provide a basis to understand the complexity of the phenomenon.

### 6 SUMMARY

In this paper we gained a better understanding of factors influencing SOA development from the business-IT alignment viewpoint. We illustrated how business-related SOA projects are carried out in organisations and what main factors affect their success. We used a qualitative empirical research approach in the study. Data was collected through semi-structured theme interviews and the data analysis was made by applying the grounded theory method. Our findings can be summarised as follows. We identified four themes, including altogether 11 different factors that are related to business-IT alignment of SOA development. The themes and factors are: Organisation culture and human resources: organisational maturity, competences and SOA team. Processes and methodologies: business driven development, governance and business stakeholder participation. Communication and artefacts: common language, strategy and EA framework. Technology: rapid development tools and process automation. These results can be used as a starting point for new research avenues and as guidelines for practitioners.

### ACKNOWLEDGEMENTS

Our sincerest thanks to Tarja Systä and Timo Kokko for their cooperation in this research project.

Abstract

What is the impact of a Service-oriented Architecture (SOA) on the efficiency and effectiveness of business process standardization (BPS)? The contribution of this paper is the development of a research model around the impact of SOA on BPS in terms of achieving fundamental efficiency and flexibility potentials while covering both the business layer and the IT layer of the firm. Drawing on an accepted and widespread enterprise architecture model, we derive propositions that explain why and how SOA’s characteristics help to standardize business processes and how the interplay between SOA and BPS leads to an increased overall business value. Additional moderator arguments, such as the level of service granularity, the centrality of SOA governance, or Business IT alignment, are added to the research model as critical success factors of achieving business value of SOA.

Keywords: Service-oriented Architecture, SOA, business process standardization, BPS, business value, research model.

1 Authors in alphabetical order of names.
1 MOTIVATION

In 2008, the use of Service-oriented Architecture (SOA) in North-American, European and Asian-Pacific companies increased from 44% to 63% (Heffner 2008). This comes along with a paradigm shift from a strongly process-oriented value chain perspective to a service-oriented perspective, viewing the firm as a set of encapsulated but interrelated services (Demirkan and Goul 2006). This shift, together with the corresponding change in the IT architecture, offers various tremendous potentials such as identifying redundant activities in the firm, supporting insourcing vs. outsourcing decisions and subsequent transitions, identifying core competencies, or changing and managing business processes in a more flexible and consistent manner.

In Business Process Management, one particularly important instrument for enabling and achieving efficiency potentials is standardization of business processes (BPS) (Hadfield 2007; Muenstermann et al. 2009a; Muenstermann and Weitzel 2008; Venkatesh 2006). In this paper, we aim at particularly merging the concepts of SOA and BPS and therefore propose a conceptual research model about the impact of Service-oriented Architectures on the standardization of business processes. There exist many works on how SOA should be designed, implemented, and managed, but there is still a huge gap on what the actual benefits of SOA are, or, whether and how SOA delivers business value in terms of Melville et al. (2004). Therefore, we want to tackle this essential question and restrict our focus on the role SOA plays for achieving efficiency potentials from BPS.

In this paper, we will develop a theoretical research model covering the following research questions:

1. What is the impact of Service-oriented Architecture (SOA) on business process standardization (BPS)?
2. How can the interplay of SOA and BPS increase both business process performance and organizational performance?
3. What are the critical success factors required as moderator for an effective interplay of SOA and BPS?

The result of the research paper at hand is a theoretical research model consisting of a set of propositions which describe the interrelationship between SOA and BPS and the role of critical success factors. This conceptual model is intended to form the basis for future empirical research.

Our paper is structured as follows: section 2 provides the theoretical foundation and a concise terminology which allow a mapping of business processes to SOA and introduce the concept of BPS. Subsequently, we develop a set of propositions explaining the interplay of SOA and BPS as well as both the consequences and necessary success factors of the interplay in section 3. The paper concludes by interpreting the results and discussing potential limitations as well as the planned following research steps in section 4.

At this point, we want to clarify about the following restrictions regarding the focus of this paper: (1) Regarding process standardization, there is often the question about the optimal trade-off between standardization and individualization (Hall and Johnson 2009; Lampel and Mintzberg 1996); nevertheless, this is not our research focus. (2) As formulated in the research questions, we focus on the role of an (already implemented) SOA for process standardization. The reverse question whether or how standardized processes facilitate the introduction of an SOA, is not tackled in this paper.

2 THEORETICAL FOUNDATION

The goal of this section is, firstly, the introduction of a concise terminology to describe organizations and their business activities to then, secondly, allow proceeding with an analysis of the interplay of SOA and BPS in the next section.

The first subsection (2.1) introduces "business process standardization" and shows exemplary value drivers. The second and third subsections (2.2 and 2.3) provide the terminology to describe enterprise
architecture and the respective building components. The fourth section (2.4) finally aims at showing
the conceptual relationship between SOA and BPS at the different enterprise architecture layers.

2.1 Business process standardization (BPS)

Standardization of business processes is increasingly receiving attention from academics and
practitioners alike. Since Venkatesh (2006) identified process standardization as one of three broad
future research directions, numerous papers dealing with BPS have been published (Bala and
Venkatesh 2007; Hall and Johnson 2009; Sánchez-Rodríguez et al. 2006; Wüllenweber and Weitzel
2007). On the practitioner side, companies hope to save significant costs by means of BPS (Hadfield
2007). However, in both academia and industry BPS has hardly been treated as discrete and concisely
defined object of research. Even very recent papers claim a lack of research on a concise definition
great attractiveness, academics' and practitioners' work on [business] process standardization is
conspicuously absent". Shaw et al. (2007, p. 92) indeed define BPS as a means to change business
processes from where they are to a standard business process and "focus on a meta process: the
process of changing a process", but completely leave open the question, how a standard business
process should look like and how a given business process at hand can be transformed into a standard
business process.

In contrast to that, Muenstermann and Weitzel (Muenstermann and Weitzel 2008) propose a definition
of BPS as well as an according conceptualization. They define BPS as a two-staged approach:

(a) **internal BPS:**
Unification (homogenization) of multiple existing business process variants to either one
single variant among the existing or to a newly designed target business process, which itself
is composed out of selected tasks of the existing business process variants

(b) **external BPS:**
Alignment respectively adaption of unified/homogenized business process variants to an
externally available reference business process or an externally available best practice
business process

BPS pursues different goals: In the short and medium term, internal BPS focuses on the
unification/homogenization of the business processes considered, foremost aiming at eliminating
inefficiencies and thereby increasing the business process performance along the dimensions business
process time, cost, and quality. In the medium and long term, external BPS aims at aligning/adapting
the previously internally standardized business process variants (to an externally available reference
business process2) to reach and sustainably guarantee cross company validity, reusability, and
adaptability. The closer a company adheres to an externally available reference process, the easier it is
to react e.g., to market and external change in accordance with the way and speed of competing
companies that also have adopted the reference process. Hence, the described alignment/adoption
within the context of external standardization on the one hand increases business process performance
and on the other hand expands organizational flexibility.

---

2 Examples of industry specific reference processes are the "Supply Chain Operation Reference Model (SCOR)" or the
"enhanced Telecom Operations Map (eTOM)". See Kindler and Nuettgens (2005) for an overview of reference processes or
Malone et al. (1999) for how to design reference processes. Such industry specific reference processes have mostly been
adopted by a large amount of companies. Hence, adhering to them can be a necessary condition to allow for easy realizable
process changes and consequently expand organizational flexibility within specific industries.
2.2 Enterprise architecture: enterprise plan, business process model and resource model

We base our terminology to describe enterprise architectures on the "Semantic Object Model" (SOM) following Ferstl and Sinz (Ferstl and Sinz 1995; Ferstl and Sinz 1997). According to the SOM methodology, an enterprise architecture comprises three layers: the enterprise plan, the business process model and the resource model as well as the respective interdependencies and relationships between the layers:

The enterprise plan describes the global tasks of the enterprise, a strategy to cope with that global task as well as surrounding conditions relevant to the solution. The business process model specifies main and service processes as solutions to realize the enterprise plan. The resource model finally provides resources, e.g. personnel, application systems, and machines/equipment necessary to follow the solution path described in the business process model to realize the enterprise plan (Ferstl and Sinz 1997).

Business process models constitute the central layer within the SOM methodology. According to Ferstl and Sinz (1997) they depict a model of the inside view of a business system. They can be interpreted as solution approach for the realization of the enterprise plan. Hence, they combine the enterprise plan – being aware of the business context of the business process at hand – with the resource model and thereby form the basis for the subsequent analysis of the impact of SOA on BPS.

2.3 Components of the business process model and resource model

Figure 1 below displays the building components of the business process model and resource model as well as the respective interdependencies between the building components. The business process model comprises the three building components "processes" (layer 1), "tasks" (layer 2) and "sub-tasks" (layer 3). The resource model (on layer 4) provides "applications systems", "personnel" and "machines/equipment".

According to Davenport a business process is a "a set of logically related tasks performed to achieve a defined business outcome" (Davenport and Short 1990, p. 12) or the "specific ordering of work activities across time and place, with a beginning, an end, and clearly identified inputs and outputs" (Davenport 1993, p. 5). Lee et al refer to business processes – according to the SOM methodology – as connecting business goals and resources realizing them as "a vehicle to build and materialize organizational capabilities" (Lee et al. 2004, p. 645). Ferstl and Sinz (1997) summarize prominent features of business processes as event driven chain of tasks" as well as the "mapping and use of resources.

In summary, on layer 1, we define a business process to be an event-driven, ordered chain of tasks pursuing the goal of reaching a previously defined business goal. Continuing, on layer 2, we define tasks as descriptions of distinguished goals that have to be reached, together with a preceding business event (input) and a resulting successing business event (output). On the next level of detail (layer 3), the SOM specifies sub-tasks, which are defined as business activities realizing parts of a task.

Now we leave the business process model and apply ourselves to the resource model. The resource model comprises the three building components "applications systems", "personnel" and "machines/equipment" and describes how and using which resource the sub-tasks are instantiated.

---

1 As alternatives to the SOM methodology, several practitioners and researchers offer further approaches to describe enterprise architectures. Among them, one example approach is the "Component Business Modeling" (CBM) approach promoted by IBM (Ramchandani and Harwood 2005). To our knowledge all available other approaches are based on an equivalent underlying internal structure and – along the parts relevant for our research approach – can directly be translated into the terminology used in the SOM approach. As a consequence within this article we can derive our terminology from the SOM approach. Moreover, SOM is a sound and completely integrated approach, which offers in contrast to other approaches the advantage to provide a consistent methodology (cf. Ferstl and Sinz 1998). This methodology guides the modeler through the entire process with concrete rules on how to transform strategic business goals into business process models and then into concrete building components (such as interfaces and objects) of application systems.

4 "variant of a business process" defines a business process similar to a given business process except for some minor tasks of the given business process left out.
As shown in Figure 1, the components of the business process model and the resource model depict consecutive layers of the enterprise architecture, each describing the preceding layer on the next level of detail.

**Figure 1.** Overview of building components of business process model and resource model.

### 2.4 Relationships between SOA and enterprise architecture

According to the presented enterprise architecture, SOA is a methodology for designing the application landscape (Siedersleben 2007). According to Erl (2005, p. 54) “SOA can establish an abstraction of business logic and technology that may introduce changes to business process modeling and technical architecture, resulting in a loose coupling between these models. SOA is an evolution of past platforms, preserving successful characteristics of traditional architectures, and bringing with it distinct principles that foster service-orientation in support of a service-oriented enterprise.” Therefore, we distinguish two interrelated paradigms associated with SOA: (1) a technical perspective, which interprets Service-oriented Architecture (SOA) as pure IT paradigm, as well as (2) an enterprise perspective, which models and organizes the entire organization according to a Service-oriented approach, which also includes business processes and workflows in contrast to the first perspective resulting in a so-called Service-oriented Enterprise (SOE) (Demirkan and Goul 2006). If solely applying the technical perspective, SOA serves the design and realization of the resource model (see Figure 1 layer 4).

Combining both paradigms, SOE/A becomes manifest in a three-stages model, consisting of process model, service model, and technology model (Siedersleben 2007). Whereas the process model corresponds to the previous business process modeling, the service model defines not only the services themselves but also the relationship to the business processes. The technology model defines the concrete implementation for realizing the services. Therefore, the service model decouples the business processes from the underlying technological realization in order to avoid that changes in the implementation will affect the business processes. Thus, the technology model enables an efficient implementation of services, whereas the service model facilitates the efficient realization of the business processes (Siedersleben 2007). In ideal circumstances, the upper models define the antecedents for the lower models in order to allow for an Service-oriented Enterprise.

However, there exist also backward links from the lower to the upper models, as organizations still use legacy systems and standard software which do not perfectly support existing business processes. Consequently, organizations make also use of bottom-up approaches for identifying services despite the pure top-down approaches. Whereas top-down approaches analyze existing business processes in order to identify adequate services, bottom-up approaches examine legacy systems and standard software for the identification of services. While organizations using the former approach may face problems realizing the identified services within an existing infrastructure, the latter approach can lead to too fine-grained (more data-centered than business-oriented) services, which are similar to an application programming interface (API). Therefore, a hybrid approach combining both methods is suggested in order to minimize the problems associated with these approaches (Arsanjani 2004).
Linking the model of SOA according to Siedersleben (2007) to the components of an enterprise architecture (see Figure 2) leads to the following relationships:

The process model corresponds to the first layer of the enterprise architecture.

Increasing the level of detail of the process model is the foundation for the service model, which is represented on the second and third layer of the enterprise architecture. The increased level of detail allows to derive the services of the service model directly from the sub-tasks (layer 3), which documents the demanded relationship between services and their business process within the service model (Siedersleben 2007).

Whereas both models mentioned before are independent from the technology used to realize SOA, the technology model describes the technology selected to implement and dispose services (Siedersleben 2007). The technology model originates from the assignment of sub-tasks (layer 3) to services, which are located at the fourth layer of the enterprise architecture.

Consequently, distinguishing between tasks, sub-tasks and application systems or services, which perform the sub-tasks supports a separation being compatible with the three-stages model of SOA. This clear separation of sub-tasks and performing services enables flexibility as well as reuse potentials of SOA (Sinz 2008).

Figure 2. Relationship between the three-stages SOA model (right side) and the components of business process and resource model of the enterprise architecture (left side).

3 SOA AND BUSINESS PROCESS STANDARDIZATION – A RESEARCH MODEL

After showing which layers and components of SOM are influenced by BPS activities (3.1), we develop propositions about the collaboration of SOA and process standardization within the layers of the enterprise architecture (3.2). The last subsection will expand the propositions by moderating success factors with respect to the effective interplay between SOA and process standardization (3.3).

3.1 BPS in the Context of the Enterprise Architecture

On the first layer (processes), internal BPS means reduction of process variants, i.e., different sequences of order and "call" of tasks. Resulting consequences for the second layer (tasks) are (1) the identification of tasks which are redundant, and thus not relevant anymore, and (2) the identification of tasks being elements of different business processes (leading to "reuse" of tasks). Moreover, rather similar tasks can be identified and homogenized as well. Regarding the third layer (sub-tasks), we can argue similarly.

Internal standardization ensures that the same sub-tasks within different tasks are performed from the same service within the resource model.
External BPS focuses on the first and second layer of the enterprise architecture and ensures that the choice, order and interface definition of tasks of processes or process variants correspond to an external reference process or best practice process.

From our point of view, the introduction of a precise terminology for the description of the enterprise architecture and the contained components allows us to point out the area of activity of BPS (internal as well as external).

3.2 Deriving the propositions

With respect to the three characteristic elements of SOA – component orientation (including standardization of interfaces), loose coupling and workflow (2007) – we develop propositions about the influence of SOA (in terms of the extent and the way of an already implemented SOA) on BPS.

As explained earlier, the first step to standardize business processes is to homogenize them internally. SOA supports this internal standardization due to the reuse of the same service (fourth layer of the enterprise architecture) for the same sub-tasks (third layer). However, organizations may face two problems when standardizing their business processes: (1) existing legacy systems may hamper the alteration of business processes, as IT is not flexible enough, or (2) the use of standard software may force an organization to change its processes according to this software (Merrifield et al. 2008; Siedersleben 2007). Due to the service model and the three characteristic elements of SOA, the latter offers the flexibility to support every possible business process. Therefore, IT does not longer hamper the business in their aim to internally standardize processes (process model) as the need to align them with the actual implementation (technology model) is not necessary anymore.

Proposition P1: SOA eases internal BPS due to loose coupling of business processes and of the supporting IT.

Introducing SOA requires a very detailed and precise documentation of business processes. Brahe (2007) shows that the implementation will hold up if tasks are not modeled sufficiently or information flows are not clearly specified. This very detailed process documentation is necessary for internal process standardization activities as well (Ungan 2006).

Proposition P2: Firms that have established an SOA will more easily conduct internal BPS since the necessary process documentation is already available.

Whereas component orientation focus on the design of a single application system, SOA focuses on the design of entire system landscapes (Siedersleben 2007). Therefore, an enterprise wide SOA aims at modularizing services of the technology model (Sanchez 2004) in order to implement them only once for reusing them at different locations, guaranteeing freedom of redundancy and minimizing maintenance costs of the IT landscape (Baskerville et al. 2005; Siedersleben 2007). For example, the use of WSDL (Web Service Description Language) promotes loose coupling and component orientation as it offers clearly defined interfaces for using a business functionality encapsulated in a service. Consistently implementing the three-stages model of SOA down to the technology model leads to a reduction of variants of tasks and sub-tasks within the service model, which in turn promotes the standardization of business processes. This results from a reduction of unplanned redundancies of business functionality within heterogeneous, historically grown system landscapes (Siedersleben 2007).

Proposition P3: Due to the concepts of modularization and reuse, SOA facilitates a reduction of redundancies within the technology model which in turn leads to enhanced BPS.

Moreover, SOA also affects external BPS (on the business process layer). While, from an enterprise perspective, the sequencing of services along a business process is primarily standardized by internal BPS (see Figure 2), the centralization of the process flow control by implementing an Enterprise Service Bus (ESB), which orchestrates the service calls, facilitates the integration of external best practices (external capabilities) – in form of services offered and provided by external providers – into firm-internal business processes. Consequently, the flexibility of the service model allows to optimize the business process model because tasks which are executed by external services can be integrated more easily. Here, adapting the business process model is not necessary; only the relationship between
the service model and the resource model have to be changed (Beimborn et al. 2008). Thus, the following proposition (P4) follows the same argumentation as P1, but applies it to the integration of external capabilities instead of firm-internal standardization.

**Proposition P4:** SOA facilitates external BPS by enabling the integration of firm-external capabilities (in form of services).

By contrast, we can also argue the opposite way: if business processes have been standardized before an SOA is introduced, redundant software can be eliminated and IT costs can be saved (Merrifield et al. 2008). But, the causality is difficult to determine because both BPS and SOA represent requirements for achieving a business value in terms of more efficient business processes and more strategic flexibility (e.g., faster and easier implementation of new business models etc.). Without revising the business processes, we cannot realize technical potentials as well (Davenport 1993; Hammer and Champy 1993). On the other side, BPS without an SOA in place can only be as broad as the used applications and legacy systems allow for. By separating the business process model, the service model, and the resource model, SOA enables step-wise evolutionary process optimization, which is different to the "classical" big bang business process reengineering (BPR) approaches proposed in the early 1990s (Davenport 1993; Hammer and Champy 1993). This flexibility advantage is even more important in times of frequently changing business and regulatory environments which require fast adaptations of the business. Consequently, we can argue that both elements, BPS and SOA, show high synergies when applied together.

**Proposition P5:** There exists a positive interaction effect between SOA and BPS, leading to super-additive benefits in terms of organizational efficiency and increased strategic flexibility.

### 3.3 Moderating effects

After deriving theoretical propositions which explain the interplay between SOA and BPS, additional moderator arguments which serve as critical success factors for achieving business value from SOA and BPS are developed. These are (1) the level of service granularity, (2) the centrality of SOA governance, and (3) Business IT alignment.

The first aspect focuses on one of the most important and most difficult questions of efficient and effective SOA design: determining the optimal degree of service granularity (Acharya et al. 2005). During service design and implementation, there are different options to determine the scope of tasks and sub-tasks and their services on the resource layer. If the "size" of the service is chosen too fine-grained, coordination and orchestration may get very complex (Baskerville et al. 2005). Moreover, the technical performance can be negatively affected since the network has to carry out higher workloads than the services themselves. In this context, several authors speak about "chatty services" (e.g. Woodley and Gagnon 2005). From a BPS perspective, fine-grained services would allow maximal standardization, theoretically, but the administrative complexity would, in many cases, prevent the identification of an existing and appropriate service within the firm’s SOA and thus lead to a redundant implementation. This will threaten the objective of BPS.

**Proposition PM1a:** If the functional scope of the implemented services has been defined too fine-grained, this will hinder internal BPS on the task layer.

By contrast, if the service size is chosen to coarse-grained, reusability potential will decrease. The higher the functional range encapsulated by a service, the more it is fitted to the specific demands of the related task on the business process layer (Baskerville et al. 2005; Brahe 2007). From a BPS perspective, the problem of specifying too large services is that slightly different process requirements from different contexts always result in new service implementations which, in turn, reduce internal standardizability on the task layer.

**Proposition PM1b:** If the functional scope of the implemented services has been defined too coarse-grained, this will hinder internal BPS on the task layer.

Thus, in both cases, there is a threat of repeatedly implementing similar business logic – which is contrary to the objectives of BPS (Woodley and Gagnon 2005).
As a further argument, we introduce the establishment of an SOA governance as moderator. Since introducing SOA often is a firm-wide change of the IT architecture and since it affects all layers of the firm, establishing a central and powerful organizational unit is a critical success factor (Yoon and Carter 2007). Similarly, standardizing business processes across the firm has to be managed by a central and superordinate instance as well (Muenstermann and Weitzel 2008). Moreover, this central unit has to be capable of administering the implemented services in order to ensure a maximum degree of reusability and reuse (Bieberstein et al. 2005). With sometimes more than thousand services implemented by a firm’s SOA (Brahe 2007), this represents a highly complex management task, which not only requires a central SOA governance, but also equipping it with adequate management, power, and documentation tools and mechanisms (Brahe 2007). Without a central SOA governance, SOA cannot be a driver of BPS. Moreover, the positioning of the SOA governance within the firm’s organizational structure will also be an adequate unit for setting up and managing firm-wide BPS activities. Since both SOA and BPS affect the whole enterprise, we propose a joint and central SOA and BPS governance to be best suited in order to capture the potential super-additive benefits from both initiatives. This joint governance can enable and ensure a consequent top-down procedure from business process via task to resource layer when implementing SOA (Vinoski 2005).

Proposition PM2: A centrally established SOA governance has a positive impact on the relationship between SOA and BPS.

Proposition PM3: Merging SOA governance and BPS governance facilitates achieving the goals of SOA and BPS (i.e., P5).

In order to implement an IT architecture which efficiently, effectively, and flexibly supports a firm’s business processes, the organization has to establish and to maintain a sufficient level of Business IT Alignment. Business IT Alignment is a multi-dimensional concept, not only covering the alignment of business and IT strategy, but also the alignment of structures, in terms of processes, capabilities, routines, and resources (Henderson and Venkatraman 1993) – which is also reflected by the SOM introduced above. Further, Reich and Benbasat distinguish an intellectual dimension and a social dimension of alignment. The first covers the congruence of explicated and documented knowledge, such as strategies, project plans etc., while the social dimension captures the "shared mindset" and a common understanding between the managers and staff from business and IT departments (Reich and Benbasat 2000). This social dimension can again appear on the strategic level (i.e., between executives or top management), such as measured by Reich and Benbasat, and on the remaining levels of the firm such as trust and mutual understanding between IT and business managers and employees involved in joint projects or even during daily business (Beimborn et al. 2006; Franke et al. 2005).

All decision problems discussed earlier, such as the optimal level of granularity or the implementation of an adequate SOA governance, ideally incorporating the BPS governance as well, emphasize the critical need for having sufficient alignment between business and IT both on the strategic and on the structural level, and along the intellectual and the social dimension. Without good alignment, which has to be adopted and carried out by each individual involved (social dimension), neither a successful SOA implementation nor effective BPS activities are possible. Exchanging knowledge and establishing a common understanding of "service" and the firm’s business processes is necessary for collaborating on process modularization, deciding about the level of service granularity, and standardizing business processes. Ideally, the firm establishes alignment engineers which show high expertise both on the business side (process layer) and on the IT side (resource layer) (Brahe 2007). This will greatly ensure the mapping between the sub-tasks of the process layer and the service implementations on the resource layer.

Proposition PM4: Strategic and structural Business IT Alignment is critical for successfully implementing an SOA and for its impact on BPS.

Figure 3 summarizes the derived propositions:
Figure 3. Conceptual research model about impact of SOA on BPS.

4 CONCLUSION AND NEXT STEPS

In this paper, we developed a research model consisting of propositions regarding the impact of Service-oriented Architecture (SOA) on business process standardization (BPS). Both concepts represent important factors for increasing a firm’s performance and strategic flexibility. Drawing on the main design concepts of SOA, we propose a positive effect on BPS resulting from loose coupling and modularity which helps to disconnect the business logic of the business processes from their supporting IT. Moreover, modularity and reuse help reducing unwanted redundancies of implemented business logic, which makes BPS easier as the same business logic does not have to be altered at different implementations. These relationships and the potential to integrate external capabilities are moderated by governance design as well as by the level of granularity, which has a direct effect on the potential to reuse services. Additionally, Business IT Alignment is expected to be a critical success factor moderating the direct effects as well as affecting the moderating effects mentioned before. Overall, we expect a combined positive influence of both SOA and BPS together on a firm’s performance and strategic flexibility.

As the next step, we intend to refine the theoretical model developed in this paper by conducting case studies. Based on interviews with managers responsible for SOA governance in large firms, we get insights into the different service design parameters and management mechanisms. Moreover, accompanying the whole process from specifying a certain demand for a new service on business side (process layer) to its final implementation and integration within the firm’s SOA (resource layer) will sharpen our understanding how reusability is determined and how reuse is finally achieved. Thus, the relation from SOA to BPS can be explored from an SOA-driven perspective (i.e., exploratory approach). In other case studies, we will explicitly interview managers involved in firm-wide process standardization activities and will examine – if an SOA is available – whether our propositions can be indicatively justified (i.e. confirmatory approach). After refining our theoretical model, we will transform it into an empirical model, consisting of testable hypotheses and measurable constructs. In this stage, it might be necessary to split single theoretical propositions into several hypotheses which can be quantitatively validated. Moreover, the rich concepts of SOA and BPS need to be unfolded to multi-dimensional constructs which are represented by measurement models each. For example, BPS has been operationalized as a two-dimensional construct, consisting of internal and external BPS, each being represented by a multi-item measurement model, in e.g., (Muenstermann et al. 2009b). Subsequently, we intend to conduct a survey in order to measure our constructs and to validate our hypotheses by using common SEM approaches.

Ultimately, this research project will clarify basic relationships between SOA and BPS and uncover essential success factors for realizing both of them. Thus, we hope to contribute to the research on the business value of flexible and modular IT architectures as well as to managerial reality.

Abstract

This paper describes how IS offshoring organisations are changing in response to increased globalisation of the practice of software development. It posits the emergence of a new form of multi-national enterprise (MNE), described in this paper as a ‘modern heterarchy’, from the construct of the heterarchy originally developed by Gunnar Hedlund in 1986. The paper draws on theoretical antecedents in the discipline of international business studies, and is supported by empirical data gathered from two extended case studies of offshore IS projects. The research uses grounded theory techniques for the collection and analysis of data, and has particular value for IS practitioners in offshore IS MNEs.

Key words

Offshoring; globalisation; heterarchy; grounded theory; multi-national enterprise; international business
1 INTRODUCTION

This research is concerned with a particular form of globalisation: the practice of offshoring Information Systems (IS) development. IS offshoring uses low cost labour in distant countries to provide IS products and services for use in developed economies.

IS offshoring is nowadays deployed extensively and is regarded by many as a mature and cost-effective approach to application development and maintenance (Lewin and Peeters, 2006). Suppliers of offshore IS services have graduated from simple sourcing models - such as providing individuals to do specific tasks - to complex and sophisticated cross-border contractual and resourcing arrangements with their customers (Soota, 2002; Murthy, 2004). New project and organisational structures are required to take account of the dislocation of staff, which in turn demands new ways of managing development activities. Cultural traditions are often disrupted, both for offshore practitioners who come to reside in an onshore location and for the onshore individuals who encounter them (Tsotra and Fitzgerald, 2007).

The rapid development of the IS offshore industry has also resulted in the creation of large multinational enterprises (MNEs). Some of these have originated in industrialised economies – recent manifestations of systems integration (SI) firms such as Accenture which typically provide offshore software development as part of a wider portfolio of ‘multi-shore’ consulting, technology and outsourcing services. Others - so-called ‘pure play’ offshore IS providers such as Wipro - have originated in newly industrialising countries (particularly India) and for the most part export labour and IT-enabled services to developed economies.

Research on offshoring is at a relatively early stage, although it is experiencing more interest in recent years, as evidenced by the special issue of MIS Quarterly (King and Torkzadeh, 2008). By contrast, globalisation, MNEs and international business have long been the focus of research, although to date, few scholars have applied MNE theory to offshore IS MNEs, or to this sector as a particular example of international business. Since MNE theory has proven valuable in explaining how aspects of traditional MNEs function, it may further the understanding of potential changes in the structure and composition of companies that provide offshore IS services, and the forms of distributed multi-national IS organisations that may emerge in the future.

The purpose of this research is therefore to apply an international business perspective to the field of IS offshoring. It asks the question: ‘are there antecedents in the field of international business that can inform the study of IS offshore practice?’ and thereby seeks to add to the body of knowledge on the IS offshore phenomenon. The conclusions from this research will have particular relevance for IS offshore MNEs, whose structure, work practices and perspectives are affected by this phenomenon.

The research comprises a multiple case study approach using grounded theory techniques to analyse respondent interviews. The epistemological approach is firmly interpretive. The researcher shares the view taken by Galliers (1992) that IS comprises computer systems embedded in a social context, and not just hardware and software. Moreover, it is often the social context that gives rise to the most interesting and problematic aspects of IS (Hirschheim and Newman, 1991). This applies particularly to phenomena like IS offshoring, which are mainly concerned with commercial, social and organisational arrangements of IS.

This paper is structured as follows. In section one, the nature and scope of the research is described; section two presents a brief review of the literature on offshoring and international business, including a description of the main organisational constructs used to describe MNE structures. Section three describes the research method, case studies and analytic framework used. Section four presents findings from the research, and is complemented by section five, which presents the conclusions.
2 LITERATURE ON IS OFFSHORING AND MNES

2.1 Literature on IS Offshoring

The perspectives on IS offshoring in the literature present a wide range of opinion, from Farrell (2005) who asserts that offshoring offers huge benefits to both organisations and the economy, to Levy (2005) who presents a more cautious view of the benefits of offshoring. It is possible to summarise the existing body of research on IS offshoring as falling broadly into four categories, determined by the main perspective of the researcher.

First, there is the economic perspective, which highlights such factors as the commercial drivers for offshoring, labour arbitrage opportunities, contractual implications and so on. Examples of this viewpoint include Ang and Straub (1998), Lacity and Willcocks (1995), Farrell (2005), and Venkatesh and Krishna (2004) amongst others. A second point of view is cultural, addressing risks and tensions inherent in distributed software development across political and geographic boundaries. Examples of research that takes this as its primary viewpoint include Carmel and Agarwal (2002), Edwards and Sridhar (2003), David et al (2007) and D’Mello (2005). The organisational perspective focuses on aspects relating to the skills, expertise and organisational structures required when application development is distributed. Research by Doh (2005), Tolentino (2002), Evaristo et al (2005) and Oshri et al (2007) offer examples of this orientation. Finally, the operational viewpoint is dominated by consideration of such elements as the processes, methodologies, tools and infrastructure involved in IS offshoring. Harmsen et al (2007), Gopal et al (2002) and Norbjer et al (1997) all provide examples of research from this point of view.

Gopal et al (2003) and Murthy (2004) look at IS offshoring from the perspective of the IS offshore provider. However, there is relatively little research on IS offshoring as a form of international trade, and on the strategic management, organisation and operation of IS offshore MNEs.

2.2 Literature on organisation of MNEs

International business research on global organisations ranges from early studies of the theory of the MNE (Hymer, 1960; Dunning, 1973; Perlmutter, 1969; Buckley and Casson, 1976; Teece, 1977; Hedlund, 1986; Bartlett and Ghoshal, 1998) to more recent work by Peng (2004), Knight and Cavusgil, (2004) and Fan and Phan (2007). Early research on MNEs tended to view international organisations simply. Buckley and Casson (1976), for example, define the MNE as “an enterprise which owns and controls activities in different countries.” Behrman (1974) identified three types of international organisation - the ‘classic investor”, the “international holding company” and the “multinational enterprise”. Porter (1986) examined firms in the context of their industries, which he categorised as ‘multi-domestic’ and ‘global’. Perlmutter’s (1969) ethnocentric and polycentric description of the MNE, essentially corresponding to centralised and decentralised operating models, offered a radically different perspective. Bartlett & Ghoshal (1998) define ‘multinational’, ‘global’, ‘international’ and ‘transnational’ businesses, characterised by the relative emphasis placed by the organisation on how it configures its assets and capabilities; by the role it assigns to its overseas operations; and by the way in which it exploits its knowledge and intellectual property.

Research from the 1990s onwards, such as Bartlett and Ghoshal’s, has tended to place less emphasis on a hierarchical view of the MNE (headquarters controlling subsidiaries directly) and more frequently takes the view of the MNE as a network of differentiated intra- and inter-firm relationships (Tolentino, 2002). This perspective assumes a distributed labour division among subunits of the MNE arranged in an integrated network configuration (ibid).
3 RESEARCH METHOD, ANALYTICAL FRAMEWORK AND EMPIRICAL DATA

3.1 Research method and design

This research comprises a multiple case study approach (Yin, 2002) using grounded theory techniques to analyse respondent interviews (Glaser and Strauss, 1967). It is inductive rather than hypothetic-deductive, an approach that is suited to grounded theory analysis. Because this approach facilitates a process-based description of change in its organisational context (Orlikowski, 1993), it seems appropriate to the study of the offshore phenomenon, which is heavily process-based and organisationally dependent.

Regarding theory, the approach in this research combines the use of theory as an initial guide to design and data collection and theory as part of an iterative process of data collection. The limited number of cases means that the output is a conceptual framework and related propositions (Eisenhardt, 1989), and does not comprise a nomothetic theory.

In this research, a set of guidelines has been formalised into what is called an analytical framework, which in addition to providing guidelines for analysis also offers a structure for data collection, description and presentation of results, and for allowing the prioritisation and assessment of the relative importance and impact of the results. In this respect, the metaphor of research framework as scaffolding seems particularly appropriate (Walsham, 1995).

The macro-level ‘actor’, or unit of analysis, is the organisation or firm – that is, the organisations that provide IS services, both onshore and offshore. Four primary dimensions of impact of offshoring were selected, comprising cultural, economic, organisational and operational impacts. These categories emerged from the data, and were selected as being the most comprehensive; others categories could equally have been used. The cultural dimension of the analysis covers those impacts of offshoring that have primarily a cultural interpretation or significance. The economic dimension address impacts of offshoring that affect the actors commercially and politically. The organisational dimension is concerned with how offshoring is affecting the structure of IS organisations, and the skills of practitioners onshore and offshore. The operational dimension is concerned with factors that pertain to how offshoring impacts the processes, methodologies and tools of the actors considered.

3.2 Case studies and empirical material

Two offshore IS projects are used to provide a body of data for analysis. These were conducted over a period of 18 months from 2005 to 2007 in separate organisations in the financial services industry: one a UK retail bank, a subsidiary of an international institution, and the other a global insurance broker headquartered in the USA with its European headquarters in the UK. The two companies differ in size, structure and culture. The bank is headquartered in the south-east of the England and has a growing, motivated and stable IT workforce. The insurance broker is located in the City of London, and exhibits some of the organisational volatility and pace of change typical in this environment.

In each instance the primary offshore outsourcing provider was Capgemini, a global systems integrator headquartered in Paris – a typical IS offshore MNE. Other IS firms were involved in more peripheral roles. One project (Project MARS) involved the development of a package-based system to support a new lending product and the other (Project EUROPA) was a custom development of an existing system used to provide retail brokerage for customers across Europe. Both developments were initially of a similar scale – over 10,000 days of development effort – and both used IBM’s Rational Unified Process (RUP) development methodology, although in different technology environments (Java for the bank; Assembler and COBOL for the insurance broker). On both projects offshore developers from Capgemini’s Indian operation were located on site in the clients’ offices in the UK and Belgium for at least part of the time. Thus the projects are philosophically similar (Orlikowski, 1993), drawing on the
same basic application development approach of use cases, separation of process and data, and iterative development phases.

The rationale for selecting two case studies is to allow the continuous comparison of evidence, and to control the conceptual level and scope of the emerging theory (Orlikowski, 1993). At a more basic level, observations made in one organisational context can be compared and contrasted with observations in the second site. The most striking difference between the two companies is in their organisational culture: the bank’s culture is one that has a balanced approach towards risk, and displays a ‘can-do’ attitude to business, reflecting its origin as a successful, marketing-driven start-up. The insurance broker, by comparison, operates on a much more traditional, hierarchically-sensitive basis, typified by extended lead times for decision making and a risk-aware approach to business.

Primary data sources in the form of semi-structured interviews were gathered from client and Capgemini staff directly involved in the selected projects, both onshore and offshore. In all, seventeen interviews were conducted over a period of eight months (October 2006 to May 2007), in various locations in the UK, and by phone with respondents in India. These were supplemented by additional phone calls to validate points of fact. In addition, written data sources—project reports, memos, emails and letters—were collected and analysed. Data collection was aimed at gathering information (loosely) identified by the categories of impact defined in the analytical framework.

Walsham (1995) notes the importance of ‘capturing’ people's interpretations effectively in the course of a normal conversation. To facilitate this, all interviews were recorded and stored electronically as digital files in a ‘wav’ format. These were supplemented by written notes. The data was later analysed manually (line by line analysis of data), and using nVivo software.

4 FINDINGS FROM THE RESEARCH

4.1 The emergence of a new organisational form for IS offshore MNEs

The research indicates that new forms of IS MNE are evolving that are characterised by:

- A blurring in the distinction between onshore and offshore, with allocation of resources from multiple locations rather than solely from offshore locations;
- Greater distribution of risk between onshore and offshore parts of the organisation, and the introduction of commercial models to support this;
- Introduction of methodologies and toolsets that accommodate distributed development across multiple sites (a global development model);
- Rebalancing of skills across locations rather than simply downsizing onshore staff numbers.

This form of organisation is best described by the construct of the heterarchy (Hedlund, 1986) which at the time of writing was viewed as a departure from the more traditional (hierarchical) structures.

4.2 Cultural observations

For both the MARS and EUROPA projects, it is clear that offshoring no longer means pure labour arbitrage. Rather, it is a consequence of an increasingly integrated corporate view of operational efficiency, from the point of view of the supplier (Capgemini) and the customer. This aspect of offshoring is highlighted in the interaction between third party software vendors on project MARS, where there was an inverted relationship between project members in Mumbai and Cheltenham (where one of the project components was developed). Since development was coordinated by Capgemini, the third party in Cheltenham was effectively treated as ‘offshore’ by the Indian development team, some of whom were located in Reading in the UK, and some in Mumbai. Despite the disparity in cost of labour at each
location, this perception seems entirely justified. For example, from the perspective of scale and sophistication, Mumbai is a world city, and Cheltenham a backwater, so it is legitimate to view Cheltenham as ‘offshore’ through this philosophical lens. Further, ‘offshore’ resources in India are just as likely to have a broad world view as their colleagues in Cheltenham.

In effect, as these firms become less location-specific, the distinction between onshore and offshore becomes less relevant, and the commonly accepted definitions of the words, which relate primarily to the physical location of the IS resources, become redundant. This applies generally to the traditional taxonomy in the literature: words like ‘subsidiary’, ‘host country’, ‘home country’, ‘headquarters’, are less relevant in the heterarchical construct, which is peer-to-peer, collaborative and mobile. This represents a fundamental (primarily cultural) shift in the perception of offshoring.

Doh expresses this viewpoint as follows:

“Moreover, as Levy (2005) notes, the development of communications technologies and the requisite mobility of labour have allowed for an accelerated internationalization of production that accords neither with the product life-cycle nor the sequential internationalization perspective. Indeed, some have argued that many firms are now ‘born global’ (Knight and Cavusgil, 2004) and that the notion of sequential internationalization – whether on a country, industry, or firm scale – is outmoded and anachronistic.” (Doh, 2005)

Buckley concurs:

“One issue is whether the firm should be divided into domestic and international divisions (in the era of globalisation now a rather redundant debate…)” (Buckley, 2002)

4.3 Economic observations

Global IS organisations are changing their business models fundamentally: in effect they are adopting a hybrid approach to offshoring that involves the use of joint onshore/offshore teams. There is a rebalancing of the development contact, with each part of the enterprise (onshore, nearshore and offshore) sharing risk and reward. This is different to the current environment, where typically the risk and reward is assumed disproportionately by either the onshore or offshore division.

This rebalancing of the development contract was illustrated in a discussion with the EUROPA delivery director, and concerned the extent of the risk assumed by the offshore division of Capgemini on the project. The traditional model is for Capgemini to use the Indian offshore business as a cost centre with a more sophisticated, risk-bearing onshore front end. The heterarchical model assumes that all development centres are equal, and capable of agreeing their own terms.

The EUROPA project delivery director proposed a different business model that involved sharing the risk – one that was readily accepted by the offshore organisation:

“Yes, India is still run as a cost centre, so the UK or France or the front office country takes all the risk. ..We were trying to resolve this for smaller projects, to transfer risks, and at the time it seemed to me that this was a new way of working but one that they (the Indian colleagues) were absolutely up for. It was an explicit conversation: “Look, guys, we're not going to take the risk on this because this is a fixed price deal - you guys will have to bear it. Are you happy and comfortable with that?” And their view was, well great, finally somebody's taking some notice of us who are actually doing things we want to do.”

This reflects a profound change in the way that offshore phenomenon is impacting IS organisations. It is independent of the pricing mechanism (the fact that the deal is fixed price is irrelevant here: what is important is how the risk is being shared between onshore and offshore components of the same organisation). This change represents a significant maturing of the offshore components and recognition on the part of the onshore part of the organisation that it can no longer dictate the terms of IS engagements with offshore colleagues.
4.4 Operational observations

The modern offshore MNE is adopting new tools and operational processes. However, these tools are basic for the most part, and often include software downloaded from the Internet. New processes - for example to conduct code reviews with developers - and new methodologies - for example to incorporate remote prototyping - are similarly being deployed. However, in the case studies in this research, these changes were basic, and were supported by web-based tools like Instant Messenger. The project manager on MARS describes the process of code review:

“The only way we all kept in contact was Yahoo! And it’s the only way to just maintain contact and you know, sometimes you’d just be cutting and pasting components of code and saying, ‘How do you think this looks like?’ or ‘What do you think?’ and it’s great.”

Similarly, few formal standards were in place, and those that existed were not strictly adhered to. Developers chose their own approach, with little apparent sensitivity around security, as described by a developer on the MARS project:

“…we now have a standard toolset that we’re supposed to use. All our J2EE components used Star Team (for change control) … and the guys in Mumbai just VPN’d in and used it … effectively, we got exemptions to do it our own way, which was maintain it on the client’s site and we would VPN in and do it.”

The rather informal use of methodology and tools on both the MARS and EUROPA projects hides the fact that all of the organisations involved in the development – users, onshore, nearshore and offshore – were closely networked and operated with a good deal of consistency and efficiency. The use of tools like Instant Messenger emphasises the immediacy of the interaction, and was complemented by the adaption of existing methodologies to cope with the new (distributed) environment: on the MARS and EUROPA projects, Capgemini had invested in building a distributed toolset and methodology to account for the fact that the operational impact of offshoring affects all aspects of the development life cycle. This illustrates a resourcefulness and agility within formal frameworks.

4.5 Organisational observations

From an organisational perspective, the skills and capabilities that offshore MNEs are retaining onshore include account management skill and technical skills. The MARS project delivery director describes these skills as:

“…the bits which … require customer intimacy and intimacy with the business users. Those are the bits that, you know, people are almost presuming that they cannot be moved offshore.”

On EUROPA, the account manager identifies the elements of her proposal that were most successful:

“We provided them with a solution that gave them the ability to talk about those additional bits of functionality to a set of people who understood their business pain.”

Her delivery director agrees, and notes that there are some technology skills that will also be needed onshore:

“I think there’ll always be early adopter technologies where people who are familiar with them will be of value locally. I think it’s likely that strategic consultancy, IT strategic consultancy skills…project management skills and business analysis type skills…”

This research shows that a hybrid development approach – a characteristic of the heterarchical development model – is preferred. On project MARS, for example, the bank stipulated that offshore resources be brought onshore to the bank’s premises for the duration of the project, as described by the MARS programme manager:
“They felt that it wasn’t an option to do any of it offshore. It would have been a preference for Capgemini to do components offshore, but they (the bank) weren’t prepared to consider that because they felt that the timescales were too quick… and the risks involved in doing that would be too great. And they felt they didn’t have the maturity as an organisation to do that. So they were absolutely clear they didn’t want anything built offshore.”

5 CONCLUSIONS

5.1 The emergence of the modern heterarchy

While the evidence that emerged from the case data is mostly consistent with previous studies, the use of an international business lens to interpret the se sheds new light on these findings and creates new insights from this research. From observing the offshore MNE on the projects, it is clear that a new organisational form is emerging that exhibits the essential qualities of the heterarchy described by Hedlund (1986).

The construct of the heterarchical organisation describes a networked organisational model. A key strategic difference with traditional organisational paradigms is that the heterarchical company seeks to exploit competitive advantage from any part of the global organisation, and not just from the ‘home’ market. The structural differences are more complex, and posit that the heterarchical company has many centres; that subsidiaries and their management are equally capable of contributing strategic thinking and value; that organisation is collaborative in nature rather than coercive, and generally that each part of the organisation is a reflection of the whole. This latter point implies that every member of a heterarchical organisation is aware of all aspects of the firm’s operation (ibid).

Hedlund presented his model as ‘radical’ and saw it more as a ‘loosely-defined’ or theoretical construct than an actual manifestation of reality. He predicted that such organisations might emerge in the future, possibly in newly developing countries. Writing in 1986, Hedlund used words like ‘novelty’ and ‘radical’, and his goal was to generate debate. He coined the term ‘hypermodern MNC’ to suggest that existing ‘modern’ theories and notions used in international business thinking were inadequate, and used ‘heterarchy’ as an antithesis to hierarchy. (Hedlund’s multi-national corporation (MNC) is synonymous with the multi-national enterprise (MNE)).

Predicting where such companies emerge, Hedlund identifies industries characterised by:

“…the use of many different technologies, high but not maximum global homogeneity of demand, fast rate of technical and market change, non-trivial scale economies (but not necessarily in manufacturing), and absence of strong local barriers to entry”. (Hedlund, 1986)

and notes that IT and biotechnology are obvious (if boring!) candidates. More importantly, he suggests that:

“In terms of geographical and corporate origins, heterarchical MNCs are more likely to evolve from less than gigantic firms, and from contexts with a history of rather autonomous and entrepreneurial subsidiaries. This may give European firms an advantage over US ones. In a larger picture, MNCs from newly modernising nations may stand an even better chance.” (ibid)

The reason the term ‘modern’ is used as a qualifier is because Hedlund’s construct does not describe IS offshoring MNE perfectly. He was writing in 1986 and even in the space of 23 years, much has changed. The pace of globalisation has accelerated, and its nature and profile greatly debated. IS offshoring in 1986 was at an early stage of development, and bears little resemblance to the nature of the phenomenon today. Although instinctively grasping the statelessness of the heterarchical MNE, Hedlund nonetheless defines the strategy of the firm in terms of ‘home’ markets, an irrelevant concept for the modern heterarchy:
“The heterarchical MNC differs from the standard geocentric one both in terms of strategy and in terms of structure. Strategically, the main dividing line is between exploiting competitive advantages derived from a home country base on the one hand, and actively seeking advantages originating in the global spread of the firm on the other.” (Hedlund, 1986)

Further, his notion of heterarchy implies differentiation, similar to the ‘differentiated network’ described by Rugman and Verbeke (2003). The modern heterarchical firm is decidedly undifferentiated, deploying its resources in a manner dictated not exclusively by location (for example, from a ‘centre of excellence’) but by a mix of factors including cost, availability, location, proximity to the client and strategic intent (for example, by the desire to expand a presence in a particular country). A good example of this was provided by Capgemini’s use of Accelerated Development Centres on project EUROPA: resources from France, Holland, India and the UK were deployed to optimise cost and expertise.

Similarly, the rebalancing of project risk on project MARS is giving rise to a new commercial model to accommodate heterarchical operation. It acknowledges that the traditional ‘brokerage’ business models of the western IS providers are changing to a more equitable distributed business model. The flexible approach towards development toolsets and methodologies on both EUROPA and MARS projects typifies modern development techniques. It is moreover entirely consistent with the heterarchical construct to the extent that the development infrastructure (telecommunications, tools, methodologies) can be defined as heterarchical. The Internet is stateless, networked and (mostly) immediate, and the collaborative toolsets that comprise Web 2.0 technologies are collaborative, peer-to-peer and instant. From an organisational perspective, the deployment of varied skills across distributed locations is consistent with the concept of a heterarchical enterprise, which recognises that low-cost offshore development on its own does not necessarily meet client demands; nor does aggressive labour arbitrage on its own represent a wise competitive stance (Hedlund, 1986).

All of these outcomes provide further evidence of the emergence of a heterarchical enterprise, and a move towards a more strategic deployment of offshoring analogous to that illustrated in Carmel and Agarwal’s stage model of offshoring (Carmel and Agarwal, 2002).

5.2 Evolution and maturity of the modern heterarchy

The research indicates that IS organisations will not necessarily find the evolution to becoming a modern heterarchy easy, particularly those organisations that are at an early stage of development and only now coming to understand the implications of a truly global market for IS service provision. This is a difficult transition for most onshore organisations, and there is little information available to guide them:

“The newly integrating nature of this global labor market has strategic and tactical implications for companies and countries alike. Information and insight about it are sparse, however, and executives and policy makers have little of either for making the decisions they face.” (Farrell et al, 2005)

Moreover, there is no definitive model: the modern IS heterarchy is not entirely uniform. The world is not flat, as Friedman (2005) has described it: it is bumpy and uneven, containing all sorts of inequalities, inconsistencies and irregularities, and one size does not fit all. For the MARS and EUROPA projects, for example, the recruitment and resourcing process was novel and problematic, as described by the Capgemini UK account manager:

“...it was difficult because it was a new process. So it was difficult identifying the right skills and getting the handshake between the UK and Mumbai working effectively. ... so we had somebody managing this, more or less full time, for about two weeks, two or three weeks, setting up the process, setting up the documentation around it, so there was clarity around who’d been interviewed...”

This led to delays in the project start date for both projects, something that was complicated by the fact that the public processes to facilitate offshoring were not optimised, and required significant client as well
as multi-shore organisation involvement. For example, the UK’s Home Office was not geared up to accommodate large scale offshoring in the UK, and the Capgemini project manager for MARS had to spend a good deal of time resolving these issues:

“Yeah, there were (difficulties bringing developers to the UK from India) and we had to write letters to the Home Office explaining what the contract was. We had to give them copies of the contract. … Initially, we got the visas for too short a period, and so we had to have people who went offshore. We sent them back to Mumbai, so that they could get visa extensions. So that was quite complicated and costly and disruptive.”

5.3 Theoretical and practical contributions of this research

This research uses powerful explanatory constructs from the related but substantially different discipline of international business and successfully applies it in the field of IS. Specifically, Hedlund’s construct of the heterarchy is adopted - together with related organisational taxonomies from Perlmutter, Porter and Bartlett and Ghoshal - to provide insight on offshoring.

This has the effect not only of validating the imported constructs, but also of illuminating the topic being researched. In this instance, the contribution validates the construct of the heterarchy and shows its continued ability to explain complex aspects of IS offshoring such as how IS offshore MNEs are organising. Such cross-disciplinary borrowing is endorsed by one of the leading researchers in this area:

“In its successful era, international business researchers not only imported concepts and paradigms, they also exported them to neighbouring areas. This does not seem to be occurring at the moment.” (Buckley, 2002)

While the explanatory power of the heterarchy is significant, it does not completely describe the new offshore IS organisations. This research accordingly extends the construct to take account of the elements of offshore MNEs that are new and different to previously researched MNEs. The extended construct – the modern heterarchy - offers a richer view of these new IS organisations, and therefore provides a significant contribution to the wider field of IS studies. It is potentially of interest also in the field of international business studies where the constructs originated.

This study has direct relevance for IS organisations engaged in IS offshoring. If it is accepted that the modern heterarchy is the form of organisation to which many IS MNEs will evolve, then there is much in this and in antecedent research that can help inform this evolutionary continuum. For ‘end user’ organisations, there is enough detail regarding the phenomenon to provide guidance in the deployment of offshoring with both offshore and onshore systems integrators.

5.4 Future research directions

While this research did not evaluate pure play MNEs to the same level of detail, secondary evidence from respondents suggests that they also are becoming modern heterarchies. This is because the pure play strategy is now focused on building solid customer relationships in local markets, while retaining the efficiencies and disciplines that come from centralised control. The onshore IS firms are also changing strategy: to compete against the structured, centrally-driven offshore organisations, these firms are developing development ‘factories’ in offshore and onshore locations that are modelled on the offshore organisations’ ‘global’ strategy. In effect, onshore and offshore IS companies are now indistinguishable in strategic intent, and each has co-opted elements of the other’s strategy.

Further planned research will look to validate this conclusion. It will also extend this reasoning to other dimensions identified in the analytic framework to assess, for example, the impact of global IS offshoring on IS practitioners ‘onshore’ and ‘offshore’.

INTERNAL MARKETS AS A SOURCING OPTION FOR THE DELIVERY OF IS SERVICES: IMPROVING OUTSOURCING AND INSOURCING

Bulchand-Gidumal, Jacques, University of Las Palmas de Gran Canaria, Facultad de CC.EE. y Empresariales, Campus Universitario de Tafira, 35018 Las Palmas, Spain, jbulchand@dede.ulpgc.es

Abstract

The delivery of IS services is very resource consuming in all organizations. In an era in which management optimization is one of the bases for competitive advantage, sourcing options must be judged carefully. Traditionally, the dilemma has been considered in terms of make (insourcing) or buy (outsourcing). But both of these options have shown a certain amount of problems. Although outsourcing has allowed firms to concentrate on their core competencies, it has also shown several issues that prove it is not a panacea. Insourcing, on the other hand, does not allow a great deal of flexibility and we also find that it is every time more frequent that firms do not want their amount of staff to grow. Between both options, the internal mechanism has arisen. Its use entitles the creation of an intermediate society between the organization and the market. This article shows two cases of organizations from different environments in which the sourcing process involved the creation of an intermediate organization to act as the described buffering mechanism. Both processes were related to the IS/ICT function, one in Spain and another one in Italy. The study of the two cases has helped us identify and confirm empirically a number of features achieved by this internal mechanism use.

Keywords: Internal markets, outsourcing, insourcing, IT function.
1 INTRODUCTION

In the last few years, we have seen the importance of information systems and information and communication technologies (hereafter IS/ICT) in organizations steadily increasing. This increase has entitled that organizations have had to deal with the way to deliver these services. Traditionally the alternatives to do this have been two poles of what is now considered to be a continuum but which for some time was considered to be just the two possible existing options: outsourcing (buy) and insourcing (make).

Outsourcing is the process by which external agents perform organization’s activities while insourcing is the process in which the organization performs the functions in-house. We also refer to insourcing when a firm undertakes an outsourcing process and later decides that the services should be performed again by its own personnel and even in the case in which an organization examines the costs and possibilities of outsourcing but finally decides not to use this sourcing option (Hirscheim and Lacity, 2000).

As time has passed, both alternatives have been examined in detail in the IS/ICT sector by different authors, practical cases have been made available, and a certain amount of problems have been found in both of them.

On the one hand, outsourcing has been blamed for making organizations lose control over IS/ICT assets (King and Malhotra, 2000; Lee et al. 2003; Gupta and Gupta, 1992), lose flexibility (Lee et al. 2003; Gupta and Gupta, 1992), have to go through the possibility of threats of opportunism from the supplier (King and Malhotra, 2000), lose IT expertise and corporate memory (King and Malhotra, 2000), lose of qualified personnel (Lee et al. 2003; Gupta and Gupta, 1992) and lose of competitive advantage in information management (Lee et al., 2003) as well as in the innovation capacity (Earl, 1996).

Moreover there are also problems derived from the complexity of breaking a contract in case of dissatisfaction (McFarlan and Nolan, 1995; Lacity et al. 1996), the use of not very qualified personnel by the contractor (Earl, 1996), the possibility of a misalignment between the outsourcing organization and the contractor (Lacity et al. 1996) and even an increment in costs when many organizations outsource as a way to cut down costs (Lacity et al. 1996).

On the other hand, insourcing means not achieving the main reasons that make organizations outsource. This is not been able to control costs, not being able to concentrate on the nuclear capacities of the organization and having a very low level of flexibility over workers.

As we can see, both outsourcing and insourcing of IS/ICT have major drawbacks. However, we must consider that these drawbacks will have a greater weight depending on how important IS/ICT are for the organization. This is, for organizations in which IS/ICT are just a commodity which must be dealt with, choosing the best combination possible of outsourcing and insourcing will probably be enough. Normally we will find that very small organizations completely outsource IS/ICT, and that as they grow they tend to start creating their own IS/ICT services; once they grow over a certain amount of employees (or the IS/ICT needs grow above a certain limit) they try to increase the proportion of outsourcing.

But, what happens when the firm considers IS/ICT to be a source of competitive advantage, a nuclear activity? Due to the problems with insourcing and outsourcing, these organizations have had to find other alternatives to overcome these problems. Between these alternatives we can mention internal markets, strategic alliances, business process outsourcing and selective sourcing. We now define these four alternatives.
Strategic alliances. Two or more organizations jointly develop functions in the search of competitive advantages. For a strategic alliance to function and be successful over time, all the participating organizations must consider that they are obtaining value from the alliance; in other words, that a “win-win” situation occurs (King, 2001). There are three types of strategic alliances (Barney, 2002): non-equity alliances, equity alliances and joint ventures. Non-equity alliances are based on contractual relationships, so firms are all stakeholders, but not necessarily shareholders. In equity alliances and joint ventures an independent company is created.

Internal markets. A company creates its own organization to undertake certain tasks or it allows one or more of its units to act autonomously and to transact with other units of the company. This is, strategic alliances and internal markets are similar mechanisms, just in the first it is two or more firms getting together to create an independent company, while in internal markets it is just one enterprise the one creating the new company.

Business Process Outsourcing (hereafter BPO). BPO consists on handing over control of an IS/ICT based process (for example, human resources management or accounting) to another organization (Rouse and Corbitt, 2004). The firm thus eliminates the need for certain IS/ICT areas since the company who supplies the service will be responsible for the IS/ICT required to provide it.

Selective sourcing. Selective sourcing consists in subcontracting just certain parts of a given organizational function while retaining others in-house (Lacity et al. 1996), this is, to find a mix between what is done outside the organization and what is done inside (King, 2000). It is specially used in the IS/ICT area, due to the complexity of the function and the number of tasks involved.

As we can now see, the two alternatives formerly mentioned in the article are just two points in a continuum (see Figure 1), that starts in insourcing, passes through outsourcing and arrives to BPO. In this continuum, as we move from the starting point to the ending point we find less effort from the company in the management of IS/ICT but also, subsequently, less potential in the form of competitive advantages.

Figure 1. The source continuum

Sourcing alternatives have been widely explored in the literature, quite often in relation to IS/ICT. Probably the theoretical framework most widely used to explore sourcing alternatives, this is, the make-or-buy decisions has been transaction cost economics, derived from the original works of Coase (1937) and Williamson (1979). According to transaction costs, markets would always be used as the organizational form, but every time a market failure appears, a firm (i.e. a bureaucracy) is created as an answer to this failure (Ouchi, 1981). These failures could be due to issues such as bounded rationality, uncertainty, complexity, opportunism or small numbers.

Bounded rationality means that people try to behave rationally but, due to limited knowledge and imperfect cognitive capabilities, this rationality is limited (Greiner and Goodhue, 2005). This bounded rationality causes uncertainty since one side can never be sure how the other side is going to behave in a negotiation. Complexity is to be expected in any relation, but in the IS/ICT area it is increased due to the object of the relation, that are normally not easily to measure (i.e. it is very difficult to estimate.
precisely how long installing a new operating system and migrating all email accounts can take). Small numbers appear when in a relation, and due to the typical evolution of tasks, the process of specialization leads to a point in which it is difficult to find an alternative supplier for a product or service. Opportunism is based on the idea of self-interest and increases even more the uncertainty.

But sometimes, in the presence of any of the above failures, moving from markets to bureaucracies is not the solution, and some other organizational forms are needed (Ouchi, 1981). This happens when tasks are “[...] highly unique, completely integrated, or ambiguous for other reasons [...]” (Ouchi, 1981: 134). As we can see, these attributes are frequently applied to IS/ICT tasks, which gives us a hint that probably in this area, the decision between make (bureaucracy) or buy (market) has a much wider spectrum of possibilities that should be explored. Ouchi himself suggests the clan form: a group based in common values and beliefs, thus allowing minimization of goal incongruence and tolerating high levels of ambiguity in performance evaluation. Greiner and Goodhue (2005) explore open source communities as an intermediate option, these open source communities having some characteristics similar to the clans found by Ouchi. However, clans are not a mechanism easily found, since there are based more in perceptions and values of the individuals than on general parameters usually found in different environments.

Strategic alliances have also been explored frequently, in the IS/ICT sector and outside it. But there seems to be a certain lack in the literature of articles exploring the buffer mechanism that internal markets allow. In this article we are going to focus on this alternative, the internal market strategy, trying to answer the following research questions: what are the advantages and disadvantages of the internal market strategy? When and how should it be used? What issues have to be dealt with in the process?

In order to answer these questions, we have based our research on two practical cases developed in Spain and in Italy. Both these cases were related with the IS/ICT function. The one in Spain involved the use of this solution in a Public University as a way to outsource certain IS/ICT functions while retaining a good level of control over workers and over management of these functions. The one in Italy was that of a SME which decided to create a buffer company to manage the implementation project of an ERP System.

This article is organized as follows. First, we explore the internal market strategy. We then present the two cases that have been studied, followed by a section in which we show the research methodology that was used in each of the two cases. We also show other cases that we know about and that we expect to study in further detail in order to confirm better the results found. Then some common findings to both cases are shown. We believe many of these findings can be generalized to all internal market strategy cases. Last we discuss on the results, we highlight some limitations to the work done up to this point and we end with some conclusions which we hope can be used by managers facing sourcing alternatives.

2 INTERNAL MARKETS

As has already been defined, internal markets is a mechanism in which a company creates its own subsidiary firm to undertake certain tasks; it is also a term used when a unit from the mother company is separated from it and starts operating as an autonomous unit. Usually this new organization or the autonomous unit will provide services not only to the parent company but also to other companies in the market, thus guaranteeing a competitive pricing structure and an appropriate quality of service (King and Malhotra, 2000) since the subsidiary should be almost the same as any other external supplier (Dearden, 1987). In the following we are going to concentrate in the case in which there is a new company and it is not a unit that has been allowed to become independent.

This created company acts as a buffer organization between the mother organization and the market, thus allowing for “[...] increased responsiveness of internal suppliers, better quality with lower cost of internally-supplied services and products, elimination of fluff, de-bureaucratization, de-
monopolization, uniform measures for comparing the performance of various units, and greater opportunity for development of management skills [...]” (King and Malhotra, 2000: 327). This is due to the created company being very close to the mother organization but, at the same time, being independent.

3 THE TWO CASES

3.1 Case 1 – Spanish Public University

The first case was that of a Spanish Public University that decided to create the buffer society as a way to outsource certain IS/ICT functions while retaining a good level of control over workers and over management of these functions. The university has roughly 20,000 students and a total budget for the management of IS/ICT of around 8 M€. It has 45 staff dedicated to IS/ICT management.

As the university faced the need to enlarge the number of staff dedicated to IS/ICT following the natural increase of IS/ICT services needed that has taken place in all organizations, it found that growing the internal structure was very difficult due to tight restrictions in Spanish Public Administrations\(^1\). Outsourcing was also considered but the geographical position of the university (the Canary Islands, more than 2,000 km. from Mainland Spain) and the specificity of tasks to outsource meant there was an important shortage of providers available.

Due to this, the decision to create a buffer organization was taken. This organization was created during the year 2005 and it started providing services in 2006. Its budget for 2007 was about 700,000 Euros with a number of staff of about 25. It provides help desk services as well as some application development services. The objective of the enterprise is to break-even at the end of each financial year.

Rough estimates showed that if the same tasks had been developed in-house the total cost would have been around 1 M€, due to higher salaries that public employees are entitled to. On the other hand, outsourcing would have also meant a figure close to the same 1 M€, since, as was stated previously, enterprise from Mainland Spain willing to provide the services would have charged that extra quantity in accountancy for their benefits and for the extra costs of having to operate a unit in a remote place. This shows that, very roughly, the internal market option has allowed for savings of about 30%. This is not absolutely true since certain overhead costs (creation of the enterprise, costs associated to the heads of IS/ICT in the university who are part of the Board of Directors of the newly created company, etc.) have not been considered.

3.2 Case 2 – Italian SME

The second case was an Italian SME (we will subsequently call it MainFirm) in the iron and steel sector that decided to create a buffer company (that will be called BufferFirm) in order to manage the implementation project of an ERP System. The company was created in 1996 and started providing consulting services immediately. The following year, the implementation project took place and the new firm started providing consulting and technical services as programming, customization and training. The turnover was 200,000 Euros the first year, 700,000 the second year, 1.5 million the third year and 2 million the fourth year. The firm ended its activity in 2001, once the rollout of the ERP was completed and it was stable.

In this case, the bases to create this firm came from the high level of outsourcing that was already being used and the reduced dimension of the IS/ICT department in the main firm. Due to this, the top

\(^1\) In Spain, Public Universities have to follow the same rules that are applied to Public Administration in general.
management decided to create a new consultancy company which was owned by the firm (45% of the shares) and by four experts in business process reengineering, programming and project management (55% of the shares).

The new firm started analyzing the main business processes, in order to identify the critical aspects that had to be taken into account in the ERP selection phase. As result of the analysis, the adoption of a national ERP called Diapason was suggested. This ERP had been developed by a software vendor (which will be named SoftwareFirm) and the recommendation was made due to economic reasons and because Diapason was considered to be the reference in the industry in Italy.

The BufferFirm management decided that the implementation would be done through a gradual rollout per module and per site. This is, rather than buying an ERP implementation project (software and services), partnership was signed with the SoftwareFirm. According to the contract, BufferFirm would become a business partner of SoftwareFirm, which meant that BufferFirm’s personnel were involved in some ERP implementation projects as observers. This would allow a group of consultants in BufferFirm to be able to understand how to run an ERP implementation project from both the technical and from the managerial points of view.

After six months BufferFirm became able to run implementation projects on SoftwareVendor's software. From that moment BufferFirm’s personnel were involved in the MainFirm’s project and in some other projects of SoftwareVendor in which “body rental” agreements were conducted.

3.3 Other cases

Apart from the two mentioned cases which have been studied in detail, the authors also know, and are in the process of studying, a number of cases in different environments which could help confirming the main results that have been found in both the above cases:

- Car dealer in Spain. This firm distributes the cars of one of the biggest worldwide carmakers. Initially they concentrated in just one region in Spain but over time they have developed in South America and Africa. Some time ago, they found the IS/ICT applications provided by the automaker were not enough for their management, so they started developing their own. As time passed, they started selling these applications not only to their own subsidiaries but also to other franchises of the automaker around different part of the world. In order to better deal with the whole process they decided to create an IS/ICT company, that provided IS/ICT services to the mother firm and to other enterprises. Now it is one of the firm’s main sources of competitive advantage.

- Banking sector. There are several cases in different European countries in which Savings Banks have created organizations specifically dedicated to the management of their IS/ICT. Our idea is to explore some of these cases, of which we already have proof in Spain and in Italy.

4 METHODOLOGY

In both cases studied, the key to the research methodology was that one of the authors of this work was an agent in the process. This, obviously, introduces a certain bias into the investigation. This bias has been dealt with by having each of the possible conclusions drawn from each of the cases carefully analyzed by the other author, in order to avoid the mentioned bias. However, even with this is not absolutely possible to state that there is not a certain bias in the whole research, which is going to be further avoided by analyzing other cases.

Four types of techniques or data collections methods where used: participant observation, document retrieval, in-depth interviews and focus groups. Evidence obtained was qualitative as well as quantitative. The time frame considered starts at the creation of the enterprise and ends when the later
had been working for one year. This accounts for a total of 20 months for the case of the Spanish University and 36 months for the Italian SME. In both cases, the analysis took about three months and it started after the enterprise's first year of operation, except for some data that was collected as the process was happening, as explained below.

Participant observation and document retrieval was possible since, as has been stated previously, the authors of this work were part of the process. More than 50 hours were spent over the one year study period directly observing the help desk area in the case of the public University. In the case of the Italian SME, one of the authors was involved in the ERP implementation project and he spent three days per week taking part in the design, modelling and training sessions. Data was transcribed, structured and double checked by the authors to ensure accuracy.

Observation was supplemented with several in-depth interviews that were carried out with participants in the two processes. In total, more than 30 interviews were done. These interviews lasted typically around 75 minutes and used a semistructured questionnaire in which several issues were considered: satisfaction with the process and with the relations between the mother and the created firm, problems found at the beginning, what was expected to happen in the near future, etc.

In case 1, four focus groups were carried out. Two of them took place with the staff from the application development and user support areas of the university while the participants in the other two were their counterparts from the created enterprise. The objective of these focus groups was to analyze with the main actors in the process what their impressions of the process were, what their evaluation of the first year of work and suggestions on improvements for the following years.

Also in case 1, measures of the performance of the services delivered by the firm were obtained through a survey carried out by the evaluation department of the university. In this survey, every service delivered by the university was evaluated: student registration process, IS/ICT services, campus services, transportation, etc.

5 FINDINGS

The study of the two cases has helped us identify and confirm empirically a number of features achieved by this internal mechanism use. First, the internal market allows a very good balance between the best of insourcing and the best of outsourcing. On the one hand, there is a good control over human resource practices and over technical decisions (i.e. which products to specialize in). On the other, a good level of control over the function being sourced is achieved, since it is no more a black box where the managers do not know what is going on, becoming a function that can be analyzed.

Second, in the process of subcontracting to the buffer organization, the mother organization learns how to organize contracts, which means to dimension properly prices, times and requirements as well as even the process of choosing which things to outsource and which not. This learning process can be very useful for a later process of outsourcing to markets directly. This is quite important, since many of the problems found with the outsourcing processes that take place in organizations could be solved by acquiring this experience. So the newly created organization really acts as a buffer between the mother firm and the market, becoming a learning experiment. Outsourcing is complex and, as was seen at the beginning of this paper, there are many possible flaws in the process, so going through and intermediate phase can help organizations to better outsource.

Analyzing the costs involved in the process, on the one hand the cost control and cost reduction that is usually followed by outsourcing processes is also achieved, as well as allowing for a good level of alignment between the objectives of both organizations. In this case, we can concrete that in the Spanish University case a savings of roughly 30% was achieved. But on the other hand it is true that, as will be seen later, the process of creating and launching a new organization entitles a series of costs that must not be undervalued.
Internal markets also ease the resistance to change in the workers of the mother organization, since the process is not a full outsourcing, which is always seen as more fearful, but a subcontracting to an organization which is quite close to the mother organization, and over which this later retains a certain level of control.

Finally, this mechanism allows for the implementation of human resource practices similar to those in the mother organization to take place, reducing resistance to change as well as problems derived from frictions between workers in similar job posts with very different contracts.

But the experience in the two mentioned cases has also shown that this is a very complex process and that there are several issues that have to be carefully dealt with. First of all, and since this kind of mechanism is not used very often, the process has to be carefully explained to all the involved workers. Even doing this, a certain resistance to change and certain fears will probably be found in workers, since they may not fully understand what is going to happen to them, specially in the long run. Basically, they can think the final objective is to pass their job posts to the buffer enterprise. Related to this, workers of the mother enterprise may not fully understand the buffer organization is an independent organization, with its own managers that make their own decisions. This means that influencing human resource practices can be done only at a very high level, not at the base level.

Last, but not least, the buffer organization works best when it also provides service to third party companies (King and Malhotra, 2000), forcing it to compete with market rules to avoid falling in the small number (Ouchi, 1980) trap which would lead towards a bureaucracy again. The dilemma is that it is quite tricky to achieve a good balance between the quantity of effort dedicated to each kind of client, specially since the mother firm will control part of the board of directors and have shares in the created company, thus being able to influence its behaviour.

6 DISCUSSION

When and why should the internal markets mechanism be used? Basically, when the organization (the bureaucracy) and the market fail to deliver a consistent solution to organizations. This is, under certain conditions the traditional make-or-buy decision can provide what organizations need.

If the organization and its stakeholders are comfortable with an increase with the number of human resources that it dedicates to a function (being IS/ICT or any other), insourcing can be used. If the organization considers the task not nuclear, and has a number of service providers in the market around it that can deliver those services, outsourcing should be considered. The latter being done taking into consideration the dangers of outsourcing that have been warned by several authors and that have been explored previously in this article.

Also small enterprises will tend to prefer more classical solutions (i.e. outsourcing, insourcing and selective sourcing) before getting into the management complexity associated with internal markets and with strategic alliances.

But when none of the above happens, when organizations cannot or do not want to increase the number of internal human resources and when outsourcing is not advisable or desirable, new sourcing strategies have to be explored, since the make-or-buy poles do not provide a good enough solution for many organizations. These sourcing alternatives include strategic alliances and internal markets. When the company can find other firms that do not strategically compete with it and that have similar interests, the strategic alliance can be explored. If it wants, or it has, to follow this path on its own, then they will be facing an internal market strategy.

Our experience with two very different cases (different geographical regions, different sectors) show that, although the process of building a new enterprise has a high initial cost, the benefits that are achieved are quite rewarding: good control over the function, organizational learning and cost savings.
7 LIMITATIONS

As was stated previously, the authors of this paper have been part of the processes being studied, which introduces a certain bias into the overall process and conclusions obtained. Although every statement has been double crossed by the authors and, when possible, all documentation has also been cross examined, this does not fully ensure that this bias has been eliminated. The authors expect that further research into other cases will allow removing this bias and better guarantee that conclusions can be generalized to a greater extent.

On the other hand, there has to be a consideration about how the selection of the cases that has leaded us to this paper was done. The selection was done, initially, just on the base of being two similar cases found by authors which came to write this paper together precisely because of having worked in similar cases in the past and having written about them. Due to this the paper is based on two very different cases. One is a public Spanish university, the other one an Italian SME. Two sectors involved, education and industry, more precisely iron and steel sector. The selection is not fully representative and was not done because of any other reason than those exposed above. This introduces some limitations in the extent to which conclusions can be extended.

8 CONCLUSION

We consider that these two cases prove that the use of the internal market mechanism trough buffer organizations allows enterprises to find a very interesting sourcing alternative, especially for their IS/ICT function, by providing a method that brings together the best of insourcing and outsourcing. This is, we have proven in practice that the internal market approach is superior to outsourcing and insourcing, as was theoretically suggested by King and Malhotra (2000).

Can we guarantee that these results can be used in other sectors and in other countries? As was stated previously, in the limitations section of this paper, from the case selection it is obvious that there is no security that under different conditions and in different sectors, the conclusions can be used. But, on the other hand, it is true that common issues that have arisen in such different environments and that coincide in both cases so precisely can be reasonably expected to be found in other cases. However, further research to be developed will allow us to confirm this.

Abstract

As information-based processes are usually independent of the location or even the processor, they 
can be oftentimes either automated or relocated to foreign sites to profit from differences in wages. 
Both strategies bear enormous micro-economic potential in terms of cost savings. However, with the 
main focus on cost reduction, risk due to the uncertain development of effective labor costs or future 
transaction volumes are oftentimes either inadequately considered or neglected. This systematically 
leads to false decisions, in particular since the two strategies – relocation and automation – result in 
different risk profiles. In this paper, we analyze the conditions for automating or relocating parts of 
business processes and propose a decision model that suggests a risk/return efficient allocation to the 
alternatives. In particular, we consider how uncertainties of effective labor costs and transaction 
volumes influence the decision. As shifting tasks to other locations has effects on the workload at the 
original location, we also take into account costs for social effects. The practicability of our approach 
is demonstrated with an example that is based on real data of a major financial services provider.

Keywords: business process sourcing, relocation, automation, social effects, risk, decision model

1 INTRODUCTION

Today, globally acting companies that are integrated into world-wide value chains are constantly in 
demand to make sourcing decisions. This includes relocating business processes entirely or in parts to 
foreign countries to profit from effects such as increased cost efficiency due to wage differences and 
opening up new labor pools. Such relocation is accomplished either by outsourcing the business 
processes to external services providers that are located abroad or by shifting the processes internally 
from one site to another. Relocating business processes, either kept in-house or outsourced, has 
become very attractive in the last years and is facilitated by better communication technologies 
(Agrawal et al. 2003). Consequently, this trend is predicted to continue in the next years, which is 
underscored by Gartner (2007), who predict the worldwide market volume for business process 
outsourcing to grow from $160 bn in 2007 to $235 bn in 2011 with an annual growth rate over 10%.

Another ongoing trend that is facilitated by technological progress is business process automation. As 
pressure for efficiency increases, firms have to evaluate whether and to what extent business processes
should be automated. Most often a mixture of both – automation and relocation – seems to be most reasonable. Gartner (2008a), for instance, conceives a combination of automation and outsourcing as a way to reach the fullest extent of efficiency and cost reduction and predicts process automation to rise from 10% in 2007 to 55% in 2017 of all processes outsourced (Gartner 2008b). Oftentimes, process automation has become a true alternative to relocation. For example, simple tasks in the financial services domain such as entering paper orders in an order processing system could either be accomplished cost effectively by staff members in low-wage countries or those tasks could be (at least partially) automated. Applying, for instance, optical character recognition (OCR) technologies, the paper orders could be automatically scanned and processed. Therefore, for making sourcing decisions, an integrated decision support model considering relocation and automation is crucial.

Relocation as well as automation bear risk and recent studies show that saving expectations were often not met (Lacity et al. 2000). Two effects are especially important when assessing the risk and the expected return of both alternatives. First, uncertainties concerning effective labor costs, wage developments in foreign countries, and future transaction volumes have to be considered. If, for instance, the risk of rising wage levels is not taken into account, cost savings intended by relocation cannot be realized. False sourcing decisions are the consequence, leading to higher costs than before (Rouse et al. 2004). Similarly, neglecting uncertainties may result in false technology investments for automation as discussed for instance in Benaroch (2001).

Second, social effects that may arise when tasks are relocated or automated have to be considered carefully. For example, relocating the entering tasks outlined in the example above to low-wage countries may have important negative effects (including reputation problems) if at the same time employees are laid off at the original site. While those effects may be unavoidable in bad times, an interesting question is how enterprises can support growth in good times by exploiting the benefits of relocating or automating without provoking negative social effects.

The objective of this paper is to analyze the economic effects of relocation and automation in such a setting (i.e. from an enterprise’s point of view) and to contribute a normative decision model proposing an optimal allocation of (parts of) business processes in a risk/return efficient way. Thus, we primarily contribute to sourcing theory by providing an integrated view over the alternatives: retention at the origin site, relocation to a new site and automation. We consider the different cost characteristics of the alternatives taking into account also possible negative effects of cutting jobs and analyze how these alternatives relate to each other. We examine the effects of uncertainty of effective labor costs and transactions volumes in a model via simulation. The applicability of our model is shown by studying a real world case with data from a large financial services provider (FSP).

The remainder of this text is organized as follows: In section 2, we give an overview of related literature. Additionally, this section lays the conceptual fundment for this paper (including the definition of important terms). In section 3, the decision model is presented, analyzed and illustrated by an operationalization. Finally, we provide some managerial implications and limitations of the model (section 4) and conclude in section 5 by giving an outlook to further research.

2 LITERATURE REVIEW

Sourcing decisions can be separated into the organizational and the regional dimension which are to a certain extent independent of each other. With respect to the organizational dimension, outsourcing is defined as the procurement of services from sources that are external to the organization (Lankford et al. 1999). With respect to the regional dimension, near- and offshoring refers to relocating jobs to foreign countries without distinguishing whether the provider is external or affiliated with the firm (Levy 2005). In this text, we generally speak of relocation (standing both for near- and offshoring) and focus on the regional dimension since the cost reduction potential of relocating to low-wage countries can be realized both with in-house and outsourcing engagements. Furthermore, we consider automation as an alternative action in our decision problem. Automation refers to replacing human work by computers or machines (Bainbridge 1983). In the following, we will discuss the literature on
relocation and automation in order to elaborate cost structures and risk factors, before we provide an overview of decision models proposed by other authors for sourcing or automation decisions.

In literature, numerous articles on the drivers and criteria for relocation decisions have been published (Farrell 2005, Quélin et al. 2003). Although a number of motives for relocating the execution of business processes such as access to a larger pool of human capital, improved position in global markets, concentration on core business activities or more flexibility in reacting to market changes have been mentioned, the main motive is wage arbitrage due to lower human resource (HR) costs (Quélin et al. 2003). This is especially true for countries with high wages such as the US, the UK or Germany because relocation yields enormous cost reduction potential due to large differences in HR costs in comparison to low-wage countries such as India, where wages are about 15 percent of the US HR costs (neoIT 2006). However, relying only on HR costs may lead to false decisions. Further costs as well as different productivity levels have to be taken into account, too. The so-called loaded costs per employee consist of costs for HR, benefits, space as well as overheads. In general, the loaded costs only show a difference of about 25-35% (Everest 2005). The effective labor costs additionally consider that productivity levels may differ from site to site resulting in another mitigation of the cost arbitrage (Criscuolo et al. 2005). The effective labor costs represent the cost efficiency in conducting a process for each site. Relocating business processes (or parts of them) to a remote location usually causes transaction costs such as management or communication costs.

Relocating business processes bears risk. In the worst case, underestimating that risk may result in higher costs than expected or may even make back sourcing inevitable, i.e. re-integrating outsourced or relocated tasks to the origin site (Rouse et al. 2004). Due to global sourcing, risk influence factors like cultural differences, environment, communication, financial markets, technology, intellectual property and law have to be considered for the decision (AT Kearney 2007, Beck et al. 2008, Winkler et al. 2006). As the volume of business processes, which are sourced to low-wage countries, and following the demand at the labor market in low-wage countries is increasing, estimating future wage levels is conjunct with growing uncertainty (Vestring et al. 2005), i.e. especially the effective labor costs are risky. At this point, it is necessary to clarify our perception of risk: In accordance with financial theory (e.g. Copeland and Weston 1988), we understand risk as deviation of an expected value. Integrating risk in our decision model consequently means to take into account the uncertainty of input parameters by considering those deviations (in the form of a probability distribution).

Costs for business process automation are primarily affected by process-specific soft- and hardware such as acquisition costs or license fees (Alpar 1992). Because of the complexity of some processes, it is not always possible to automate the entire process or it may result in uneconomical high expenses for the latest technologies to rebuild the most complex process steps (Nikolaidou et al. 2001). Thus, by rising degree of automation, the costs increase exponentially. Business process automation bears risk, too. Due to initial investments, particularly uncertain transaction volumes are troublesome because resulting uncertain earnings could lead to reduced revenue and upfront investments may not be amortized (Benaroch 2001). Therefore, one has to evaluate the effects of unstable future transaction volume, which in general cannot be forecasted exactly due to incomplete information.

Relocation and automation of business processes may lead to a reduction of workload at the origin location resulting in costs for reassigning employees to other tasks (including e.g. training costs) or even in layoffs including severance payments (Lee 1997). Furthermore, such situations may result in lower productivities due to decreasing employee motivation (Brockner 1988). Thus, the effects on employees should be considered. In the sequel, we consider severance payments, costs for reassignments as well as trainings and possible effects on productivities as costs for social effects.

In the literature, most articles dealing with decision support on sourcing or automation are qualitative approaches (see e.g. Levina et al. 2008, Rouse et al. 2004 for sourcing and Gebauer et al. 1999, Stohr et al. 1997 for automation). There are only few quantitative approaches in related research areas:

- Yang et al. (2007) identify influence factors for sourcing and propose a decision model using the analytic hierarchy process method. Beimborn (2007) analyzes cooperative sourcing with different
independent actors. His analytical models and simulation approaches are based on game and agent theory. Consequently his work and the work of Yang et al. (2007) differ from our approach both in methodologies and in the research questions covered.

- Vom Brocke et al. (2004) and vom Brocke (2007) apply investment accounting methods to support sourcing decisions on business processes. They distinguish three levels of evaluation: the operational level, the budgeting level and the corporate level. At the operational level, in-payments and out-payments are directly related to process design and sourcing decisions. In contrast to our model, their approach requires detailed modeling of the processes and allows decisions for individual process steps in a multi-period model. We are, however, interested in the general relationship between sourcing and automation (and the different characteristics with respect to uncertainty) and therefore apply a one-period model.

- In the classical area of location theory, quantitative decision models can be found applying decision criteria similar to ours. For instance, Hanink (1985) employs a mean-variance approach for finding factory locations considering returns and risks. Similarly in IT sourcing theory Zimmermann et al. (2008) present a method to allocate software development projects efficiently over sites using Markowitz’s portfolio theory. In both cases, research questions are different to our contribution as automation is not considered.

- Finally, in the area of business process automation, Wei et al. (1998) propose a quantification of the optimal automation degree considering task load and process complexity. Additionally, Sheridan et al. (2000) propose a method to quantify the expected value of the gain of either human execution or automation. Both approaches neither propose a risk-return-integrated model nor do they consider sourcing or social effects.

Summarizing – to the best of our knowledge – there is no publication that takes an integrative quantitative approach combining sourcing and automation. Thus, we want to fill this research gap.

## 3 A MODEL FOR SOURCING AND AUTOMATION DECISIONS

Our leading questions in the following are: Which degree of relocation and automation is optimal for a business process considering the specific cost structures elaborated in section 2? How do costs for social effects influence the decision? How does a combination of two major risk factors – namely the uncertainty of effective labor costs both at the origin site as well as on the new site and the uncertainty of the future transaction volume – affect the optimal relocation and automation degree? To answer these questions, we introduce a quantitative decision model that is developed in two steps. We introduce a basic model in subsection 3.1. A first analysis provides an in-depth understanding of the underlying optimization problem (under certainty). In subsection 3.2, uncertainty is included into the model, then. The section concludes with an operationalization including a simulation approach.

### 3.1 Basic Decision Model

**Notations and Assumptions**

In our one-period model, we consider a FSP that currently conducts a business process at its origin site (in general a high-wage country such as the US or Germany). For each transaction processed, the FSP receives a fixed income \( E \). The FSP plans to reengineer and to re-evaluate the sourcing strategy for the business process. The business process (or a part of it) can be carried out at the origin site, it can be relocated to a new low-wage site or it can be automated. More precisely, we assume that the overall work required to conduct the process can be performed with any possible combination of the substitutive alternatives (retention, relocation and automation). To model this, we introduce the decision variables \( \omega, \kappa \) and \( \lambda \) \((\omega, \lambda, \kappa \geq 0)\) where \( \omega \) represents the degree of work conducted at the origin site (retention), \( \lambda \) represents the degree of relocation and \( \kappa \) represents the degree of automation. The variables \( \omega, \kappa \) and \( \lambda \) are normalized to 1 \((\omega + \lambda + \kappa = 1)\), i.e. their sum represents the complete workload of the business process.
The cost structures of the alternatives differ significantly: “Manual” work at the origin or at the new site causes costs that are assumed to be variable and proportional to the amount of work. For the new site additionally transaction costs $T$ arise due to international coordination. Automation, in contrast, causes a fixed upfront investment depending on the specific degree of automation chosen. These costs are assumed to grow exponentially by $\gamma$ ($\gamma>1$) with the degree of automation and with a maximal amount of money $A$ for full automation.

At present, the FSP processes an amount of transactions $V_0$ at its origin site. In the following period, the FSP has to conduct a number of transactions $V_l$. As outlined in the introduction, we are especially interested in situations where the transaction volume is expected to grow, i.e. $V_l>V_0$. If – due to relocation and/or automation – the new transaction volume conducted at the origin site falls below $V_0$, costs for social effects have to be considered, which are assumed to increase proportionally depending on the reduction in volume. The estimated costs for a complete shutdown of the origin site are represented by a parameter $S$.

Model Description

To reduce writing overhead in the following, we introduce the index $n$ to denote the different sites, work can be conducted at. The origin site ($n=1$) and the new low wage site ($n=2$) are characterized by their productivity $P_n$ and their loaded costs $L_n$. To determine the effective labor costs of the business process at a site, we calculate the ratio of loaded costs and productivity as shown in equation 1:

$$L_n = \frac{L_n}{P_n}$$

The overall effective labor costs are $\omega \cdot V_l \cdot L_1$ for the origin site and $\lambda \cdot V_l \cdot (L_2 + T)$ for the new site, then$^1$. Depending on the degree of automation $\kappa$, the maximal expenses for automation $A$ and the exponent $\gamma$, automation costs are calculated by $\kappa^\gamma \cdot A$. Costs for social effects only arise, if the share of volume retained at the origin site falls below the original volume because in this case the workforce on the origin site would be larger than required. We model this applying the maximum function, i.e. $\max\left(\frac{V_0}{V_l}, \omega, 0\right) \cdot S$. Finally, substituting $\omega$ by $1-\kappa-\lambda$ and expressing the return only depending on $\kappa$ and $\lambda$ leads to the following objective function:

$$R(\kappa, \lambda) = V_l \cdot E - \left( (1-\kappa-\lambda) \cdot V_l \cdot L_1 + \lambda \cdot V_l \cdot (L_2 + T) + \kappa^\gamma \cdot A + \max\left(\frac{V_0}{V_l}, (1-\kappa-\lambda), 0\right) \cdot S \right) \to \max$$

s.t.: $\lambda \geq 0; \kappa \geq 0; \lambda + \kappa \leq 1$

The optimization problem can be solved by differentiating between the two cases: no costs for social effects occur and costs for social effects occur. Comparing both cases finally delivers the solution to the optimization problem. A general (and not very surprising) finding is that with a prohibitive high cost factor for social effects $S$ and in case costs for relocation are smaller than costs for retention, the optimal automation degree and the optimal relocation degree are chosen so that costs for social effects just do not occur. Additionally, it can be shown that for the case that no costs for social effects occur, it is economically reasonable to automate process steps until the marginal costs of automation reach the marginal costs of human conduction (relocation or retention). Interestingly, an automation degree of $\kappa=0$ is not a feasible solution, i.e. under the given assumptions it is always reasonable to automate at least a marginal share of the process. Since the costs of relocation increase proportionally with $\lambda$ and the costs of retention increase proportional with $\omega(=1-\kappa-\lambda)$, the relationship between relocation and retention is rather simple: If the sum of effective labor costs at the new site and transaction costs is higher than the effective labor costs at the origin site ($L_2+T > L_1$), then the maximal possible volume

---

$^1$ We are aware that there are differences between inhouse-relocation and outsourcing. Nevertheless, production and transaction costs come up for both types, but with a different extent. Therefore, the model is designed to be applicable for both types. The specifications of inhouse-relocation and outsourcing must be set by parameterization.

---

Proceedings ECIS 2009
Having understood the general structure of the model, we can now extend the model and analyze the effects of uncertainty due to unpredictable effects that may occur during the planning horizon.

### 3.2 Analyzing the Effects of Uncertainty on the Decision

We consider two important risk factors, uncertainty of the effective labor costs and of the transaction volume, in the model. For this integrated approach, we introduce Assumption 1:

**Assumption 1:** To model risk, the effective labor costs \( L_n \) and the transaction volume \( V_1 \) are assumed to be normally distributed \((N(\mu, \sigma))\) random variables. Risk is hereby understood as possible negative or positive deviation from the given expected value \( E(L_n) = \mu_{L_n}, E(V_1) = \mu_{V_1} \) and is quantified by the given standard deviation \( \sigma(L_n) = \sigma_{L_n}, \sigma(V_1) = \sigma_{V_1} \), respectively.

As the input parameters \( L_n \) and \( V_1 \) for the return function are uncertain now, its result \( R \) is uncertain, too. This uncertainty has to be considered by the decision maker, who needs to make the decision based on a random variable \( R \) (instead of return \( R \) as defined in equation 2). This means the specific risk/return position of each allocation (i.e., each possible combination of \( \kappa \) and \( \lambda \)) has to be evaluated. Implicitly or explicitly this is done by a utility function that expresses the decision maker’s attitude towards risk and enables calculating the utility of an uncertain result \( R \).

**Assumption 2:** There exists a utility-function \( u(R) \), which assigns a specific utility to every random variable \( R \) and which is compatible with the Bernoulli-principle. We assume a risk averse decision maker that maximizes utility.

Based on a utility function, one can derive a preference function that integrates return and risk and can be used as a decision rule. A classical \( \mu\sigma\)-rule that is compatible – under the constraints of normally distributed random variables (Assumption 1) and a risk averse decision maker – with the Bernoulli-principle (Assumption 2) is given by the following equation (cp. Freund 1956):

\[
\Phi_R(\kappa, \lambda) = \mu_R - \frac{1}{2} \cdot \alpha \cdot \sigma_R^2 \rightarrow max!
\]

This function calculates a preference \( \Phi_R \) based on the expected value of the return \( \mu_R = E(R) \), the risk in realizing the return \( \sigma_R = \sigma(R) \), quantified by the standard deviation, and the decision maker’s attitude towards risk, which is represented by the Arrow-Pratt parameter \( \alpha \). The parameter \( \alpha \) is a positive value, which indicates risk aversion (Arrow 1971). The expected return \( \mu_R \) and the variance \( \sigma_R^2 \) can be derived from equation 2 and from the distribution parameters of the input parameters \( L_n \) and \( V_1 \) \((\mu_{L_n}, \sigma_{L_n}, \mu_{V_1}, \sigma_{V_1})\), respectively). However, in contrast to equation 2, determining a closed analytical solution to the optimization problem is not possible, since more than one risk factor is considered at a time (several stochastic random variables are multiplied). Thus, we employ a simulation approach, which is introduced in the following subsection.

### 3.3 Operationalization and Simulation

Now, we demonstrate how to apply the model in a typical decision situation. The following operationalization is based on a real business case of a FSP. Names as well as all identifying details are omitted and the business case data have been anonymized for reasons of confidentiality.

The A-BANK, a large European FSP, operates all over the globe and plans to reengineer and reorganize several of its business processes. For reasons of clearness, we consider only the process for handling high-value payments and checks for business clients which consists of 23 process steps. Besides cost reduction, the reason for reorganizing the process is motivated by an expansion and the number of transactions is expected to grow from presently 1,210,000 to 2,200,000 in the next period.
The following alternatives have been identified by A-BANK for the process under consideration:

- **Site 1 – Germany:** Up to this point, A-BANK processed their checks at its origin site characterized by high wages, but also high productivity. If less transaction volume than at the beginning is handled at this site, it would result in layoffs and/or partial reassignment of staff to new tasks requiring additional training. Both may result in increased costs and resistance of staff. A complete shutdown of the process at the site is estimated to result in costs for social effects of about €2.5 mn.

- **Site 2 – India:** A-BANK runs a large shared service center in India. This offshore site has become very popular due to the large and mature talent pool. A disadvantage lies in the cultural differences to Western countries. The labor costs are significantly lower than in Germany, but with a considerable large rate of increase. In addition to labor costs, transaction costs due to international distribution arise. Thus, the total costs for each transaction consist of labor and transaction costs.

- **Process Automation:** A-BANK is able to implement several process steps with a new software system and can install OCR systems for check handling. There are different levels that differ in the scope of the automation and in the recognition quality. The latter influences the manual effort required in subsequent process steps. For instance, low recognition quality means that (manual) controlling steps are still required in the process. By rising degree of automation, the costs are expected to increase exponentially.

By means of the model introduced before an optimal allocation of the process steps to the different alternatives should be found. A major challenge was to parameterize the model. For the automation costs, the following procedure turned out to be reasonable: For each process step, automation costs were estimated. Similar process steps were clustered by complexity and costs. The analysis revealed that some process steps were easy and inexpensive to automate whereas others were extremely complex or difficult resulting in very high automation costs. Five different types could be differentiated with estimated costs for the automation as shown in Table 1 and Figure 1. Based on the cost estimations, we approximated automation costs to increase exponentially with an exponent $\gamma$ of 2.0 (cp. Figure 1). The maximal automation costs (parameter $A$) were determined by the sum of the costs for automating all steps, which were estimated to €21 mn.

*Table 1. Breakdown of the automation costs*

In order to determine the risk aversion parameter $\alpha$, we compared the cost estimations and risk surcharges of the business case with the estimated variances of our approach. Based on the ratio of investments to estimated risk, we found a constant risk aversion parameter $\alpha$ with the value of 0.0001 to be reasonable. Figures about transaction volumes were available from the A-BANK. Further parameters such as productivity parameters, loaded costs and costs of social effects could be estimated.
based on experience and based on public (e.g. neoIT 2006) as well as A-BANK internal reports. Table 2 summarizes the input parameters for the simulation:

Table 2. Model parameters for the simulation

The simulation works as follows: For each possible \( \kappa-\lambda \)-combination (we iterate over the feasible interval \([0,1]\) for both \( \kappa \) and \( \lambda \) in 0.01 steps), we draw values for the normally distributed random variables \( \bar{L}_n \) and \( \bar{V}_1 \) using the Monte-Carlo method (according to the distribution parameters \( \sigma_{V_1} \) and \( \sigma_{L_1} \)). With these values, we calculate the return \( \bar{R} \) according to the return function 2. This procedure is repeated 10,000 times (denoted by \( i \)). With the resulting 10,000 values for \( \bar{R} \), we calculate the mean \( \mu_R \) and the standard deviation \( \sigma_R \):

4) \[ \mu_R = \frac{1}{i} \cdot \sum_{i=1}^{10000} \bar{R}_i \] \[ \sigma_R = \sqrt{\frac{1}{i-1} \sum_{i=1}^{10000} (\bar{R}_i - \mu_R)^2} \]

These values are inserted into the preference function (equation 3). Repeating this procedure for each possible \( \kappa-\lambda \)-combination, we get a value \( \Phi_R \) for each \( \kappa-\lambda \)-combination. Consequently, the \( \kappa-\lambda \)-combination with the highest value of \( \Phi_R \) is the optimal allocation for the current constellation of input parameters.

To analyze the influence of increasing risk to the optimal \( \kappa \) and \( \lambda \), we repeat this procedure with different values for \( \sigma_{V_1} \) and \( \sigma_{L_1} \), increasing both \( \sigma_{V_1} \) and \( \sigma_{L_1} \) from 0% to 20% by 0.5% and determine the optimal \( \kappa-\lambda \)-combination for each \( \sigma_{V_1}-\sigma_{L_1} \)-combination as described above. \( \sigma_{L_1} \) always has the value of 3% during the whole process.

Figure 2 depicts the change of the optimal automation degree (\( \kappa \)) (left plot) and relocation degree (\( \lambda \)) (right plot) for increasing both \( \sigma_{V_1} \) and \( \sigma_{L_1} \). For illustration purposes, we extracted profile cuts I, II, III and IV (cp. Figure 2) and show them in Figure 3 and Figure 4:

Figure 2. Graphical representation of the results of the simulation

---

2 We are aware that the return \( R \) as specified in equation 2 may not be normally distributed in any case (because we multiply several normally distributed random variables and a maximum function). However, an analysis of the distributions in the simulation approach has shown that \( R \) is at least approximately normally distributed, i.e. the differences cause little and acceptable deviations in the results.
In the following, we analyze the influences of the different risk factors and of costs for social effects. Growing uncertainty of the effective labor costs at the new site $\sigma_{t_2}$, e.g. caused by unpredictable wage developments or productivity deviations, in tendency fosters automation as the less risky alternative ($\kappa$ rises, $\lambda$ decreases; cp. Profile I). This effect can be observed up to the point where automation becomes too expensive due to increasing process step complexity. After exceeding this point, the automation degree stagnates (cp. Profiles I and II). This means, automation can be seen as a substitute for relocation as long as it is not surpassed in attractiveness by retention. In contrast, rising uncertainty of the transaction volume leads to a higher share of relocation and less automation. This is due to high upfront costs for automating a process and in turn probably lower earnings resulting from uncertain transaction volumes. Interestingly, when the automation degree $\kappa$ equals zero, relocation becomes less benefiting, too (cp. Profile III and IV), which means, uncertainty of the transaction volume affects both, automation and relocation.

Considering the effects of both factors together, we find that in the area of low uncertainty (low $\sigma_{t_2}$ and $\sigma_{t_1}$), the relocation degree $\lambda$ reacts very sensitive on deviations (cp. Profile III). This effect, which is especially strong for $\sigma_{t_1}$, is caused by the linear behavior of relocation costs, i.e. in the area of low uncertainty, little changes may have enormous effects on the optimal allocation resulting in completely different relocation degrees $\lambda$. Furthermore, changing uncertainty of the transaction volume $\sigma_{t_1}$ in general has a stronger impact on the optimal solution than changing uncertainty of effective labor costs $\sigma_{t_2}$ which is because the first affects both $\kappa$ and $\lambda$ (cp. Profiles III and IV). Interestingly, the results in this particular case additionally show that automation is still a viable alternative even with volume risk of 7% (cp. Profile II).
As there is also uncertainty of effective labor costs at the origin site ($\sigma_{\lambda_1} = 3\%$ here), retention is no longer a certain alternative to relocation and automation. The effects are the following: With rising $\sigma_{\lambda_2}$, the automation degree $\kappa$ is steadily rising with a small slope (cp. Profile II). The relocation degree $\lambda$ is affected stronger since retention and relocation have similar cost characteristics. Thus, rising unattractiveness of the first – in terms of risk – directly means higher attractiveness of the latter. This effect is illustrated in Profiles I and III with high values for $\lambda$ in particular in the range of low $\sigma_{\lambda_2}$.

While – even high – costs for social effects are accepted when there is no or only low uncertainty (cp. Profiles I and III), increasing uncertainty fosters the effects of these costs since cost reduction potential of relocation and automation becomes uncertain and the costs for social effects also support this trend (cp. Profiles II and IV). In general, we can state that avoiding costs for social effects, for instance by moderate automation and relocation, is a preferable option as the sum of the optimal allocation $\lambda$ and $\kappa$ is running on or nearby the social cost border (cp. Profiles I and II).

4 DISCUSSION AND LIMITATIONS

Summarizing, uncertainty significantly influences optimal relocation and automation decisions on business processes. One source of uncertainty in today's global economy are effective labor costs. In the near past, for instance, wage levels in countries such as India increased faster than expected, which turned out to be a major problem also for the A-BANK. Our model includes those risks suggesting automation as an interesting alternative, if at the same time the uncertainty of the transaction volume is not too high. In this case, the decision maker should first choose process steps that are easy and inexpensive to automate. A further result is that with increasing risk, taking costs for social effects should be avoided. To put it in other words, the decision maker should have complete information or should at least be able to estimate parameters with the required precision before relocating work to a foreign country and cutting jobs at the origin site. If effective labor costs and the transaction volume are uncertain, the automation and relocation potential should be exploited only up to the point where costs for social effects would arise. If uncertainty is exceptionally high, even staying significantly below this threshold is a favorable strategy. In the light of the current economic crisis with high uncertainty of the transaction volume, the results suggest that postponing costly automation projects and keeping the work at the high wage and less risky site can be the preferred alternative.

The introduced model is based on a set of assumptions. These limitations at the same time define extension potential. First, we assumed infinitely divisible processes. In reality processes may not always be cut as proposed by the model. Still, most processes consist of several steps and can nearly be allocated as optimized. Thus, feasible discrete allocations may lie near the theoretical optimum, also delivering a good economic solution. Our model is especially applicable, when process steps can be more or less independently sourced or automated since interdependencies are not explicitly included in the calculations. Second, we proposed a one-period model which was reasonable to understand the fundamental relationships between sourcing and automation under uncertainty. Extending our model to multiple periods (in terms of a cash-flow oriented perspective) is an interesting direction for further research. Investment accounting methods (as discussed in the literature section) may be a starting point for this extension. Third, specific characteristics of in-house relocation versus (external) offshoring could be considered. Fourth, we assumed normal distribution of the random variables – which is a common assumption in literature (e.g. Hanink (1985)). Nevertheless, our approach could be extended by including empirical estimations of probability distributions which could then be applied in an enhanced model. Last but not least, not all of the results can be generalized and further simulations are required to validate our findings.
5 CONCLUSION

Though relocating and automating business processes bear much economic potential, there are only few quantitative decision support models. In particular, there is a lack of research considering both alternatives in an integrated approach. Thus, in this paper we propose a risk/return based approach to calculate optimal degrees of relocation and automation for individual business processes considering the specific cost structures and risk profiles. In comparison to previous research, this approach comes up with several enhancements: First, we simultaneously consider relocation and automation. Second, such decisions also have effects on the original site since jobs may be abolished. Hence, we consider such social effects by quantifying negative outcomes of disestablishing jobs. Finally, we analyze the influence of uncertainty. Applying the model, the results provide a recommendation for automation or site selection for business process steps. Employing data of a business process of a major FSP, the applicability of this approach is illustrated.

The model provided evidence for several facts. First, automation becomes unattractive, if information of the future transaction volume is incomplete. But, automation is a viable alternative, if the effective labor costs cannot be predicted precisely. Second, relocating process steps is affected negatively both by uncertainty of transaction volume and uncertainty of effective labor costs. Third, taking costs for social effects is only sensible, if the decision maker has sufficient information. This is an interesting finding since it suggests that social effects should be assessed carefully. Finally, not considering uncertainties may lead to false decisions. Summarizing, the analysis of the proposed model for supporting sourcing and automation decisions not only revealed interesting insights, it can also form the foundation for further research.

Abstract

Following calls to enhance risk-sensitivity of second generation Operational Risk-Aware Information Systems (ORISs), this paper aims to address the lack of ontological/epistemological grounding for the concept of Operational Risk (OR). Herein, OR is regarded both as a property of a real system and as a representational phenomenon forming part of the core of ORIS in line with Weber’s (2003) view of the core of IS. The paper explores how the ontological/epistemological position of the Critical Realist philosophy of science assists in the Requirements Definition of ORISs by providing an ontology-driven representation of the heterogeneous nature of OR. The retroductive mode of logical inference enabled by Critical Realism supports the discovery of OR causal mechanisms when the historical data about operational loss events is limited. The ontological/epistemological position suggested in the paper contributes to better understanding and representation of OR, informs OR assessment in conditions of a constantly changing socio-economical environment, and so assists in the Requirements Definition of ORISs.

Keywords: Operational Risk, Critical Realism, Causality, Operational Risk-Aware Information System
1. INTRODUCTION

Last decade saw a rise in frequency and magnitude of Operational Risk (OR) loss events in most areas of business including supply chain management (Lewis 2003) and banking and finance (Chernobai et al. 2007; Moosa 2008). In response the introduction of regulatory requirements and recommendations (i.e. Sarbanes-Oxley Act 2002; Basel Committee for Banking Supervision (BCBS) 2006) established the role of Operational Risk Management (ORM) as a strategic function that assures sustainability of organisations (Scandizzo 2007; Chernobai et al., 2007; Lewis 2003). Today, in ORM theory and practice, Information Systems (ISs) are regarded as both a source of ORs (BCBS 2006; Wolf 2005) and a tool for managing ORs (Flores et al. 2006; Chartis Research Ltd 2008). This research focuses on the second aspect, wherein ISs are seen as a tool for managing ORs, and explores their ability to represent the phenomenon of OR. Reports on risk technology (cf Chartis Research Ltd 2008) detail a forthcoming transition from first generation “compliance ‘tick-box’ approaches”, to a new generation of Operational Risk-Aware Information Systems (ORISs), although explicit support in the research for this is still scarce (Flores et al. 2006).

Following Weber (2003 p.vii), this research views “representation... [as] the essence of all information systems”, which implies the ability of “track[ing] states of and state changes in other systems” (ibid). By “other systems” Weber (2003 p. vii) means the real world systems that exhibit the patterns of events and behaviours according to certain rules. These also inform the development of “artificial information systems” (ibid). Leveraging off Weber’s work, we assume that an IS can represent OR as an intrinsic component of the real world socio-technical system. To facilitate this understanding we explore the nature of OR as an object of research inquiry (ontological positioning). Further, given research in the IS field has insistently called for “examin[ing]g and clarif[y]ing the underlying set of ontological and epistemological assumptions that underpin every research activity” (Kanellis and Papadopoulos 2009, p.1; Becker and Niehaves 2007), we also look at how the knowledge about this phenomenon is built (epistemological positioning). To date research on OR has not explicitly explored the ontological assumptions that support understanding about the heterogeneous nature of OR (Holmes 2003), nor has it provided the epistemological grounding to enable the knowledge acquired through different OR methodological approaches to be addressed. Consequently, this questions the ability of ORISs to represent, in a non-contradictory and rigorous way, the phenomenon of OR as part of the corresponding real system.

The aim of this paper, therefore, is to address the research gaps mentioned above by exploring how the ontological/epistemological position of the Critical Realist (CR) philosophy of science assists in: 1) representing the phenomenon of operational risk as part of the real system reflected by an Operational Risk-Aware Information System; and 2) more informed decisions in the Requirements Definition stage when designing an Operational Risk-Aware Information System. The novelty and original contribution of this paper concerns the non-contradictory ontological/epistemological support provided by multimethod operational risk assessment that combines the data-driven and scenario-based approaches as an integral component of Operational Risk-Aware Information Systems.

The reminder of this paper is organised as follows. The next section addresses the issues of OR representation and assessment, and suggests a list of desirable properties that aim to overcome these issues. In Section Three the suitability of the dominant philosophical paradigms adopted in both the IS and Risk Analysis literature are critically assessed by examining their ability to meet these desirable properties. This is followed by discussion of how the alternative ontological/epistemological position brought by the philosophy of science of CR leads to a better set of desirable properties. Section Four illustrates the implications of the CR ontological/epistemological support in the development of ORISs. This is followed in Section Five by an illustration of how CR can inform the OR assessment process of an ORIS model. Section Six provides conclusions and offers suggestions of future research directions.
2. REPRESENTING OR AT THE REQUIREMENTS DEFINITION STAGE OF DEVELOPING ORIS
