**Proposition 10:** Capabilities based on competencies of supplier will positively influence supplier’s intention to participate and the level of participation in the B2G e-auction market.

### 4 CONCLUSION

In this paper, we have attempted to derive a theoretical framework for explaining supplier behaviours in a B2G e-auction context, by drawing from multiple disciplines. The outcome is derived from extensive and rigorous literature review. It is anticipated that the examination of four key constructs: efficiency motive, legitimacy motive, environmental uncertainty, and supplier capabilities will help to identify reasons for suppliers’ decision to participate in B2G e-auction markets in Thailand. Overall, we believe that this paper extends the understanding of supplier behaviours in the B2G e-auction markets. We also hope that the outcome of this study encourages new thinking and research into the B2G e-auction markets. Future steps include qualitative interviews and focus groups with suppliers in the Thai B2G e-auction markets. These techniques will uncover empirical evidence for possible relationships amongst the independent variables specifically addressing the Thai context and therefore help us refine the theoretical model. Based on the improved model, we will develop survey instruments, followed by pre-test of the instruments, the main survey, and follow-up interviews (if necessary) to explore unexplained results.

Abstract

The application of market mechanisms for the allocation of computing services is a demanding task, which requires bridging economic and associated technical challenges. Even if the market-based approach promises an efficient allocation of computing services, the wide heterogeneity of consumer requirements and the diversity of computational services on provider side are challenging the processes of finding, allocating, and using an appropriate service in an autonomous way. The focus of the most papers is mainly devoted to the optimization embedded in the allocation process itself. However, we think that the optimization process starts much earlier and contains the information gathering until the final market-based resource allocations.

In this paper we introduce an integrated framework for market-based allocation of computing services, integrating information retrieval of market information, prediction models, bidding strategies and marked mechanisms. As proof-of-concept, we implemented a first prototype of the framework. Furthermore, we propose a methodology for evaluating strategic behavior in market mechanisms with bidding strategies using market information and statistical prediction techniques. First simulation results show strategic behavior in selected market mechanisms by applying the proposed techniques.

Keywords: Market Mechanisms, Market Information, Bidding Strategies, Evaluation.
1 INTRODUCTION

Grid and Cloud Computing become not only in science increasingly popular, but also in industry. Prominent examples are Sun Microsystems's Network.com, Amazons Elastic Compute Cloud (EC2) and its Simple Storage Service (S3) and SimpleDB Service. The companies frequently offer a fixed pay-per-use price for static resource configurations. Fixed prices can lead to inefficient utilization, reward and usability, as it does not reflect the dynamics of the market supply and demand. Efficient provisioning and usage of computational resources as well as pricing in vigorous environment like Grid Computing is not manually manageable. Such processes should be automated with no or minimal human interaction. Hence, market mechanism and strategic behavior play an important role for the design of the environment. Self-organization and automatic adaptation to the changing market conditions are key prepositions for efficient offering and consuming of computational resources.

An efficient allocation of consumers' jobs to providers' resources is a complex task, where agent decisions on resource provisioning, market-based allocation and information processing is included. Moreover, the wide heterogeneity of computational resources challenges the process of finding an appropriate resources for given consumer preferences. Since demand and supply of computational resources fluctuates in the course of time, information about current and future resource utilizations and prices are often not known a priori to the participants. In this case consumer and provider agents try to maximize their utilities by generating bids based on available information. This enables strategic behavior both on provider as well as on consumer side.

The knowledge about a market is essential for the design of efficient bidding strategies. Examples are computational approaches incorporating game theory that allow predicting the future through forecasting or learning rules on former or actual trading information. Bergemann's survey (Bergemann and Valimaki 2007) shows that the economic aspect of information acquisition in market mechanisms got more attention by the economic research community. Moreover, the study demonstrates the importance of the economic information disclosure for market participants. The need for this information lies in both being able to apply efficient economic strategies and to feed business models, which are behind these strategies.

The first contribution of this paper is to survey and bring together results for market-based allocation of computational resources. More specifically, to structure the allocation processes in individual steps, we go further in regard to specify mechanisms for information provision and retrieval, price prediction, bid generation and market-based resource allocations. Based on them, we propose an integrated system for market-based computational resource allocation, which organizes the discussed processes. Finally, we specify a common evaluation scenario and present first results.

Following the structure of the paper, section 2 presents promising market mechanisms and bidding strategies. Section 3 shows the role of market information and prediction models for improving allocation efficiency. Thus, section 4 shows an integrated model of a market-based allocation system. Evaluation methodology and first results are depicted in section 5 and related work in section 6.

2 MARKET-BASED RESOURCE ALLOCATION

Auction and strategy selection are closely connected in the sense that a given choice of strategy should affect the choice of auction, and vice versa. For example, some bidding strategies perform well in a Continuous Double Auction, but not in other auctions such as the Dutch auction. This also implies that the choice which auction to participate in depends on the available strategies. Other factors to take into account are the bidding rules – when, how and what to bid, current and average prices, transaction costs, and pricing schemata in the different auctions.

In this section, we discuss potential market mechanisms for allocation of computing services as well as potential bidding strategies enabling the automation of the provisioning and usage processes.
2.1 Market Mechanisms for Computing Services

Economic models for resource scheduling are widely explored in the literature (Wolski et al. 2001, Parkes et al. 2004, Lai et al. 2005, Nassif et al. 2007). According to the allocation modes, scheduling mechanisms can be distinguished into mechanisms, which execute periodically, called also “offline mechanisms”, and mechanisms which execute continuously, called also “online mechanisms”. Mechanisms like Vickrey, English, Dutch, double auctions (Grosu and Das 2006) and combinatorial mechanisms (Bapna et al. 2005) involve a scheduling problem that is complex. The complexity of such mechanisms drives research to look at allocation models, which can be adapted to real-world scenarios and requirements.

Following section presents promising market mechanisms, implemented within the integrated model (section 4) to evaluate market-based allocation of computing resources as well as strategic behavior using the market information from the proposed market information service.

2.1.1 Continuous Double Auction

The CDA has been widely employed in experimental economic studies, where different agent strategies (Gjerstad and Dickhaut 1998, He et al. 2003, Vytelingum et al. 2008) are investigated for applying automated bidding behavior by the provisioning and usage of resources. The matching in CDA is mostly based on a single value – price, which in a computing resource scenario incorporates the consumer’s preferences for a job i.e. his value $v_j$ per time unit. Based on a preferred bidding strategy (see section 2.2) a consumer generates and submits a bid price ($b_j \leq v_j$) to the CDA market. Respectively, based on a preferred bidding strategy, a resource provider also generates an offer price ($o_i \geq v_j$) and submits it to the market. In the provider case $v_j$ represents the reserve price (minimum price) for using the provider’s machine for a unit of time. In case of a match, the consumer executes immediately his job on the provider’s machine with a payment to the provider, calculated by the winning bid and offer prices. The market price of a match is calculated using the pricing schema $k$-pricing (Satterthwaite and Williams 1989): $p_m = kb_j + (1 - k) o_i$, with $k = 0.5$ in our case.

2.1.2 Decentralized Online Machine Scheduling

In the case of the Decentralized Local Greedy Mechanism DLGM (Heydenreich et al. 2006), each time a job $j$ arrives on the consumer side, his bidding agent creates a request in the form $t_j = \{r_j, d_j, v_j\}$ with its release date $r_j$, duration $d_j$ and valuation $v_j$, and reports this to all known providers. The valuation $v_j$ expresses the costs of the job for waiting one additional time unit in the provider machine’s queue. Based on the received bids, the machines perform real-time planning based on a local scheduling policy – if job $j$ has a higher priority value than $k \Leftarrow \frac{v_j}{d_j} \geq \frac{v_k}{d_k}$, then $j$ is scheduled before job $k$ in the waiting queue. Depending on the current local waiting queue, the machine $i$ reports a tentative (ex-ante reported) completion time $\hat{C}$ and payment $\hat{p}$ to the agent of job $j$. The payment $\hat{p}$ contains the aggregated compensations to all job-agents whose jobs are currently waiting at machine $i$ and are delayed due to allocation of $j$.

Upon receiving information about its tentative completion time and required payments, the job-agent makes a binding decision to queue at certain machine $i$, and pays $\hat{p}$ to the delayed jobs. The decision on which machine to submit the job is taken based on the consumer’s utility function $u(j) = -\sum t_j * \hat{C}_{j,i} + \hat{p}_{j,i} , \text{ which selects a provider machine’s offer } i \text{ with the shortest weighted tentative completion time } v_j * \hat{C}_{j,i} \text{ and tentative compensation payments } \hat{p}_{j,i}$. The providers applying the DLGM mechanism do not behave strategically and do not get compensation for the use of their services. The payments are divided only among the consumers. Heydenreich et al. showed that the plain DLGM mechanism achieves a performance ratio of 3.281 against an optimal offline scheduling mechanism.
2.1.3 Fix-Price Technical Scheduling

In order to compare the outcomes of the introduced market mechanisms, we implemented FIFO as baseline scheduling mechanism. The agents submit their jobs to a central scheduler, which schedules and executes them through the FIFO scheduling policy on the various registered provider machines. For each machine the providers request a fixed reservation price.

2.2 Defining Bidding Strategies

Bidding strategies for market-based scheduling are well explored in the economic literature (Reeves et al. 2005, Li and Yahyapour 2006a, Vytelingum et al. 2008). Wellman et al. 2007 give an overview of the various agents and their strategies taken place in the trading agent competition. In general, bidding strategies can be classified into non-adaptive, where the generated bid price do not depend on past and market information e.g. Truth-Telling, and ZI as well as adaptive strategies, where the generated bid price depends on past and market information e.g. ZIP and GD.

Although a simple strategy, truth-telling is essential in case of strategy-proof mechanisms, where in such mechanisms this strategy guarantees to obtain optimal payoffs, no matter what strategies are adopted by the others. A comparison of state-of-the-art bidding strategies is evaluated by Das et al. 2001. The authors of Adaptive-Agressiveness (AA) strategy (Vytelingum et al. 2008) describe and evaluate a novel bidding strategy, which implements short and long-term learning, considering and responding also to dynamic market fluctuations. Simulation results show that the AA outperforms the ZIP and GDX (Tesauro and Bredin 2002) strategies.

Although mainly designed for financial markets, these strategies are fundamental for the design and evaluation of bidding strategies and market mechanisms for Grid and Cloud services (Foster et al. 2008). Following sections present bidding strategies, which we aim to adopt in a Grid market scenario.

2.2.1 Zero-Intelligence Plus Strategy

Zero-Intelligence Plus (ZIP) agents are widely explored and become a popular benchmark for agents trading on continuous double auctions (Das et al. 2001). In Cliff 1997, the author showed that zero intelligence (ZI) agent strategy is not enough, since the bids are uniform generated between a given interval and not depend on current market information or past bids. They introduced ZIP agents, which use public market information to adapt the bid price of a certain market. Experiments (Das et al. 2001) show that ZIP agents perform better than (non-expert) human traders on CDA markets as well as it converges quickly to equilibrium price by high demand and supply.

In most experiments in the literature (Cliff 1997, Tesauro and Das 2001, Das et al. 2001), the ZIP agents receive information of all bids and offers, whether they are accepted or not. There are, however, experiments showing that ZIP based agents perform well also in auctions where the agents only receive information on the winning bids (Bagnall and Toft 2005). In our scenario we will adopt the ZIP strategy in the same way, considering only the winning bids and clearing price of the market.

2.2.2 Gjerstad-Dickhaut Strategy

The Gjerstad-Dickahaut, GD (Gjerstad and Dickhaut 1998, Tesauro and Bredin 2002) bidding strategy is also mainly developed and evaluated in CDA markets. Compared to ZIP, this mechanism is memory based, thus it is using historic market information of the last M bids and offers, H_M, in order to calculate a “belief” function f(p) estimating the probability for a bid or offer to be accepted at price p.

Provider belief function \( f_o(p) = \frac{\sum_{o \in H_M} l + \sum_{b \in H_M} l}{\sum_{o \in H_M} l + \sum_{b \in H_M} l + \sum_{o \in A_H} l} \)
Consumer belief function $f_b(p) = \frac{\sum_{b \in H_M \cap o \geq p} i + \sum_{o \in H_M \cap b \geq p} i}{\sum_{b \in H_M \cap o \geq p} i + \sum_{o \in H_M \cap b \geq p} i}$

For the provider, $\sum_{o \in H_M \cap b \geq p} i$ represents the number of accepted offers in $H_M$ with offer price $o \geq p$, $\sum_{b \in H_M \cap o \geq p} i$ is the number of accepted bids $H_M$ with bid price $o \geq p$ and $\sum_{o \in A_{H_M} \cap b \geq p} i$ is the number of unaccepted offers in $H_M$, $o \notin A_{H_M}$, with offer price $o \leq p$, respectively in opposite for the consumer. Interpolation is applied for prices at which no bids and offers are registered in $H_M$. The bid or offer price is calculated by the product $f(p) \times g$, where $g$ is the calculated gain for a trade at that price, $g = p - v$ for providers and $g = v - p$ for consumers, where $v$ is the valuation.

Although mainly evaluated in CDA markets, GD is applicable as a state-of-the-art strategy in markets for computing resources to the estimation of bids, considering past bids and market information.

2.2.3 Q-Strategy

Q-Strategy (Borissov and Wiström 2008), is a novel bidding strategy adopting a reinforcement learning approach with an e-greedy selection policy. Using the Q-Strategy, an agent explores the environment, exploitation phase, with a probability of $\epsilon$, learning available provider machines and the reward of executing a job on them. With a probability of $1-\epsilon$, exploitation phase the strategy exploits the collected knowledge (i.e. market information) for generating bids more intelligently.

Using Q-Strategy, the agents can bid and adapt also in markets, where market information is incomplete. Simulations show that Q-Strategy adapts to market dynamics (fluctuating prices and changing utilities from providers machines) in different market mechanisms and against bidding strategies like ZIP and Truth-Telling. A common drawback of reinforcement learning algorithms is that learning the optimal bid price needs “training time”. In worst case, Q-Strategy will perform worse at the beginning, but will converge to optimal values in the time (Watkins and Dayan 1992).

3 THE ROLE OF MARKET INFORMATION

Bidding strategies (section 2.2) and prediction techniques (sections 3.1.1 and 3.1.3) require market information in order to efficiently bid in selected markets. However, in a distributed environment like in open and wide Grid markets like in SORMA (http://www.sorma-project.eu/) such information is not locally accessible. (Bergemann and Valimaki 2007) demonstrate the importance of economic information disclosure and show the increased attention, paid to economic information acquisition. Traders require information that enables them to deduce entry prices for available markets and trading times. Centralized markets are able to furnish the current information necessary for simple or sophisticated bidding strategies - such as ZIP agents (Preist and van Tol 1998) or human traders. Therefore, this is an issue for distributed and segmented markets. Distribution and segmentation of markets result in loss of information such as prices, products and effective supply (Brunner et al. 2008). An efficient information system should allow participants to choose a compromise between exact global information and partial information. Furthermore, aggregated, anonymous and summarized information contribute to scalability and may in most cases be sufficient. We conclude the following hypothesis for the influence of information to distributed markets.

Bidding strategies need information about a state of the market, commonly through the offered resource type and price dynamics in time. The main focus here is the treatment of market information by agent’s bidding strategies applying statistical price prediction techniques.

Statistics are used in markets to measure current conditions as well as to forecast financial or economic trends. Indicators are used extensively in technical analysis to predict changes in stock
trends or price patterns. Economic indicators quantifying current economic and industry conditions are used to provide insight into the future demand for commodity goods. In our approach, we use statistical prediction methods for price forecasting.

3.1.1  Trend Extrapolation

The trend extrapolation indicates new trends within the market. In computation markets this is important when newer or higher performance resources entered the market, which will start a deceasing trend for older resources. We will use different kind of moving averages that are indicators in technical analysis of market charts and show the average value of a security's price over a set period. Moving averages are used to emphasize the direction of a trend and to smooth out price and volume fluctuations, or noise. Most bidding strategies implement learning mechanisms, which use statistical prediction models. The ZIP bidding strategy, for example, uses a Widrow-Hoff gradient algorithm, a learning rule (Preist and van Tol 1998), which is a variation of the moving average rule.

In time series analysis, the Moving Average model is common approach to model univariate time series models. A Simple Moving Average (SMA) is the unweighted mean of the previous n data points. For example, a 10-day simple moving average of closing price is the mean of the previous 10 days' closing prices. If those prices are \( P_M, P_{M-1}, \ldots, P_{M-9} \) then the formula is

\[
SMA = \frac{P_M + P_{M-1} + \ldots + P_{M-9}}{10}
\]

In all cases a moving average lags behind the latest data point, simply from the nature of its smoothing. An SMA can lag to an undesirable extent, and can be disproportionately influenced by old data points dropping out of the average. This is addressed by giving extra weight to more recent data points, as in the weighted and exponential moving averages.

A SMA calculates the average of a whole period to predict the future price, which has poor ability to react to new market events. Therefore we will evaluate our approach with a Weighted Moving Average (WMA) to give more weight to recent prices: 

\[
x = \frac{1}{n} \sum_{i=1}^{n} x_i = \left( \frac{1}{n} \right) x_1 + \left( \frac{1}{n} \right) x_2 + \ldots + \left( \frac{1}{n} \right) x_n
\]

where \( \left( \frac{1}{n} \right) \) are the weights, which sum to 1.

An Exponential Moving Average (EMA) is based on the WMA and applies weighting factors which decrease exponentially. The weighting for each older data point decreases exponentially, giving much more importance to recent observations while still considering older observations

\[
EMA = \frac{p_1 + (1-\alpha)p_2 + (1-\alpha)^2p_3 + (1-\alpha)^3p_4 + \ldots}{1 + (1-\alpha) + (1-\alpha)^2 + (1-\alpha)^3 + \ldots}
\]

3.1.2  Cyclic and seasonal component models

Cyclic and seasonal prediction models are applied to detect deviation and trends according to the properties of computational market, which follows periodic type of behaviour. This can be the property of different prices due to the demand on daytime or weekdays. We evaluated workloads (Feitelson 2008) resolving that e.g. in a university network the demand for computational resources is significantly higher during official working hours than during night times or weekends. In our analysis, we will use the autoregressive moving average model (ARMA) and the seasonal autoregressive moving average model (ARIMA).

Autoregressive Moving Average Model ARMA (p) refers to the autoregressive model of order p. The ARMA(p) model is defined as

\[
X_t = c + \sum_{i=1}^{p} \varphi_i X_{t-i} + \epsilon_t,
\]

where \( \varphi_1, \ldots, \varphi_p \) are the parameters of the model, \( c \) is a constant and \( \epsilon_t \) is white noise. An autoregressive model is essentially an all-pole infinite impulse response filter with some additional interpretation placed on it. Some constraints are necessary on the values of the parameters of this model in order that the model remains stationary. For example, processes in the AR(1) model with \( |\varphi_1| \geq 1 \) are not stationary.
3.1.3 Grid specific models

As we investigate computational market we will also apply models, which are successful in predicting the demand of computational resources. Sandholm and Lai (Sandholm and Lai 2008) showed that a prediction based on Chebyshev is better suited for predicting performance guarantees, which need worst case scenarios than perfect forecasting.

4 AN INTEGRATED MODEL – INFORMATION AND MARKETS

We propose an integrated architecture for market-based allocation for computational resources. The components have clear separated capabilities and interactions to achieve an economically efficient allocation of applications to needed computing resources. The model is composed by different independent systems (Borissov and Wiström 2008, Brunner et al 2008), which allow a clear separation of code, functionality and expert domain for an easier development, maintenance and fault-detection. The BidGenerator, the Market Information System, the Trading Manager and the Resource Manager are the main components, building an infrastructure for market-based allocation of computing services.

Real applications of the proposed model are listed and described in detail in (Nimis et al. 2008). The application component expresses batch jobs or real (web or desktop) applications, which has to be executed on demanded computing resources. Therefore, the consumer of the application submits a resource request to the BidGenerator. On the other side, the resource manager manages the resources of the provider and is responsible for the execution of the allocated applications. In order to offer a free resource, the resource manager submits a request to the BidGenerator for the resource provision.

![Figure 1. Integrated architecture of the related components.](image)

The BidGenerator (Borissov and Wiström 2008) implements common and new bidding strategies (section ), that autonomously generate and place the consumer bids and provider offers. The bids and offers are generated based on the consumer's preferences and the provider's business model, both initiated in the requests to the BidGenerator. A consumer specifies its preferences in form of a description of the required computing resources, duration of the job/application usage, valuation (maximum price) and preferred bidding strategy. A provider specifies its supply request in form of a resource description, duration of the provision, valuation (reserve price) and preferred bidding
strategy. Then the BidGenerator instantiates the selected bidding strategy and starts the bidding process.

The bids are submitted to the Trading Management (TM) component, which implements and runs market mechanisms (section 2.1) for technical and economic matching. The TM is a platform, which defines the interfaces and rules for implementing market mechanisms and the conversation protocol. In our case, the bids and offers (e.g. simplified example will be a CDA for CPUs with 2GHz), which are generated by the BidGenerator, are submitted to the TM via well defined interfaces of the selected market mechanism. When there is a match, the BidGenerator receives and informs the consumer or provider to execute its application on the allocated resource.

The Market Information Service (MIS) (Brunner et al. 2008) obtains economic data from the Trading Manager and provides it to the BidGenerator. The architecture has been designed to meet both the economic information requirements and that of scalability and robustness of distributed environment. Aggregation mechanisms are used to reach scalability in number of data and agent requests. Many of the introduced bidding strategies (Section 2.2) like ZIP, GD are exploiting prediction techniques (see Section 3), which require public market information. The MIS retrieves and aggregates public market information from the TM to provide them to the BidGenerator.

A short sample of products are commodity goods which are analysed commonly in markets, however, we seek to extend the model to more realistic goods for computing resources. We introduce a resource tuple with core description entities as baseline for representing and aggregating market information for computing resources.

**Definition 1:** We define a resource tuple \( R = \{CPU, M, S, T_s, T_e, D\} \), where \( CPU \) is the processing power, \( M \) is the memory, \( S \) is the storage, \( T_s \) is the earliest start time, \( T_e \) is the latest end time and \( D \) is the duration of the job or resource reservation.

A demanded resource request can technically be allocated if each of the individual requirements is met e.g., minimum \( CPU \) of 2GHz, memory capacity of 1GB, storage of 10GB, etc. The same principle is used for the market information system, a bidding agent can search for the minimum, maximum or average price of \( R \), where the individual requirements are met. This information will be used by the prediction mechanisms described in Section 3.1.

## 5 EVALUATION METHODOLOGY

To evaluate the integrated architecture in section 4, market mechanisms, bidding strategies and prediction techniques, we propose a common agent-based evaluation scenario and present first results.

### 5.1 Agent-Based Simulation

Table 1 summarizes the bidding strategies and mechanisms to be evaluated in varying job workload settings. The trading object is a computing resource as a commodity good or resource bundle. Within the simulation we aim to measure the consumer \( U_c \) and provider \( U_p \) utilities and overall welfare adopting various bidding strategies (see 2.2 and 3) in three market mechanisms (see 2.1). Furthermore we aim to measure the quality \( Q \) of the forecast, deviation of real \( R(t) \) to forecast value \( F(t - 1) \), applying the prediction techniques (section 3) in novel bidding strategies, Prediction Traders.

In order to compare the strategies and market mechanism, we define 6 settings, Table 2, whereas each setting comprised from 20 until 200 providers and consumers. Settings 1 to 3 are generated with a Poisson arrival process, suggested by (Feitelson 2008), by increasing the mean \( \lambda \), generating 1000, 3000 and 5000 jobs. Settings 4 to 5 are real workloads, taken from (Feitelson 2008).
### Table 1. Overall simulation scenario.

The workloads *LPC EGEE* (Medernach 2005), *LLNL Atlas* and *LLNL Thunder* are real cluster usage workloads, each containing 234,889, 42,725 and 121,039 jobs, occupying settings 4, 5 and 6. The LPC log was chosen as a basis because it contains a large variety of jobs with different run-times, numbers of used CPUs, and varying submit and start times. Finally, the valuation of a job and the reserve price of a resource are taken from a normal distribution.

#### 5.2 Simulation Results

First results are shown in Table 3. The table shows the evaluation of consumer strategic behavior using Truth-Telling and Q-Strategy (2.2.3) in a centralized CDA (2.1.1), decentralized DLGM (2.1.2) and in a FIFO (2.1.3) mechanisms. The providers are acting strategically only in CDA, in DLGM and FIFO they are offering their resources for free.

### Table 3. Consumer strategic behavior in three mechanisms.

Each line in the table represents the evaluation of a selected bidding strategy in a selected market for one setting. The workloads – setting 1-3 – are created with a Poisson distribution with means $\mu =$
{0.1, 0.3, 0.5} generating 751, 1502 and 3004 jobs. Setting 4 is the real cluster workload – LPC-EGEE, taken from a Parallel Workload Archive (Feitelson 2008). The first two columns represent the setting (corresponding to those of Table 1) and the evaluated strategy. The next two columns represent the average utility per job \( \mu = \frac{\sum_{i=1}^{n} v_{i}^j C_{i}^j + \pi_{i}^j}{n} \) as well as the standard deviation \( \xi \) of job budget and actual payment in DLGM and the last four columns represent the same for CDA and FIFO.

The results show that Truth-Telling strategy achieves the highest average utility for all settings in both DLGM and CDA, which follows that bidding truthfully in DLGM (2.1.2) and CDA (2.1.1) can only increase the consumer utility. Understating the truthful valuation in lower bid results in a poorer “job priority” by DLGM and thus job can be displaced by other jobs which have higher priority. In case of CDA, the prices depend on the current demand and supply, bidding a lower price instead of the truth valuation increases the risk of no allocation by the mechanism. However, in CDA, the matching is based only on the price without considering the “priority” of a job as with DLGM, and thus achieves very low utility compared to DLGM. Furthermore, CDA-provider machine agents do not maintain a priority queue of the submitted job bids and by an allocation the job is immediately submitted and executed on the provider machine. A provider submits an offer as soon as he becomes idle. Thus each time the agents are competing by adapting their job bids based on the used strategy. In overall, the DLGM mechanism outperforms FIFO in all four settings using the Truth-Telling bidding strategy and achieves the highest common wealth for all participating consumer agents.

\[ \text{Figure 2. ZIP agents trading in a CDA with market information.} \]

Figure 2 contains results from simulation of that market in which agents with a ZIP strategy are competing so sell resources as commodity goods. It depicts that the simulations run stable over a period of 50000 trading rounds with 2000 buyers and sellers.

## 6 RELATED WORK

The influence of information to market-based resource allocation mechanisms expands over different research areas. In Section 3, we explained related and potential market-based resource allocation methods and bidding strategies for these mechanisms. We summarize explicitly the information retrieval process and the individual prediction models in Section 4. This related work section describes work concerning the overall evaluation process of different prediction and learning mechanisms based on historical information.

Sandholm and Lai (Sandholm 2008) apply different mechanisms to predict the future demand of computational resources. They conclude to deduct the price of the resources from different real workload traces; however, markets with real market are not analyzed. The goal is to predict high peaks and though allow the consumers to avoid these to get lower prices or other benefits. This is especially important as sophisticated strategies change the markets behaviors. Moreover, different market mechanisms result in different peaks and distribution of the allocations. (Cardosa and Chandra 2007) analyze statistical aggregation for resource allocation. This information retrieval aggregates
historical data, which builds the basis for the prediction mechanisms. They provide further breakout of
a commodity good like analyzed in most market-allocation mechanisms into resource bundles, however, economic mechanisms are not considered. A market-based scheduling mechanism for the
allocation of time-specific resources is shown by (MacKie-Mason et al. 2004). It evaluates different
prediction mechanisms to govern the time slot in competitive bidding process. They started with the
combination of price prediction and bidding strategies to conclude that price prediction improves
performance in a decentralized market-based scheduling environment.

Another survey and evaluation of market-based prediction mechanism is (Wellman et al. 2002), which
analysis the prediction mechanisms of all participants of a trader competition. The evaluation compares price prediction mechanisms such as historical averaging, machine learning, and a
competitive economy analysis in regard to their relative prediction accuracy. Wellman et al. conclude
that a combination of historical data with current information produce the best prediction in a
competitive analysis. In our work we will analyze and compare processes as entities in competition.

We can conclude from the presented related work that many mechanisms for the statistical prediction
of prices exist for markets. Furthermore, different learning mechanisms and trading strategies are
introduced, which are shown in previous sections. The related work, stated in this section, began with
the comparison and analysis of these techniques. However, to our knowledge an overall approach combining the different areas of efficient information retrieval, statistical prediction, learning rules,
trading strategies, and different market mechanisms is still an open issue.

7 CONCLUSIONS

In this paper, we proposed and analyzed alternative approaches to improve information flow within
markets. Those approaches are measured with respect to the impact endogenous trading information
has on the allocation quality. More precisely, we introduced promising market mechanisms, bidding
strategies and prediction techniques, which have been evaluated and selected regarding their potential
to optimize the resource allocation. Afterwards, we explained how these methods can be technically
combined, integrated and evaluated within the allocation and information gathering process. For an
easier and complete evaluation process, we developed a prototype for the proposed framework and
showed baseline experiments with the proof-of-concept implementation. Positive integration results
were obtained within an implemented market system for computing resource allocation.

As part of our analysis, we found that related work often proposes mechanisms in isolation for each
topic, like the market mechanism, bidding strategy or information treatment, without regarding the
complete interaction of components. Moreover, the focus of these mechanisms is not on the
optimization of computational resource allocation. With the prototype, we show the integration of the
approaches in a real framework, enabling autonomous provisioning and usage of computing resources.
We identified evaluation scenarios and metrics for the impact of information in order to determine
suitable combinations of market mechanisms, bidding strategies and related prediction techniques.

The future focus is on the evaluation of the proposed market mechanisms, bidding strategies and
related prediction techniques from consumer to provider side. Applying the evaluation model with the
proposed metrics will enable to measure the impact of real systems and identify optimal configurations
of market mechanisms and bidding strategies with related prediction techniques to enable efficient
market-based allocation of computing resources.

Abstract

Risk/return management has not only evolved as one of the key success factors for enterprises especially in the financial services industry, but is in the times of the financial crisis crucial for the survival of a company. It demands powerful and at the same time flexible computational resources making it an almost ideal application for service-oriented computing concepts. An essential characteristic of service-oriented infrastructures is that computational resources can be accessed on demand and paid per use. Taking the estimation of covariances for a portfolio of risky investment objects as an example, we propose quantification for the economic value of fast risk/return management calculations. Our model analyzes the influence factors on the optimal computing capacity dedicated to these calculations and reveals interesting insights in how far the optimal computing capacity depends on market parameters. Our main result is that more volatile markets require a lower computing capacity as the optimal computing capacity depends positively on changes of the market risk but negatively on the risk itself.

Keywords: Risk/Return Management; Service-Oriented Infrastructures; Grid Computing.
1 INTRODUCTION

Risk/return management is crucial for today’s enterprises in order to strive and even to survive in a market environment that can be characterized by tight competition and global integration of markets. This is more than ever emphasized by the problems arising from the current crisis on the financial markets. Especially in the financial services industry, already strict rules and regulations – that nevertheless have not prevented the crisis – are expected to be much more tightened as generally decided by the G20 meeting in April 2009. Consequently, very sophisticated and resource intensive methods for risk/return quantification and aggregation have to be in place. Innovative approaches of distributed computing like grid computing, cluster computing or service-oriented architectures (SOA) are en vogue in academia as well as in practice, offering potentially suitable infrastructures for the corresponding complex calculations. We will speak of service-oriented infrastructures (SOI) in this context as an instance of (the abstract principle of) SOA where (mostly resource-intensive) distributed services are made available transparently over a grid network. Up to now the intellectual treatment of SOI is usually technically oriented and most often neglecting the necessary economic aspects. Even though these aspects are addressed in general by approaches like for instance “grid economics” or “utility computing”, the reflection on benefits and cost still constitutes a widely unresolved issue for specific application domains. We are therefore striving to narrow the gap between the technical capabilities of service-oriented computing and its economical application in risk/return management.

One basic task in risk/return management is the frequent estimation of the risk exposure associated with a portfolio of investment objects (e.g. securities). Today, enterprises mostly calculate their risk exposure during fixed time intervals like e.g. several days. With the possibly huge amount of computing capacity a SOI based on grid technologies offers (embracing resources of the whole enterprise or even of external resource providers), calculations can be accelerated dramatically (Middlemiss 2004). Nevertheless, economic models quantifying the business value of a more frequent recalculation of the risk exposure are not available yet. Thus, the question arises, what is the optimal amount of computing capacity that should be allocated to risk quantification, considering benefits as well as cost? We will deliver a solution to this problem in the form of an optimization model.

Concerning risk/return management, we restrict our considerations to publications addressing risk forecasting and in particular the estimation of covariance matrices. Huther (2003, pp. 111), or Faisst and Buhl (2005, pp. 408) for example describe the use of covariances for a comprehensive enterprise-wide risk/return management. Other publications are dealing with the question of how covariances can be empirically estimated or forecasted by analyzing historical data. In fact forecasting is “one of the important problems in finance” (Elton and Gruber 1972) and consequently there are a lot of publications already covering the question of how many and which historic quotations should be used to determine a suitable risk forecast. To give an impression about applicable techniques we refer to Engle (1982), Kupiec (1995) and Hull and White (1998). Alexander (1996, pp. 233) provides an overview of the corresponding methods used in volatility and correlation forecasting. Recent approaches to volatility forecasting like conditional autoregressive Value-at-Risk (CAVaR) models are presented in Taylor (2005). Although it is widely known that the corresponding calculations are very resource and time intensive, there is to the best of our knowledge so far no publication dealing with the specific problem of quantifying the economic value of a frequent (re)calculation of risk.

Grid computing can be regarded as an infrastructure technology enabling the virtualization of physical resources. Available definitions for the term grid computing are mostly of descriptive nature and provide little more than certain essential characteristics (see e.g. Foster 2002; Foster et al. 2001, 2002;
Foster and Kesselman 1998). However, various proponents have agreed with Foster and Kesselman (1998) that “a computational grid is a hardware and software infrastructure that provides dependable, consistent, pervasive and inexpensive access to high-end computational capabilities”. Recently, an evolution towards SOA can be observed (Longworth 2004). Grid technologies are one possibility to realize a SOA consisting of so called “grid services”. Grid services are based on specific web service standards, like the specifications (Open Grid Services Architecture) and (Web Services Resource Framework). They extend web services insofar as they imply the dynamic, yet for the user transparent, allocation of (physical) resources to services by a grid middleware and therefore are especially suited to fulfill resource intensive tasks. There is an extensive literature on service-oriented computing or grid computing in general (see for instance Berman 2005; Foster and Kesselman 1998; Silva 2006; Singh and Huhns 2004). Some publications even consider the application of these technologies for portfolio management, derivatives pricing or other areas of financial risk management (Brownlees et al. 2006; Crespo et al. 2006; Schumacher et al. 2006). However, these approaches describe how grid technologies can be applied, but do not quantify the resulting business value. In the context of grid computing also resource allocation mechanisms have been widely discussed—most often under the term “grid economics”. We refer to Regev and Nisan (1998), Buyya et al. (2000), Nabrzyski et al. (2003) and Wolski et al. (2004) which provide an overview of this area. They most often dwell either on the question which principles are appropriate to resource management or on technical and architectural issues connected with the development of resource management systems. Accordingly, in most of the existing approaches demand for computational resources is merely an external factor whereas in our approach it is subject to optimization.

In this context an important characteristic of SOI based on grid technologies is the on-demand access to distributed resources. When resources stem from an external provider this concept is often labelled utility computing, meaning that resources can be consumed und priced as easy as for instance electricity or water. Utility computing has been subject to research as well. Bhargava and Sundaresan (2004) analyze pay-as-you-go pricing scenarios where providers guarantee computing capacity, but users do not make a commitment towards actual use. Our paper to some extent continues the ideas of Bhargava and Sundaresan (2004). However, we take the perspective of a service user and present a rationale for decisions on computing capacity in the context of risk/return management.

2 RISK/RETURN MANAGEMENT

The term “risk” is used heterogeneously in general speaking as well as in academic circles. Therefore we feel that it is appropriate to begin with a definition of risk before we describe the various requirements and objectives of risk/return management applications. While in the economic literature risk is often generically explained as the “possibility of missing a planned outcome” we will follow a more finance-related approach. From this point of view we define with Schröck (2001, p. 24) risk as “the deviation of a financial value from the expected value”. A positive deviation is often in general speaking referred to as “chance” while a negative deviation is characterized as “danger”. Because of this two-sided perception of risk, variance or standard deviation of a risky value are suitable and well accepted measures of risk. We will use the standard deviation of historical portfolio returns as the risk measure later in this text. Synonymously we will speak of the volatility of a portfolio and define it as the “annualized standard deviation of percentage change in daily price” (Spremann 2003, pp. 154).

Enterprises are investing capital into investment objects in order to generate cash inflows and subsequently to increase the return of the invested capital. Typically risk-averse management is making risky investments hoping to achieve an excess return over the risk-free rate. There is a general connection between risk and return of an investment object: higher return is systematically associated with higher risk. This connection is theoretically explained by economic models like the CAPM (the “Capital Asset Pricing Model” was originally developed by Sharpe (1964), Lintner (1965) and Mossin (1966) and empirically evaluated later on (an overview of relevant empirical studies can be found e.g. in Copeland and Weston (1988, pp. 212)). Following the argumentation of Wilson (1996, pp. 194) it is
therefore crucial for the survival and success of an enterprise to be able to allocate the available capital to the right combination of investment objects, taking into account their specific contributions to the overall risk and return. Investment objects in this context are not restricted to securities. Almost all business transactions are associated with uncertainty and thus contribute to an enterprise’s overall risk exposure. Thus in the spirit of an enterprise-wide risk/return management all investments an enterprise is engaged in, like credit decisions or even customers or projects can be seen as components of the enterprise’s overall investment portfolio, having a return and a variance (as a measure of risk).

One major goal of risk/return management in this context is the prevention of bankruptcy by restricting potential losses resulting from risky investment objects. The increasing importance of this goal is emphasized by the current crisis on the financial markets. A growing number of rules and regulations require enterprises to hold a part of their available capital to back their risky investments (Jackson et al. 1998, pp. 8). This share of the available capital then makes less or no contribution to the overall earnings. By management decisions these restrictions are broken down along the organizational hierarchies into guidelines on business unit or departmental level. We are assuming in the following text that those guidelines are essentially representing limits for the maximum risk a department, business unit and consequently an enterprise is willing (or able) to take.

In order to evaluate whether an enterprise or department complies with a given risk limit, it is necessary to calculate the current risk exposure frequently. For simplifying means, we concentrate on one fundamental instrument in this paper: The covariance approach. This constitutes a basic principle in finance and forms the foundation for many risk/return management applications ranging from Markowitz portfolio optimization to Value-at-Risk (VaR) calculations. In our context covariances are used for determining the overall risk position of an enterprise taking into account diversification effects that exist between the investment objects. Nevertheless, the proposed methods are also applicable to other risk measures as long as they take dependencies between single investment objects into account.

Following the covariance approach, we can represent risky investment objects by random variables. Typically historical data are used in order to derive a distribution for a random variable and calculate the distribution parameters. It is worth mentioning that considering the portfolio risk and return merely on an aggregated level is not satisfactory because all information is lost about the risk attributable to a single investment object. It is crucial to separate the portfolio and decompose it into data per investment object, i.e. to calculate the covariances. Only then the enterprise can perform economically rational investment decisions on different aggregation levels. With \( \sigma^2_i \) and \( \text{Cov}_{ij} \) denoting variance and covariance of investment objects respectively we can determine the overall risk of a portfolio \( \sigma^2_j \), consisting of \( n \gg 0 \) investment objects (numbered from 1 to \( n \)), as

\[
\sigma^2_j = \sum_{i=1}^{n} \sigma^2_i + \sum_{i=1}^{n} \sum_{j>i} \text{Cov}_{ij} = \sum_{i=1}^{n} \sum_{j=1}^{i} \text{Cov}_{ij}
\]

The so defined matrix of all covariances is called covariance matrix. An important characteristic of covariances is that \( \text{Cov}_{ij} = \text{Cov}_{ji} \). This makes the matrix symmetric and thus not all of its values have to be calculated. The total number of covariance calculations necessary is given by \( n(n+1)/2 \).

3 A VALUATION MODEL FOR FAST RISK QUANTIFICATION

We consider an enterprise which has access to (and is possibly engaged in) a set of risky investment objects as well as to a risk-free investment alternative. It is frequently (re)calculating its overall risk position by estimating the covariance matrix of its portfolio. Our main hypothesis for the valuation of

\[A\] A thorough overview and discussion of the statistical analysis of financial data can be found in Shiryaev (1999) pp. 314.

\[B\] As we analyze the complete investment objects and not parts or quantities of investment objects (e.g. stocks), this formula contains no weights.
benefits is: the faster risk/return management calculations can be executed the higher will be the return of the enterprise because given risk limits can better be exploited.

Since the enterprise is acting in an uncertain and dynamic environment its risk position is changing willingly (by investment decisions) or unwillingly (by “movement” of the markets). Because the estimation of risk cannot be accomplished in real-time the covariances at hand are always significantly outdated. We are in the following recurring to the fact that the enterprise is adjusting its risk position to a value somewhere below a certain threshold thus constituting a “safety margin”. In the regulatory context this is often called “haircut”, like in Basel Committee on Banking Supervision (2004). The financial crisis made clear, that – depending on the assets invested in – a high safety margin is necessary to account for changes of parameters, especially in liquidity. It is doing so by using the capital allocation between the risky investment objects and the risk-free alternative for balancing their overall risk position. It is important to understand that our model is not addressing the evaluation of the efficient set of investment objects or portfolio optimization (both require covariances), but the aggregation and management of the risk position of an enterprise. Whenever covariances are available the safety margin can be adjusted immediately in a way that the resulting (and over time changing) overall risk position of the enterprise does not exceed the given risk limit at any time. Hence, the faster covariances are available, the smaller the safety margin can be. We will use this effect to quantify the benefits of fast covariance estimations depending on the time needed for the completion of one covariance matrix.

3.1 Model Setting and Basic Assumptions

The time interval under consideration consists of equidistant periods such that $t=0$ denotes the beginning of the current period. We shall write for example $\sigma_t$ to indicate the value of a model parameter at the end of period $t$. Correspondingly (dis)investment decisions take effect only at the end of each period. If not mentioned otherwise all variables assume real values, i.e. values $\in \mathbb{R}$.

The enterprise is equipped with a total capital of $K>0$ which is always completely allocated to the risky portfolio and/or the risk-free alternative. We denote the risky portion of $K$ with $x \geq 0$ and furthermore use $x$ for risk adjustment. $T$ indicates the length of the calculation time frame, $T \in \mathbb{N} \setminus \{0\}$ with $\mathbb{N}$ as the set of natural numbers. At the end of each time frame we choose $x$ in a way that the risk limit is “probably” not exceeded during the next time frame. We will formulate more precisely what is meant by “probably” later on. Future returns of the portfolio are modelled as independent random variables. Their probability distribution for each period can be characterized by mean and standard deviation. This implies that the investment objects can be marked to market, i.e. there is a price attached to them. We additionally need a set of assumptions for the deductions following thereafter.

**Assumption 1** The enterprise is generally risk-averse and striving for efficient combinations of investment objects. Investment objects are perfectly divisible and traded on a no-frictions market.\(^4\)

**Assumption 2** The risky part of the enterprise’s capital yields the expected return $\mu$, the risk-free investment pays the time-invariant risk-free interest rate $i$, which is equal to the borrowing rate.\(^5\) We always have $\mu>i>0$.

Assumption 2 is made in the spirit of the model of (Modigliani and Miller 1958) where enterprises and investors can borrow or place money at will for a risk-free rate, but expect a premium for taking the risk associated with the investment in risky assets. With the so defined parameters and $x$ as decision

\(^4\)In the sense of the “Portfolio Selection” theory (Markowitz, 1971) investors are trying to achieve the highest possible return on their investment for a given risk. They are acting under perfect trading conditions, i.e. no arbitrage, no transaction cost, strong information efficiency etc.

\(^5\)The equality of lending and borrowing rate is assumed for sake of simplicity and justifies the case $x>1$, where the enterprise is actually borrowing money for making risky investments.
variable we can determine the overall expected return \( \mu^U(x) \) and risk \( \sigma^U_t(x) \) of the enterprise according to common rules of statistics as

\[
\mu^U_t(x) = x\mu + (1-x)i = i + x(\mu - i) \quad \text{and} \quad \sigma^U_t(x) = x\sigma_t.
\]

(1)

The overall risk of the enterprise is expressed by the portfolio risk (the enterprise is the weighted “sum” of its investment objects) and thus changes over time driven by the varying \( \sigma_t \). Note that due to our focus on changing risk we do not regard a changing \( \mu^U_t(x) \) over time (which would result in an index \( t \) as in \( \sigma^U_t(x) \)). As we see, with ascending \( x \) the overall returns as well as the overall risk of the enterprise are both increasing. On the one side the enterprise certainly strives for the highest possible return, on the other side a limitation exists for \( x \) from the given risk limit.

It is common practice to use some variation of a random walk for the price movement on security and commodity markets. This approach goes ultimately back to Louis Bachelier (1900) who compared the stock market with a “drunkards walk”). Although controversially discussed, it was picked up more than half a century later by Mandelbrot (1963, 1972) and Fama (1965) among others. Following this theory of random walks historical (e.g. daily or weekly) portfolio returns can be used for estimating mean \( \mu \) and standard deviation \( \sigma_t \) of future portfolio returns. It is important to understand that in our model the standard deviation is possibly changing in each period (indicated by its index \( t \)).

**Assumption 3** The initial calculation of covariances starts in \( t=0 \) and is finished after \( T \) periods. Each new covariance calculation begins in the finishing period of the previous covariance calculation.

According to assumption 3, whenever a covariance matrix is completed, the input data used for its calculation are \( T \) periods old. We can immediately determine the portfolio risk by summing up the covariances in the matrix. This can then be used for a risk adjustment decision as well as for portfolio optimization. The moment before the next matrix is finished the input data used for risk calculations are already \( 2T \) periods outdated. Therefore the uncertainty interval that has to be taken into account spans \( 2T \) periods: in the worst case the risk has been going up over \( 2T \) periods before the enterprise realizes that it is exceeding the maximum risk it is willing (or able) to take (see figure 1). Without loss of generality we will concentrate our analysis on the first covariance matrix calculation and the corresponding adjustment decision, therefore focussing on the time interval \([0;2T]\). During this time the portfolio risk is fluctuating in a non-predictable way.

![Figure 1. Period Model and Relevant Time Intervals.](image)

### 3.2 The Risk-at-Risk Approach

We will now dwell on the portfolio risk at time \( t \), denoted as \( \sigma_t \), modelling it as a random variable. This relates to a phenomenon known from the behavior of stock market prices called **heteroscedasticity** (see e.g. Spremann 2003, pp. 152). In analogy to the periodical returns we write

**Assumption 4** The \( \sigma_t \) are normally distributed.

This distribution assumption can (and would in practice) be relaxed by approximating the distribution of the \( \sigma_t \) delivered by the calculated sequence of standard deviations. Arranged in increasing order one
can easily deduce the quantiles needed in our model. Nevertheless, for reasons of simplicity and without significantly changing the general result we assume \( \sigma_t \) to be normally distributed here.

We will again focus on two distribution parameters: Our notation for the (strictly positive) mean will be \( \mu \), for the standard deviation \( \sigma \) (both tagged with an \( \sigma \) indicating the fact that the distribution applies to the portfolio risk), thus \( \sigma_t \sim N(\mu_t; \sigma_t) \) with \( N \) short for the normal distribution.

The distribution parameters in our model can again be estimated using historical data. For example, the standard deviation of the portfolio risk can be taken as an estimate for the expected portfolio risk \( \mu_t \) and thus as the starting point for the random walk of \( \sigma_t \). In order to maximize \( x \) in equation (1) under the given constraints we have to consider the uncertainty interval \([0;2T]\). Because of assumption 4 the standard deviation of the expected portfolio risk after \( 2T \) periods is (as a sum of normally distributed random variables) again normally distributed according to \( N(\mu_t; \sigma_t \sqrt{2T}) \). As a consequence for the overall risk of the enterprise we have \( \sigma^x_t(x) \sim N(\mu_t; \sigma_t \sqrt{2T}) \).

In order to rephrase the fuzzy formulation “the risk limit is probably not exceeded” we will follow an approach comparable to the VaR for quantifying portfolio risk. We speak of a Risk-at-Risk over a holding period and a confidence level \( \alpha \), \( 0 < \alpha < 1 \) and think of it as the standard deviation \( \sigma \) which is exceeded within the holding period only with the (small) probability of \( (1-\alpha) \). With \( \Phi(x) \) denoting the standardized normal distribution function, we know for the distribution of \( \sigma^x_t(x) \) over \( 2T \) periods that

\[
P(\sigma^x_t(x) \leq \sigma) = \Phi\left( \frac{\sigma - x\mu_t}{\sigma_t \sqrt{2T}} \right)
\]

At the same time we require in the spirit of the Risk-at-Risk approach the probability given above to be greater than or equal to the confidence level \( \alpha \), i.e.

\[
P(\sigma^x_t(x) \leq \sigma) \geq \alpha \quad \text{for } t = 2T
\]

In the marginal case both sides of the equation are equal and we can therefore state—with \( q_\alpha \) as the (onesided) \( \alpha \)-quantile of the standardized normal distribution—that

\[
\frac{\overline{\sigma} - x\mu_t}{x\sigma_t \sqrt{2T}} = q_\alpha \iff x = \frac{\overline{\sigma}}{q_\alpha \sigma_t \sqrt{2T} + \mu_t} = q_\alpha
\]

\( x \) gives us the portion of risk-free and risky investment objects in a way that equation (2) holds. We can calculate the overall expected earnings of the enterprise, given this capital allocation, as

\[
B(x) = \mu^U(x) \cdot K = (i + x(\mu - i)) \cdot K
\]

Obviously \( B(x) \) represents only expected, calculatory (and not real) earnings because the returns are not fully cash-flow effective and the earnings themselves subject to interpretation. We will neglect the adjectives “expected” and “calculatory” and speak of earnings or, more generally, of benefits.

By inserting \( x \) from equation (3) into \( \mu^U(x) \) from equation (1) we find for the benefits (with the number of periods needed for the completion of one covariance matrix as the independent variable)

\[
B(T) = \left( i + \frac{\sigma(\mu - i)}{q_\alpha \sigma_t \sqrt{2T} - \mu_t} \right) \cdot K
\]

Considering equation (4) an enterprise could maximize its benefit by minimizing the time \( T \) that is needed to calculate a covariance matrix. Yet there is a trade-off between the benefits and the cost, i.e. cost caused by the infrastructure that is necessary to compute the calculations.
4 SERVICE-ORIENTED INFRASTRUCTURES FOR RISK QUANTIFICATION

From a SOI point of view the risk calculation can be regarded as a service providing its user transparently with up-to-date risk information for the relevant investment universe. In this section we derive the relationship between the computing capacity (i.e. cost) allocated to risk quantification and the time needed for the computation.

4.1 Computing Capacity for Risk Quantification

We denote with $z$ the computing capacity necessary for estimating one covariance matrix in exactly $T$ periods. We use CPUs as a measure for computing capacity and are aware of the fact that this means a one-dimensional view on matters as other determinants of system performance are ignored. We denote with $w$ the workload—measured in CPU hours—for estimating one covariance. Applying a simple moving average technique with a rolling sample of historical data (Elton and Gruber 1972, pp. 409) we get unbiased estimators of the expected value and (co)variances for every point in time.

**Assumption 5** The same workload $w$ is necessary for estimating variances and covariances. Furthermore every covariance is estimated from scratch, i.e. no intermediate results are used.

**Assumption 6** The length of the calculation time frame $T$ depends solely on the time needed for the computation, neglecting e.g. latency or transmission times. Correspondingly the only cost relevant is cost for computation which occurs in the form of a (internal or external) factor price per CPU hour over a given time.

Note that for the calculation of covariance matrices on a SOI it is convenient that the computations can be distributed on several nodes and executed in parallel, as all pairwise covariances can be calculated independently from each other. Thus efficiency losses are considerably low.

We can now deduce the computing capacity $z(T)$ (workload per time) that is required in every period over $T$ periods. We already know that for $n$ investment objects $n(n+1)/2$ covariances have to be calculated. Multiplied with the workload per covariance this determines the total number of CPU hours needed. This in turn—divided by the calculation time frame—leads to the functional relationship

$$z(T) = \frac{n(n+1)w}{2T} \Leftrightarrow T(z) = \frac{n(n+1)w}{2z}$$

(5)

Given $n$ investment objects and a computing capacity of $z$ CPUs, the covariance matrix will be completed after $T(z)$ periods. This constitutes an important parameter of the covariance estimation service since it describes the economic value that should be attributed to the consumption of capacity for covariance estimation. By inserting (5) into equation (4) and neglecting the mean risk compared to the standard deviation of the risk we quantify the benefits as

---

$^6$Variance estimation requires only one historical time series, so its intrinsic workload is smaller than the workload for covariance estimation. Nevertheless, this effect can be neglected since for $n$ variances there are $n(n-1)/2$ covariances in a given covariance matrix. With $n$ sufficiently large the variances have merely no effect on the number of calculations (e.g. with $n=201$, the number of variances is only 1% of the number of covariances to be calculated).

$^7$This could be considered awkward for the simple moving average procedure but is a realistic approach for more sophisticated methods.

$^8$Here as well as for the optimal $T(z^*)$ later in this text the outcome is assumed real-valued. In reality and in order to fit it to the discrete-time period model one has to check the neighboring integer values to obtain the discrete optimum.

$^9$The exact quantification would lead to a strictly increasing and concave benefit function $B$, as well. It would nevertheless be tedious to continue in our analysis with the exact expression. In order to avoid writing overhead we deliberately simplify our objective function by neglecting the mean risk, which is a numerically justifiable approximation in our context.
\[ B(z) = a + 2b\sqrt{z} \quad \text{with} \quad a = iK > 0, \quad b = \frac{\sigma^2(\mu - i)K}{2q_0\sigma_\alpha \sqrt{n(a + 1)w}} > 0, \quad B'(z) = \frac{b}{\sqrt{z}} > 0, \quad B''(z) = -\frac{b}{2}\frac{1}{2z^2} < 0. \] (6)

\( B(z) \) is a strictly increasing and concave function.

4.2 Optimizing Computing Capacity on a Service-Oriented Infrastructure

In this paper we abstract from a specific SOI framework or technological implementation, but only consider the essential characteristics of such an infrastructure: A service user can consume exactly the amount of resources needed and is charged by the service provider on a pay-per-use basis. Thereby, it makes no difference whether resources stem from internal sources like enterprise-owned desktop computers and servers that are connected via a grid network or from an external provider. In the case of allocating the (limited) resources of an internal SOI, the enterprise faces opportunity cost that may be taken as a usage price. For external resources a price per unit of computing capacity is set by the provider. The price can be changing depending on the contract and service level agreement used. For example resources could be more expensive when delivered fail-safe during peak times while covering basic load on a lower service level might be cheaper (Bhargava and Sundaresan 2004, p. 203).

In an external provisioning scenario we assume a straightforward cost function using a factor price \( p \) (measured in e.g. $ per workload over a period). Using equation (6) our cost function \( C(z) \) and our objective function \( Z(z) \) then are defined as

\[ C(z) = pz, \quad Z(z) = B(z) - C(z) = a + 2b\sqrt{z} - pz. \]

Note that—as it is generally the case for the parameters in our model—\( C(z) \) describes the cost per period and \( B(z) \) the benefits per period depending on the capacity used per period for the completion of the covariance matrix over \( T \) periods. As the difference of a strictly concave benefit function and a linear cost function, \( Z(z) \) is again a strictly concave function. The first derivative \( Z'(z) = b/\sqrt{z} - p \) features its only null at \( b^2/p^2 > 0 \). Due to the strict concavity of \( Z(z) \) and with respect to equation (6) the only maximum of \( Z(z) \) is at

\[ z^* = \frac{b^2}{p^2} = \frac{\sigma^2(\mu - i)^2K^2}{4q_0^2\sigma_\alpha^2n(n + 1)wp^2}. \] (7)

On a short-term, iterative basis this result can be used to allocate resources of an external provider to risk/return management services. It is possible to examine in detail how input parameters affect \( z^* \). For example the more capital the enterprise has to its disposal the more (in absolute terms) it will invest into risky investment objects. Higher risk exposure in turn increases the importance of risk/return management which is correctly reflected by the positive sign of \( \partial Z/\partial \alpha \). The same argumentation holds when the enterprise faces a higher risk limit \( \sigma \). In this case it should allocate more capacity to risk/return management applications, which is consistently leading to an increasing \( z^* \). Eventually when the risk premium \( (\mu - i) \) rises (due to higher \( \mu \) and/or lower \( i \)) investing into risky objects becomes more attractive, resulting in a larger share of risky capital. In order to manage the consequently more voluminous portfolio our model suggests that additional capacity should be allocated. In the denominator of equation (7) we have the parameter \( w \) determining the CPU hours needed for one covariance estimation. Increasing \( w \) generates higher cost. This in turn leads to less capacity allocation in the optimal case, reflecting the known trade off between accuracy and speed of risk/return management calculations. The behavior of \( z^* \) depending on the confidence level \( \alpha \) is quite surprising. Theoretically \( q_\alpha \) could grow infinitely (with increasing confidence level \( \alpha \)) leading to an infinitesimal small \( z^* \). This is the case because in our model the only way to account for a higher confidence level is a larger safety margin. This causes diminishing benefits and therefore a decreasing \( z^* \) in the optimum. Another interesting and to some extent counter-intuitive result is produced in combination with the parameter \( \sigma_\alpha \). One would possibly expect that with increasing volatility of the portfolio risk the optimal capacity allocation increases which is actually not true. Basically, for a given risk limit \( \sigma \) a higher volatility of the portfolio risk can be leveraged by faster risk calculations (so that the enterprise...
can still get close to the risk limit without hazardously exceeding it during the uncertainty interval). Going back to Bachelier’s proposition the benefits of fast covariance calculations are of order $\frac{1}{\sqrt{T}}$. On the other side, the cost are depending on $T$ in a reciprocal ($1/T$) fashion. As a consequence for higher volatility of the portfolio risk the cost are increasing more quickly than the benefits, leading ultimately to an increasing $T^*$ and decreasing $z^*$, respectively.\(^{10}\)

Figure 2 shows a numerical example of the described optimization. All values are per hour and were in parts estimated from intraday data of the German stock index DAX. The example pictures a company with capital of $K=50$ million $ and $n=200,000$ investment objects. The company tries to hold a risk limit of $\sigma=0.1\%$ with a confidence level $\alpha=99\%$. It can realize a risk free return $i=0.0008\%$ and a risky expected return $\mu=0.001\%$. The workload per covariance is assumed $w=2.5\times10^{-10}$ CPU hours, the price per CPU $p=2\$. It features an optimum at 72 CPUs.

Besides this straightforward linear cost function, especially in an internal provisioning scenario, more complex cost structures may apply. For instance, in a scenario where a high number of services are competing for a limited number of resources, opportunity cost may not increase proportionally, because ever more services with increasing opportunity cost are suppressed. After all, it becomes clear, that a detailed analysis of cost structures along with the knowledge of the concrete utility function of a service not only delivers the opportunity to allocate resources on-demand. The analysis also supports design decisions concerning for instance the questions whether external or internal provision or a mixture of both is preferable, whether or not the service should be deployed doing risk calculations in the background and whether an existing SOI is sufficient or should be enlarged due to an already high utilization rate resulting in high opportunity cost.

5 LIMITATIONS OF THE MODEL AND CONCLUSION

In this paper we demonstrated how the economic value that can be derived from risk/return management calculations can be measured considering an enterprise that has to decide on the amount of capital it wants to reserve to cover potential losses resulting from a risky investment portfolio. Several assumptions (e.g. regarding the distribution of the expected portfolio risk) were necessary to achieve an analytical solution.

Using the covariance approach as an example we moreover developed an optimization model that delivers the optimal amount of computing capacity that should be allocated to risk calculations at a time. In doing so we restricted our analysis to one well-defined risk/return management problem. Although covariances are fundamental and widely used in financial applications we thereby covered only one element of numerous risk/return management methods and algorithms. Other approaches and applications for SOI concepts (like for instance Monte-Carlo simulations which also have a very high parallelization potential) have to be examined as well. In fact, most of the basic principles introduced in this paper can be adapted to other scenarios in more sophisticated and complex surroundings.

Putting it all together a SOI is especially advantageous when market parameters determining the benefits of risk calculations are highly volatile as could be observed during the crisis since July 2007.

\(^{10}\)Such a situation could be observed e.g. during a “regime switch” between two volatility clusters where a time interval with relatively low volatility switches into an interval with higher volatility or vice versa.
resulting in varying demand for computing capacity. With a SOI, resources can be reallocated at any time to reach an economic optimum. As discussed, not only benefits but also (opportunity) cost may vary depending on the total demand for capacity. For example, during “quiet times” risk calculations may be computed more frequently generating added value out of readily available excess capacity even if benefits are comparably small. One caveat not mentioned in this paper is information security. As information on investment objects may be sensitive business data, spreading the calculations over the company or even over service providers may not be desired. Implementing a system as described would therefore require additional security mechanisms and persuasion of the management.

After all, this paper is a contribution to understand the application of service-oriented infrastructures in the specific domain of risk/return management. Although a validation of our findings based on real-world data is still subject to further research, in our point of view, such a systematic and economic analysis is a requirement as a first step for the further development of the new concepts like service-oriented computing or utility computing.

Abstract

This paper summarizes an empirical investigation that explored biased project reporting by Information Systems (IS) professionals. The study is based on a survey of 91 professionals who were involved with system implementations in various governmental agencies. Our investigation assessed the impact of project importance, control, structure, and size on biasing behaviors. To formulate the research hypotheses for our study, we adopted a Message Exchange Perspective. The results reveal that IS professionals are more likely to bias their project status communications when working in projects that are (1) large, (2) important, and (3) lack controls. The practical and research implications of our findings are discussed.

Keywords: Information systems development, project reporting, biased reporting.
1 INTRODUCTION

Recent empirical evidence has highlighted an important impediment to the effective management of information system (IS) development initiatives: inaccurate project status reports (Iacovou, 1999, Snow and Keil, 2002b, Snow and Keil, 2002a, Snow et al., 2007, Smith and Keil, 2003, Keil et al., 2004, Keil et al., 2007). Project status reporting refers to the communication of information about the status of a project to interested decision makers, such as project managers, sponsors, and auditors. Typically, in such updates, the reporter compares the state of the project versus expectations in a project plan, and identifies issues that may cause problems in its completion. Without accurate status reports, project executives are unable to direct their projects effectively, allocate resources efficiently and respond to problems in a prompt fashion (Thompson et al., 2007).

The research stream that investigated the presence of inaccurate status reports in IS initiatives identified two sources of misreporting. The first source is reporting error and it refers to unintentional inaccuracies and omissions that the providers of status updates make due to cognitive and information processing limitations. The second source is reporting bias and refers to the deliberate distortion of project status updates by such reporters (Snow and Keil, 2002a). While we recognize the importance of both sources of misreporting, the focus of our investigation is on bias. Specifically, we focus on the set of behaviors that an individual pursues in order to convey an impression of the project status to his/her supervisor that it is different from the one that is actually perceived by him/her.

Biased status reports in IS projects seems to be a significant issue. In a survey of 56 project managers, Snow et al. (2007) found that bias was employed in 60% of the reports. And in surveys of 485 IS project managers and 210 project participants, Thompson et al. (2007) found that status reports are frequently “less than perfect” and that biased reporting is associated with poor project outcomes. Given the occurrence and negative impacts of biased reporting, our investigation aims to identify the types of projects that are prone to such biasing. The research question that frames our work is: how do project characteristics influence the propensity of project participants to bias their status reports? To address this question, we adopt the Message Exchange Theory (MET) to provide a conceptual foundation for our investigation. To the best of our knowledge, this is the first empirical attempt to identify project traits that affect biasing in project reporting.

The rest of the paper summarizes our investigation. In the next section, we review prior organizational communications and IS literature to summarize MET and relevant empirical findings. This is followed by a summary of our research model and the hypotheses that support it. The research methodology that we employed to carry out the investigation is described next. We conclude the paper by discussing the study’s findings, limitations and implications.

2 A MESSAGE EXCHANGE PERSPECTIVE OF BIASED REPORTING

The Message Exchange theory (MET) considers communications as message exchanges within dyads of organizational actors; for an overview of the theory, see Stohl and Redding (1987). A major research stream in MET deals with the study of deliberate misreporting in hierarchical dyads (Read, 1962, Fulk and Mani, 1986, Mellinger, 1958, Jablin, 1979, Roberts and O'Reilly, 1974, Athanassiades, 1973, Chow et al., 2000). Given the consistency between the scope of the MET theory and the focus of our work, we decided to adopt it as the conceptual foundation for our investigation.

The MET proposes that messages can serve various functions in organizational settings. For example, they can be used to provide directions, to establish and nurture relationships, and so on. A predominant purpose of such messages is to serve to attain specific goals (Fulk and Mani, 1986, Stohl and Redding, 1987, Jablin and Sussman, 1983). Thus, while full disclosure may be desirable from the perspective of facilitating project management, the MET posits that such disclosures may be
inconsistent with the needs or goals (such as a desire to further their own careers, to secure resources for their work tasks, etc.) of the message senders. Depending on the situation, reporters may prioritize their needs-goals higher than the need to provide accurate and complete information to others (Read, 1962, Tesser and Rosen, 1975, Pfeffer, 2004, Grover, 2005). Consequently, biased reporting will occur in the transmission of reports in organizational settings (Read, 1962, Grover, 2005, Fulk and Mani, 1986, O'Reilly, 1978, Roberts and O'Reilly, 1974, Keil and Robey, 2001).

A variety of communication techniques can be pursued to bias reports, such as the alteration or withholding of relevant status information (Keil and Robey, 2001, Smith and Keil, 2003, Snow and Keil, 2002b). In our context, alteration refers to the misstating of the condition of project activities and/or the magnitude and causes of problems (or achievements). Withholding refers to the deliberate omission of relevant facts or issues that are related to the state of project activities (Fulk and Mani, 1986, O'Reilly, 1978, Roberts and O'Reilly, 1974, Bavelas et al., 1990, Athanassiades, 1973).

A recent study (Snow et al., 2007) identified several motivations that might lead reporters to offer biased status updates in IS projects. The study found that biased reporting could arise both from self-serving motivations (to further the reporter's own goals) and project-supporting motivations (to increase the likelihood of success for the project). According to the study, reasons cited for biasing included: 1) a fear of communicating bad news (because of a risk that executives might “shoot the messenger”); 2) a desire to make the reporter look good or to avoid looking bad; 3) a belief that project problems could be overcome in the end; and 4) a desire to avoid letting others down. Other reasons for biasing included the reporters’ desire to secure slack resources for their project, concerns about the team’s ability to meet the project’s goals, or a hope to be perceived as a “hero” who turned around a troubled project.

While the MET recognizes that biased reporting may provide perceived benefits for the reporter or the project, it is important to acknowledge that such biased disclosures are risky (for the reporters) and are likely to result in negative consequences if they are detected. Therefore, biasing is more likely to occur when (1) the expected benefits of biased reporting are high, and (2) the risk of detection and expected severity of reprimand are low. This assumption is supported by the findings of prior research, which illustrated that selective reporting is more likely under conditions of information asymmetry (Baiman, 1990, Keil et al., 2000). Consistent with this prior research, we expect that reporters in IS projects will recognize the risky nature of biasing, as the recipients of their reports are likely to view biasing unfavorably (even when well-motivated) as it hinders their ability to monitor and lead the project effectively. Consequently, we expect that project conditions that enhance the perceived benefits of biasing (to reporters or projects) and minimize its risks will increase the likelihood of misreporting in status reports.

3 RESEARCH HYPOTHESES

Based on our review of the IS project management literature, we identified four project factors that are likely to be significant in terms of their influence on biasing in project reporting. These factors are: project importance, structure, control, and size. We decided to focus our investigation on these four factors because (1) they appear to be salient to the arguments of the MET-based perspective and (2) they have been shown to impact both project outcomes and communications (Barki et al., 2001, Henderson and Lee, 1992, McFarlan, 1981, Francalanci, 2001) suggesting that they may be affecting project results through their influence on reporting. By investigating the influence of these factors, we are hoping to identify the types of projects that are prone to biasing. To identify the role that these factors play with respect to biased reporting, we use MET-based arguments to derive the hypotheses that form our research model (see Figure 1). Each hypothesis is described next.
Project Importance: Importance refers to the significance that the organization places on the system under development (Barki et al., 2001). It is determined by its strategic potential and the operational value of the system. Importance is likely to increase the likelihood of biasing because it enhances the potential benefits that can be accrued to reporters who engage in effectual misreporting. When faced with bad news in major undertakings, reporters will be more likely to hide problems in order to avoid the negative political repercussions that may be delivered to those associated with the project or those that deliver negative assessments (Iacovou, 1999). Likewise, the political benefits to those seen as responsible for the success of a significant project are likely to be more consequential (Keil, 1995). In sum, we expect that biasing is likely to yield higher rewards in important projects. Consistent with this assertion, Bean (2001) found empirical support for the relationship between project importance and distortion. Thus, we anticipate that participants in high importance projects will bias their reports more frequently than those in low importance ones (Hypothesis 1).

Project Structure: Structure refers to the level of preciseness and stability in the specifications of the desired project deliverables (McFarlan, 1981, Nidumolu, 1995). Low structure projects experience a lack of specificity in the system requirements and frequent changes to them over the course of the project; high structure projects, on the other hand, have clearer and more stable requirements (Nidumolu, 1996, Lee and Xia, 2002). Biasing is more likely to occur in low structure projects because ambiguity and dynamism make it more difficult for report recipients to detect it, which in turn makes it a less risky behavior. Further, the unclear specifications of a low structure project are likely to intensify the difficulty of project management, making it more difficult for supervisors to monitor the progress of project work (Campbell, 1958). When faced with conditions of unstructured requirements and dynamism, even experienced managers must rely on the specialized expertise of team members to gauge progress and direct the project, which makes biasing less likely to be detected and scrutinized. Thus, we assert that participants in low structure projects will bias their reports more frequently than those in high structure projects (Hypothesis 2).

Project Control: Control refers to “the set of mechanisms designed to motivate individuals to work in such a way that desired objectives are achieved” (Kirsch et al., 2002). The introduction of structured
controls in a project is likely to decrease the incidents of biasing as it will make their potential
detection more likely (and thus will make biasing more risky). Misrepresentation and omission of
project facts from status reports will be more difficult to cover when specific metrics and templates
must be used by participants to communicate the status of their activities (as dictated by control
methodologies). Because of this, we anticipate that project participants would be less likely to engage
in misrepresentations when their work is closely controlled. Pinto and Mantel (1990)’s findings lend
support to this argument. They found that the use of schedules, plans, and other control mechanisms
was associated with better communication and improved trouble-shooting. Research showing that
the use of control tools in IS projects positively impacts their performance (Henderson and Lee, 1992) is
also consistent with this assertion. We therefore propose that participants in projects with lax controls
will bias their reports more frequently than those in projects with stricter controls (Hypothesis 3).

In addition to their direct effects, the above two factors (project structure and control) are likely to
have an interaction effect on biasing. Specifically, we argue that the effect of structure will be
moderated by the impact of control. In other words, for low structure projects, we assert that the use
of controls will be important in reducing biasing; the use of similar controls will not be as important
(for biasing detection) in high structure projects --as the specific nature of the project requirements
will deter the likelihood of biased reports. The interaction effect between control and structure is
supported by prior empirical work (Nidumolu, 1995) which demonstrated that dimensions of these two
constructs affect the residual performance risk in an IS project and that their “fit” affects project
outcomes. Thus, we hypothesize that the effect of project structure on biasing will be moderated by
project control (Hypothesis 4).

**Project Size:** Size refers to the magnitude of the resources that are needed to complete the project.
Past research illustrates that the level of resources is affected by the complexity of the development
initiative (Baccarini, 1996, Holttta-Otto and Magee, 2006, Francalanci, 2001). In general, biasing can
be both more beneficial and less risky in large projects. Using biased reports to avoid delivering bad
news can be more desirable because in projects that consume high levels of organizational resources
the risk of potential scape-goating (i.e., shooting the messenger) can be consequential. Likewise, other
benefits of biasing (such the ability to be seen as a hero who rescued a project) are likely to be more
important in larger, more expensive undertakings. In terms of detection risk, the ability of report
recipients to detect inaccurate status updates in large projects is diminished as the complexity (i.e. the
diversity and volume of work tasks) increases (Holttta-Otto and Magee, 2006). Given that biasing is
likely to yield higher rewards in larger projects and may be more difficult to detect, we anticipate that
participants in large projects will bias their reports more frequently than those in small projects
(Hypothesis 5).

While the focus of our work is on biasing behaviors, we recognize that prior work in IS project
communications (Thompson et al., 2007) has focused on a related, yet distinct construct: quality of
project reporting. **Quality of project reporting** refers to the extent that project updates are complete,
accurate, timely and informative to their recipients. Although biasing behaviors have a degrading
effect on the quality of reporting, they are not the only factors that influence the quality of status
updates that are produced in a project (Muller, 2003). Such other factors include the reporting
experience, communication skills and other traits of the reporter, limitations of the report transmission
media (face-to-face meetings versus email updates, for example), the frequency of reporting, and so
on. While it is not our intent to develop an exhaustive model that attempts to explain all the
antecedents of reporting quality (for a comprehensive review of misreporting antecedents see Smith
and Keil, 2003), we incorporate one final hypothesis in our model to depict the distinction between
biasing behaviors and reporting quality: the frequency of biasing will be negatively associated with
reporting quality in a project (Hypothesis 6)

In the next section, we describe the sample and the methodology that we utilized to empirically assess
the validity of our hypotheses.
4 RESEARCH METHODS

Sample: The sample for this study consisted of people who were team members in state governmental projects in an Eastern state in the U.S.A. The data collection for this study took place as part of a larger effort to study biased project reporting involving interviews and surveys with project personnel, auditors and other involved executives. We selected a diverse subset of projects based on several dimensions (project duration, vendor involvement, etc.) from a listing of all major on-going projects that were being pursued by state agencies. The data that was used to assess our hypotheses were collected using survey questionnaires that were sent to all non-executive IS participants in each of the selected projects. 203 surveys were mailed, and two reminders were emailed to each subject. Ultimately 130 participants responded, yielding a gross response rate of 64%. Of these, 39 cases were removed because of missing data. We embraced an intentionally conservative algorithm in deciding which cases should be removed: a case was removed if the respondent did not complete two or more of the items for any construct. This left 91 usable responses, with a net response rate of 45%.

Scope: The respondents were instructed to answer the questions within the context of a specific IS project: the project on which the participant was currently spending most of his or her time. Moreover, they were instructed to focus on their status reporting to their project manager when responding to questions that were related to biasing and reporting quality. Thus, our data collection focused on the "IS professional to the project manager” reporting dyad.

Measures: Where possible, we used previously developed and validated instruments to measure the constructs of interest. To measure frequency of biasing we used five measures (see Table 1 below): two were adapted from Fulk and Mani (1986), one was taken from Roberts and O’Reilly (1974), and the remaining two were created by the authors.

Table 1: Measures of Bias in Project Reporting

To measure reporting quality, we used Mohr and Spekman’s (1994) communication quality scale, which measured communication timeliness, accuracy, adequacy, completeness and credibility. (For space reasons, only the measures for bias are included in this paper, but the others are available from the authors upon request). For project importance, we used the 8-item scale developed by Barki et al. (2001). Following their approach, we summed the responses from the 8 items to create a summated index for importance. For project size, we asked the respondents to report the total budget for the
project. Project structure was modeled as a higher-order construct, with two separate but related dimensions; requirements instability and requirements diversity. Taken from Nidumolu (1995), four items were used to measure requirements instability, and three for requirements diversity. We also modeled project control as a higher-order construct, with internal integration and formal planning as the two dimensions. Four items measuring internal integration and three measuring formal planning were taken from Barki et al. (2001). To assess the impact of biasing on reporting quality in a more accurate fashion, we included a control variable in our instrument (frequency of reporting). To measure this control factor, we created three new items (these were modeled after a frequency of reporting measure from Roberts and O’Reilly, 1974 which we felt lacked face validity within this research context). All new items in our instrument were validated using a card-sorting technique as described in Moore and Benbasat (1991).

For data analysis, we utilized the Partial Least Squares (PLS) technique: specifically, PLS-Graph version 3.0 (Chin and Frye, 2001). Table 2 shows the loadings of multi-item indicators on the constructs they are intended to measure, as well as the cross-loadings on other constructs.

Table 2: Indicator Loadings and Cross-Loadings

For adequate item reliability, ideally the item loadings should be higher than .70, although slightly lower loadings for individual items are usually acceptable providing other items measuring the construct are greater than .70. The only item that appears to be potentially problematic is the first measure of reporting bias, RB1, which displayed a loading of .57. After reviewing this item from a face validity basis, we decided to retain it in an effort to capture as much of the meaning of the reporting bias construct as possible. (As an aside, we tried re-running the model without this item and...
observed no significant differences in the results obtained).

To assess scale reliability and internal consistency, we computed the Composite Reliability (CR) score (similar to Cronbach’s alpha) and the average variance extracted (AVE). For adequate reliability, the CR score should be greater than .70 (or .80, for more mature streams of research). All of our CR scores exceeded .80. In addition, the AVE scores ranged from .59 to .78, comfortably exceeding the recommended level of .50. The CR and AVE scores are shown in Table 3.

For discriminant validity, two tests were performed. First, the cross-loadings of the items were examined, to ensure that: 1) each item loads more highly on its own construct than on any other construct, and 2) there are no items that load more highly on a construct than the items intended to measure that construct. All measures passed this test. Second, we compared the square root of the AVE for each construct to ensure it was greater than the correlations between that construct and all other constructs (see Table 3). All measurement scales passed this test as well.

Note: CR – composite reliability score; AVE – average variance extracted; RB – report biasing; RQ – report quality; RI – requirements instability; RD – requirements diversity; II – internal integration; FP – formal planning. For adequate discriminant validity, the diagonal elements (i.e. square root of AVE) should be larger than the off-diagonal ones.

Table 3: Tests of Reliability and Discriminant Validity.

Satisfied that the measures were adequate, we then examined the structural model results. These are shown in Figure 2. Note that we have expanded this model from the earlier research model, to show the higher-order constructs (project uncertainty and project control) with their separate dimensions, as well as the interaction term (Uncertainty × Control) that was added to test for a moderating influence of control on uncertainty (see hypothesis 4). Finally, in addition to the control variable of reporting frequency, we also added the influence of project size on importance as a control (as those two factors are likely to be related). Table 4 summarizes the results with respect to our tests of hypotheses.

Table 4: Results of Tests of Hypotheses
DISCUSSION OF FINDINGS

We note from Figure 2 that the amount of variance explained ($R^2$) in biasing was .24 indicating that a substantive portion of the variation in biasing behaviors can be explained by the project factors that were identified as antecedents in our model. Moreover, the variance explained for reporting quality was .25, and the path estimate from biasing to reporting quality was -.43, suggesting that the frequency of report biasing does have a substantive, negative impact on report quality. This confirms that understanding the factors that influence report biasing is indeed important.

With respect to the effects of the antecedents, three of the four factors hypothesized to influence biasing (project importance, control and size), did in fact do so. As hypothesized, it appears that participants in more important projects are more likely to engage in biasing behaviors. Similarly, in larger projects the participants are more likely to bias their reports. In contrast, the more perceived control over the project, the less frequently biasing will occur.

As our results indicate, the degree of project structure did not have an influence on the frequency of report biasing. We had hypothesized that the more uncertainty that existed in project requirements (both in terms of the diversity and variability of requirements), the more that biasing would occur. Our rationale was that low structure projects would have more ambiguity and dynamism, making biased reporting more difficult to detect, and hence participants would see it as a less risky behavior and tend to bias more. Our results did not support this hypothesized relationship. One possible explanation is that the degree of structure was average, not low, in the projects that were included in this sample. An examination of the descriptive statistics for the seven indicators measuring requirements diversity and instability revealed that the means ranged from 3.5 to 4.5 (on a 7-point scale), suggesting that this might have had a dampening effect. One reason for the presence of a higher level of structure (across all projects in our sample) is that the state that was the focus of our data collection effort required all of its major projects to undergo a certification review before receiving funding. Moreover, the state required periodic reviews for such projects. Thus, it is possible...
that these reviews compelled agencies to structure their projects (and reduce variability in requirements) in a way that is not typical in other environments. We also recognize the limitations of using interval scales when testing for interaction effects (hypothesis 4). We tried running the PLS model without the interaction effect, and found adding it only increased the variance explained by a nominal amount, and hence we conclude there was no evidence of an interaction.

6 LIMITATIONS AND IMPLICATIONS

Before discussing the practical and research implication of our findings, there are several limitations with this study which need to be acknowledged. First, our data was cross-sectional in nature, which does not allow us to truly test for causality. While we can propose directionality in relationships based on previous research, our data and statistical analyses can only detect correlations and not causation. Nevertheless, it is important to recognize that the associations that we have identified among the constructs of interest are consistent with the causal relations in our chosen theory. Second, our sample was taken from participants involved with projects at state governmental agencies. As such, we cannot generalize the results outside of that context without caution. Third, while we took several steps to enhance and assess the validity of our measures, a couple of measurement issues exist. Specifically, project size was measured with a single indicator and new items were used in measuring three of our constructs.

Despite the above limitations, we believe the results from this study provide interesting implications for both practitioners and researchers. For practitioners, our work has confirmed empirically that biased reporting exists in IS projects and that such biasing is likely to be affected by three dimensions of the project itself: its size, importance and use of controls. Our findings indicate that risk of biased reporting gets amplified as the size and importance of the undertaking increases. Thus, managers who are tasked with the oversight of large and/or important projects will be well advised to pursue tactics that could reduce the potential benefit of biasing and increase its probability of detection. Such tactics include regular communication audits, the use of multiple sources to triangulate the exact state of project tasks without relying on a single source, and the nurturing of an open project communication culture that minimizes the need for face saving behaviors. As the pursuit of such tactics is likely to require substantial resources and time, we advise project executives to focus on high biasing-risk projects when identifying initiatives that could benefit from the use of such measures. Moreover, it is important for such executives to recognize that the potential for increased biased reporting can be countered through the use of normal project control activities, such as internal integration efforts (e.g. regular project meetings) as well as formal planning techniques (such as project management methodologies and software). Our empirical findings have confirmed the suppression effects of such controls on biasing.

Finally, our study’s findings yield several opportunities for further research. First, it would be interesting to see whether the lack of an influence of project structure on biasing would hold in a different sample that included more low-structure projects. Perhaps there is a necessary threshold with respect to project structure that has to be reached before it begins to influence biasing behavior. Second, our results were obtained from projects undertaken by governmental agencies. While we anticipate that the findings would hold across projects drawn from the for-profit sector, it would be useful to replicate the study in a different (non-governmental) context to confirm this assumption. Third, our study’s sample consisted of IS professionals acting as project team members reporting to their project manager. It could be fruitful to see if similar reporting behaviors exist in other dyads that are present in project settings (when a project manager reports to an auditor, for example). Fourth, now that we have established that project characteristics do influence the propensity of reporters to bias their status updates, it would be useful to identify additional project traits that could complement the set of the four that we have identified. This will yield a more comprehensive perspective on the effects that project environments have on biasing.
In conclusion, our research findings have confirmed that biasing is indeed present in IS projects and has identified three project characteristics that influence it. We hope that the results of our study will guide practitioners in improving their project monitoring and oversight practices and will provide fruitful exploration avenues to researchers who are interested in helping such executives. Only with such additional scholarly explorations will we be able to gain a complete understanding of the biasing phenomenon and find ways to reduce its undesirable effects.

Abstract

Pre-investment evaluation of information system project proposals persists in being problematic and highly risky in practice. Numerous evaluation approaches and methodologies, offered in the literature, have not contributed to major improvements in practice. As the literature review shows, these methodologies have assumed an ideal of objective and scientific evaluation and taken the view of methodology as science. In this paper we aim to revisit the notion of IS evaluation methodology in practice and specifically explore the methodology as both the ‘science’ and the ‘art’. We achieve these aims by conducting an Actor Network Theory (ANT) study of IS evaluation in a large financial services company. The ANT study allowed us to investigate the methodology as it is enacted in IS project evaluations in practice without making any a priori decision of what methodology is or should do. By defining a series of processes, inscription aids and mandated checkpoints we found that the evaluation methodology engenders the evaluation process as ‘science’; and by allowing a degree of freedom in conducting the evaluation processes, the methodology is also enabling the evaluation processes to emerge as ‘art’ and by doing so stimulating creativity and innovation. Thus the ANT approach assisted in our discovery of the dual nature of methodology as simultaneously science and art.

Keywords: Pre-investment IS project evaluation process, IS project proposal evaluation methodology, Actor-network Theory, socio-technical approach
1 INTRODUCTION

The increasing costs of investments in information systems (IS) and persistently high failure rate of IS projects in practice indicate that IS project evaluation is of critical importance to organizations. The evaluation of IS projects before the decision is made to fund it – referred to as pre-investment evaluation – is potentially critical to increase both the success rate of IS projects and to achieve expected business value. Making the right IS investments is, and will continue to be, a critical component of organisational planning for the future (Lin & Pervan 2001b, Murphy & Simon 2002).

To improve the practice of pre-investment evaluation of IS project proposals, IS researchers have over the years proposed numerous evaluation methodologies with the aim to advance and assist ‘rigorous’ and ‘scientific’ assessments (Berghout 2001). The focus of scientific evaluation of IS projects has been on the tangible aspects of IS costs and benefits, thus privileging the technology and its measurable impact on performance. The assumption has been that the more evaluation methodology is scientific, that is objective, rigorous and based on precise measurements and calculations, the more accurate and certain the evaluation result will be. The failure of evaluation of IS is attributed to the lack of appropriate adoption of the scientific rigour of the methodology.

The IS evaluation literature has been largely dominated by an objectivist view of the IS evaluation process, technological determinism and the perception of IS evaluation methodology as a ‘science’. However, there are indications which suggest that organizations generally ignore these IS evaluation methodologies, because they are perceived to be too complex, difficult to understand and unreliable (Al-Yaseen & Eldabi 2004). While we have seen a growing number of ‘scientific’ methodologies in the literature (Nagm & Kautz 2007), we have also seen reports about the lack of methodology adoption in the practice of IS evaluation (Nagm & Kautz 2008). Is something wrong with practice or with evaluation methodologies?

We propose that IS evaluation in practice is not well understood by proposers and proponents of “scientific” evaluation methodologies of IS. In this paper we argue that IS evaluation in practice is not only a science but is also an art form which involves creativity, improvisation, imagination and community building. More precisely we aim to demonstrate that the IS evaluation methodology in practice has a dual nature: that it is simultaneously science and art. We achieve this by conducting an Actor Network Theory (ANT) (Latour 2005, Law 2002) study of IS evaluation in a large financial services company. The ANT study enables us to investigate the nature of methodology as it is enacted in IS project evaluations in practice without making any a priori assumptions about what a methodology is or should be.

Before we present our results we first discuss the IS evaluation literature and raise key problems and themes. We proceed by presenting the ANT approach to the case study. We then present an ANT account of an IS project evaluation methodology in an exemplary case company, based on which we reveal and discuss the dual nature of methodology as simultaneously science and art.

2 LITERATURE REVIEW

The IS evaluation literature is divided into two distinct areas, pre-investment evaluation and post-implementation evaluation. The focus of pre-investment evaluation is on the justification of IS investments before being initiated (Murphy & Simon 2001). It is also known as ‘predictive evaluation’, emphasizing the speculative nature of the estimation of an IS worth and impact on the organization in future that depends on the evaluator’s judgement (Remenyi & Sherwood-Smith 1999). This differs from post-implementation evaluation which aims to evaluate IS projects after the implementation has occurred. In this paper, we focus on pre-investment evaluation of IS projects.

The predominate stream of research in the IS evaluation literature has been on the development of ‘scientific’ evaluation methods and their use in practice. There have been numerous attempts at counting and investigating these methods, Berghout (2001) for instance identified the existence of
Over 65 evaluation methods, most centred around ‘scientific’ appraisal techniques like discounted cash flow analysis (DCF), net present value (NPV), internal rate of return (IRR), cost benefit analysis (CBA) and payback period. These methods often described as being formal, summative or functionalist. They offer some advantages for IS investments that are expected to produce cash flows or some other tangible financial benefit, but disadvantage IS investments which may add value to the organization in a less tangible way. They exemplify a scientific ideal to prescribe a rational, formal, quantitative and exact evaluation process. These represent as Stockdale, Standing & Love (2006) argue the hallmark of the scientific paradigm.

These ‘hard evaluation techniques’ (Ballantine, Galliers & Stray 1994) or ‘rigorous scientific methods’ (Smithson & Hirschheim 1998) have been often questioned and criticized:

- For their assumption that value and impact of IS can be reduced to numbers which can be calculated and counted (Williams & Williams 2004).
- They ignore intangible/qualitative aspects of IS investments (Hirschheim & Smithson 1999)
- They ignore the wider context within with the evaluation takes place (McBride & Fidler 2001)
- By ignoring organisational issues, they are difficult to apply (Ballantine & Stray 1998)
- They are susceptible and sensitive to manipulation (Hirschheim & Smithson 1999)
- They stifle innovative development by focussing on formal-rational approval processes (Howcroft & McDonald 2004)
- They obscure subjective aspects of IS evaluation (McBride & Fidler 2001)

More recently there has been a growing awareness among researchers that the scientific rational view of evaluation has to be expanded, perhaps being replaced by a perception of evaluation as a social and political phenomenon (Berghout, Nijland & Grant 2005). A number of alternative or complimentary methods have been proposed that include more ‘subjective’ aspects of evaluation (Klecun & Cornford 2005). The emergence of such methods has no doubt been inspired by a new way of thinking in the IS discipline. For instance May (1997) states:

“This new world of IT-enabled value creation contains none of the cold sterility of scientifically precise, formula-driven absolutes. Our central certainty of value has given way to a series of negotiated, mutually-agreed-on business objectives” (pg. 92)

However despite the criticism we still don’t have a clear understanding of IS evaluation methodology that is more than science. If IS evaluation is not a completely scientific enterprise, the question is: What is it? If an IS evaluation methodology is criticised for being overly "scientific", what is missing?

We sought to answer these questions by drawing on an empirical study of IS evaluation processes in practice. Without assuming any view or position from the literature we aimed to find out what is a nature of IS evaluation methodology in practice. We therefore examined the practices of IS evaluation in a company that has extensive experience in assessing, developing and deploying IS, and a track record of successful IS adoption and implementation. It also has well established processes for developing and evaluating IS proposals, including the use of a range of evaluation techniques. Throughout the empirical study, lasting 16 months we encountered many actors, such as business managers, IS managers, project managers; a plethora of documents including an IS evaluation methodology, IS project ideas, project proposals, IS business case, etc. We came to realise that all of them, human actors and various documents and technologies (that can be seen as non-human actors or ‘actants’) play a role and exert agency due to their mutual interactions and influences. This led us to adopt actor-network theory (ANT) to enable a more comprehensive understanding of IS project proposals and their evaluation methodologies and processes (Latour 2005, Callon 1986, Law 2004).
METHODOLOGY: AN ANT CASE STUDY

ANT is an approach to sociomaterial analysis developed in the sociology of science and technology (Callon 1986, Latour 1986, 2005, Law 1999, 2004) which found a fertile soil in IS research (Walsham 1997, McLean & Hassard 2004). ANT considers entities such as IS, organisations, methodologies, and users, as actors or actants that have agency by virtue of their relations with other actors/actants in heterogeneous networks (Law, 2004). ANT is grounded in an ontology of relationality and treats actors as enacted and relational effects. The world is seen as being comprised of enumerable heterogeneous actors engaged in a continuous process of mutual interconnecting to form or diminish actor-networks. Actor-networks thus emerge, grow, sometimes stabilize and black-box and sometimes destabilize and dissolve. The emergence of actor-networks result from enrolment of other actors (allies) and alignment of their interests with that of the network. Generally, ANT enables analysis of the conditions, constraints and modification of agency within actor-networks that intertwine the humans, culture, language, artefacts and technology (and many other things).

In particular two concepts drawn from ANT assist in analysing IS evaluation practices. These concepts are, ‘translation’ and ‘inscription’. Translation is the process by which an actor creates a body of allies by enlisting other actors to align with their actor network (Walsham 1997, Latour 2005, pg. 218). Inscription describes the process by which designers inscribe their interests into technical artefacts such as information technologies or into other actants such as policy documents and methodologies. Inscription can be said to define the roles and use of these artifacts and has been described as “frozen organizational discourse” (Walsham 1997 pg. 469).

Furthermore, ANT presents challenges for researchers aiming to investigate emergence of heterogeneous actor-networks. How to adopt ANT to conduct empirical studies remains open to researchers’ imagination and is not prescribed by ANT’s proponents and followers. For instance in their particular kinds of ethnographic studies – Latour’s investigation of a “laboratory life” (1979) and later on a failed technology project called Aramis (1986), Law’s aircraft stories (2002) and Mol’s treatment of atherosclerosis in a hospital (2002) – they followed their objects and subjects, recorded events and collected other material evidence in many different ways. The major feature in their work is a detailed description of a story as a basis for examining and theorizing novel and often complex concepts and questions. Latour himself describes ANT as a “very crude method to learn from actors without imposing on them an a priori definition of their world building capacity” (1999, pg. 20). We learn from him and other ANTs to ‘follow the actors’, let them tell their own stories, use their own vocabularies and unfold their own meanings.

Our study started without any pre-conceptions about a theoretical foundation or the nature of evaluation processes. It was motivated and initially driven solely by the research questions. It focused initially on the human actors and what they do, how they go about proposing ideas for new projects and how the ideas grow into official IS Project Proposals. In the process we were particularly interested in the evaluation processes and how methodology acts as a non-human actor. It turned, almost intuitively, into a ‘journey’ of following the actors, not only humans but also objects, documents and other devices employed during projects’ evaluations.

We conducted our study in a large multi-national financial services company referred to as ALFA Group. The Australasian operation – which we shall call ALFA Bank – has an impressive history spanning approximately 150 years and with an investment portfolio in excess of $1 trillion dollars. One of its divisions, ALFA Invest, was the prime focus of the study. This organisation was selected because the company is known to have a well established practice of IS project proposal evaluations; secondly it has a track record of successful IS deployment and implementation; thirdly, it has recently overhauled its evaluation methodology worldwide and finally because it was quite receptive to our request to study these practices in depth; hence this presented a unique opportunity to study the adoption of the methodology in depth.

A financial crisis in 2004 forced ALFA Group to reassess the way in which it evaluated IS project proposals. In order to manage the $2 billion commitment which ALFA Group made to rebuild ALFA
Bank, ALFA Group decided that it needed more discipline around the way proposals for the $2 billion spend would be evaluated. To facilitate this, a new Evaluation Methodology was introduced with two core principles at its heart – doing the ‘right projects’ and doing the ‘projects right’. From 2005 to 2007, over $3 billion worth of projects have gone through the new methodology which has helped ALFA achieve a way to produce consistent and comparable IS Project Proposals.

Data collection includes a) interviews with 36 senior executives and managers of ALFA Invest division as well as some from ALFA Bank (the parent company) over a 16 month period from July 2006 to October 2007 (listed in Table 1), and b) company documents related to IS project evaluation methodology including examples of recently approved IS project proposals.

Our investigation started with an interview with a Senior Project Analyst who explained how projects are viewed by people in the company, as well as how they are evaluated within the broader business context. From that point the inquiry detoured into several directions following the Senior Project Analyst’s suggestions including Head of Regional Projects Board, and other Senior Business and IS Analysts. We started with semi-structured interviews guided by an interview schedule but soon departed from it and adopted unstructured interviews that proved more suitable to addressing emerging issues. The length of each interview on average was approximately one hour, but in some cases interviews spanned two hours over two separate sessions. Through these interviews we encountered non-human actors, IS project documents, evaluation methodology and strategy.

The analysis of empirical data started early on as we encountered new actors (humans and non-humans) and cannot be clearly separated from data collection. Namely, following the actors and their relations with objects and other actors prompted the chain of interviews and collection of documents. The analysis of the interviews and documents in turn led to seeking explanation of activities, events and outcomes by interviewing new actors and seeking new documents. These interviews revealed how different business realities and interests are negotiated and inscribed in the production of IS project proposals. After data collection the analysis became more refined focusing on stages in the production of IS project proposals, evaluation methodology, the roles of specific actors or actants and the ways they enrolled and acted upon the production and evaluation of the proposals while creating actor-networks. Snapshots of networks were presented in a graphical form as ANT maps. Our ANT inquiry included coding the interviews and documents using Nvivo. The coded texts were then extracted in a
systematized form, assisting our investigation of actions and their relations in the networks. These also helped writing the story of IS projects evaluation processes and the nature and role of methodology.

4 IS PROJECT EVALUATION METHODOLOGY: DEFINING THE ‘SCIENCE’ AND ENABLING THE ‘ART’

At the pre-investment phase of a project, each IS project proposal has to go through five stages of the evaluation methodology, the Idea Stage, Concept Development Stage, Business Case Stage, Proposal Submission Stage, and Proposal Assessment Stage. In the process an IS project proposal is developed and continually evaluated. Initially, an idea for an IS grows and increasingly becomes more defined and concrete to the people involved as it moves through the stages defined by the methodology. From the first idea stage, which involves informal discussions and the fermentation of ideas, the IS idea converges into a concept through the Concept Development stage before forming a coherent IS Business Case drafted during the Business Case stage. This business case is then transformed into an IS Investment Submission document before being further refined and shaped in a consolidated form that will be put forward to the Regional Investment Committee for deliberation during the final proposal assessment stage.

For example the business case stage as described by Figure 1 involves a number of human actors (like the Business Sponsor, Finance Partner, Critical Business Stakeholders and more) who Business Case Document. As these actors directly determine the content of the Business Case Document, we presented them in the core of the actor-network. The core describes the actors and relations at the centre of an activity. Other actors such as Business Plan, ALFA Group Management and the Methodology are presented in the periphery which indicates that they are acting from a distance.

Figure 1 - IS project evaluation methodology acting from the periphery of the actor-network
The methodology in this case acts in two major ways: first, the methodology can be seen to act as a scientific method by prescribing a set of systematic processes, inscription forms, norms, rules and checkpoints that need to be passed. The evaluation methodology as science is systematic, formal, prescriptive and rigorous. It ensures standardization and comparisons across projects, equitable treatment of all projects, and involvement of relevant stakeholders in each project evaluation. However, it is at the same time enabling and encouraging the “art” of evaluation to emerge. The art in this context refers to the “expression or application of creative skill and imagination” (OED 1989), innovation, improvisation and informal relations. In the section below, we explore these two ways in which the methodology acts – as science and as art – and in doing so, reconceptualise the notion of an evaluation methodology.

4.1 Evaluation methodology acts by defining the ‘science’

By defining a number of elements, the methodology acts to inscribe the process interests as well as control (checkpoints), standardisation (inscription norms), consistency (inscription forms), and policing (inscription rules) interests of ALFA Group management.

The methodology specifies a number of processes that should be carried out in each stage; it also defines key ‘obligatory’ human actors that need to be engaged for certain processes. For example, the methodology stipulates that the Business Sponsor needs to approve and sign off all major documents (for instance the IS idea document) before they can be submitted to the Local Investment Committee for deliberation as Figure 2 below illustrates.

While there are some processes that must be performed as defined by the methodology, others are less prescriptive. For example in producing the IS Concept document the methodology defines a linear sequence from developing the concept, to developing the high-level architecture to finalising and reviewing the concept document; however, in practice it is possible for all three processes to be carried out simultaneously as Figure 3 demonstrates.
The methodology does describe some actors and processes but leaves others flexible. In such a way the methodology is an actor that shapes the IS Project Proposal emergence sufficiently strictly to meet management needs, but with the flexibility to ensure enrolment of actors and the growth of the actor-network. The power of the methodology is in part the ‘science’ it imposes (in varying degrees) and in part the ‘art’ it enables in creating relations and building networks.

The methodology does not only define a series of processes to follow, but also defines a set of inscription devices to complete (see Figure 1), in order to create an audit trail and evidence of actions in all stages. The Head of Project Methodologies in ALFA Bank states: ‘the methodology we have built, is saying what you have to do, [and] also provides the tools and templates to help project managers actually do it and to deliver [projects]’.

While the methodology does not define how these inscription devices can or should be put together, it does define a series of inscription forms, norms, and rules that help create inscriptions that strategies and business plans are enacted. It also ensures that different IS project proposals can be compared to one another. These inscription aids also act to ensure that people are serious when they develop IS Project Proposals. There is a audit trail that is left behind. To enforce some control especially around estimations and value articulation, ALFA Group have embedded inscription rules into key inscription devices (financial analysis spreadsheet for example) that cannot be manipulated and must be reviewed by GM Finance.

The methodology also acts by clearly defining a number of checkpoints that each IS Project Proposal must pass through from the Idea Stage right through to the Proposal Assessment Stage. The Head of Project Methodologies in ALFA Bank states:

‘At the end of these stages you have what is called a ‘stage gate’ where you have to pass the gate to get into the next stage. So there is a check mark by certain people at the end of each of those stages to see if the project should then progress to the next stage’

These checkpoints, called ‘stage gates’ in ALFA, not only act out management’s control interests but they promote a practice of continuous evaluations which are both formal and informal. Importantly for each checkpoint, a ‘gatekeeper’ has been made obligatory by management through the methodology ensuring that progress of an IS Project Proposal from one stage to the next is regulated and policed by someone who does not stand to benefit or suffer from the progression of an IS Project Proposal. By defining a number of checkpoints, the methodology acts by helping to identify and eliminate ‘bad’ proposals; those that do not provide justifiable benefits, are not feasible, are not supported by key actors or are misaligned with the strategic priorities of the business. The current methodology has been instrumental in helping to ‘stop wasting a lot of the organization’s money on projects that never go anywhere’ (who said this?). In fact, statistics in ALFA suggest that the methodology has helped stop 30% of all projects before they were approved. These projects would have been allowed to go through...
with the previous methodology, and this demonstrates how the methodology acts to increase instances of project success by helping to detect and eliminate bad projects (those with a weak financial case, unsupported by key people or unaligned to agreed strategic priorities). It also acts by amplifying beneficial, valuable or strategically aligned IS Project Proposals.

4.2 Evaluation methodology acts by enabling the ‘art’

By not being overly prescriptive, the methodology also acts by providing the creative freedom for actors to explore the ‘art’ in IS project evaluation – the art of translation. The art of engaging with others, the art of finding the right stakeholder or forum to present ideas, the art of persuading and influencing and enrolling others, the art of shaping, synthesising, sizing and crafting the IS proposals, the art of rallying support in meeting rooms and corridors, the art of story telling, the art of adapting (undefined, and un-prescribed) paths to develop an IS Project Proposal -- what the people in ALFA call a journey. The ‘journey’ refers to how people enact the processes, inscription aids and control points to enrol actors, to build allies and ultimately to make a compelling case for the selection of the proposed IS over others which are all competing for funds from the same limited pool. The methodology acts by not explicitly defining the paths people take to travel between processes and by not strictly defining how they carry out the processes. This enables people to approach each project different and attend to unique nuances that arise. By acting to allow both the ‘science’ and the ‘art’ in IS project evaluation the methodology is both a powerful and essential non-human actor in the heterogeneous actor-networks that help steer the emergence of the IS Project Proposal.

Allowing individual people to adopt their own approach to developing an IS Project Proposal, ensures that the culture of each local business unit can influence ‘how’ IS Project Proposals are initiated and assessed. It also ensures that people are free to find their own path to develop the IS Project Proposal recognizing not all projects are the same and that prescribing a strictly pre-defined path would not work in practice. Thus, because the IS Project Proposal involves many different people (business and IS actors) each bring to the journey their own understanding of process, and their own preferences for the path to take. This means potentially multiple different paths exist which can be taken by different people simultaneously. Many people in ALFA have described it as a ‘journey’ because the path is emergent, unknown and always different. For example, during the IS concept development process in the methodology, everyone has a different view of how the concept should be developed, what approach should be taken, which processes and tools should be involved. The methodology does not define how this should be done, or even how to clarify differences. That is why the people selected as IS project champions and IS/business relationship partners must have gone through development and assessment of many other IS project proposals. Their experiences, relationships and trust thus created enable identification and enrolment of the right people to the project the actor-network. Through organizing forms (meetings and forums) actors come together, raise issue, question, and debate the approach to take to develop the concept. They do this not in a predetermined manner, but they will do in the words of the Head of Central Business Operations ‘whatever works’.

Finding their own way to travel through the process defined in the methodology does not mean that anything goes or that projects are necessarily chaotic. As long as they do not break the inscription rules - rules that bring some order to the creative process, and which are defined in the methodology, actors can pursue different ways to debate ideas, clarify ambiguity, minimise conflict, and resolve misunderstanding. Similarly, they use different ways to inscribe their interests and visions in inscription devices. In this way, the methodology acts by being tolerant of multiple, messy and non-coherent realities that gradually cohere through the journey – helping to deal with both conflict and ambiguity.

Even though processes can be defined and standardised in a methodology, what matters is not the perfection of these defined processes or the prescribed elements but rather what the methodology does not prescribe – how people take others on the journey of translation. The journey adapts to the individual and specific needs of the project and is not determined by a ‘one size fits all’ methodology. This is like ‘stepping into the unknown’ as the Head of Central Business Operations explains, there is not necessarily ‘a clear way of getting to anywhere’. This is because the ‘best path needs to be found’.
‘Sometimes -- he continues -- you have to take the long way and sometimes you have to take the short way’. Similar views are shared around ALFA. As one IS/Business Relationship Partner says; ‘every initiative that goes through that process [IS Project Proposal development and assessment] has to find its own way to get there’. In finding the path as the Head of Central Business Operations states, ‘you evolve and adapt and think “what do I need to do to get through”’ and concludes by saying ‘not all roads are going to lead us to there but eventually with the right convergence you’re going to get there’. This makes the practice of IS project evaluation less of a ‘science’ and more of an ‘art’. As a Senior Project Manager comments, ‘there is some art within each of those steps of the process’.

IS Project Proposal evaluation being part ‘art’ does not mean that the journey is always smooth. Conflict does arise in many ways and forms as is evident in the ALFA case. Conflict between human actors (actor-network versus actor-network) for example who are competing for limited funds to demonstrate they have contributed to the organization through projects (that add strategic value) and wish to improve their bonuses for the year. Conflict also comes about within the actor-network as personalities and viewpoints clash, or with people who have hidden agendas or intend to cause disruption to a proposed IS. Ambiguity also surfaces around the initial idea, around how it should be conceptualised, around the estimations of costs and benefits. Ambiguity exists around the new business reality enacted by the proposed IS and how this reality is aligned to strategic priorities and the existing portfolio of projects. However, a prescribed rulebook on how to deal with conflict and ambiguity does not exist in this case, perhaps because conflict and ambiguity cannot be dealt with ‘scientifically’. Actors do find ways to deal with both elements (conflict and ambiguity) through the ‘journey’ itself. In dealing with both conflict on the one hand and ambiguity on the other through the journey, the actor-network stabilises resulting in IS Project Proposal that sufficiently inscribes the interests of the actors involved.

The evaluation methodology presented in the ALFA case, thus acts in these ways; first it defines the ‘science’ through a set of processes to follow, and people that need to be involved, and by defining a series of inscription aids (inscription forms, inscription norms and inscription rules), as well as defining a series of mandated checkpoints. Second, it enables IS Project Proposals to be described by comparable and unambiguous sets of measures. Third, it enables the ‘art’ of translation to surface, and thus encourage innovation and creativity in every IS project journey, allowing enrolment of relevant actors and inscription of their interests.

5 CONCLUSION

The paper makes two contributions. First the paper demonstrates that the IS Evaluation Methodology in practice has a dual nature, that it is simultaneously a science and an art. It redefined the nature of IS project evaluation methodology by revealing how the science and the art of methodology are intertwined and mutually dependent. Second, the paper contributes to better understanding how IS evaluation methodology encourages IS project proposals that are likely to be successful and identifies and discourages those that are likely to fail.

The dual nature of IS evaluation methodology has important implications for practice. The methodology-as-science acts though a series of processes, inscription devices, enrolment of key people, and mandatory checkpoints. It thereby ensures that systematic steps are taken and responsible actors engaged in the process. It also ensures that different IS project proposals by various departments are presented in a comparable form, using similar measures. However, this is just one side of the story. The methodology-as-art acts by intentionally introducing flexibility in the processes and procedures, leaving freedom for participants to adjust the processes and find the appropriate paths to develop and evaluate proposals. The art of the methodology is necessary to deal with realities that are in flux, not well defined and often non-coherent. This dual nature of the methodology as a science and as an art describes what actors in practice call the “journey”.

The notion of the dual nature of the IS evaluation methodology addresses many criticisms of the dominant view of methodology in the literature: that qualitative and organisational aspects are ignored (Hirschhem and Smithson 1999), that it stifles innovation (Howcroft & McDonald 2004), obscures
subjective aspects of evaluation (McBride and Fidler 2001), and that the wider context within which evaluation place is ignored (McBride and Fidler 2001).

Understanding the IS evaluation methodology as a science and an art is important because it reveals the production of successful and unsuccessful projects. As an art the methodology leaves space for the actors to negotiate and enact their meanings, and translate interests and objectives in the IS project proposals. These include negotiation and checking that the projects are aligned with the company strategic priorities. The trails of these negotiation processes are recorded in various documents (an IS idea, IS concept or a business case document) as inscription devices prescribed by the methodology as science. In such a way the discursively produced IS ideas, concepts and business cases are materially inscribed in the respective documents. This is a basis for “detecting” weak or bad IS project proposals, and for their elimination before reaching the final stage of project selection. The implications for a company are significant: it identifies and eliminates bad project early on and thus saves time, money and effort in the organisation. The methodology also acts by “amplifying” beneficial or valuable IS project proposals from the point of view of different participants.

Our findings also show that the practice of IS project evaluation – for which various evaluation methods propose a range of rigorous and well structured processes, models and calculation techniques – is rarely rigorous, is often messy, and seemingly unsystematic. Are these signs of poor evaluation methodology? – as is assumed in most IS evaluation literature. Should (could) the practice be improved by the adoption of, and stringent adherence to, a more rigorous, formal and exact methodology as most of the literature argues? Our case company ALFA Invest learned hard way the answers to these questions – through their own mistakes. Lessons from this company indicate that this is a limited view of practice and evaluation methodology that neglects the embedded art forms of project proposal development and evaluation. It is now the researchers’ turn to find more evidence from practice and develop further the theoretical and practical understanding of IS project proposal evaluation methodology.

Abstract

Information systems projects play an important strategic role in organisations and are key drivers to the delivery of change. Given this prominence it is essential to find measurement methods that effectively analyse and communicate the performance to its stakeholders. Further, to assure contribution to both research and practice it is essential to verify the utility of the artefacts (i.e. methods) developed to help validate or justify that the solutions are suitable for practice, and fit the needs and contexts for which it is created.

Grounded in the design science paradigm, this paper reports an exploratory evaluation of the perception of certain qualities of two recently developed measurement methods (The Project Performance Scorecard and Project Objectives Measurement Model) against the traditional Triple Constraint method. An analytic scenario-based survey of fifty-one (51) participants, comprising of three (3) sets of independent sample of seventeen (17) respondents each was used. The study analysed dimensions of task performance, ease of use, perceived usefulness, perceived semantic qualities and user satisfaction from the perspective of the participants. The preliminary study revealed encouraging results for the new methods and the general design process which can help guide current use and further refinements. The limitations of the study and future research directions are discussed.

Keywords: IS projects; measurement methods; project evaluation; design science.
1 INTRODUCTION

Recent developments have seen increased proposals on suitable perspectives or approaches for the evaluation of information systems (IS) project performance. For many years, the de facto standard has been the standard conformance to time, cost and specifications, or the triple constraint method (TCM) (Atkinson, 1999; White & Fortune, 2002). However, some researchers have questioned the suitability and completeness of this approach to effectively analyse the contribution of IS projects to the organisations and its stakeholders (Atkinson, 1999; Cohen & Graham, 2001). In response, several alternative approaches have been developed (Atkinson, 1999; Stewart, 2008) to help address this gap. However, an analysis of the project evaluation literature reveals that diverse empirical investigations have also become a top priority.

Against this background, the research adopts the principles of design science (Hevner et al., 2004) and evaluates two recently developed measurement methods, the Project Performance Scorecard (PPS) (Barclay, 2008) and Project Objectives Measurement Model (POMM) (Barclay & Osei-Bryson, 2008) against the standard approach, the TCM. Hevner et al (2004) proposed that the utility, quality, and efficacy of a design artefact must be rigorously demonstrated via well executed evaluation techniques, and can be evaluated in terms of functionality, completeness, consistency, accuracy, performance, reliability, usability, fit with the organization, and other relevant quality attributes. They further proposed several evaluation strategies including: observational (e.g. case studies and field studies); descriptive (e.g. scenario construction); analytical (e.g. static analysis, architecture analysis); experimental (through controlled experiments and simulation); testing (through functional or black box and structural or white box testing). As part of the design process, observational case studies were first used to help validate and justify the two artefacts/methods in previous studies (see Barclay 2008; Barclay & Osei-Bryson 2008). This approach was used as it allows for an in-dept study of the given artefact in an organizational context that would in turn provide feedback that may be used for the appropriate improvement of the artefact (Hevner et al., 2004). In this current exploratory study, the evaluation process is extended through the application of a mixed-method approach in the implementation of both the descriptive and analytical techniques. This involves the development of a real-life project scenario and the evaluation of the structures of each method using static analysis (e.g. complexity or performance) to identify attributes based on the perceptions of business and project practitioners. Static analysis is commonly used in software development to analyze the components and resources without running the programme (Chess & McGraw, 2004). While the proposed methods are not software components, the technique is suitable as practitioners are given the documented information (i.e. the components) to analyze each method in terms of elements such as usability, perceived semantic quality and completeness. To support this process, the conceptual model proposed by Maes & Poels (2006) is used as a basis to develop the research measurement instrument. This instrument was chosen because it addresses the limitation of procedures to help analyse the static qualities of IS artefacts (e.g. models or methods), and is based on seminal IS Success models (DeLone & McLean, 1992, 2003; Seddon, 1997), and are therefore consistent with the goals of this research.

The research provides contributions to both research and practice. The study extends the knowledge base in the IS project evaluation field through the analysis of the empirical observation of users’ interaction with three (3) distinct measurement approaches. The exploratory findings also have positive implications for both newer methods, and provide an opportunity for them to be implemented in practice to assist in the analysis of the contribution and performance of IS projects.
2 OVERVIEW OF IS PROJECT EVALUATION METHODS

There are various forms of evaluation methods that have been applied to analyse the performance of projects in different contexts. The traditional approach (TCM) has been the most popular technique used to help determine the success or performance of many projects in industries, and is largely endorsed by project management bodies (PMI, 2004). With the growing demand to find techniques that better fit the complexities of contemporary projects, research has begun to respond to this call. Some studies have reviewed factors impacting performance while others have developed strategies to assess performance. A review of key project evaluation literature reinforced that the primary responses to examining the performance of projects, outside of the TCM, have been to develop alternative success criteria to assess these projects (Atkinson, 1999; Morris & Hough, 1987; Nelson, 2005), and critical success factors (Belassi & Tukel, 1996; Fortune & White, 2006; Pinto & Slevin, 1987; Shenhar et al., 2002) while others have focused on the business value contribution of these investments (Fitzgerald, 1998; Kaplan & Norton, 1992; Kumar, 2003). Similarly, in an analysis of the project literature over a forty-year period, Jugdev & Muller (2005) showed the evolution of our understanding within the framework of the project and product life cycles in the discourse of performance evaluation perspectives. The four (4) evolving research themes were categorized into project implementation and handover, critical success factor (CSF) lists, CSF frameworks and strategic project management paradigms (Jugdev & Muller, 2005).

It is noted that the studies on project evaluation techniques or methods have been a mix of conceptual and empirical studies, with the latter primarily involving only validation or observation of the proposed solutions. This provides an opportunity for our current examination.

2.1 Description of Alternative Project Evaluation Methods

2.1.1 The Project Performance Scorecard

The Project Performance Scorecard (PPS) proposed that several considerations are essential to help project practitioners to enhance their analysis of the contributions of IS project activities. It is argued that to effectively analyse performance in these dynamic projects, a multi-dimensional perspective is necessary to help provide a more robust view. This includes considerations of the project events throughout the life of the project, the project management processes and the impact of the project’s product. Six (6) interconnected dimensions are therefore introduced which can be used as a platform to evaluate the performance or success of the project in different organisational settings: stakeholders, project process, benefit, quality, learning and innovation, and use (Barclay, 2008), figure 1. The PPS framework relied on theoretical contributions of IS success (DeLone & McLean, 2003), Balanced Scorecard (Kaplan & Norton, 1992) and quality paradigms to help communicate its purpose.

*Stakeholders* include those that are involved in the program or have a vested interest in its outcome (PMI 2004; 2006). While there may be stakeholders with negative and positive agenda, the method concentrates on the positive view. Understanding and accounting for what is important to the stakeholders establish the framework for better management of expectations during the project because of earlier involvement and consensus of what is important to them.

*Project process* considers the processes of the project from conception to handover to the client. It incorporates the view of the classical paradigm and looks closely at the project processes to gather
insights into areas such as the financial gains, the efficient use of time, management of uncertainty and resource allocation.

*Benefit* focuses on the gains and business value that are attributable to the project including the rationale for the project selection and considerations of the project business case are embedded within this dimension. It is important to note that while organizations are primarily concerned with the bottom-line; there are other important considerations that affect performance (Kaplan & Norton, 1996).

![Figure 1: The Project Performance Scorecard](image)

*Quality* is concerned with meeting or exceeding the stated objectives. Within the IS context, considerations of reliability, usability, efficiency, maintainability, portability and functionality of the product are essential in determining the value of the product and the project process.

*Learning & Innovation* focuses on the knowledge capabilities that can be garnered from the project, including gains, advantages, and value creating capabilities that may have been arisen as a result of involvement in the project.

*Use* considers how the results of the process are being used. For example, providing a software application aimed at improving internal efficiency is only part of the contribution, assessing how the application is being used and whether it achieves its stated objectives are necessary components in determining the contribution of a project.

2.1.2 The Project Objectives Measurement Model

The Project Objectives Measurement Model (POMM) involves the elicitation and development of objectives and measures that reflect the strategic and tactical vision of the project from the perspectives of its multiple stakeholders (Barclay & Osei-Bryson, 2008). It is distinct from other methods including the PPS as it focuses on the structured development of project criteria that are representative of the project stakeholders and does not rely on particular measurement dimensions.
Three key questions are reflected throughout the framework: do the project measures reflect the fundamental objectives identified? Do the project objectives reflect the project contexts? Does the evaluation process reflect the realities of the project? To achieve these goals, the POMM is supported by two decision techniques: the Value Focused Thinking (VFT) (Keeney, 1992), and the Goal Question Metric (GQM)(Basili & Weiss, 1984). The VFT is used to help elicit and ground the values & objectives of the projects from the views of the different stakeholders, i.e. what is important to them from the context of the particular project. The GQM technique facilitates the identification of useful measures and aligns these to the identified objectives. Therefore, it can be seen that this method ensures continued collaboration with the project stakeholders to assure that their values and objectives are represented, tracked and evaluated in the project; useful and appropriate measures are identified; and the project can be evaluated based on the actual events that occurred. The POMM uses a series of iterative steps to achieve its mandate:

1. Identify key stakeholders of the project, taking into consideration the roles involved, the organisations or personnel that may be impacted by the project and its results
2. Elicit project values and objectives for each key stakeholder, including standard objectives relating to time, cost and scope
3. Apply VFT method to determine the fundamental (end) and means (facilitating) project objectives
4. Prioritize the fundamental objectives
5. Develop, review and refine (where necessary) the project means-end network that shows the relationships between the objectives
6. Apply GQM method to elicit project measures
7. Develop, review and refine (where necessary) the project objective-measure network that shows the relationships between the objectives and measures
8. Implement, monitor and take corrective actions throughout the project
9. Determine or assess the cumulative outcome of the project

3 EVALUATION METHODOLOGY

The study is influenced by the design science paradigm (March & Smith, 1995) and presents the evaluation phase of the design process (Hevner et al., 2004). Within this context, a preliminary analysis of three (3) project evaluation/measurement methods is performed to help guide the refinement and use of the alternative methods (POMM and PPS). Based on the principles of Hevner et al., (2004) a mixed approach of descriptive and analytical evaluation approaches is used in this instance. A construction of a detailed project scenario is used to demonstrate the utility of the artefacts while static analysis is used to study them for qualities such as complexity and usability. Thus a scenario-based survey was implemented among selected group of fifty-one (51) participants (business professionals and graduate students) to obtain their perception of the specific artefact in a controlled context. The participants were randomly separated into three (3) independent groups of seventeen (17) for each project evaluation method. The scenario-based survey consisted of two parts; (1) A hypothetical IS project scenario that describes a core application system implementation project. Ten (10) multiple choice questions were given to test the participants’ task performance based on the specific project evaluation method given. Documentation on the methods was also provided as it was assumed that they had no prior knowledge about any of the approaches. (2) A questionnaire with 16 questions adopted from the Maes & Poels’ (2006) conceptual model with likert-like scale of 1-5 (strongly disagree to strongly agree) was used to assess the perception of static qualities.
Surveys are practical research instruments, particularly when there is a need to move from observation to theory validation, and is useful in gathering data about individual preferences and expectations (Newsted et al., 1998). Thus, by studying a representative sample of the environment surveys seek to discover relationships that are common and facilitate the provision of generalisable statements about the phenomenon under study (Babbi 2004; Newsted et al., 1998). Further, Babbi (2004) suggested that evaluation research is undertaken for determining the impact of “some social intervention”. This information provided additional motivation to apply this research method and therefore it is used as the basis to evaluate the three (3) different project evaluation methods. Future studies will extend the survey and apply different evaluation approaches such as descriptive and experimental studies.

3.1 Test of Independent Samples

In experimental research it is often necessary to manipulate what happens to people so that casual inferences can be made (Field, 2005). Our research undertakes three experimental conditions using different sets of individuals to participate. There are several techniques available to achieve this objective through the comparison of the mean of independent groups. Suitable techniques include the Independent Samples T Test (t-test), the Mann-Whitney (M-W) test and ANOVA (Babbie, 2004; Field, 2005). The t-test and M-W test are used to evaluate the scenario-based conditions relating to an assessment of task performance, and to analyse the likert-like scaled data generated from the survey of the perception of static qualities respectively. It is noted that the techniques differ but are specifically chosen because of the types of data being collected. Moreover, the t-test on independent samples and the Mann-Whitney test have similarities in that both are testing the identity of two independent populations. The t-test compares the mean scores of two groups on a given variable, and is used when two experimental conditions and different participants are assigned to each condition (Field, 2005).

3.2 Empirical Observation Framework

3.2.1 Task Performance

To assess the three (3) methods with respect to task performance, a project scenario was used as the basis to compare the measurements methods against the performance of certain tasks. Hevner et al., (2004) posited that a useful approach that can help to demonstrate utility of an artefact is through scenario construction. Against this background the project scenario was developed in which the participants were asked, given a specific measurement method, to perform the particular set of tasks, i.e. answer the questions given based on the scenario and the measurement method given. The scenario detailed a typical contemporary event of an organisation experiencing the implementation of core application system. Within the scenario the stakeholders faced several competing objectives with varying perspectives on what is important to them, including conformance to tight deadline to implement the system, managing the budget, acceptance of the system by user, and use of application by its users. The ten (10) questions were aligned to the project process including identification of the relevant stakeholders, identifying and prioritising different types of objectives, determining suitable measures based on the scenario context, and determining what criteria would indicate successful completion of the stated project. The participants were explicitly asked to use only the information provided to answer the questions.

3.2.2 Perception of Static Quality

The Maes & Poels (2006) was adopted as the framework upon which to assess the static qualities of the measurement methods. They argued that there is a paucity of practical evaluation framework that
considers the quality of conceptual models from the user’s perspective. The Maes & Poels’ model (2006) relies on seminal IS Success models (DeLone & McLean, 1992, 2003; Seddon, 1997) which acknowledge quality as an antecedent to system success. Their model identified four interconnected constructs as necessary to help assess the quality of an artifact, which is adapted for our research context (Table 1). Perceived ease of use (PEOU) refers to “the degree to which a person believes that using a system would be free of effort” (Davis, 1989) or perceived as being difficult to use (Moore & Benbasat, 1991). Perceived semantic quality (PSQ) describes the correspondence between the information that users think the model contains and the information that users think the model should contain, based upon their knowledge of the problem domain (Krogstie et al., 1995). Thus, the users or participants can view the semantic quality of the model as how valid and complete it is with respect to (their perception of) the problem domain. Perceived usefulness (PU) relates to “the degree to which a person believes that using a particular system has enhanced his or her job performance” (Davis 1969). Within this context, the participant can evaluate the respective method based on completing certain task i.e. the project scenario activities. User satisfaction (US) is a subjective evaluation of the various consequences evaluated on a pleasant-unpleasant continuum (Seddon 1997). Against this background, the Maes & Poels’ model is suitable for this research as it applied in similar contexts, i.e. the evaluation the three IS-related measurement methods from the perspective of users. Additionally, the framework has been empirically validated as an end-user evaluation tool (Maes & Poels, 2006) and have been applied in other recent studies.

Table 1: Measurement Instrument for Assessing Perception of Static Qualities

3.3 Research Procedures

To accommodate the examination of the measurement artifacts, procedures were developed and made available to the participants. The following strategy was adopted for conducting the study:

1. Design survey measurement instrument and extract the project evaluation methods’ documentation. This included the development of a practical case scenario and questions on which the assessment and/or interaction with the measurement models are performed. The
second part of the evaluation includes the measurement instrument (Table 1) which is adapted from the Maes & Poels (2006) with minor modifications including assessment of a specific measurement method instead of conceptual model for the process, and project measurement process in place of a process.

2. Obtain independent review (pre-pilot) of the instrument and models documentation on the sufficiency of the variables and to confirm if the documentation is sufficiently informative and helpful in completing the scenario-based questionnaire. The scenario was later refined to improve its clarity and readability.

3. Identify and recruit pilot study participants.

4. Present each group with documentation on TCM, POMM and the PPS models accompanied with the research instrument and scenario. The instrument/questionnaire also includes the moderating variables of gender, experience and age along with other relevant data collection aids such as role and industry represented.

5. Record and analyze the responses of the study using the SPSS application

6. Refine questionnaire based on suggestions of the respondents. The documentations on the models were refined for clarity, particularly in the POMM where unnecessary areas removed (e.g. the conceptual diagram). The scenario questions were refined to improve its understandability.

7. Identify and recruit at minimum an additional 45 study participants and randomly divide them in three groups. Graduate students and experienced professionals were identified. The set of graduate students included those who are full-time and part-time students, with a large portion of them being currently employed.

8. Repeat steps 4-5.

4 RESULTS AND DISCUSSIONS

4.1 Task Performance

Our assessment of task performance was based on the average accuracy level of the participants when using the respective measurement method to interact with the scenario and complete the set of questions (i.e. tasks). We did pairwise comparisons of the three (3) methods using statistically difference of means tests. Table 2 provides a description of our results. These results suggest that with respect to task performance, PPS and POMM are attractive competitors to TCM as PPS outperforms TCM in a manner that is statistically significant, and POMM also outperforms TCM but with a difference that is not statistically significant. This suggests that participants using POMM or PPS were better able to accurately determine the most suitable project evaluation tasks including identifying complete list of stakeholders, applicable project objectives and measures and determination of success of the project. This finding coincides with objectives of the designing both PPS and POMM such as to provide practitioners with an improved alternative in performing project evaluating tasks and be better to analyse the performance of a project using multiple criteria.

4.2 Perception of Static Qualities

The perception of static qualities is used to assess the quality dimensions identified (PEOU, PU, PSQ and US) based on the views of the participants as a result of their interactions with the requisite measurement methods. Also, pairwise comparisons of the assessment of the static qualities of the methods using non-parametric tests were also performed (Tables 3a-d). The results showed that there were no significant variations between the three methods. The average response per respondent primarily laid between 3 and 4 on the likert-like scale for all four dimensions being tested (figure 2). This means that that the respondents were fairly neutral and agreeable in relation to their perception of the quality dimensions for all methods. This has interesting implication for the newer methods in that the participants showed no significant negative reactions to them during their application. It is noted that while the results did not reflect a significantly strong positive review over and above the TCM, the opposite is also true. Thus, it can be argued that users may require more time to better understand the components of the methods, plus further simplification of the methods’ structure to facilitate ease of application may also be needed. Moreover, the results also imply that POMM and PPS may be adopted in practice with little difficulty while providing an alternative perspective in the project evaluation process.

### Table 3d: US: Results on Comparison of the 3 Models

#### 4.3 Implications for the 3 measurement methods

The results provide an interesting outlook on the methods under examination. The TCM continue to reveal fairly positive reviews by users despite the growing criticisms in research and practice. While both researchers and experienced professionals have suggested that the TCM does not sufficiently meet the analytical needs of current projects (Atkinson, 1999; Barclay 2008; Cohen & Graham, 2001; Nelson, 2005), the results show that it has been consistently positive in areas such as task performance, perceive ease of use, semantic qualities and user satisfaction. This may possibly help explain its continued use in practice (White & Fortune 2002) despite some identified weaknesses. This paradoxically relationship is worth additional investigations.

The newer methods POMM and PPS are also shown to suggest positive application in practice. For example, the PPS is shown to significantly perform better than the other methods with regards to task performance, i.e., evaluation activities for projects. This may be as a result of the additional dimensions (e.g. use or benefit) that can be used to help decision makers in their analysis of project contribution or performance. The POMM on the other hand facilitates better perception of static qualities in areas of usefulness, semantic qualities and perceived ease of use. This may be linked to the clear structured procedures and required stakeholder collaboration which are inherent in the approach.

While we can derive positive implications for this study, it is noted that a larger sample size may be required to draw conclusions with high(er) degree of confidence. We however acknowledge that the study underscores the need to have continued dialogue with practice and to search for improved decision tools for projects.

### 5 RESEARCH LIMITATIONS & FUTURE RESEARCH

The study provides a preliminary analysis of certain quality attributes of the measurement methods based on participants’ interaction with them. This is intended to help guide future investigations and refinement of the alternatives approaches, POMM and PPS, and improve the understanding TCM’s use in practice. Based on the resources available, a fair percentage of the participants were graduate students.

Proceedings ECIS 2009
students with relatively limited experience in IS projects although they otherwise had industry experience. Also, the time taken to learn about the artifacts (measurement models) was significantly less than what would be required in a real-world project environment. While the participants provided important insights into the perceptions of the methods, issues such as incomplete or imperfect understanding of the capabilities of the artifacts are taken into consideration. Thus, additional training may be required to facilitate a better understanding of the goals and capabilities of the PPS and POMM in particular.

We concur with the observations of Newsted et al (1998) that the survey approach is an effective research method because of its usefulness in gathering data about individual preferences and expectations, however, a key limitation is its provision of a just a snapshot of how individuals may be feeling at a particular time. This issue is taken into consideration as the participants’ state of mind may have impacted their responses and therefore the results. Consequently, further analysis preferably under real-world project settings are required to better gauge the attitudes towards them and the actual performance of these tools. Action research, field studies, case studies in diverse project, organisational and industry settings are some of the considerations for future studies.

6 CONCLUDING REMARKS

The research is intended to encourage debate on the application of different measurement methods in practice and the perception of its users. We observed that while this research area is evolving, the path to assuring that the developed artefacts satisfy the needs of the project environment for which they are developed is sometimes ignored. This is evident by the number of conceptual contributions (e.g. Atkinson 1999; Stewart 2008) and the paucity of analysis on the perception of users to the traditional paradigm for example. This study therefore attempts to redress this concern through the comparison of three (3) measurement methods including the traditional method TCM, and recently developed alternatives, the PPS and POMM. This was conducted within the ambit of utility, perceived semantic qualities (PEOU, PSQ, PUS, US) based on the perceptions of users in experimental conditions. The initial results provide encouraging results and support the value of different approaches to help users and decision makers in evaluating IS project performance.

Abstract

The design and evaluation of IT-systems are usually supported by different usability criteria. Our hypothesis is that criteria are predominantly formulated as supporting interaction between a user and an IT-system. We are claiming that there is a need for criteria formulated at higher levels such as communication and business processes. One example of a criterion formulated at the interaction level is “Visibility of system status” and one example of a criterion formulated at the business process level is “Quality of work”. If criteria is formulated and used on the interaction level only, the impact on design and evaluation can only take place at this level. This choice will also mean that you are only able to speculate whether the IT-system is supporting higher levels. We are not saying that criteria belonging to the interaction level are unimportant; rather we are saying that there is a need for formulating complementing criteria that resides on the communication and business process level.

Keywords: Usability criteria, Usability heuristics, Design principles,
1 INTRODUCTION

There is a lot of support available for designing and evaluating IT-systems (Jones 1970; 1990; Preece et al. 1994; Shneiderman 1998). The type of support we are addressing in this paper is normally referred to as usability criteria, principles, golden rules, factors or heuristics. We will use the name criteria in this paper when we refer to any of the concepts above. A common definition of criterion reads: a standard on which a judgment or decision may be based (AskOxford 2008; Merriam-Webster 2007). When we use the word criterion in this paper we mean a basis for comparison, like a reference point against which other ‘things’ can be evaluated. The aim of usability criteria is to support the design or evaluation of IT-systems (see section 2). We define usability as “a set of attributes that bear on the effort needed for use, and on the individual assessment of such use, by a stated or implied set of users” (AS/NZS_4216 1994).

The problem we are addressing is that several of the existing criteria seem to support the interaction between a user and IT-System and not the business process. In order to support this hypothesis we present a few concrete examples that can be found in the “Ten heuristics” constructed by Nielsen & Molich (1990). The first heuristic reads “Visibility of the systems status”. The second heuristic reads: “User control and Freedom” and the third heuristic reads: “Consistency and Standards”. All these heuristics are important but they are not primarily referring to the business process. They are formulated to support the interaction between a user and an IT-System. The same observations can be made from studying the “Eight golden rules” constructed by Shneiderman (1998). One of the golden rules reads: “Enable frequent users to use shortcuts” and another golden rule reads: “Offer simple error handling”. Our claim is that usability criteria should also be formulated to support communication between users and the business process.

We are viewing IT-systems as media or instruments that are used in order to support communication between users and business actions that are performed in the business process (Goldkuhl 2005), (see section 3). Therefore the use of an IT-system per se is only a means to achieve a higher goal; to successfully manage a business action that produces value for a client (Porter, 1985). Another basis supporting this hypothesis is a famous quote from Norman (1998), “I don’t want to use a computer, I want to accomplish something”. The first part of the quote “I don’t want to use a computer” is related to the interaction between a user and IT-System. The second part “I want to accomplish something” is directly related to the business process. Norman (1998) doesn’t want to worry about the system status, IP addresses, search algorithms or database structures. Norman (1998) wants to perform business actions in order to achieve a goal of a task. The IT-system is only a tool that should support him to achieve the goal through the performance of tasks. Therefore, the tool should reside in the background and the task (the business process) should reside in the foreground. The same way of reasoning is valid for usability criteria. Besides supporting interaction, we claim that usability criteria should support the design of the IT-mediated communication between users and should support the business process.

We have identified a few criteria that support the communication between users in a business. One example reads: “Satisfy communication needs” (Cronholm and Goldkuhl 2002). The meaning of this criterion is that a user should be able to “say” what he/she wants through the IT-System. We find these criteria are important, since they are highlighting the human-to-human perspective and not the more limited user-to-computer perspective (see section 2 for a more exhaustive discussion). Thereby, the use of an IT-system can also be viewed as a social process consisting of technology mediated business communication.

We have also identified a few criteria supporting the business process. We find these criteria very important since they are oriented towards the actions or activities that exist in a business process. One example of a business oriented criterion is “Task sequencing” (see Participatory Heuristic Evaluation constructed by Muller et al., (1998)). “Task sequencing” is important since it governs the designers’ attention towards how the IT-system can useful in the business. Our view is that there is a need for complimentary criteria supporting interaction, communication and business processes.
It seems that there are at least three levels that criteria can reside on; the “interaction level”, the “communication level” and the “business process level” (see section 3). Furthermore, it also seems possible to create relations between the levels. The formulation of criteria at the “business process level” can be formulated as business goals that should be achieved. The formulation of criteria at the “communication level” can be formulated as means for achieving the criteria formulated at the “business process level”. Consequently, criteria formulated at the “interaction level” can be viewed as means for achieving the criteria formulated at the “communication level”. This hierarchy and a classification of criteria will be the focus of this research.

The relation between the three levels constitutes a hierarchy. The advantage and role of a multilevel abstraction hierarchy is discussed in Rasmussen et al. (1994). Rasmussen et al. (1994) compares a multilevel abstraction hierarchy with a means-end hierarchy and claim that a multilevel abstraction hierarchy is often used in practical problem solving processes. Furthermore, having access to several levels of abstraction is important for effective problem solving. That is, the hierarchy could be used for identifying more concrete interaction criteria that supports the fulfilment of more abstract business process criteria. Vice versa; the hierarchy could be used for searching more abstract business process criteria when that is needed. Shifts in the level of abstraction during problem solving have proved to be supportive and has been demonstrated by Wason & Johnson-Laird (1972). We are not saying that usability criteria formulated at the lower “interaction level” are unimportant; vice versa they are an important means for supporting the achievement of a higher level and to offer concrete criteria.

Research on the concept of interaction is reported within the area of Human-Computer Interaction (i.e. (Bratteteig and Stolterman 1997; Löwgren and Stolterman 1999; Preece et al. 1994). Research on the concepts of business processes is reported within the area of business processes and information systems (Davenport 1993; Hammer 1990). The growing number of criteria lists has intensified the need for practitioners to be able to understand that criteria are formulated on different levels. Our ambition is that the results will hopefully contribute to both novice and experienced practitioners; primarily as an imperative to look for criteria supporting the business process level. A second aim is to persuade criteria constructors to formulate criteria residing on all levels. This introductory section is followed by a definition of the concept of criterion (section 2). In section 3 the concepts of interaction, communication and business process are discussed. Section 4 describes our research method and in section 5 we present the findings. Finally, in section 6 we present the conclusions drawn.

2 INTERACTION, COMMUNICATION AND BUSINESS PROCESSES

The aim of this section is define the concepts of interaction and business process in order to further explain why there is a need of criteria being formulated on communication and the business process level. An interaction is defined as the interplay between a user and an IT-system (Ågerfalk 2003). To further clarify the concept of interaction with IT-system we have used the Elementary Interaction Model (EIAL) originally introduced in Ågerfalk (2003) and revised in Goldkuhl et al. (2004) (see figure 1). According to the EIAL an interaction consists of four phases: informing, execution, IT-system reaction and interpretation (see figure 1). The first phase, informing, means that a user interprets the action possibilities offered by the IT-systems and in order to reach a decision about what to do. The second phase, execution, describes that the user is performing the action chosen. The third phase, IT-system reaction, describes the IT-system’s response to the user action. Finally, the fourth phase, interpretation, means that the user is interpreting the result of the IT-system’s reaction.

In the middle of the interaction loop there is an interface containing documents with which a user interacts. A document can be a form or a web page. The screen document plays different roles in the phases, providing a multifunctional interface. In the informing phase the document is used when the user is reading the screen to figure out what to do. It contains information about the action possibilities and other conditions. In the next phase the screen document is used for execution. In this sense, the
document functions as an action medium. For example, the user enters some data in a field and clicks on a button on the screen in order to perform an action. The phase of the IT-system reaction should be understood as a response to the user execution. The IT-system’s reaction can result in changes of the screen document (as a feed-back to the user). In this sense, the document consists of action results and functions as a basis for interpretation. This interaction can be examined in more detail from the human perspective by describing the low-level capabilities that may impact the interaction, like sensory, cognitive and motor domains (Persad et al. 2007).

![Diagram](image)

Figure 1. The Elementary Interaction Loop (Goldkuhl et al. 2004)

As mentioned in section 1, IT-systems are viewed as media that support the business actions. In most businesses or social contexts there is a lot of communication. Employees are communicating with each other through IT-system and employees are communicating with clients through the IT-systems in order to achieve business goals (Goldkuhl 2005). One example of such communication is a confirmation of an order. This is a communication that takes place between an employee and a client and it is also a communication that is taking place between employees (the order agent is informing a store man about the confirmation of an order).

The theoretical basis for viewing IT-system as communication and business systems are social action theory (e.g. (Weber 1978) and language action theory (Goldkuhl and Lyytinen 1982; Habermas 1985; Searle 1969; Winograd and Flores 1986). One main point in Weber’s (1978) theory of social action is that communication is intentional. Using a social action perspective means that it is not acceptable to view IT-systems as a black box with some social and organizational consequences (Dietz 2001). IT-systems should therefore be perceived as systems for business action. The language action theory conceives communication as one type of action. Communication is not restricted to a mere transfer of information. To communicate is to establish interpersonal relationships between the sender and the receiver (Searle 1969). In a language action perspective, IT-systems are not considered as “containers of facts” or “instruments for information transmission” (Goldkuhl and Ågerfalk 2002). This perspective emphasizes what users do while communicating through an IT-system. IT-systems are thereby socio-technical systems for action in business and such actions are the means by which business relations are created.

The need of communication between employees and between employees and clients can be supported by IT-systems. The use of IT-systems is not an end in itself. The use of IT-systems is instrumental in relation to other aims and actions. The aim of using IT-systems in a business context (or a public context) is to support the communication that is taking place when performing business actions. The communication is important since it contributes to fulfilling business goals. The communication level can in this respect be considered as means for the level of business action. Business communication is therefore part of business processes. The aim of a business process is to produce product(s) and/or service(s) in order to satisfy the need of a business client and business goals.
The concepts of interaction, communication and business process are depicted as three sets or three levels (see figure 2). As pictured, the interaction is the interplay between a user and IT-System and the communication is something that occurs between two users; mediated by an IT-system. The arrow in the picture symbolizes the business; a business that produces something (a product or a service) for a client. The communication level is viewed as a subset of the business process level and the interaction level is viewed as a subset of the communication level. That means that if the IT-system is considered as providing good support for the business level it consequently also provides good support for the lower communication level and interaction level. On the other hand, if an IT-system is evaluated at the interaction level no predictions can be made of the higher communication level and business process level. Our claim is that there is a need to formulate a balanced set of criteria at all the three levels discussed, not only at the interaction level. We are not saying that criteria formulated at the interaction level are useless; ideally we would like to see criteria residing at all the three different levels and that they are coherent and complementary.

## 3 RESEARCH METHOD

Our hypothesis reads that there is a need for formulating criteria on higher levels than the interaction level. To verify our hypothesis we need to establish that existing criteria lists mainly reside on the interaction level. Looking closer into existing criteria lists it is obvious that some of them can be characterized as general while others are more context specific. In order to choose lists that represent a variation we have used the following criteria of selection: general/context-specific, variation in perspectives, thoroughness, easy accessible and familiar to practitioners.

The first selection criterion, general and context-specific, means that we have chosen criteria list that represents both general and context-specific criteria (see appendix). The need for using context specific criteria is touched upon, in a study performed by Beck et al., (2003). Results from a literature survey indicate that 44 of 114 papers in the area of mobile human-computer interaction (small-screen devices) utilized traditional usability evaluation techniques such as heuristic evaluation (Nielsen 1993; Nielsen and Molich 1990) and that only six of the papers employed new methods in realistic mobile use situations. A mobile phone or a PDA, provide a significant increase in supporting communication of a large range of business actions. Examples communication and business actions supported by small screen devices are buying and delivering of tickets for travelling or tickets for entertainment.

The second criterion, a variation in perspectives, means that different perspectives should be represented such as business, communication, technical and user. The third criterion, thoroughness, means that the criteria lists should have a broad coverage. A broad coverage is condition since the

Proceedings ECIS 2009
designer (or evaluator) is focused on finding as many ‘problems’ as possible and wants the results to be as complete as possible (Sears 1997). The lists of criteria chosen must also be accessible to us, that is, they should be well described and easy to understand. Finally, as far as possible we have chosen lists of criteria that are well known.

We have also selected a research oriented, or an “academic”, criteria list that is not well known to practitioners. The reason for choosing this list is that it is based on a communication perspective and it has good thoroughness. The idea of incorporating this list is to understand if and how criteria generated from a communication perspective will relate to the more familiar criteria lists. Our final selection consists of six different criteria lists. All criteria lists (except the “academic” list) meet the selection criteria. Two of the lists can be characterized as being of a general character; these lists are the 10 usability heuristics (Nielsen 1993) and the Eight Golden Rules (Shneiderman 1998). Two of the lists represent the context of small-screen devices; the chosen lists are design guidelines for small screen devices (Kärkkäinen and Laarni 2002) and context-aware mobile applications (Häkkilä and Mäntyjärvi 2006). The final two lists represent the communication and business context. The chosen lists are Participatory Heuristic Evaluation (Muller et al. 1998) and the “academic” criteria list Actability Principles (Cronholm and Goldkuhl 2002).

The model presented in figure 2 has served as an analysis model (see section 2). Two coders (the authors) have classified the formulation of each criterion as belonging to the interaction level, the communication level or to the business process level. Both coders have been involved with the concept of usability for the past ten-year, in a pedagogical and research perspective. Each coder was provided with the criteria lists, which included the description text published by each criteria list author. The coder performed the categorisation of each criterion in the criteria list individual (separately). The coders identified that some of the criteria are formulated in a way that they can belong to more than one level. In these cases the coders needed to make a judgement for a primary classification based on the emphasis placed on the criteria’s description. Through classifying criteria an understanding of the scope and limitations of each criteria list has been achieved. The result of the classification of the criteria is based on the interpretation of the definitions and clarifications of the criteria presented in the literature. The results of the individual coding were then compared using the Cohen Kappa coefficient to ascertain the level of agreement between coders (Cohen 1960). This measure provides an easy calculation that test whether agreement between coders exceeds the chance levels of the coder classification. The calculation of classification of the criteria shows the level of agreement between coders (see section 5). The translation of the Kappa Statistics into strength of agreement is described by Landis and Koch (1977).

Once agreement levels were ascertained the similarities and discrepancies in the interpretation between coders of the criteria have been discussed. Where a disagreement existed, the criterion description was examined. The classification was then decided on the wording of the criterion and related to the level with the strongest relation. This process is not dissimilar to the conducting of a heuristic evaluation (Nielsen and Molich 1990), where inspectors examine an interface individually on two separate occasions and then come together to discuss their findings. In this way, both coders have ultimately agreed upon the final classifications discussed in the findings.

4 FINDINGS

The findings are presented according to the different contexts of the criteria lists chosen. First, we present the findings for criteria lists categorized as being of a general character (i.e. 10 usability heuristics (Nielsen 1993) and the Eight Golden Rules (Shneiderman 1998)). Second, we will present findings concerning the small screen devices (i.e. design guidelines for small screen devices (Kärkkäinen and Laarni 2002) and context-aware mobile applications (Häkkilä and Mäntyjärvi 2006)). Third, we will present our findings concerning the communication and business oriented criteria lists (i.e. Participatory Heuristic Evaluation (Muller et al. 1998)) and Actability Principles (Cronholm and Goldkuhl 2002)). Finally we will present a summary of the classifications. For each context the
criteria classification is made according to one of the levels interactive, communicative or business process. All the criteria lists are presented in the appendix.

4.1 Classification of criteria lists of general character

The findings show that most criteria belong to the interaction level, a few to the communication level and none to the business process level (see Table 1). This means that there is a heavy weighting towards the interaction level. The level of agreement between authors for this context is a Kappa value, $\kappa = -0.1$, that shows a poor agreement level. This disagreement was mainly due to the different interpretations of the wording of the description for criteria. The proportion of classifications made where authors agreed was $P_o = 0.6$. The main contention from the classification was with the interaction and communicative level.

Examples of criteria proposed by Nielsen (1993) that are classified as belonging to the interaction level are “Visibility of system status”, “Match between system and the real world”, “Consistency and standards” and “Aesthetic and minimalist design”. Another example proposed by Shneiderman (1998) reads: “Offer informative feedback”. The reason for classifying them at the interaction level is that they are all primarily referring to the interplay between a user and an IT-system. Examples of criteria belonging to the communication level are “Flexibility and efficiency of use” (Nielsen 1993) and “Design dialog to yield closure” (Shneiderman 1998). The reason for classifying these at the communication level is that they support the communicative intent of an action.

4.2 Classification of criteria lists of small screen devices

The findings concerning the criteria lists of small screen devices show that most criteria belong to the interaction level, a considerable number to the communication level and one to the business process level (Table 2). It is clear the concentration of criteria is predominantly found in the interaction level. It is interesting that the classification of the criteria list “context aware mobile applications” resulted in five of the criteria being classified as belonging to the interaction level and four of the criteria as belonging to the communication level. The level of author agreement for this context was a Kappa value, $\kappa = 0.4$, that is considered a fair level of agreement between the authors. The proportion of classifications made where authors agreed was $P_o = 0.7$. The disagreements in classifications were spread across all levels.

Examples of criteria proposed by Kärkkäinen and Laarni (2002) that are classified as belonging to the interaction level are “Present the most important information first at the top of the hierarchy”, “Re-think the navigational aids”, “Indicate the links clearly” and “Optimize the reading process”. Another example proposed by Häkkilä and Mäntyjärvi (2006) is “Avoid information overflow”. Clearly, the primarily aim of these criteria is to support interaction within the context of small screen devices.

Examples of criteria proposed by Häkkilä and Mäntyjärvi (2006) that are classified as belonging to the communication level are “Consider the uncertainty in decision-making situations” and “Prevention from interruption”. These criteria support the communicative intent of the performance of a task. These criteria are especially important for small screen devices because the mobility of the device can find the user in various situations that can have an impact on the communicative intent of IT-System (mobile device). Examples of criteria belonging to the business process level are “Determine the
The purpose of the site / service” (Kärkkäinen and Laarni 2002) and “Usefulness” (Häkkilä and Mäntyjärvi 2006). The argument for classifying these criteria at the business process level is that they are primarily referring to purpose and usefulness to the business.

### 4.3 Classification of criteria lists of communication and business process

The findings concerning the criteria lists of communication and business processes show that most criteria belong to the interaction level, a fair number to the communication level and a fair number to the business level (Table 3). Some interesting differences are that the actability principles are predominant at the interaction level and the communication level while the participatory heuristics evaluation criteria are predominant at the business process level (the +5 in the column “number of criteria” refers to the extension of the 10 heuristics (Nielsen 1993) and number between brackets refers to the 10 heuristics). The level of agreement by the authors for this context was a Kappa value, $\kappa = 0.9$, that is considered an almost perfect level of agreement. The proportion of classifications made where authors agreed was $P_o = 0.9$. The one difference was the criteria “Understand used concepts (familiar and understandable vocabulary)” (Cronholm and Goldkuhl 2002), which was classified within the interaction level by one author and communication level by the other author. This difference was discussed placed primarily in the interaction level based on the emphasis placed in the wording of the criteria’s description.

Table 3: Classification of criteria lists of communication and business process

Examples of criteria proposed by Cronholm & Goldkuhl (2002, 2005) that are classified as belonging to the interaction level are “Clear action repertoire”, “easy to navigate and “Familiar and understandable vocabulary”. Another example is “Skills” (Muller et al., 1998). The aim of these criteria is to support interaction. Examples of criteria proposed by Cronholm & Goldkuhl (2002, 2005) that are classified as belonging to the communication level are “Satisfy communication needs, “Understand the communicative intent of different messages” and “Offer good support for business actions”. All these three examples are primarily aimed at supporting the communication between users. Examples of criteria proposed by Muller et al. (1998) that are that are classified as belonging to the business process level are “Task Sequencing” and “Quality of work”. The reason for viewing these criteria as belonging to the business process level is that they refer to the business tasks or work. They are aiming at providing value for a client.

### 4.4 Summary of Classifications

The findings concerning all the criteria lists show that a huge majority of the criteria is classified as belonging to the interaction level, some to the communication level and a few to the business level
Five of the six analyzed criteria lists consist of a majority of interactive criteria. It is not surprising that the business process orientated contexts embrace more criteria that are characterized as related to the communicative or business process dimension. What is notable is that both the contexts of general and small screen devices have a strong focus on interaction. The analysis shows that the communicative and business process levels have been neglected in several of criteria lists. An interesting observation is that even criteria lists characterized as being communication and business oriented, embrace criteria that mostly belong to the interaction level.

In summary, for all the criteria lists analysed, the proportion of classification made where authors agreed, $P_o = 0.78$, and the proportion of categorisations made where agreement is expected by chance, $P_c = 0.51$. This describes a very high level of agreement on classifications between authors, based on $P_o$. The coefficient of agreement, Cohen’s (1960) Kappa, for all of the criteria lists classified, $\kappa = 0.56$, is a moderate level of agreement between authors, as describe by Landis and Koch (1977), see figure 3. This provides an excellent starting point for the two authors to come to a consensus in the classification of criteria. The heavy weighting towards the interaction level has also been identified by Sears (1997). Sears (1997) discusses this gap from an evaluation technique perspective and proposes a combination of a heuristic evaluation (Nielsen 1993) with a cognitive walkthrough (Nielsen and Mack 1994) in order to achieve a better usability outcome. Our interpretation of the research by Sears is that he attempts to compensate for the gap between the interaction level and the business level. All the lists contain gaps in one or two of the proposed levels. It seems that the inventors of the lists have applied, consciously or not, a specific perspective while constructing the lists. The best coverage of all the levels can be found in Participatory Heuristic Evaluation (Muller et al. 1998).

5 CONCLUSIONS

Our hypothesis reads that there is a need for formulating criteria at higher levels than the interaction level. The analysis has shown that criteria: mainly support the interaction between a user and an IT-System, are not formulated to support a human-to-human communication (mediated by an IT-System) and are not formulated to support the higher level of business processes. The definition of usability (see section 1) puts the onus on the practitioner to define the “set of attributes” that defines the usability goals for a project. The aim of the model presented in section 2 is to support the practitioner to explicitly define and select criteria at different levels.

Before drawing conclusions we would like to say that criteria are not something that should be used in a mechanical way. You should always be open to other problems and strengths that are not covered by the criteria used. But, using criteria means to intentional focusing on certain aspects that correspond to the criteria selected. That’s why a selection is important. If criteria formulated on the interaction level only are used, design and evaluation can only take place at this level. This choice will also mean that you are only able to speculate whether the IT-system is supporting the higher levels, i.e. the communication level and the business process level. If a designer or evaluator is using criteria belonging only to the interaction level, there can be a risk of unconsciously overlooking other
important aspects of the IT-systems. We are not saying that criteria belonging to the interaction level are unimportant, rather we are saying that there is a need for formulating complementing criteria residing on the communication and business process level.

In order to get a broad coverage of different criteria lists, we selected three different contexts. The importance of identifying different contexts is acknowledged by Henninger et al. (1995). They claim that “If the potential of usability guidelines as an interface design technique is to be fully realized, they need to be augmented with context-specific guidelines and examples that synthesize isolated guidelines into domain-specific solutions to design problems”. One conclusion is that the contexts do not differ that much when looking at each list’s relative distribution of interactive, communicative and business process oriented criteria. Most of the criteria, considering all the contexts, are formulated as interaction criteria. Otherwise, there are no major differences between the lists, except that the lists “Context Aware Mobile Devices” (Häkkilä and Mäntyjärvi 2006) and “Actability principles” (Cronholm and Goldkuhl 2002) that tend to lean more towards the communicative level.

Our conclusion that most criteria are oriented towards interaction is supported by Hartson et al. (2001) who are claiming “Usability is seated in the interaction design”. Another observation that supports our conclusion is the criteria list constructed by Muller et al. (1998). We interpret the criteria added by Muller et al. (1998) to Nielsen’s 10 heuristics (1993) as a reaction towards Nielsen’s formulations. The five added criteria by Muller et al. (1998) are mostly formulated at the business process level. Table 4 clearly shows that the work done by Muller et al. (1998), has identified the imbalance in the original criteria, proposed by Nielsen (1993). Hornbæk & Erik Frøkjær (2008) support the importance of using criteria residing on higher levels. They claim that problems discovered will have higher business relevance.

The result is based on the analysis of six usability criteria lists and the results have to some extent been compared to existing theory. Our opinion is that the direction of the results works as a good basis for further elaborations. There is a need of further elaborations considering other criteria lists and other types of IT-systems. As future research we also propose a deepened elaboration on the relations between the three levels described.

**Nielsen’s (1993) Heuristics**
- Visibility of system status
- Match between system and the real world
- User control and freedom
- Consistency and standards
- Error prevention
- Recognition rather than recall
- Flexibility and efficiency of use
- Aesthetic and minimalist design
- Help users recognize, diagnose, and recover from errors
- Help and documentation

**Shneiderman’s (1998) Eight Golden Rules**
- Strive for consistency.
- Enable frequent users to use shortcuts.
- Offer informative feedback.
- Design dialog to yield closure.
- Offer simple error handling.
- Permit easy reversal of actions.
- Support internal locus of control.
- Reduce short-term memory load.

**Häkkilä & Mäntyjärvi’s (2006) Context Aware Mobile Application Guidelines**
- Consider the uncertainty in decision-making situations.
- Prevention from interruptions.
- Personalization.
- Avoid information overflow.
- Secure the user’s privacy.
- Remember mobility.
- Secure the user control.
- Access to context.
- Visibility of system status.
- Usefulness.

**Kärkkäinen & Laarni’s (2002) Small Screen Device Guidelines**
- Determine the purpose of the site / service

Re-evaluate the interface metaphors
Present the most important information first at the top of the hierarchy
Re-think the navigation aids
Indicate the links clearly
Optimize the reading process
Use markers while scrolling or paging text
Use pictures with caution

**Cronholm & Goldkuhl’s (2002; 2005) Actability Principles**
- Easy to understands what can be done with the system (clear action repertoire)
- Able to “say” what he/she wants through the system (satisfy communication needs)
- Can easily move to another document (easy to navigate)
- Understand consequences of proposed and performed actions (action transparency)
- Can immediately see if the intended action is executed (clear feedback)
- Can easily access information of what has been done previously (easy access to action memory)
- Know who has said what (personalized information)
- Understand used concepts (familiar and understandable vocabulary)
- Understand the communicative intention of different messages
- Offer a good support for business actions

**Muller et. al.’s (1998) Participatory Heuristic Evaluation (the added five criteria to Nielsen’s 10 heuristics)**
- Task Sequencing
- Skills
- Pleasurable and Respectful Interaction with the User.
- Quality Work
- Privacy

USING GROUNDED THEORY FOR STUDYING BUSINESS PROCESS MANAGEMENT PHENOMENA

Seidel, Stefan, University of Liechtenstein, Fuerst-Franz-Josef-Strasse 21, 9490 Vaduz, Principality of Liechtenstein, stefan.seidel@hochschule.li
Recker, Jan, Queensland University of Technology, Brisbane QLD 4000, Australia, j.recker@qut.edu.au

Abstract

Grounded theory has emerged as a promising research approach for generating theory in emerging and relevant domains of IS research. In this paper we advance the use of grounded theory in one important and under-researched IS domain, business process management, which is characterized by an abundance of conceptual work with very little thorough theory development. We provide an illustrative case study that shows how grounded theory allowed us to develop theories about creative organizational processes, and the influence of creativity requirements on the management of such processes. Based on the experiences gathered, we then suggest a set of key issues that highlight why and when grounded theory can be particularly suitable for the study of phenomena associated with the business process management domain. We also provide examples for other inquiries that could benefit from the use of grounded theory.

Keywords: Grounded Theory Method, Business Process Management, Research Methods, Qualitative Research
1 INTRODUCTION

Development of theory is key to Information Systems research and to any scientific endeavour pertaining to the development of a deep and meaningful understanding of certain real-world phenomena that we observe in day-to-day life. Theory development can take many forms, from analysing available literature and extending existing theoretical models, to using common sense or experience (Eisenhardt, 1989). Over the last decades, other forms of theory development have also emerged, using case study research (Eisenhardt, 1989) or the grounded theory method (GTM) (Glaser & Strauss, 1967; Strauss & Corbin, 1998).

These types of qualitative research have gained increased popularity in IS research (e.g., Urquhart, 2001; Fernández et al., 2002), suggesting that grounded theory is becoming a well-accepted research method in IS research. The grounded theory approach essentially attempts to explore for, and develop, generalised formulations about the general features of a phenomenon while simultaneously grounding the account in empirical observations or data (Martin & Turner, 1986). One of the key advantages – and challenges – of the grounded theory approach is that it is applicable to research domains that are characterized by their emergence and lack of substantive theory.

One such domain is the area of business process management (BPM), a recently emerging key area of IS research that is characterized through high relevance to practitioners (Gartner Group, 2009) but also the absence of rigorous or mature theoretical foundations (Rosemann et al., 2006). It is not the case that no empirical work or theory development has been carried out. Known studies report on the use of Delphi studies (Indulska et al., 2009), case studies (Bandara et al., 2005), focus groups (Radulescu et al., 2006), experiments (Mendling et al., 2009) or surveys (Recker, 2008) in their endeavours of exploring the BPM domain for generalizable insights and testable propositions. Continuing alongside the work of our colleagues, in this paper, we advance the Grounded Theory Method as an alternative research method for studying phenomena typically associated with business process management.

Over the last years, we have conducted a grounded theory study in order to investigate organizational creative processes (e.g., Seidel et al., 2008; Seidel, 2009). In this paper, we use examples from this study to illustrate the benefits and challenges in applying GTM to business process management research. Accordingly, our paper seeks to contribute to the IS body of knowledge by discussing the use of GTM in studying BPM phenomena. In doing so, we present a set of issues that are grounded in findings we have made conducting a BPM study where GTM was used in order to analyse data and generate theory.

We proceed as follows. The next section provides a brief overview of the use of GTM in IS research as well as a brief introduction into the area of BPM including a review of related BPM research. We then advance GTM as an appropriate research method for BPM. This is followed in Section 3 by the description of a GTM study on organizational creative processes. Then, we discuss in Section 4 issues that emerge when studying BPM phenomena through the lens of GTM. The paper concludes with a discussion of limitations and contributions and provides an outlook to future research endeavours.

2 BACKGROUND

2.1 Grounded theory

Over recent years, the grounded theory method has increased as a popular research approach employed in a number of IS studies (e.g., Orlowski, 1993; Urquhart, 1998; Trauth, 2000; Fernández, 2003). Furthermore, several papers discuss issues around the usage of GTM in order to study IS phenomena (Urquhart, 2001; Fernández et al., 2002; Urquhart & Fernández, 2006). Usually, these
studies focus on some kind of IT-related processes. Urquhart (1998), for example, investigated processes of early requirements gathering, while Orlikowski (1993) studied the adaptation and use of CASE tools over time. The nature of the phenomena that were studied highlight that GTM can be used in order to gain contextualized, rich description of certain phenomena.

Grounded theory, in general, is seen as a method for building theory, not verifying it (Strauss & Corbin, 1998). The approach is based on two main principles. First, the process of theory-building is highly iterative, during which theory and data are constantly compared. This process can be referred to as comparative analysis. Second, GTM builds upon theoretical sampling as a process of data collection and analysis that is driven by concepts that emerge from the study and appear to be of relevance to the nascent theory (Strauss & Corbin, 1998).

Two main streams of grounded theory can be distinguished. Grounded theory was first introduced as a general qualitative research method by Glaser & Strauss (1967). Strauss (1987) and later Strauss & Corbin (1998) then revised this general understanding and provided detailed procedures and techniques for the analysis of data. In IS research, both types of approaches have been used in studies, those that are rather “Glasarian” (e.g., Fernández, 2003) and those that are rather “Straussian” (e.g., Urquhart, 1998). Urquhart (2001) notes that whether the more rigid approach suggested by Strauss (1987) works may depend on the nature of the phenomenon studied.

In the study conducted we applied the paradigm suggested by Strauss & Corbin (1998) – with some adoptions, which will not be discussed in detail in the interest of brevity – as their approach promised to lead to meaningful results with regard to the particular BPM phenomenon we were investigating. The Straussian approach is conducive to studying processes because “by answering the questions of who, when, where, why, how, and with what consequences, analysts are able to relate structure with process” (Strauss & Corbin, 1998 p 127). Straussian GTM studies typically follow a basic three stage procedure:

- **Open Coding:** In general, open coding is a process of identifying a set of themes or categories that appear to be relevant in order to describe and explain the phenomenon under investigation. Such category is a conceptual element of a theory – an abstract representation of something identified through the data as being significant. Moreover, the researcher identifies properties and dimensions of categories.

- **Axial Coding:** In axial coding, relationships between categories are identified. To do so, Strauss & Corbin (1998) distinguish different types of sub-categories, which they label conditions, actions/interactions, and consequences. By grouping categories, the researcher starts to link structure with process. This involves taking the categories that emerged during open coding and reassembling them with propositions about their relationships. These emerging propositions form a theoretical framework.

- **Selective Coding:** In selective coding the core category, the central phenomenon of the research, is identified and other concepts are related to the core category. Thereby, the nascent theory is integrated by linking the different categories to the central research phenomenon.

In summary, grounded theory is thought to ensure that nascent theory is informed by the data; it is not preconceived or forced upon the data but rather emerges from it. However, it has been argued in the literature that grounded theory studies do not completely omit any existent theory. Urquhart and Fernandez (2006), for instance, call this misconception the myth of the “researcher as a blank slate.” Strauss and Corbin (1998) suggest that researchers may consult literature or experience in order to uncover examples of similar phenomena. When doing so, researchers should be self-reflective, so as to be aware of biases that may result from their own background knowledge. In the study we discuss in this paper, this suggestion encouraged us to constantly ‘step back from the data’, and to question ourselves whether concepts and relationships were actually grounded in the data, or were imposed by us through preconceived knowledge.
2.2 Research on BPM phenomena

Business process management (BPM) is a holistic management practice that (re-) emerged during the 1990s based on work on business process re-engineering (Hammer, 1990), total quality management (Powell, 1995) and process innovation (Davenport, 1993). BPM denotes a holistic, complex practice to organizational management that builds upon the notion of a business process, a series of tasks or activities that need to be carried out in order to collectively realise an organisational objective or policy goal, and a set of conditions that determines the order of the tasks (Hammer, 1990). These processes span an organization from end-to-end and include the involvement of organizational as well as IT resources, policies, regulations, contextual environments, risk factors and other phenomena. In its attempt to manage these processes effectively and efficiently, BPM addresses various aspects of strategic alignment, governance, methods, IT, people and culture (Rosemann et al., 2006) – indicating not only the complexity of the problem but also the complexity of the management approach.

The complexity and richness of business process management makes it certainly attractive as a research domain. And indeed, recent years have seen an increasing number of scholarly works examining various, discrete phenomena and artifacts pertaining to BPM. Much work, for instance, has been carried out in areas of process modeling artifacts (Rosemann et al., 2008), the development of process-aware information systems (van der Aalst et al., 2007), or approaches towards process optimization (Reijers & Mansar, 2005). This work has in common that it is mostly conceptual or analytical in nature, and considers discretely (i.e., in isolation) a particular BPM artifact, stripping away the contextual environment in which such artifacts are being put to use in practice.

This situation indicates a lack of substantive or holistic theory on the management of processes, the lifecycle of related phenomena (such as adoption or use of tools or methods), suitable governance mechanisms, decision making strategies and other related aspects of interest (de Bruin, 2007). While the lack of foundational theory denotes a challenge to academia and industry, it also denotes a window of opportunity for IS scholars to contribute to theory development in this emerging and relevant area of IS research. And indeed, some exploratory work has been carried out. For example, on the basis of case studies, Bandara et al. (2005) developed a theoretical model of the critical success factors of process modeling. Rosemann et al. (2006) use a multiple case study approach together with a Delphi study to develop a theory of BPM progression in organizations; and Recker (2008) used semi-structured interviews and the survey approach to building and testing a theoretical model of process modeling standard usage.

These studies are stimulating examples for theory development work, using ‘typical’ research methods prevalent in Information Systems. Continuing this work, we now advance the grounded theory method as an alternative, complementary or additional research method that we deem highly applicable to the BPM research domain.

2.3 On the Applicability of GTM to the Challenge of Studying BPM Phenomena

Business process management is concerned with the management of complex social, organizational processes that involve various stakeholders as well as other organizational or IT-based resources, policies or artifacts (Rosemann et al., 2006). We argue that the BPM domain, due to the complex and contextualized nature of its associated phenomena, is a primary application area of the GTM method. More specifically, we advance that GTM as an inductive, data-driven method can provide new insights into BPM phenomena.

This argument rests on three key observations. First, business processes are highly dependent on, and influenced by, the contextual environment in which they are embedded (Rosemann et al., 2008). Grounded theory aims at generating substantive theory and places special emphasis on the premise that contextual complexities and particularities need to be incorporated into an understanding of a particular phenomenon (Orlikowski, 1993). Thus, GTM as an inductive approach to generating theory...
can help researchers to gain an in-depth understanding of business processes and themes related to these.

Second, BPM research focuses on practical issues and, thus, emphasizes practical relevance. Similarly, GTM studies are suggested to generate theories that are not only rigorously developed but also provide useful insights for practitioners. Glaser (1978) argued that GTM has the potential to generate theory of high practical relevance. His arguments include the capacity of grounded theories to support practitioners in providing additional aspects that were not empirically known to them as well as increasing the experts’ ability to deal with new situations (Fernández et al., 2002).

Third, process management philosophies have at their core the notion of a business process as a collection of activities that takes one or more kinds of input and creates an output that is of value to the customer (Hammer, 1990). Such processes are dynamic in nature and range from highly structured, to highly unstructured, even artistic processes (Hall & Johnson, 2009). Grounded theory is seen as being particularly fitting to study such types of processes because it facilitates “the generation of theories of process, sequence, and change pertaining to organizations, positions, and social interaction”(Glaser & Strauss, 1967 p 114). Orlikowski (1993) frames GTM as a research approach that specifically includes elements of process and change, thereby implying a close connection to the process phenomenon that builds the core of BPM.

In the following section we provide further details about the applicability of GTM to the study of BPM phenomena, by describing our experiences gathered in a GTM study of organizational creative processes. We complement our experiences with the consideration of extant literature on the use of GTM in IS research.

3 A STUDY OF ORGANIZATIONAL CREATIVE PROCESSES

3.1 Study objectives

The research aimed at studying business processes that are characterized by creativity. Creativity is a process, carried out in complex social settings, that leads to creative products that are both novel and purposeful (Woodman et al., 1993). While a number of theories exist that describe the occurrence of creativity, creative behavior and creative products (e.g., Rubenson & Runco, 1992), they are only of limited value when considering a process perspective. This is because, typically, business processes that contain creativity are constituted by both transactional, well-structured parts as well as creative parts where the first and the latter are closely interrelated. Thus, organizations are required to gain a holistic understanding of such end-to-end business processes; they need to understand what factors shape the process and what process-related strategies and IT systems can be applied in order to deal with particular characteristics, such as particular risks being caused by high demands for flexibility and high uncertainty with regard to the creative output. Understanding the phenomenon of creativity at a process level is imperative to the development and adaptation of information systems artifacts, as well as of organizational change within creative organizations, so as to ultimately enhance organizational effectiveness without compromising creativity. Besides this high practical relevance, such a study also exhibits an academic challenge, as it can contribute meaningfully to the IS body of knowledge by providing substantive theory that can then be used as a starting point to conduct research in other substantive areas in order to proceed to more general theory in the field of BPM. Consequently, the themes that were identified within the contextualization stage of this research were business processes that contain creativity, and the question of how these processes can be managed. This could be expressed in terms of a quite general research problem. Correspondingly,

**Research problem:** How does creativity influence business processes and business process management?
Note that this rather broad research problem was further developed into a set of more specific research questions which evolved during the course of this study. Specific research questions aimed at the identification of contextual factors, strategies and information technology that organizations apply in order to manage their processes, as well as intended and unintended consequences. In the following we demonstrate how the different stages of the approach (as described in Section 2.3) were utilized in order to study a particular BPM phenomenon. We also provide reflections hinting at different issues that came up throughout the study.

### 3.2 Data Collection

Data was collected from three Australian organizations from the field of film and visual effects production. Processes in this industry can be described as highly dependent on creativity, interdependent, intensively involving the client, complex, but also repetitive (Seidel, 2009). The products, such as visual effects sequences, are highly creative as they are characterized by both novelty and purposefulness.

Glaser and Strauss (1967) encourage researchers to include multiple data collection techniques, to allow the researcher to consider multiple viewpoints from which an emerging concept can be analyzed, substantiated, and its properties be developed. Our data collection strategy involved semi-structured interviews, process modeling and document analysis. More than 30 individuals were interviewed over two years. Process models provided the researchers with an advanced understanding of the nature of the processes being studied. This knowledge was then used in order to conduct further semi-structured interviews and theoretical sampling. For instance, the process models allowed the researcher to ask more focused questions with regard to IT systems, involved actors, or required resources. The analysis of documents, such as press releases, helped to further contextualize this research. Due to space limitations, in the present paper we limit our illustrations to data that was collected in semi-structured interviews.

### 3.3 Open Coding

Open coding started with a process referred to as microanalysis (Strauss & Corbin, 1998). That is, a line-by-line analysis of semi-structured interviews to identify initial codes was carried out. This enabled comparisons within the same group as well as comparisons with different groups (i.e. the case organizations). A close examination of data to identify both differences and similarities allows for fine discrimination and differentiation among categories” (Strauss & Corbin, 1998 p 102). Table 1 provides some exemplary open codes.

By grouping concepts into categories, the number of units the researcher works with can be reduced. In our case, Table 2 provides an overview of how concepts were integrated into higher level categories. For example, various concepts could be identified as supporting the strategy of communication with the client, whereas other could be identified as supporting the category of managing creativity internally. Similar, different potential roles of persons in creative organizations could be grouped under the category of the artist, whereas other roles were grouped under the category of the creative supervisor. For example, leads, visual effects supervisors, producers, and team leaders were grouped under the category of the creative supervisor as these concepts share various characteristics that are of relevance in order to explain how processes in creative environments are managed.

</tr>
</tbody>
</table>

Having formed categories, these could be further developed by identifying their properties and dimensions. As properties can vary along dimensional ranges, they give concepts variation. For example, artists are characterized by a certain attitude towards IT. This attitude varies on a continuous range from IT-averse to IT-affine.

Arguably, even though GTM concerns the emergence of theory from data, such research also starts with some (inevitable) preconceptions. Yet, through the open coding exercise, a number of apparent concepts emerged during the research that the researchers had not thought about beforehand. Moreover, open coding enabled the development of categories with great explanatory power that was expressed by properties and dimensions that enabled to cover a broad range of various situations. Thus, open coding provided rich insight into the processes that were studied. For instance, it became apparent that managing processes in creative environments requires the managers to gain an in-depth understanding of a complex interplay of various factors in order to decide what strategies and tactics can be used and combined in a particular situation.

3.4 Axial Coding

The central purpose of axial coding is to relate structure with process. In this study it was sought to understand the structure of processes in creative environments, that is, involved stakeholders, resources, etc., as well as how organizations effectively deal with such processes. In order to identify relationships, Strauss & Corbin (1998) propose a paradigm that differentiates categories into conditions (contextual, causal, and intervening), phenomena, actions/interactions, and consequences. Eventually, this process of relating categories results in the formation of conjectures or hypotheses. To that end, categories are related at a dimensional level.

In the present study, for example, requirements specifications to the creative product was identified as a contextual factor that impacts the context of organizational creative processes. The data further suggested that requirements specifications may vary from low to very detailed. Thus, requirements
specifications can be qualified dimensionally and then be related to the category of the creativity-intensive process. This insight, in turn, leads to the following preliminary proposition:

**Detailed requirements specifications to the creative product (dimensionally qualified factor) lead to low variance in outcome (dimensionally qualified consequence) of the process (phenomenon).**

This way, the conditional structure was identified and thus structure was linked with process. The paradigm was useful to studying the phenomenon under observation. The distinction between contextual factors, strategies, and consequences enabled the researchers to generate an understanding of the studied processes, which very much represents common perspectives on business processes, as, for instance, evidenced in the wide range of different required capability areas for progression BPM in organizations (de Bruin, 2007).

### 3.5 Selective Coding

Axial coding was followed by selective coding, where the core category representing the central phenomenon of the study was identified and other (sub-) categories were related to it in order to proceed to an integrated theoretical scheme. The **creativity-intensive process** representing organizational creative processes was identified as being the core category of this research. When the act of selective coding was started, we could see that there was need to further group concepts in order to densify categories. For example, in open coding and axial coding two main groups of strategies could be identified: those referring to internally managing creative processes, and those referring to externally managed creative processes. Table 3 shows how the categories of communication with the client and managing creativity internally were grouped under a higher-level category strategies in managing creativity-intensive processes. The category of strategies in managing creativity-intensive processes by itself became a sub-category of creativity-intensive processes, explaining how creative organizations deal with the phenomenon of creativity within business processes.

**Table 3: Relating categories to sub-categories**

<table>
<thead>
<tr>
<th>Category</th>
<th>Sub-category</th>
<th>Specific strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strategies in managing</td>
<td>Communication with the client</td>
<td>Creative brief, matching requirements with capabilities, providing stimuli, showing</td>
</tr>
<tr>
<td>creativity-intensive processes</td>
<td></td>
<td>references, ongoing communication, showing work in progress, approval and review</td>
</tr>
<tr>
<td></td>
<td>Managing creativity internally</td>
<td>Task allocation and team building, resource allocation, managing the scope of creativity,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>internal reviews, internal task breakdown</td>
</tr>
</tbody>
</table>

All contextual factors, strategies, and consequences were mapped to the creativity-intensive process. As business processes provide a cross-functional perspective onto an organization, they are of such complex nature that they can be viewed as a concept with the capacity of integrating both structural and dynamic aspects of the emergent theory. Moreover, selective coding led to a substantial reduction to few categories with greater explanatory power. Thus, a parsimonious theoretical frame was established that consisted of only a limited number of concepts grounded in a multitude of incidents.

### 4 ON THE USE OF GTM FOR STUDYING BPM PHENOMENA

Orlikowski (1993) justified the usage of grounded theory through its focus on contextual and processual elements, and its focus on the action of key players associated with organizational change. Obviously, these aspects are of relevance also to BPM: the researcher studies processes as well as the action of key players (usually referred to as actors) who participate in organizational processes or see to the governance or management of these.
As the above described example shows, understanding BPM issues not only requires understanding what tasks are carried out in what order and what resources are required and what is the process output (i.e., a mere ‘process’ focus). It also requires the researcher to understand a variety of contextual factors that impact the business process and also strategies and tactics that individuals and organizations apply in order to handle these complex phenomena. Moreover, one must understand both intended and unintended consequences. Such strategies and tactics, for example, often involve the application of IT systems (van der Aalst et al., 2007), involve the assessment and mitigation of organizational risks (Lambert et al., 2006) or other contextual elements (Rosemann et al., 2008).

In the BPM study conducted, the grounded theory study allowed us to uncover that organizational processes in film and visual effects production organizations are characterized by a complex interplay of artists, clients, creative supervisors, and organizational resources. Creativity in such business processes causes high unpredictability with regard to process structure, required resources and process outcome. Therefore, the processes are characterized by the iterations between creating a mutual understanding of the requirements of the creative product, generating the creative product, and reviewing it. In order to manage this process, creative supervisors act as process intermediaries and apply various strategies in both internally managing the process and communicating with clients while they pursue both creative and operational process performance.

The experiences in our study strongly suggest that GTM as an inductive, theory-building research method is appropriate to provide insights into BPM-related phenomena. We found that particularly the GTM focus on involving a variety of data sources as a valuable approach to research. The triangulation can help researchers to consider various viewpoints onto a particular phenomenon (e.g., a process), and, in turn, develop rich and comprehensive insights. Yet, with all benefits considered, we also encountered challenges and issues in our study. Table 4 provides an overview of such issues that advocate the use of GTM in order to study BPM related phenomena. The different issues are illustrated by examples from the above study.

Table 4: Using GTM for studying BPM issues

<table>
<thead>
<tr>
<th>#</th>
<th>Issue</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Practical Relevance</td>
<td>GTM aims at producing substantive theory of high practical relevance.</td>
<td>The substantive theory that was developed is applicable to the particular context. It provides practitioners with profound knowledge about factors that need to be considered when managing organizational creative processes. Moreover, the theory explains what strategies and tactics can be used and combined in order to handle specific situations.</td>
</tr>
<tr>
<td>2</td>
<td>Starting point for developing formal theory</td>
<td>Substantive theory can be the starting point to proceed to more general theory.</td>
<td>In our study we first generated a theory on business processes applicable to the substantive area of the creative industries. By engaging with existent theory we proceeded to a more general theory. In later work such theory may then be formalized and/or tested.</td>
</tr>
<tr>
<td>3</td>
<td>Accounting for contextual factors</td>
<td>GTM produces theory that accounts for both intervening and causal conditions and, thus, recognizes the context of business processes and business process management issues.</td>
<td>Particular attention was paid to the various factors that impact business processes in creative environments. It turned out that processes highly depend on both internal and external factors that must be considered when managing processes.</td>
</tr>
<tr>
<td>4</td>
<td>Inductive nature</td>
<td>The inductive, emergent nature of GTM enables researchers to discover new concepts and relationships that have not been considered in previous studies.</td>
<td>The GTM approach led to the development of complex categories with great explanatory power. For each category a number of properties was identified that enabled to explain a variety of situations. Thus, the method enabled not only to identify ‘obvious’ concept (e.g., tasks and roles) but also other concepts (e.g.,</td>
</tr>
</tbody>
</table>
personal traits and abilities of actors) that need to be considered when managing processes.

Various techniques of data collection were used, including semi-structured interviews and the usage of process modeling techniques and related process documentations. This triangulation across methods provided rich insights incorporating different viewpoints.

It turned out that the method could capture the dynamic nature of organizational processes. Different stages of processes could be identified and various strategies and tactics could be linked to these stages.

The detailed procedures of GTM helped the researchers to rigorously develop theory without being lost in vast amounts of data.

5 Using multiple methods of data collection

Grounded theory enables the researcher to include a variety of data sources; for example, process models, process descriptions or voiced process experiences, that can often be found in organizations.

6 Studying processes

GTM is particularly fitting in order to study process-related issues.

7 Guidelines

GTM provided guidelines how to actually conduct a study

Over and above the issues and examples described in Table 4, GTM also comes with the label of being highly relevant to practice. Glaser (1978) argues that grounded theorists can contribute a great deal by providing the ‘man in the know’ with substantive theory, and expresses a number of arguments suggesting the high practical relevance of GTM studies (see Table 5, leftmost column). Arguably, the BPM domain is a field characterized by high relevance to practice (Gartner Group, 2009). In this domain, the relevant ‘man in the know’ may be a BPM professional, process owner, or manager responsible for a particular process. We argue that GTM-generated theory does in fact provide these stakeholders with information and insights relevant to their task settings. Accordingly, in Table 5 we provide exemplary evidence for the arguments provided by Glaser (1978) to substantiate of relevance.

Table 5: Practical relevance of GTM studies of BPM phenomena

<table>
<thead>
<tr>
<th>Arguments for practical relevance, adopted from (Glaser, 1978)</th>
<th>Practice of BPM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Practitioners get the ability of identifying additional consequences, conditions, and strategies beyond those that were empirically known to them</td>
<td>Particularly those BPM practitioners that are relatively new to a field will profit from theory that explains essential conditions, strategies and consequences. Thus, grounded theories can be used to inform practitioners about both intended and unintended consequences and, for example, may facilitate risk management.</td>
</tr>
<tr>
<td>Practitioners are supported in expanding the description and meaning of incidents by placing them into the greater context. Increasing the expert’s capacity to know by introducing a limited number of concepts that can be applied in various situations.</td>
<td>The BPM practitioner is able to abstract from a specific situation (such as a specific process failure), reflect on it, and develop new solutions to the problem situation at hand.</td>
</tr>
<tr>
<td>By expanding the practitioners’ theoretical knowledge, they are enabled to expand their capacity to deal with new, more complex situations, as their knowledge is not limited to particular incidents anymore. The theory helps experts to emancipate from restrictions of their specific expertise as theory enables them to become more open to change as they begin to see that certain incidents are mere patterns of a process.</td>
<td>Grounded theorists try to generate categories with great explanatory power. Such powerful concepts can be easily remembered by BPM practitioners and applied in various contexts.</td>
</tr>
<tr>
<td></td>
<td>BPM practitioners can assume responsibility for more complex processes. By applying theoretical knowledge they are no more limited to only knowing certain instances of particular processes.</td>
</tr>
<tr>
<td></td>
<td>Business processes in many industries are highly dynamic and require BPM practitioners to constantly adapt to new challenges. Thus, emancipation can be seen as an important enabler for process change.</td>
</tr>
</tbody>
</table>
Practitioners see their knowledge in a theoretical view and can capitalize on it through sharpened judgment and the improved ability to identify new strategies etc.

BPM practitioners become sensitized and are empowered to identify new strategies and practices in order to successfully manage processes.

5 CONCLUSION

In this paper we advanced the use of grounded theory as a research method appropriate to the study of phenomena typically associated with business process management. Based on the experiences gathered during a study of organizational creative processes, we outlined arguments for the use of GTM in general, and the ways in which it can be used for theory development in the context of Business Process Management in particular.

With our paper we seek to contribute to the ongoing discussion on the application of qualitative research methods to the IS discipline. We have argued that GTM is particularly fitting to study BPM phenomena. This is mainly reasoned by the nature of such phenomena and related studies: (1) BPM phenomena are often bound to particular contexts, (2) BPM research is thought to provide practical insights, and (3) business processes are characterized by interactions between various actors and IT artefacts to, collectively and collaboratively, carry out organizational processes.

We hope that our example stimulates fellow colleagues to also employ GTM in the area of BPM research. We believe that such studies can develop rich and comprehensive understandings into complex and dynamic phenomena such as business processes, and the management of these. We particularly would like to encourage fellow scholars to use GTM in multi-method approaches, for example, to inductively develop theories and hypotheses and, then, to test the propositions using typical deductive theory-testing methods such as experiments or surveys. Recently, we have seen some studies employing some form of multi-method research (Recker, 2008).

We believe that GTM, and more generally speaking theory development – could be highly beneficial to a range of BPM-related phenomena, such as the factors critical to success – or failure – of process optimization projects, the phenomenon of organizational adoption of BPM standards, the key contextual factors facilitating process change, or the embodiment of a process-aware culture in organizations, to name just a few.

Abstract

The objective of this paper is to evaluate the semantic building block-based approach as a means for improving comparability in business process modelling. It is described whether and why the semantic building block-based approach reduces the variations in comparison to traditional modelling approaches. Our argumentation is grounded on the assumption that business process modelling projects in large organisations have to be conducted in a distributed manner. However, the goal of these projects is to integrate single models into a consistent process landscape. This allows the organisation to mine the processes for potential improvements. A lack of comparability could deteriorate the quality of the process landscape and the analysis performed on its basis. In a laboratory experiment the variations of distributed process modelling in the traditional and the building block-based approach have been compared. Results indicate that the semantic building block-based approach leads to considerably fewer variations between business process models and, thus, improves the comparability of them.

Keywords: Model Comparison, Domain Specific Languages, Business Process Modelling, PICTURE.
1 INTRODUCTION

Comparability is an important quality criterion for business process diagrams (BPD). In large business process modelling projects, as they are often executed in huge companies, the documentation of relevant domain knowledge has to be accomplished in a distributed manner. This is even more important if the modelling project crosses organizational boundaries. The challenge of such projects is not to represent the domain knowledge in single process models that are later on analyzed separately, but rather to combine all the models to a process landscape providing an overview over the companies business. The involvement of multiple actors in the modelling process causes the resulting models to differ in terms of vocabulary, level of detail and level of abstraction (Hadar & Soffer 2006). Creating an integrated description based on such models is thus hampered. Hence, an overall view on the organization is blurred by deviating ways of describing it. The possibilities to set up a holistic business process management based on the complete set of process models is therefore limited (Becker & Algermissen & Falk & Pfeiffer & Fuchs 2006).

The problem of variations between business process models can be addressed in two different ways. On the one hand, variations can be seen as given, which makes it necessary to resolve conflicts. This can either be done in an automated fashion (van Dongen & Dijkman & Mendling 2008), which, however, delivers only approximate results, or manually (Pfeiffer & Gehlert 2005), which involves significant efforts. The second way of dealing with variations is to avoid them during the construction of a BPD. This can be accomplished by constraining the choices a modeller can make when he creates a BPD. Domain specific modelling languages lower the ambiguities during the construction of conceptual models (Pfeiffer 2007). Thus, we claim that the application of a domain specific modelling language reduces the variations between BPDs compared to a traditional process modelling language. The aim of this paper is to deliver empirical evidence to support this assumption.

The paper proceeds as follows: In the next section the different variations within and between business process diagrams are described that can emerge in distributed modeling projects. In the following section of this paper the fundamental characteristics of the semantic building block-based approach are discussed. The specific structure of this approach is confronted with the properties of traditional modeling languages. Subsequently, the semantic building block-based approach is evaluated in a laboratory experiment. The distributed modeling conflicts that can emerge in the building block-based approach are compared to the traditional approach. The paper closes with a short summary of the main results and an outlook to future research.

2 NOTIONS OF VARIATION IN BUSINESS PROCESS MODELING

A real world phenomenon can be represented through BPDs in many different ways. BPDs are constructed by using two different languages. The first one is the modelling language. Its meaning can be formally specified, which makes this part of a process diagram unambiguous. The other component of a BPD consists of a domain language. It is used to make understandable statements about real world phenomena. In order to create a BPD, both languages must be applied together to create (human) readable process descriptions. Domain languages are owned by a linguistic community that decides on the meaning of its statements by shared conventions, which have been established implicitly by using the language. Because of the ambiguity of such natural languages it is possible to express the same meaning by different combinations of constructs and domain statements.

Variations in BPDs arise from both, differing perceptions of reality and from the process of explicating this perception. A variation is a semantic or syntactic deviation between different BPDs which refer to the same or a similar real world phenomenon. They can be due to two different reasons (Soffer & Hadar 2007).

- Variations due to varying mental representations: The mental representations of two model creators are most likely not exactly the same. This means the model creators perceive or structure
real world phenomena differently. Likewise, they can, consciously or unconsciously, consider deviating aspects of the phenomenon as relevant. This can lead to BPDs at diverse levels of abstraction. Likewise, in these models the sequence of activities can vary or the model elements can be annotated with a different number of details.

- **Variations due to the explication:** Even when the model creators share “the same” mental representation variations can arise. These variations result from a different explication of the mental representations. Domain and modeling languages offer certain degrees of freedom to express a given fact. Model creators can utilize this freedom in diverse ways. For example, different domain statements can be chosen to express a specific aspect of the mental representation. Similarly, a model creator may have the choice between multiple constructs to describe a given fact. Thus even with an equivalent mental representation, different BPDs with corresponding conflicts can emerge.

Deviations between models have been investigated empirically especially in the context of structural models. UML Class Diagrams have been analyzed in multiple modelling experiments (Hadar & Soffer 2006, Lange & Chaudron 2006, Soffer & Hadar 2007). Other empirical studies have focused mainly on the advantages of specific constructs in comparison to alternative forms of representation, such as entity types and attributes (Shanks & Nuredini & Tobin & Moody & Weber 2003), properties of relations (Burton-Jones & Mesu 2002, Burton-Jones & Weber 1999), optional properties (Bodart & Patel & Sim & Weber 2001), or whole-part relations (Shanks & Tansley & Nuredini & Tobin & Weber 2002). There are only a very few empirical studies that refer to variations in process diagrams. Mendling et al. (2006), for example, have analyzed the SAP Reference Model to identify errors and inconsistencies. Gruhn and Laue (2007) have investigated the role of OR-connectors in Event-driven Process Chains (EPC). Beneath these empirical studies, conflicts between models have theoretically been discussed in the database schema matching and integration literature (Kashyap & Sheth 1996, Parent & Spaccapietra 1998), in publications about metamodeling (e.g., Rosemann & zur Mühlen 1998), and ontology engineering (Davis & Green & Milton & Rosemann 2003). In this paper we draw upon Pfeiffer (Pfeiffer 2008) who has derived a comprehensive theoretical analysis of the variations in the context of business process modelling. The different variations are described in Table 1.

*Table 1: Description of the variations between business process diagrams*

In the following we will focus on type, synonym, abstraction, order and separation variations as part of the analysis. Homonym, control flow, and annotation variations are not taken into account. The reasons for this limitation are discussed in Section 4.
3 TRADITIONAL AND SEMANTIC BUILDING BLOCK-BASED PROCESS MODELLING

The application of traditional business process modelling languages leads to business process diagrams that are hard to compare. Every model created with a traditional language can include many of the variations described in the previous section of this paper. For instance, an EPC basically consists of events and functions, whose semantics are essentially defined by the domain statement the modeller assigns to it (Kellger & Nüttgens & Scheer 1992). Only by applying various rules and modelling conventions, comparability between the BPDs can be achieved (Schütte & Rotthowe 1998). The creation as well as the implementation of such regulations within a specific modelling project involves significant efforts.

By using a business process modelling language which belongs to the semantic building block-based approach, the comparability of the resulting business process diagrams can be significantly improved. These semantic building block-based languages (SBBL) achieve this advantage by avoiding the conflicts that occur when traditional modelling languages are used (Becker & Pfeiffer & Räckers 2007d, Pfeiffer 2007). The semantic building block-based approach guides the modeller through the modelling process and restricts him in his decisions. By decreasing the choices a model creator can make during the model construction, the comparability of the BPDs can be increased (Pfeiffer 2008).

Analysing BPDs created with a SBBL on a semantic level can be more cost-effective compared to the analysis of BPDs created with traditional languages. While the effort of creating a SBBL is relatively high, various analysis methods can be predefined and executed automatically on models created with it (Pfeiffer 2008), which may compensate the creation effort. Using traditional languages to create BPDs requires business process experts to perform every analysis manually or semi-automatically. Such an approach does not scale.

The main modelling construct of the language class SBBL is the so-called process building block (PBB). PBBs limit the degree of freedom within the process of model creation. Unlike traditional business process modelling languages the SBBLs employ PBB as their most important modelling constructs. Every PBB represents one or more reoccurring activities from a particular domain (Baacke & Rohner & Winter 2007, Becker et al. 2007d, Lang & Glunde & Bodendorf 1997). The difference between a PBB and a modelling construct from a traditional language is that the PBB already incorporates a domain statement. Modellers do not create and assign a domain statement to a construct, they can only choose from a given set of PBBs and, thereby, from a given pool of statements. Thus, the PBB are semantically specified and have a defined level of abstraction (Rupprecht & Funffinger & Knublauch & Rose 2000). If additional information is needed, the PBB can be further described by a predefined set of attributes.

Concerning their semantics, the PBB are unambiguously and mutually exclusively defined. To specify the constructs of a SBBL, a domain ontology is used. Every PBB stands for a set of elements taken from this ontology. Hence, the meaning of a PBB is explicitly defined. With the aid of the ontology, it is possible to ensure that no element of a SBBL contains semantics already covered by another element of this language. Given a real world phenomenon, there exists only a single possibility to represent it in a SBBL-based language. In ideal, every construct would be derived from the domain ontology, but from a practical perspective it is often necessary to include at least some constructs from other languages. For instance, this could be a construct to split up and join the control flow. In Figure 1, for example, the ontology element ‘encash/receive a payment’ has been incorporated into a SBBL as a PBB. Also the corresponding attributes of the PBB are taken from the domain ontology. This encompasses not only the attributes themselves, but also their possible values. In the given example, the attribute ‘Information System’ has only three allowed values: ‘Open Office’, ‘MS Office’ and ‘MS Money’. The available labels for the PBB, which specify the domain task more detailed, are defined in the same manner. For the PBB ‘encash/receive a payment’, the labels
’encash/receive a cash payment’, ‘encash/receive a credit card payment’, and ‘encash/receive a money transfer’ are allowed.

Figure 1: A Process Building Block and a Section from a Domain Ontology

Languages from the class SBBL either avoid or at least decrease the previously described variations between BPDs. By using the semantic building block-based approach, some types of variations between models can be fully eliminated. As the PBB do not offer multiple ways to express a specific fact, variations due to explication cannot occur. However, variations due to varying mental representations are still possible. But, because of the ontology incorporated into the language that is guiding the modeller through the modelling process, their frequency can be significantly reduced. In the following the impact of the language class SBBL is discussed with regard to the five variation types considered:

- **Synonym variations**: Because of the fact that the constructs of languages from the class SBBL are derived from an ontology, they offer a controlled vocabulary to the modeler. Synonyms can be detected in the ontology, which makes it possible to eliminate them in advance of the model creation. Hence, as long as the modeler can only choose from the given vocabulary of a SBBL, no synonym variations can occur.

- **Type variations**: During the language construction, it is ensured that no semantically overlapping modeling constructs are included in the SBBL. If every PBB and every attribute of the language is semantically disjoint, it can be proven that no type variation can occur (Pfeiffer 2007). For every observable real world phenomenon only one single construct exists which is able to represent it within the language. Therefore, every modeler who wants to describe the phenomenon is forced to use same construct.

- **Abstraction variations**: The type in combination with the label defines the semantics of a PBB. Because every PBB is semantically disjoint from the others, every modeler has to choose the same PBB to express a specific matter. Thus, the number of possible choices for the selection of domain statements and, thereby, also the number of abstraction variations is reduced. To completely avoid
them, a specific level of the ontology has to be defined from which all the domain statements of a model have to originate.

- **Separation variations:** This type of variation cannot be entirely removed from models created with the language class SBBL. Nevertheless, it can be at least reduced because during model construction the modeler is guided by the ontology-based PBBs he can choose from. With the meaning of the PBBs in mind, he focuses on the semantics covered by them. Therefore, the models better fit to each other concerning the semantics they express.

- **Order variations:** Just like the separation variations, this type of variation cannot be completely avoided. In traditional modeling languages, it is hardly feasible to make any statements about the correct order of specific elements on the basis of their type. In contrast to that, the semantic building block-based approach allows to define heuristic order rules based upon the predefined semantics of the PBBs. For example, it is reasonable that the activity ‘approve’ always follows the activity ‘perform a formal verification’.

The creation of languages from the class SBBL can only be accomplished successfully with a specific domain in mind. In order to be able to express every real world phenomenon by using a modelling language of this type, it is necessary to restrict the application to a specific domain. Otherwise, no appropriate ontology can be created due to the complexity of the real world. Hence, languages from the class SBBL are domain specific languages. A well documented example for such a language is the PICTURE-language, which is specifically designed for public administrations (Becker & Algermissen & Falk 2007a, Becker & Algermissen & Pfeiffer & Räckers 2007b, Becker et al. 2007d, Falk 2007). It consists of 24 PBB and over 50 attributes. The PBBs in PICTURE can only be connected in a sequential form. For an in-depth description of the language, we refer to (Becker et al. 2007a).

### 4 EVALUATION OF THE SEMANTIC BUILDING BLOCK-BASED APPROACH

#### 4.1 Setting of laboratory experiment

The hypothesis to evaluate is that modelling with a semantic building block-based language results in a smaller number of variation compared to traditional modelling languages. In order to do this, an empirical evaluation was conducted. EPC was chosen as an example of a traditional modelling language, PICTURE as an example for a domain specific one.

Within a laboratory experiment, twelve graduate students from the University of Muenster were asked to create an EPC and a PICTURE model independently from each other based on a given case description. This case description was used to examine the variability between BPDs in both languages. This experimental setup simulates the process of distributed modelling and facilitates the validity of the analysis for two reasons. Firstly, all participants are modelling the same situation, which eliminates the case description as a source of variability. Secondly, every participant creates both an EPC and a PICTURE model. Thus, all variations resulting from a different understanding of the case description or from deviating opinions about the adequate degree of detail or abstraction influence the modelling process of both languages in the same way. The remaining variations can be fully explained by the process of explicating the mental representations of a participant in the form of a process diagram. Because the order in which the models had to be created was not specified, the participants were able to correct mistakes they made during the creation of their first model if they notice a misunderstanding during the creation of their second one. Thus, in case the understanding of the case description changed over time due to a learning process, the validity of the results is not threatened.

As PICTURE is a domain specific language designed to be used in public administrations, the case description was taken from this domain. It is about handling an application for a resident parking permit. First, the application has to be checked according to various criteria. Depending on the results, it is either accepted or rejected. In the latter case a rejection letter is created and send to the applicant. If the application is accepted, the application data must be entered into a software system, the parking
permit has to be created, an annual fee must be encashed and the parking permit has to be delivered to
the applicant. Various methods of payment as well as different ways to deliver the parking permit are
possible. The analysis has been carried out in two steps:

- **Automated analysis:** In the first step, both EPC and PICTURE models were tested for similarity
  with an automated comparison algorithm (van Dongen et al. 2008). This algorithm has been
designed to quantify the similarity of the process flow as well as to detect and resolve problems
resulting from the ambiguities of natural languages. The applicability of the algorithm has been
demonstrated empirically by using the SAP Reference Model.

- **Manual analysis:** The second step was, in contrast to the first one, conducted manually to
  reconfirm the results from the automated comparison. In order to do this, the authors analyzed the
  BPDs from both groups to find and quantify variations from the types described above. If a high
degree of similarity between the two models is found in the automatic analysis a small number of
variations can be expected in the manual analysis. The automated analysis of the models only
provides a percentage value of similarity. As the analysis is conducted manually in the second step,
the nature of the variations can be explored in more detail.

### 4.2 Characteristics of the Automated Analysis

The comparison algorithm which has been used to determine the degree of similarity between the
BPDs can be used for both PICTURE and EPC models in the same way. This is ensured by the fact
that the models themselves are not used for the similarity calculation. Instead, the result is computed
by using what is called a *causal footprint*. This is a construct that can be derived from the BPD. It is a
directed graph whose vertices represent the various activities in the process. Vertices are connected by
arcs whenever the corresponding activities of the vertices are always performed either before or after
one another. In the first case, the arc is called a look-back-link, in the second case it is a look-ahead-
link (van Dongen & Mendling & van der Aalst 2006). If, for example, there is an arc connecting the
vertices A and B, this means that, depending on the type of the arc, activity A is either always
performed before activity B or after it. In order to finally execute the comparison, the causal footprints
of the models must be transformed into vectors. Their similarity is then determined by the deviation of
their directions. For more details concerning the transformation, we refer to (van Dongen et al. 2008).

The comparison algorithm is able to identify ambiguities of natural languages within the labels of the
model elements. To calculate the similarity of BPDs, common elements must be identified. Therefore,
equivalent vertices need to be identified in order to compare two footprints. Natural languages allow
expressing the same real-world concepts in different ways. This hampers the automatic identification
of similar or equivalent activities. In order to deal with this problem, the comparison algorithm uses
the lexical database WordNet, which allows to detect synonyms (Miller 1995). With the aid of this
information, the semantic similarity of activities can be computed. Comparing the similarity score of
an activity and of all elements connected to it, it is possible to map equivalent activities of different
process diagrams (van Dongen et al. 2008).

The comparison algorithm determines the similarity of process diagrams regarding their content and
their respective process flow. The causal footprint consists of both the vertices representing activities
themselves and look-ahead as well as look-back-links, which stand for the procedural relations of the
activities. Therefore, the comparison does not only consider the similarity regarding the content, but
also takes the process flow into account.
4.3 Results of the Automated Analysis

Figure 2: Average similarity degrees for PICTURE and EPC models

12 BPDs from each group were compared pair-wise with each other. This resulted in a total of 66 comparisons for each group. Within the group of the EPC models, an average similarity of 0.54% has been measured. The maximum similarity was 4.02%, the minimum was 0%. This means that the comparison algorithm perceived the BPDs as being totally different. In contrast, the PICTURE models achieved an average similarity of 43.75%. Some comparisons resulted in a value of 100%, which means that the models were identical. Other PICTURE models scored lower values as well. The minimum value was 13.99%.

Detailed results are described in Figure 2. In this diagram the average similarities of the individual BPDs compared to all other models are depicted. Figure 2-I presents the similarity values for the PICTURE and the EPC group on a single scale, Figure 2-II uses separate scales instead.

4.4 Characteristics of the Manual Analysis

Detailed statements about the nature and the degree of variability between BPDs can only be given manually. A framework, which classifies possible variations between process diagrams into different categories, was introduced in Section 2. To identify these variations in process diagrams, a semantic analysis of BPDs is necessary. Thus, a specific meaning needs to be assigned to every model element according to the modeller’s intention. By this means, an ontology which describes the whole semantic of the case description has been developed. Thereafter, it was possible to assign statements of this ontology to every model element. The intended meaning had to be carefully explored by the authors. With the resulting assignments, the basis for the identification of variations was established.

When variations are identified they need to be counted in compliance with strict rules to assure a reasonable quantification of the variability. With the previously given definitions, variations can easily be identified. But the definition alone was not sufficient to generate a meaningful result. A set of rules for quantifying the identified variations had to be developed. They allowed for a consistent and uniform measurement. For example, rules were designed to prevent counting some variations multiple times. Different types of variations were not weighted, because there was no information about the extent to which an individual type of variation influences the comparability of BPDs. To measure synonym variations, all words in the EPC models were stemmed and frequently occurring words like “a”, “an” or “and” were not considered in the comparison. Taking variations resulting from such differences into account would distort the results, because transforming strings into the described form can be easily accomplished automatically (Porter 1980).

With the given experimental setup, a reasonable measurement of homonym, control flow, and annotation variations was not possible. All models were created on the basis of the same case
description. This makes the measurement of homonym variations difficult, because they occur when different concepts are expressed by the same terms. This usually happens in complex systems of different BPDs, however, not within a single case. Annotation conflicts were not measureable because no attributes were used within the EPC and only a fixed set of attributes within the PICTURE models. The PICTURE as well as the EPC language has strict rules concerning the incoming and outgoing control flows. In fact, only the AND, OR, and XOR operators from the EPC language allow for deviating numbers of control flows. Hence, no control flow variations were detectable during the analysis.

4.5 Results of the manual analysis

Within the variation analysis an average of 31.93 variations between EPC models were identified. An average of 12.59 of these variations were synonym variations, 5.95 were abstraction variations, 10.70 were separation variations, 2.15 were type variations, and 0.53 were order variations. The group of the PICTURE models scored an average value of 4.59 variations. It consists of 0.63 synonym variations, 0.83 abstraction variations, 1.77 separation variations, and 1.32 type variations. Order variations were not found between PICTURE models. A comparison of the combined results can be found in Figure 3.

![Figure 3: Numbers of variations for PICTURE and EPC according to the different variation types](image)

4.6 Discussion of the results

The results of the automated similarity calculation are confirmed and further detailed by the manual analysis. While the automatic analysis can hardly find any commonalities between EPC models, it provides very good results for PICTURE models. In compliance with these results, the manual analysis shows a significantly higher number of variations of any kind for EPC models compared to PICTURE models. These results support assumption that the automated analysis is correct and further specify the results by categorizing the variations.

The semantics of BPDs that contain natural language elements cannot be captured automatically. The use of ontology-based labels for the PBBs in PICTURE actually results in a massive reduction of synonym variations compared to EPC. Although the algorithm used is build to detect synonyms, the low similarity degrees for EPC models imply that it fails to do so in most of the cases. The avoidance of many synonym variations by PICTURE in parallel with the high similarity degrees indicates that synonym variations cannot be resolved automatically.
The degree of detail and abstraction are fixed when using a SBBL-based modelling language. The limitation of the number of choices a modeller can make within the modelling project when he is using a SBBL in fact increased the comparability of the created models. A significant decrease of abstraction and separation variations in the manual analysis supports this conclusion.

It remains to be demonstrated that the expressiveness of a SBBL is sufficient. The increased comparability of models created with a SBBL leads to a decreasing expressiveness because of the predefined semantics of the PBBs. It is possible that the modeller is limited in his decisions that he is not able to represent all relevant real world facts by using the PBBs. Hence, the creation of a SBBL is very time consuming and error prone. This analysis only shows that the language class SBBL produces models with a higher degree of comparability, but it does not take the expressiveness of the models into account. Although there is a study focusing on this issue by evaluating PICTURE against workflow patterns (Becker & Algermissen & Pfeiffer & Räckers 2007c) and despite of the fact that PICTURE has been successfully used to create a total of more than 1,000 process diagrams in 12 german administrations until now (Bergener & Pfeiffer & Räckers 2009), a comprehensive empirical study is up to future research.

5 CONCLUSION

In the beginning of this paper we argued that BPD created in a distributed process modelling project exhibit a significant degree of variability which is a major obstacle to the creation of a sound overview over the organizations process landscape. In order to overcome this problem in BPD, we proposed to use languages from the SBBL class. Such languages reduce the variations between BPD by limiting the freedom of choice during model creation. To support our argumentation, an empirical evaluation of the PICTURE language, a well known example for a language coming from the class SBBL, was conducted. In a laboratory experiment that simulated a distributed modelling project the potential advantages of the language class SBBL have been analyzed. Both an automated and a manual approach were chosen to compare the performance of the two languages EPC and PICTURE. The results of the analysis demonstrate that the type of the language has a strong influence on the number of variations in the resulting BPDs. PICTURE considerably decreased the number of variations and, thereby, improved the quality of the corresponding BPDs.

However, the number of variations is only one component of the evaluation of the semantic building block-based approach. Furthermore, it is necessary to assess the efficiency and the effectiveness of the resulting languages. Efficiency means that a SBBL-based modelling language is able to acquire a specified number of processes at minimal cost. The creation of a domain ontology, whose existence is a necessary precondition for a language from the SBBL class, requires a considerable amount of effort, which could outweigh quality improvements. Effectiveness requires that a language of the class SBBL is expressive enough to describe the relevant phenomena of the domain at hand. In other words, effectiveness makes sure that the modelling language can indeed be successfully applied in a given domain. An empirical analysis of these two aspects is open to further research.

Abstract

The central idea of this paper is to comprehend knowledge integration in inter-organizational IS projects through a knowledge cluster view of inter-organizational IS projects. The proliferation of such projects combined with the complexity of managing them, motivated this study. The study is based on a single case study which involves four organizations collaborating on a project. Findings suggest that knowledge integration in inter-organizational projects occurs through knowledge clusters and involves the interaction of complementary specialized knowledge bases within a structure and influenced by the clusters’ perceptions towards the project. Implications of the findings and future research opportunities are discussed.

Keywords: Knowledge cluster, knowledge integration, multi-level analysis, inter-organizational projects

1 INTRODUCTION

Inter-organizational arrangements for mutual benefits in the form of partnerships, alliances and joint ventures are very common. Such arrangements take place for several reasons including resource efficiency, resource acquisition, and skill enhancement (Simatupang et al 2002). Of the different types of inter-organizational arrangements, this study focuses on inter-organizational IS projects, an organizational form in which multiple organizations collaborate on an IS project for a specific period of time and that involve a client-vendor relationship. The simplest of such projects may involve one client and one vendor, but the more complex may have multiple clients or/and multiple vendors. With companies increasingly outsourcing all or some of their IS activities (Lacity and Hirschheim 1993), including IS development, it is very common indeed to see IS projects that involve multiple organizations.

Development of Information systems is a complex, intensive, and dynamic activity that requires close cooperation and coordination among diverse stakeholders who house the knowledge required for the execution of the project. In inter-organizational IS projects, knowledge required for the project is situated in the diverse stakeholders that belong to different functional groups (departments, users, management, IT etc) and are part of different organizations. Typically for a project some representatives from each of these departments/functional groups/stakeholders, referred to as knowledge clusters in this paper, are involved in the project. Specifically, knowledge clusters in this study refers to a group that possesses certain specialized knowledge essential for the project (e.g. users, IT department representatives) and that is governed by similar rules and boundaries (e.g.
departments) and hence the members share similar perceptions towards the project. This definition of knowledge clusters is similar to that adopted by Yayavaram and Ahuja (2008), although they have not explicitly defined the term and they base their definition on technologies. Other studies that have defined the term are in the context of industrial clusters, as cluster of firms, a more macro level view than our consideration. Knowledge from multiple knowledge clusters in each collaborating organization can be highly differentiated and specialized and therefore has to be integrated for the project.

Knowledge integration, in this context is conceptualized as the process through which disparate, specialized knowledge located in multiple knowledge clusters across organizations is combined, applied and assimilated. For instance, in an IS project, the users from the client organization communicate system requirements to the vendor’s IT consultants who use their software expertise and knowledge from the users to build the system. Users then assimilate the system by making necessary changes to their work practices (Faraj and Sproull 2000; Huang et al 2001). Knowledge integration is essential since if knowledge from a particular cluster is missing or is not integrated, for example, lack of user participation and hence unclear requirements, the project outcome may suffer. The several constraints like time, budget, specifications require knowledge integration in an inter-organizational IS project to be effective, i.e. knowledge for the project has to integrated within the stated constraints.

Managing the knowledge integration process between the organizations in a project is a crucial task (Walz et al 1993) and is a challenge not only because knowledge is often dispersed, differentiated and embedded (e.g. Tsoukas 1996) in various knowledge clusters but also because the clusters have their own agendas within organizations that are intrinsically different, that may possess diverse competencies (Pisano 1994) and conflicting interests. The fact that many of the systems are developed under extreme time constraints and often with the help of external consultants exacerbate the challenges associated with combining diverse forms of expertise on particular projects (Levina 2005). Client-vendor relationships in outsourced IS development projects have always been presumed to be adversarial (e.g. Chowdhry and Sabherwal 2003) and the associated factors, along with the difficulties in obtaining quick feedback, meeting frequently, and building interpersonal relationships, make their management an arduous task.

How then is knowledge across multiple knowledge clusters from multiple diverse organizations integrated for effective knowledge integration in inter-organizational IS projects? To address this question and increase our understanding of this complex phenomenon in a challenging environment an empirical study of an inter-organizational IS project is conducted. Related literature is reviewed and knowledge cluster concept explained in the following section.

2 LITERATURE REVIEW

2.1 Knowledge and Knowledge clusters

This study bases itself on the view that knowledge exists in the individual and the collective (Nonaka 1994) and both include the tacit and explicit dimensions of knowledge as suggested by the early works of Polanyi (1966). Individuals in their clusters are assumed to be the prime vehicle of knowledge delivery to the project irrespective of its nature and location. The notion of collective knowledge is important because Collective knowledge can also refer to knowledge situated in various departments, groups or teams. The representatives of certain departments, groups, teams are referred to as knowledge clusters in this study and they house the different types and forms of specialized knowledge (e.g. process knowledge, requirements) required for the project. The concept of knowledge cluster is represented in figure 2.1.
Each knowledge cluster groups representatives from a certain knowledge area that will be involved in the project. This group can include some representatives from one knowledge base, more than one knowledge base or the entire knowledge base. For instance, knowledge cluster can be a few members from a certain department (e.g. users), representatives from two or more departments (e.g. multiple user departments) or the entire department (e.g. when the user department is small and everybody’s knowledge is required for the project). These three possibilities are shown in figure 1 above.

Yayavaram and Ahuja(2008) used the term knowledge cluster more in the context of their definition of a knowledge structure with respect to a firm’s technical knowledge. According to them a knowledge cluster can be a group of people, but that need not always be the case and sometimes it can be a group of related technologies. Although the usage of the term is similar the distinction in our adoption of the concept is mainly due to the context. Knowledge clusters in this paper are a group of people, encompassing individuals’ knowledge, the collective knowledge and embedded routines and practices thus including related technical knowledge as well. In identifying clusters for the current study, groups that were to contribute the same type of functional knowledge were considered; i.e most of the identified clusters belonged to different functional areas such as users, IT, management, or different vendor organizations with their specialized knowledge. The specialized knowledge of the clusters also provided a sense of the cluster’s role in the project, attitude, perception hence knowledge integration behaviour of the cluster towards the project.

2.2 Knowledge Integration and Inter-organizational IS Projects

Scholars have proposed different definitions of knowledge integration (table 2). For this study the knowledge integration as proposed by Bhandar et al (2007) is adopted since it incorporates a process view and is easily applicable to an inter-organizational context. Based on their view, knowledge integration for this study is viewed as the process through which relevant knowledge from different clusters is combined, applied and assimilated for the goal of the project. This view implies that knowledge integration is achieved through several activities starting from project negotiations to the post-implementation stages and is also influenced by certain antecedent conditions like reason for initiating the project. It also suggests that knowledge integration process requires the knowledge clusters to be involved in the process to contribute, apply and assimilate knowledge. Okhyusen and Eisenhardt (2002) add that knowledge integration is not about assembling discrete pieces of knowledge, but depends on how members know and integrate their individually held knowledge and so is influenced by the surrounding environment.
The process of knowledge integration in inter-organizational IS projects as described involves ongoing interaction between the clusters to contribute knowledge and share common experiences to redefine shared beliefs through social interaction (Huang et al. 2001) thus entailing that the clusters have a motivation to be part of the project. For instance, top management may need the system but the user department may not. This can affect the users’ assimilation of the system hence their participation in the knowledge integration process. Okhyusen and Eisenhardt (2002) highlight the importance of structures to improve interactions among group members for knowledge integration and Van Den Bosch et al. (1999) and Grant (1996) suggested the importance of the ability of the firm for knowledge integration. Clusters need to possess the ability to comprehend the ideas and perspectives being exchanged so as to contribute knowledge to the project and reinforce the common knowledge base, i.e. the overlap of knowledge that exists between the network members (Demsetz, 1991; Grant, 1996). Knowledge integration in inter-organizational IS projects is not easy given it involves the integration of knowledge spanning cross functional capabilities (Carlile and Rebentisch 2003) which is more complicated compared to integrating one kind of knowledge across individuals or groups (Grant 1996), notwithstanding the inherent characteristics of knowledge that can make its integration difficult. The common knowledge that exists in an inter-organizational set-up is modest and the fact that knowledge in each organization exists in multiple entities further adds to the challenge. Additionally, these projects involve managing knowledge clusters from different organizations. The clusters are affected by the inter-organizational dynamics such as distinct competencies (Pisano 1994) and conflicting interests that have to be overcome before their knowledge can be integrated (Pan et al. 2001). Conflicts inherent in a client-vendor relationship (Lacity and Hirschheim 1993) although healthy from the perspective of the organization can affect the behavior of knowledge clusters towards knowledge integration. So how then is knowledge integrated in inter-organizational IS projects? To address this question and understand this complex phenomenon in a challenging set-up, an empirical study of a four organization project is undertaken. The methodology followed for the study is discussed next.

### 3 METHODOLOGY

Qualitative research method was adopted for this study since it allows an emphasis on processes and meanings (Denzin and Lincoln 1994) essential for this study investigating a knowledge integration process. The case study method was deemed appropriate for data collection since the phenomenon of knowledge integration is closely intertwined with the context of the inter-organizational project (Yin 2003). The study also required informants to reveal sensitive data that required comprehension of the context (e.g. to interpret the quotes in light of their relationships) which was possible through long and

informal interviews. This project was chosen for the study based on three criteria: the project was recently completed to ensure that participants could recall events, permission to study the project was granted by the top management so as to allow access to rich data, and it provided a right context for the study, an inter-organizational project with four organizations and client-vendor relationship.

The main source of data was face-to-face interviews conducted with representatives of each organization involved in the project at different hierarchies (top management, middle management, team members and users). Questions were asked to understand the motivations/expectations/views of each organization/cluster for the project, their account of how the project progressed, the conflicts and resolution of conflicts. Secondary data was collected from organizational websites (e.g. organizational background), articles, and third parties (employees of the companies not involved in the project). The multiple sources provided for triangulation (Stake 1994) of evidence, ensured that facts stated by one cluster could be verified by the other and also provided multiple perspectives on issues.

Data analysis was done in iteration with data collection (Myers 1997; Walsham 2006). Initially analysis was conducted at an organizational level, through which the behaviour of some members could be explained. The researcher then adopted a cluster level analysis, since they saw behaviour of members could be better explained from the cluster they area associated with rather than the organization. Data collected was transcribed in consideration with recording media for qualitative studies (Walsham 1995, 2006). Themes were identified using open-coding (Strauss and Corbin 1990) that influenced the organizations knowledge integration behavior throughout the project. For instance, ‘prior experience’ and ‘lack of motivation’ were identified as themes that influenced ‘requirement gathering’ since they affected time taken/outcome for that activity. Interesting comments, surprising revelations, special notes/observations made during the site visits or interviews were also considered. For example, highly sceptical tone, formal atmosphere, and interviewees being very guarded in disclosing facts were all noted. The case data collection details are presented in table 2.

*Table 2: Case Data details*
4 CASE DESCRIPTION AND ANALYSIS

This project was the development of a data warehouse and it involved four organizations. The client was a leading bank in Asia and the three vendors; a banking solutions firm, systems integrator and business process consulting firm that were all engaged on a time and material contract\(^1\). The four organizations were multinational firms with distinct competencies and were represented by an expert each that were all data warehouse experts with 20 plus years of experience. A project team with representatives from all four organizations was set-up and collocated in the client’s premises. The project was on for two years at the time of data collection.

4.1 The knowledge clusters and their roles

Based on the case data and the definition of knowledge clusters the various knowledge clusters from each organization, their roles and representation to the project team are summarized in table 3. From the client there were four clusters; Client_Management, Client_Users, Client_IM and Client_IT. Client_Users comprised of business users and data analysts and this cluster had to communicate process flows to be incorporated in the data warehouse model and had to use the data model as it was being developed to assess suitability and usability. Client_IT was involved in building the data warehouse along with the vendor organizations. Client_IM was the Information management department which initiated and owned this data warehouse. It coordinated the project and the head of Client_IM was the project manager. Client_Management was involved initially to grant funding for the project after which it followed up with Client_IM after every quarter on the project progress. From the three vendor organizations there was one expert each that was the main coordinator and each brought in a small team for the area of expertise they were hired for. Each vendor organization is therefore considered as a single cluster. The three vendor clusters were; Vendor_Bankingsolutions, Vendor_Systemsintegrator and Vendor_Consulting.

Table 3: Knowledge Clusters in the Case

\(^1\) Contract where vendors are paid for whatever time and material they put into the project.
4.2 Interaction of the knowledge clusters

The knowledge clusters’ interaction in this project is shown in figure 2. Although there was representation of every cluster to the project team, some of the links were not effective. The dotted lines indicate ineffective links/impeded knowledge flow from those clusters to the project team.

The client had several hierarchies and knowledge flow between the hierarchies was ineffective. Client_IM was the project manager for the project and this cluster had little clout on the other clusters in terms of getting their buy-in for the project and enthusing their involvement and participation. Client_User and Client_IT did not perceive a need for the system which meant lack of their involvement and hence knowledge contribution for knowledge integration. Client_IM said: “Client_Management agreed to the project, but the user departments were only passively involved in the project. Client_Management also never followed up with them.” Due to the lack of perception of strategic benefit, Client_Users did not use the system when it was ready thus affecting system assimilation for knowledge integration as well. Client_Management acceded to the project but was seldom involved in the project activities had very little communication and interaction with the other clusters so its commitment was not visible to the other clusters. Restructuring in the client further disrupted knowledge from some clusters since key people left. Communication with the vendor clusters was simpler since each had a lead representative who was the single point of contact to that cluster. The project team was collocated in the client’s office which did help in technical team communication between all those who were actively involved.

Although representatives were assigned from Client_User to streamline communication between the vendors and Client_Users, they seldom participated in the project activities and hence their knowledge contribution to the project was affected. Effectively it was only Client_IM that served as a link from the client to the project team. Vendor_Consulting said: “Although each of the vendors was assigned a user representative, they never participated in the project and were hardly present for meetings and so it was very difficult to get the knowledge needed from users.” Client_IT was also in the project team to assist in building the data warehouse but during system development it had issues in accepting the development methodology proposed by the vendors despite having a lot of experience with IT projects. The vendor’s attributed this to Client_IT’s lack of experience in building data warehouse which required a methodology different from standard systems development life cycle followed for normal IT applications. This friction between impeded knowledge integration since more time was spent in convincing each other. One of the vendors said: “Client_IT’s lack of experience in data warehouse meant lot of time convincing them on the development methodology and necessary process changes.”

Figure 2: Interaction of the knowledge clusters
If knowledge integration was affected due to the lack of common knowledge in terms of development methodology between Client_IT and the vendors, knowledge integration was also affected due to too much common knowledge. The lead representatives of all the three vendor clusters had over 20 years of data warehouse experience and were all equally passionate about data and this project. Though hired for expertise in a particular area the overlap in their knowledge bases made technical knowledge communication between them easier but also led to frequent clashes on the best way of doing things. Client_IM had to frequently resolve such clashes and admitted: “We needed all of their expertise, but unfortunately they came from different organizations and there was too much overlap of knowledge. There should be just enough common knowledge to have a shared understanding of things, but not overlapping expertise.” Knowledge integration was affected since more time was spent resolving issues, there was lack of knowledge dependency between the clusters, lack of appreciation for specialized knowledge base of other clusters and hence lack of harmony in the process.

Client_management intended to have the data warehouse within a certain time and budget but the vendor clusters were hired on a time and material contract that provided little motivation for them to speed-up the project when delays were imminent. Vendor_bankingsolution said: “Our contract does not state that we have to complete the project within the time frame.” Even when there were process changes in the client organization which meant delays Vendor_Systemsintegrator was unfazed: “It is alright for me if they have changes, the customer is the king, We are hired on time and material basis, so any delays does not affect us since we get paid for every man-hour we put in.” Knowledge integration suffered since the time and material contract on which the vendor clusters were engaged did not ensure a concerted effort on part of all clusters to work towards achieving effective knowledge integration in terms of finishing the project on time. This is in addition to ineffective knowledge integration due the lack of knowledge from some clusters reaching the project team.

5 DISCUSSION AND FINDINGS

In recent years organizational researchers have tried to examine multilevel theoretical perspectives for concepts such as creativity, learning and system usage (e.g. Burton-Jones and Gallivan 2007). Many knowledge management scholars (e.g. Merali 2001) also suggest the importance of considering knowledge management approaches across different organizational levels and also acknowledge (Nonaka and Takeuchi 1995) the difficulties in doing so. This is something evidenced in this study as well and as mentioned in the methodology section, the use and change of theory and analysis was subject to the data and preliminary analysis. Initial analysis for this study was conducted at the organizational level but many issues could not be explained very well. For instance, although a typical client vendor relation, where in one client hired three vendors for a project and motivation for all parties should be obvious, this was not witnessed and it could not be explained at the organizational level. The problem was the various clusters within the client organization had different perceptions towards the project. A cluster level analysis was then used and that could explain the behavior of the different groups; Client_User and Client_IT, toward knowledge integration. Based on this understanding of knowledge cluster and the case, inter-organizational knowledge integration is explained as a process that involves complementary specialized knowledge clusters interacting within certain structures and influenced by the clusters’ perception towards the project.

For the project, complementary specialized knowledge bases are identified from within the organization (e.g. users, IT departments) and outside the organization (the vendors). This is an important process considering organizations often have problems identifying the content, location, and use of the knowledge for software engineering (Inkpen and Tsang 2005). This is also consistent with the importance accorded to partner selection in alliances (Dodgson 1992) considering the length of time needed to build effective communication paths between organizations and the nature of knowledge to be shared. The concern is alike in long term collaborative IS projects. The case shows that in identifying the knowledge clusters, organizations base their selection in trying to find complementary knowledge bases that are needed for the project and make some effort to facilitate
exchange between the clusters by building a common knowledge base through social activities and team collocation, for instance. Common knowledge is the common understanding of a subject area (Demsetz 1991) that enables easier transfer, sharing or integration of knowledge (Alavi and Tiwana 2002). Although the three vendors were selected for their specialized knowledge in different domains, the representatives were all data warehouse experts and the common knowledge they shared did make knowledge exchange easier but also led to conflicts. Too much common knowledge is shown to be impeding for knowledge integration as much time was spent in resolving conflicts. The specialized knowledge bases of the vendors were not sufficiently complementary and hence dependency between the clusters was lacking. The lack of common knowledge between the vendor clusters and Client_IT in terms of system development methodology and between the vendor clusters and Client_Users in terms of understanding of data warehouse benefits also hampered knowledge integration. The case therefore suggests that when specialized knowledge of the clusters is sufficiently complementary there is a dependency between the clusters and more harmonious interaction for knowledge integration while at the same time common knowledge between the clusters enables a shared understanding of issues for knowledge integration but too much redundancy can also be ineffective. This emphasis on a balance between specialized and common knowledge is the contribution of this finding to existing literature.

The knowledge clusters interact within their own organizational structures (clusters from within an organization) as well as within the project structure (project team) and that serves as means through which their knowledge reaches the project. Gulati (1995) affirms there are usually no preexisting reporting relationships in an alliance or systems that serve as natural conduits for information and therefore structures have to be created for that purpose. This is typically the case in inter-organizational IS projects where the project team consists of members from different clusters across organizations and a reporting structure can be cross organizational and is created for the duration of the project. In the case, clusters within the client were all represented to the project team but the representatives were not actively involved in project activities (refer figure 2) and hence access to their knowledge was inefficient. Infrequent involvement of the Client_Management and Client_Users, lack of ties between them and Client_IM and restructuring in the client hampered their knowledge flow to the project. The structure was present but was ineffective in providing access to certain clusters’ knowledge thus blocking required knowledge to the project. The case shows that knowledge flows, enabled by the structures, should exist within the various knowledge clusters involved in the project and within the core project team. The main idea of the structures should be to provide a channel for knowledge from all the involved clusters to reach the project. Prior literature has stressed on communication channels for knowledge flows (e.g. Ravasi and Verona 2001). Grant (1996) argues that structures that provide organizations with a comparative advantage in managing the various knowledge processes are a critical strategic variable while Huang and Newell (2003) suggest that efficient collaboration in a team requires the explicit definition of the communication channels desired within the team. The distinction on the findings in this paper is the observation that when the structure allows effective communication between all the knowledge clusters and not just between organizations and simultaneously between the clusters and the core project team knowledge integration better facilitated.

The involvement of the knowledge clusters in the knowledge integration process is contingent on their motivation for the project determined by factors such as: their need for the system, effort and cost incurred, value for their business and contractual terms. Lack of motivation of the knowledge clusters affects their knowledge integration behavior in terms of lack of effort, involvement and knowledge contribution to the project. In this case, Client_Management intended to have the system within a certain time and budget but the vendors were hired on a time and material contract that provided them little incentive to hasten the project. Their goals were not synchronous and that led to ineffective knowledge integration due to lack of concerted effort on the part of all clusters to expedite the project as Client_IM confirmed: “The distinct KPIs of all four organizations affected the project.” Further, the lack of perception of benefits form the data warehouse affected Client_Users effort in contributing and assimilating knowledge for the project. Motivation in different forms has been identified as an influencing factor for several knowledge processes (e.g. Kankanhalli et al 2005) but the focus was on...
individuals or organizations. The contributions of this finding is the emphasis of motivation at the level of knowledge clusters as against at the individual/organizational level. Project benefits are usually mutual in a client-vendor relationship (client needs system; vendor needs business) but concerted effort towards knowledge integration (Huang and Newell 2003) is not always present as shown in the case because of differing perceptions among the knowledge clusters. The study also finds that contractual terms used for legal protection and as means to control behavior of partners (e.g. Choudhury and Sabherwal 2003) can help synchronize goals in the project towards effective knowledge integration.

The above discussion and understanding of inter-organizational knowledge integration are summed up in table 3 below as three findings.

Table 3: Findings for effective knowledge integration

6 IMPLICATIONS AND CONCLUSION

One of the key contributions of this study is the concept of knowledge cluster (figure 1) that affords conceptualization of the complex phenomenon of inter-organizational knowledge integration by abstracting the multiple levels (individual, group, organizational and inter-organizational) and their interactions in an inter-organizational context. The concept of knowledge clusters allows escalating issues at each level to a knowledge level, thus making it easier to comprehend the issues from a unified perspective. Knowledge clusters stem from and exist within the organizational structure thus encapsulating the inter-organizational dynamics, organizational and inter-departmental dynamics, as well as the dynamics of the individuals within the cluster. The concept is also a contribution to multi-level research and it addresses a call for such studies by Burton-Jones and Gallivan(2007). In a setting such as collaborative project involving knowledge integration it is essential to understand the correct behavior of organizations within the collaborative set-up. As the case shows it is at times hard to understand the behavior of the organization as such since the multiple clusters within behave differently so when grouped as clusters this behavior and hence possible solutions are clearer. This concept is of significance to knowledge integration literature in various inter-organizational contexts like joint ventures and alliances as well as to any knowledge intensive contexts like R&D and new product development. The understanding of inter-organizational knowledge integration through processes involving the knowledge clusters contribute to the underlying inter-organizational knowledge integration theory and go beyond those identified by earlier studies and restricted to intra-organizational contexts. Although the processes identified by Huang et al(2001) can be also be applicable to this context, they do not incorporate multiple dimensions critical to the
context (structural, motivational and cognitive) and aspects critical to the inter-organizational context (synchronizing goals of all clusters across the organizations).

The challenge in managing IS/IT projects, especially those involving multiple organizations, is well known and acknowledged. This paper provides a knowledge integration perspective to address the knowledge related challenges that traditional project management strategies did not address. This is essential since the goal of the project is to integrate the various knowledge bases. Based on this approach project management strategies can be developed to manage the knowledge clusters within the project environment to influence their knowledge integration behavior for the goal of the project. Specifically (column 3 in table 3), this study suggests that for effective knowledge integration, knowledge clusters for the project should be identified keeping in mind the complementary nature of their knowledge bases and providing mechanisms for fostering common knowledge between them.

Secondly, all clusters buy-in for the project should be obtained so as to ensure their concerted effort towards the project. Although this finding is not new, the implication is on focusing on the knowledge clusters rather than departments/organizations/individuals since it is the knowledge of the clusters that has been identified as essential for the project. Lastly, structures instituted should enable interaction between the clusters and effective knowledge flows.

This study was conducted in an Asian country and there was an element of conservatism shown by the interviewees in revealing data that may have affected some of the insights. To overcome this limitation, multiple people were interviewed on the same subject. The organizations also hesitated to share too many project related documents and to make up for this multiple people were interviewed to get oral confirmation of the data. It must also be noted that this study has the inherent limitations of a case study in terms of it being very context specific. The goal of this paper is therefore not to make generalizations applicable to all settings, but to be able to contribute to the underlying knowledge integration theory. The concept of knowledge clusters introduced in this study is novel and should be examined more rigorously especially their evolution and behaviour over the life cycle of the project and suitable structures for their interaction in different client-vendor settings. Another interesting aspect would be to explore their dynamics in specific inter-organizational arrangements (one client vs. one vendor, multi client vs. one vendor). The observations in this study are based on a single case and need to be further researched through questionnaires or more detailed case studies.

Abstract

The structure and interrelationships of formal knowledge produced in the scientific disciplines have long been of interest to academics. One increasingly important domain of Information Systems (IS) research is the study of the creation and evolution of knowledge. Recent discourse about the intellectual structure of IS has revealed Latent Semantic Analysis (LSA) as an analytic technique that reduces problems associated with human categorization and citation analysis. This exploratory research positions IS within a ‘science of business’ using LSA to analyze semantic relationships in 24,841 abstracts from core business journals and begins to chart research concepts around which IS and other business disciplines converge. Results indicate that IS research has greater conceptual similarity to the disciplines of Management, Operations, Strategy, and Marketing than previously thought, and that these disciplines are converging on semantically similar research topics and concepts. This organizational-behavior-technical domain is distinct from an economics focused domain dominated by Finance and Accounting. The convergence suggests that IS is contributing to research and knowledge creation useful to other business disciplines and that strategic and functional dependence among the disciplines is increasing. This potentially leads to more integrated systems-oriented knowledge and greater practical relevance for both IS and other business disciplines.

Keywords: Business science, Latent Semantic Analysis, reputational networks, knowledge production, functional dependence, strategic dependence.

1 INTRODUCTION

The discipline of Information Systems (IS) has a long history of research into the design and management of socio-technical systems for the capture, storage, dissemination, retrieval, and management of information and knowledge. One increasingly important domain of IS that has received less attention is the study of the creation and evolution of knowledge. Recent discourse regarding the intellectual structure and core concepts of IS (Larsen et al. 2008; Sidorova et al. 2008) has illuminated Latent Semantic Analysis (LSA) (Deerwester et al. 1990) as an analytic technique that reduces some of the problems associated with human categorization and citation analysis that has been observed in prior studies. Furthermore, studies of the status of IS as a reference discipline (Grover et al. 2006, Wade et al. 2006) examine the positioning of IS among related business and computer disciplines. But as Straub (2006 p. 242) notes: “scholarly endeavor should not draw artificial boundaries within the domain of information systems, and without any persuasive logic or reasoning, cut itself off from topics that are clearly intimately related to the practice of the IS profession.” In response, this paper uses LSA to analyze semantic relationships among 24,810 abstracts from a selection of core business journals, thereby broadening our perspective to encompass the context of the IS discipline among the business disciplines. We are not seeking to identify IS’s own structure or asking whether IS has become a reference for other disciplines, but instead we are beginning to chart the creation and evolution of concepts around which IS and other business disciplines orbit.

The structure and interrelationships of formal knowledge produced in the scientific disciplines have long been of interest to academicians. Formal knowledge derived from business school research has been seen increasingly as an economic resource (Machlup 1962; Whitley 2000). Questions regarding the basis of knowledge production, academic rewards, rigor, and relevance of research results have been raised by the business community, government, and business schools themselves. Business research is rarely considered holistically due to institutional structures that preclude integration (Campbell 1969; Whitley 2000). The production of knowledge has been dominated by natural categories “in terms of discipline (business economics, industrial sociology, occupational and organizational psychology) or functional orientation (operations, marketing, finance, HR)” (Tranfield 2002 p. 409). External professional associations and job markets are organized by discipline, and internally, most business schools are organized by discipline – with each discipline its own cost center. Often, each business discipline is presented pedagogically as ‘the most important’ to students.

An alternative view holds that because industry requires functional areas to be highly applied, functional, and integrated, business school research may emulate this model (Starkey and Madan 2001). Businesses are striving to create integrated value (arguably the basis for much of the reengineering revolution of the 1990s). To some extent this is the model followed by most business schools when designing undergraduate and MBA educations. If business school research is less fundamental in nature and more applied, then there should be a parallel between academic research and business in practice. However, in practice, whereas businesses serve customers who are not concerned about the academic reputation of a finance or marketing department, business school departments develop independent reputations and consider other departments in the same discipline as the primary consumers of their published research.

This exploratory research addresses the position of IS within a ‘science of business’ which is seeking to created integrated knowledge about business problems, practices, and opportunities. LSA was used to analyze the semantic content of 24,8141abstracts from top journals in the core areas of business as identified by Trieschmann et al. (2000), including Accounting, Finance, Information Systems, Management, Marketing, Operations, Insurance/Risk and Real Estate. Following Whitley’s (2000) framework of science as “the product of the social transformation of intellectually constructed objects” in a reputational system (p. 35), the functional and strategic dependence of disciplines was used as lens to examine the conceptual convergence of business disciplines over a thirty year timespan. An increasing degree of consensus on core themes and topics in the academic community would indicate the emergence of a paradigmatic ‘business science’ that would position the discipline of IS as moving toward integration. Divergence would indicate that academic business research is best represented as moving towards an adhocracy of stove-piped silos of knowledge, in which IS as a discipline is marginalized.
2 FROM CITATIONS TO CONCEPTS

Banville and Landrey (1989) suggest that the “preoccupation about the actual state and future evolution of MIS as a scientific field” (p 48) is a warranted and essential epistemological endeavor. Numerous studies that examine the structure, core issues, reference disciplines, and position of IS as a legitimate, mature discipline have been published (see Larsen et al. 2008 for a review). These studies have been widely influential in the discipline and most rely on citation analysis or human derived content analysis in attempts to capture the conceptual relationships in a large set of wide-ranging literature.

There have also been numerous bibliographic studies in the business disciplines that examine the emergence, growth and spread of ideas, which also trace changes in the intellectual structure of disciplines. Disciplines analyzed include Strategic Management (Ramos-Rodríguez and Ruíz-Navarro 2004), Operations (Pilkington and Liston-Heyes 1999), Management (Podsakoff et al. 2008), and Information Systems (Cheon et al. 1991; Culnan 1986), but generally these empirical studies do not involve a comparison among different disciplines. However, recent citation studies have examined IS as a reference discipline to other business disciplines (Grover et al. 2006; Wade et al. 2006) and determined interdisciplinary citation patterns (Biehl et al. 2005). Although citation studies can show patterns of knowledge movement, they generally do not address the specific content of the knowledge itself – the semantic relationships of research terms, concepts, and problems addressed by the disciplines in question.

How intellectual disciplines are organized, how they become mature, how they are controlled, and how they coordinate and orient research have been the focus of research on knowledge production. Scientific knowledge is increasingly seen as the product of social transformation of intellectually constructed objects, and scientific change is increasingly viewed as the outcome of social processes of negotiation, conflict, and competition (Whitley 2000) or “as a complex knowledge market, the constitution of which is, and has been, subject to shaping by institutional forces” (Ramiller et al. 2008, p. 5). These views are in contrast to Kuhn’s (1962) internalist view of mature sciences as being characterized by "uniformity and inevitability in knowledge development" (Whitley 2000 p. 3) rather than subject to external economic and political controls. In this latter perspective of formal knowledge production, disciplines are organized and controlled in different ways to produce different knowledge.

One basic type of knowledge production system is produced by political and organizational structures that compartmentalize university departments. Well-bounded and distinct departments support local reputational networks, determine employment criteria, and institutionalize training programs, which together lead to fragmented and internally-referential silos of knowledge (Shove 2000). A contrasting type of knowledge production is based in the social unit of the intellectual discipline in which moderately-bounded and distinct organizations "control and direct the conduct of research on particular topics...through the ability of their leaders to allocate rewards according to the merits of the intellectual contribution" (Whitley 2000 p. 7). Disciplines gain reputation through the production of novel research regarding concepts which have utility in other disciplines. The social systems (e.g. conferences, working groups, journals) provide coordination of task outcomes through access to rewards. Historically, the intellectual disciplines “have been very dominant in the organization of the science system, in the reward system, and in the career system...” (van den Besselaar and Heimeriks 2001, p. 1). Formal public communication and distribution channels (e.g. journals, conferences) provide the arena for conflicts over reputations as well as interpretations of the relative importance of research concepts and ideas. Selection of representative sample sets becomes a critical factor in determining the structure and relationships among and within disciplines. The different views of the IS discipline presented in Larsen et al. (2008) and Sidorova et al. (2008) show this quite clearly, with the former relying on a expansive set of journals (65 total) to examine the IS discipline, and the latter making the assumption that three high profile journals are representative of the core concepts in the IS discipline. The reputation of the high profile journals will influence researchers to pursue questions that align with the concepts that appear in those journals.

Therefore an important characteristic of reputation in intellectual disciplines is the degree of control the researcher has over work processes and research goals. Where research concepts, terms, and priorities are similar to commonsense ones, or are borrowed from other disciplines, it is more difficult to maintain unified control of research than in disciplines where vocabularies and work methods are distinct and arcane. In addition, highly selective distribution channels, result in greater dependence of researchers on
the gate-keepers of such channels, and thereby an increased disciplinary control of reputation and research direction. Finally, with increased diversity of legitimate audiences come increasingly differentiated research goals, leading to limitations on coordination and integration of intellectual priorities.

Rather than examining which disciplines cite other disciplines as reference sources, we examine the conceptual linkages among the disciplines to determine the position of IS in relation to other business disciplines. At one extreme, business science is comprised of isolated disciplinary silos, each with its own distribution channels, in which researchers do not utilize concepts from other disciplines and distribution channels limit the range of research topics, concepts, and problems they will accept. In this conception, reputations are forged within disciplines, and researchers depend less on other disciplines for coordinating integrated knowledge and building valid knowledge claims. At the other extreme, there is a “paradigm,” loosely defined as an understanding of shared topics, concepts, and models for the science of business that is recognized and accepted by its sub-disciplines. Researchers who often focus in one area are also observed in working in other areas as attempts are made to coordinate and expand research to increase the value of intellectual contributions.

Whitley's (2000) framework for reputation proposes that the major objective of scientific endeavor is couched within a reputational system. Progress in reputation is determined by the degree to which the contribution offers novelty, and the extent to which it is useful to others in the discipline (Figure 1). Conflicts between the two demands create particular tensions between scientists, and variations in their mutual balance affect the organization of knowledge. Structural characteristics of a discipline can influence the ways in which these objectives are sought and knowledge is produced. These foundation characteristics are: Strategic Dependence, Functional Dependence, and Strategic Task Uncertainty.

Our research focuses on two of these factors:

1. Strategic Dependence can be defined as the "extent to which researchers have to persuade colleagues of the significance and importance of their problem and approach in order to attain high reputation from them" (Whitley 2000 p. 88). Although this is a complex construct, for this study it was operationalized by determining the association of distribution channels. The correlations among the representative journals of each business discipline was based on the shared topics that were published (e.g. the amount of concept sharing between academic disciplines).

2. Functional Dependence can be defined as the "extent to which researchers have to use the specific results, ideas, and procedures of fellow researchers in order to construct knowledge claims that are regarded as competent and useful contributions" (Whitley 2000 p. 88). In this study, functional dependence was measured by the convergence/divergence of different business disciplines around specific research topics and ideas.

The science of business can be represented as a continuum between an integrated bureaucracy at one end, and a fragmented adhocracy at the other. An integrated bureaucracy would have high strategic dependence and high functional dependence between sub-disciplines. Positive indicators would include consensus around important concepts and topics for business research, and the valuation of opinions of researchers in other disciplines. If the science of business is a fragmented adhocracy, there would be low strategic dependence and low functional dependence among sub-disciplines. All sub-disciplines work in their own domain using different methods, focusing on different topics, and seeking internal reputations.

If the science of business is becoming a conceptually integrated bureaucracy, it is creating knowledge that is contextualized and shared among the disciplines. This would be recognized in the convergence of
disciplines around fundamental topics (functional dependence) and strong associations among the
distribution channels (strategic dependence). If, on the other hand, the science of business is a fragmented
adhocracy, then it is creating important and perhaps more fundamental knowledge within sub-disciplines
but is losing out on the contextualization and integration of knowledge between disciplines that is
necessary to create value. Prior citation analyses of business sub-disciplines (Cheon et al. 1991; Grover et
al. 2006; Wade et al. 2006) have shown a limited boundary-crossing of intellectual research topics among
sub-disciplines. The degree of fragmentation/integration also stimulates questions of research relevance.
The practice of business benefits from knowledge of integrated strategies and business functions that are
not separated by the artificial stovepipes that characterize academe (Campbell 1969). In a strongly applied
science such as business, research relevance can be increased by production of integrated knowledge that
views business activities from a systems perspective (Alter 2004).

3 METHOD

In contrast to prior scientometric studies based upon citation analysis, this study analyzed the co-
ocurrence and proximity of words as a measure of semantic similarity or meaning. We argue that this is a
semantic analysis, as it determines the similarity in meaning of “a word, phrase, sentence or text.” In
contrast to citation patterns as indicators of diffusion of ideas among disciplines, semantic analysis
emphasizes identifying the similarities and differences among disciplines regarding topics and concepts
presented in the research and envisioning a semantic network that clarifies the conceptual focus of research
in different business disciplines. Abstracts are a distilled and valid representation of the conceptual
meaning of research papers, and have been used in analysis of intellectual communities in the IS discipline
(Larsen et al. 2008). LSA is a computational technique that decomposes the semantic content of a textual
corpus (abstracts, in this study) into a numerical representation of the ‘meaning’ of each text unit. The
underlying theory of LSA is that the aggregate of all the word contexts in which a specific word does (and
does not) appear is a measure of the similarity of the meaning of words or of texts, to other words or texts
(Landauer 2007). This technique assumes that written/verbal meaning comes from the relationships that
are represented and activated by collections of words. Furthermore, it is these abstract relationships that
"make thinking, reasoning, and interpersonal communication possible" (Landauer 2007 p. 8) and the
relationships among the words in an abstract are precisely what the human, and the LSA technique, uses to
determine meaning. LSA is a method, although new to Information Systems, that is part of a long history
of computational research on semantic relationships, theory of meaning, and cognition (Jurafsky and
Martin 2000; Manning and Hinrich 1999) which assumes that human interpretation is not the only path for
representing human knowledge. LSA allows for rapid analysis of very large text-based data sets, while
minimizing many of the problems associated with human categorization. LSA offers: 1) the means to
handle very large data sets (24,000+ abstracts in this study) and 2) a consistent and replicable technique
that allows for comparison between researchers, data sets, and time horizons. This consistency provides the
ability to state that the differences (or similarities) in "meaning" we ascribe to the data are not due to
methodological or interpretative differences. If you reanalyze data with the same parameters, you will get
the same result. The converse is also true: if you use LSA with the same parameters on a different data set,
then any differences in meaning arise from the data, and not from the method or human interpretation.

3.1 DATA COLLECTION

As an exploration and proof of concept, this study used Trieschmann et al.’s (2000) determination of a
warranted set of A-journals from each business discipline, based on the proportion of academicians in each
discipline. They concluded that eight disciplines and 20 journals best represented the business disciplines:

Our goals were to develop a research "bread basket" of business school journals that was
representative of research in the 13 business school disciplines defined by AACS (1998). Within
each discipline, there are many "good" journals. For example, Glick, et al. (1997) and Johnson
& Podsakoff (1994) identify more than 30 "good" journals in the management group, which
accounts for about one fifth of business school faculty (3,457 out of 15,474). While this number

* http://wordnetweb.princeton.edu/perl/webwn?s=semantics
of journals is useful for evaluating one discipline, it becomes challenging to find and analyze the 150 or so "good" journals this number would imply for the business school as a whole... Instead, we decided to focus on a smaller set of the "best" journals in each discipline. Thus our measure of business school research productivity is deliberately biased to only one form of business research: publications in leading research journals. We exclude other forms of research such as articles in "good" but lower ranked journals, conference papers, books, book chapters, and articles in practitioner journals (Dennis 2000).

Our research utilized 24,841 abstracts from Trieschmann et al.'s (2000) list of 20 journals over a period of 30 years. Twelve of the journals provided full datasets beginning in 1973, and eight journals initiated publication between 1974 and 1990. Only two disciplines (Management Information Systems (1977), Production/Operations Management (1980)) began publication after 1973, but were included beginning with the first year of their publication. Abstracts were obtained from ProQuest's database of journal abstracts. Exhibit A lists the business disciplines and journals published by Trieschmann et al. (2000).

3.2 LATENT SEMANTIC ANALYSIS

This research represents the first application of Latent Semantic Analysis (LSA) to a longitudinal inter-field dataset, and the first empirical analysis of research topics within all the major business disciplines. LSA can be used to determine the conceptual similarity among text units (artifacts), is capable of handling large datasets, and aims to:

- develop a reproducible representation of artifacts (e.g., documents, interview data, survey data, etc.) and an approach to labeling that representation in a way that would (a) reduce problems of human interpretation of the data; and (b) allow the application of quantitative techniques based on cardinal, rather than ordinal or nominal, data. Such an advance would offer an alternative as well as a complement to some existing methods for categorizing and labeling qualitative data (Larsen and Monarchi 2004, p. 351).

LSA begins by treating each abstract as a set of words without structure. “Stop words,” or words that have little or no meaning when taken out of context, but that provide structure to the sentence, are removed. Stop words typically include articles, prepositions, pronouns, and conjunctions, as well as common adjectives and adverbs.

The remaining words are stemmed to avoid having multiple forms of a word (its morphological variants) represented in the analysis. Stemming converts a word to a related form, i.e. it “conflates” the word. For example, removing an “s” or “es” will convert some plurals to singulars, and stemming the words “walks,” “walking,” and “walked” reduces all three to “walk.” Stemming reduces processing time as well as increases identification of similar words.

After stemming, words reflecting research methods or techniques, such as “regression,” “correlation,” “ethnographic,” etc. are removed to allow the focus to be completely on the topics of interest rather than the specifics of research approaches. Although the meaning of objects is constituted by the epistemological perspective, we assumed that the contextual similarity of concepts would still be present. A sparse matrix of unique stems as rows and abstracts as columns with the number of occurrences of a specific stem in a specific abstract as the cell value is created next. This matrix is submitted to a singular value decomposition (SVD), which creates a high-dimensional space in which each abstract and each stem in those abstracts occupies a specific location. Furthermore, by aggregating the SVDs of the abstracts, a centroid for those abstracts may be located in the high-dimensional space representing that collection of abstracts (for example, all abstracts published in a specific journal over 30 years). This representation allows measurement of distance (or cosine or angle) between individual abstracts in all disciplines to the centroid representing a specific discipline.

3.3 DATA ANALYSIS

Data analysis consisted of two steps. First, the 30 years of abstracts in Trieschmann et al.’s list of journals was subjected to LSA analysis. Once each abstract was represented as a vector, the midpoint for all abstracts in each journal was calculated, and the "distance" from each of the 24,841 abstracts to every one
of the 20 journal midpoints was measured. The results were compiled in a table of 20 columns and ~24K rows which was used in a factor analysis using principal component analysis with varimax rotation. As a test of the association of distribution channels (strategic dependence), a correlation table between the semantic content of all journals was calculated and the resultant variance used to map a semantic network.

Second, functional dependence was examined by calculating the relative distance in semantic space of research topics which characterize the journals from each discipline over time. A sliding window of a 3 year period, centered on the target year, was used to select the abstracts for each discipline within that window. The centroid of each discipline’s abstracts for a given period was plotted against the centroid for each of the other disciplines for the same time period. This pairwise comparison reveals relative convergence/divergence of concepts in the journals from each discipline over time.

4 FINDINGS

The analyses revealed two surprising results: 1) The distribution channels for the business disciplines are semantically more closely related than prior studies indicate, and 2) within the business disciplines, there exists a significant degree of conceptual convergence on two distinct domains of topics and concepts.

4.1 ASSOCIATION OF DISTRIBUTION CHANNELS

As a test of the association of distribution channels (journals) in this sample, semantic analysis of the total aggregate set of abstracts for each journal was performed to find the centroid for each journal. These results were then submitted to two subsequent analyses. First, multi-dimensional scaling (MDS) of the distances was calculated to determine the relative proximity of the journals centroids (the S-stress score was small, indicating that the resulting two-dimensional map is quite accurate). The relative positions of the journal centroids were construed to represent the relationships among the disciplines they represent (Figure 2). This mapping suggests the formation of two distinct domains of business interest based on conceptual csimilarity: a organizational-behavioral-technical domain composed of Management, Strategy, IS, Marketing and Operations, and an economics domain composed of Finance, Accounting, Real Estate and Risk & Insurance. This result is in remarkable agreement with the structural equivalence map based on citation analysis of the Financial Times basket of business journals (Biehl, 2001).

Second, using the same dataset as for the factor analysis, correlation coefficients between journals were calculated. Using the significant correlations (after Bonferroni correction) between journals in the different disciplines, a diagram of the network of interdisciplinary relationships between journals, and again by extension between disciplines, was developed and overlaid onto the MDS perceptual map (Figure 2). In this semantic network the network nodes are the centroids of each journal and the weight of the network links is determined by the correlations between journal abstracts. As the journals themselves are representative of the disciplines, the resultant relationships articulate "the groups…who share common understanding, those who have idiosyncratic meanings…and those who serve as liaisons and boundary spanners (Monge and Contractor 2003, p. 187).
The semantic network suggests that over the 30-year span of journals included in this study, the business disciplines as represented by these journals are more tightly linked regarding the research topics and concepts they publish than previously thought. The network map shows two distinct domains that exhibit a significant degree of shared interest and consensus about important research concepts, topics, and problems as evidenced by the proximity of research articles in semantic space. By showing the semantic associations between journals, we can visualize the strategic dependence between the disciplines the journals represent. The line weighting of the ties indicates the percent variance for which each tie accounts (from 10-50%). The line weighting is therefore an indicator of the relative strength of the semantic association between journals. Overall, this network map indicates that there is a significant degree of strategic dependence within these two discrete business domains. The strongest associations are between Strategy and Management, IS and Management, and between Finance and Accounting. At lower degrees of association there are significant semantic relationships between Management and Information Systems, IS and Operations, and Marketing and Operations. Interestingly, Real Estate and Risk & Insurance are relative isolates with weaker associations with Finance.

4.2 POSITIONING IS AMONG BUSINESS DISCIPLINES

The final analysis reveals the changes in semantic content of each business discipline over time in comparison to each other discipline (Figure 4 A-F). An increase in the semantic distance (the angle) between the target discipline (listed first) and any other specific discipline indicates that the topics, and concepts in the journals are diverging. A decrease in distance indicates greater convergence on semantically related concepts. As words pertaining to research methods, epistemologies, and ontologies were removed from the analysis, any convergence/divergence of the centroids representing the discipline reflects changes in the meanings of the abstracts.

Given the limitations of representing discipline centroids in a two-dimensional semantic space, for the purpose of displaying the data one discipline must be used as a baseline to be compared to each other discipline. In Figure 3 A-F, the baseline discipline is noted in the figure heading and does not appear in the figure. We found that Real Estate and Risk/Insurance were very insular and did not converge or diverge with any other discipline. Therefore, for clarity, they were not included in these figures. Lastly, only significant relationships have been displayed in each figure.

Figure 3A shows that the semantic content contained in IS abstracts is converging with the semantic content in the abstracts of the other six disciplines, with the exception of Accounting, which is diverging in
semantic content (i.e., the "distance" in semantic space is becoming greater). An analogous pattern is observed when Accounting is held as the baseline (Figure 3B). In this figure, we observe that all business disciplines are diverging in semantic content from Accounting with the exception of Finance, which is converging.

Surprisingly, this pattern holds when each of the other business disciplines is held as the baseline - as a group, Operations, IS, Management, Strategy, and Marketing are converging with each other. Accounting and Finance are also converging with each other but are simultaneously becoming more distant from the organizational-behavioral-technical domain. Although there are annual oscillatory variations, in each case the trend lines are converging at significant values.

**Figure 3 A-F Comparison of Conceptual Trends in Business Journals**

Examination of these figures show that in the formative years of the disciplines much of the research published in these journals was semantically less similar regarding the research topics, concepts and problems than they were in recent publications. Although there is no baseline distance in semantic space
that serves as a demarcation between fragmentation and integration, these patterns show that the business disciplines were conceptually more fragmented 30 years ago than now and that in general, there is increasing agreement on conceptually related concerns and problems.

It is clear that the business disciplines are increasingly focusing on semantically similar research topics, concepts, and problems over time. There are two discrete but associated "domains" within business science: a convergence on financial concepts (Finance and Accounting, with weaker associations with Real Estate and Risk & Insurance); and a convergence around strategic, managerial, and technical concepts. These large-scale domains indicate a growing degree of functional dependence among sets of the previous more fragmented business disciplines. In addition, if research topics are held in common more frequently, there must be a greater association among distribution channels over time. This is a logical argument, rather than one with direct empirical support. But it suggests a greater degree of strategic dependence among the business disciplines within the separate domains.

Prior citation studies of business disciplines have shown that “the management field is becoming more integrated and interdisciplinary” (Biehl et al, 2006, p. 363) while other disciplines are becoming more insular. Our evidence suggests a broader pattern of conceptual integration and a long-term trend. It is important to note that semantic similarity is a continuum, not a point of demarcation. Our study indicates a greater degree of conceptual similarity among IS and other business disciplines than has been observed in prior citation studies. It should be noted that citation analysis may not always indicate consensus on the concepts under inquiry, but rather may reflect issues of method, history, or areas of distinction. Our semantic analysis of concepts shows that the research concepts published in top IS journals are similar to research in highly ranked journals in Management and Operations and to a lesser degree, Marketing and Strategy.

4.3 LIMITATIONS

This is an exploratory study and the set of business journals included do not necessarily capture the full extent of research topics and concepts in the business disciplines. For example, as shown in Larsen et al. (2008), the conceptual breadth of IS studies is not fully represented by MISQ and ISR. As noted in Straub (2006) the choice of journals will have a strong effect on any study of disciplinary structure and relationships. Additionally, the “basket of words” approach used in LSA flattens the semantic content of abstracts to a single point and may uniquely categorize studies that address multiple research terms. But these findings show long-lived trends of conceptual change in the research topics and concepts published in these highly ranked journals. Future research should include a broader data set which includes European and Asia-Pacific journals to determine whether these changes hold across the disciplines globally. In addition, the concepts or themes around which the journals publications are converging should be identified.

5 DISCUSSION

This study analyzed the semantic content of abstracts in a warranted set of representative journals of the eight business disciplines identified by Trieschmann et al. (2000). By determining the proximity of the aggregated semantic content that contributes most to the position of a journal in semantic space, it is possible to show conceptual relationships among journals and the disciplines that they represent. By examining the actual terms and concepts underlying research, this research shows that two domains of business disciplines are more related, both conceptually and by distribution linkages, than previously thought. In one domain, Management holds a central position between IS and Strategy, and IS has centrality between Operations and Management. In the other large-scale business domain, Finance and Accounting research concepts are tightly intertwined with a lesser shared interest in some concepts within Real Estate and Risk & Insurance.

This study also highlights the importance of longitudinal analysis in scientometric research. A sliding window analysis clearly demonstrates conceptual convergence semantically related topics among journals in the organizational-behavioral-technical with a simultaneous divergence from an accounting/finance domain. The use of LSA was critical, in that it allows consistent semantic analysis of large data sets and enables comparison across time periods.
The focus on concepts and research problems shared with other business disciplines potentially leads to more integrated knowledge and greater practical relevance for IS. It is important to recognize the importance of this finding without overstating it. This does not indicate the direction or timing of boundary spanning knowledge, and no claims are made about IS as a reference discipline. But at the same time, it does suggest an increasing centrality of IS concepts as a contribution to knowledge regarding a broad set of problems that other business disciplines are concerned with.

As noted by Biehl et al. (2001), “PhD students are trained to focus on a single discipline...tenure is easier to obtain in a fairly focused research stream...and publishing in a variety of cross disciplinary journals is often seen in a negative light” (p. 369). But despite these institutional structures and the contrasting result from interdisciplinary citation studies (Biehl et al. 2005; Grover et al. 2006; Wade et al. 2006) these data suggest that IS and business disciplines are trending towards greater conceptual integration. Research, particularly in IS, is not as much transdisciplinary as neo-disciplinary, and is at risk of being marginalized by traditionally bounded business disciplines concerned with the same concepts. Although there is evidence that “business academics tend to publish in discrete and mostly non-overlapping disciplines” (Biehl et al. 2005, p 368), the disciplines themselves are converging on semantically, and arguably conceptually, similar research ideas, concepts, and problems.

Although the sources and direction of knowledge movement among disciplines is not apparent, this research suggests that IS is more conceptually related to other business disciplines in an organizational-behavioral-technical domain than prior studies would indicate. This implies that IS is becoming a central part of a maturing ‘science of business’ that has a network of functional and strategic dependencies that may lead to interdisciplinary perspectives on common research problems. These reputational networks can influence the institutional direction of research funding and programs. The allocation of subject domains to the sciences is not due to clear demarcations of content. Instead academic disciplines themselves exist due to a wide variety of internal, external, and historical forces, and reinforce ethnocentrism due to “the tribalism or nationalism or in group partisanship in the internal and external relations of university departments, national scientific organizations and academic disciplines” (Campbell 1969 p. 328).

Recognition of the role played by IS in producing integrated knowledge has implications for collective coordination of task outcomes and for academic reward structures. Supporting, encouraging, and rewarding the trend toward interdisciplinary studies may have the effect of aligning research with the institutional and economic forces that drive research. This may increase both integrated systems-based knowledge and the relevance of academic knowledge to practice.

Abstract

In this paper we attempt to assess the impact of IS research on practice. It is important to show a positive impact, if we can, so that academia, prospective students and the outside world more generally sees that the IS discipline has made a positive and major impact on organizations, people and society. Our research fills a gap as there has been little or no work to date that systematically assesses the effective relevance of IS research to practice. We find that the use of bibliometric indicators to trace the flow of ideas from research published in our top journals to practitioner journals does not detect any strong link between IS research and practice. We suggest several alternative means of assessing effective, rather than imagined, relevance and also consider how more effective diffusion of our IS research might be encouraged.

Keywords: Information systems, impact, research, practice, bibliometric indicators
1 INTRODUCTION

The positive impact of using information systems (IS) in practice is well demonstrated, with studies of the business value of information technology (IT) showing contributions to competitive advantage and productivity (see for example, Dedrick et al., 2003). However, the role that IS academic research plays in the adoption and effective use of IT is not clear. We would like to think that IS research has relevance and contributes to practice so as to be of benefit to individuals, organizations and society. Moreover, government research funding bodies are increasingly asking that external impact be implicated in research proposals (for example, European Union, 2008; National Science Foundation, 2008).

The impact of IS research on other research disciplines is evidenced by Baskerville and Myers (2002), and is extremely important, but this does not evidence impact on practice. Many research papers make claims that the work described is ‘relevant to practice’: for example, many of those describing action research, case studies and organization surveys. However, making this statement is not enough. In a discipline like IS, as in many applied disciplines, it is vital that we demonstrate that our research is actually being used by practitioners and so increase our claims to legitimacy.

In this paper, therefore, we address the question: Does IS academic research have demonstrable consequences for practice concerned with the use and implementation of IT? In answering this question, we found we also had to address a secondary question: How can we show that ideas and knowledge flow between IS researchers and professional practice?

The motivation for addressing these questions is strong. It is not enough to espouse relevance: it must be demonstrated. If we show that IS research has an impact on practice, then we achieve several useful ends. We can, for example:

1. Use the evidence as a weapon to show academia and the outside world that the IS discipline (not just technology) has made a positive and major impact on organizations, people and society.
2. Provide our students with a context which demonstrates the impact of IS research on organizations, people and society so that they appreciate its present and its potential impacts and thus see the study of IS as potentially worthwhile.
3. Demonstrate that we have means for assessing the flow of ideas from IS research to practice that can be used for benchmarking and for making arguments to funding bodies.

In contrast, if it appears that little of our research ideas flow through to practice, then we believe we are being alerted to a situation which our community should make considerable effort to address. If we cannot provide convincing evidence of how ideas flow between academia and practice, because there are no obvious means to do so, then we need to devise suitable indicators and measures.

We begin from an underlying position that IS academic research should have practical relevance, as IS is an applied discipline; a view recognized by our journals when they ask that articles indicate potential practical significance. Our work is significant because we could find no prior work that attempted to answer our questions for IS academic research, research that is published in our leading journals.

When we set out to address our primary question, we did not know the answer! Was our research being used by practitioners? However, even more interesting perhaps, we did not know how we could provide the answer. How could we demonstrate that our research was having such an impact (or not)? This paper discusses our exploration as we began to address these questions.
2 BEGINNING OUR EXPLORATION: SEARCHING FOR EFFECTIVE RELEVANCE AND KNOWLEDGE TRANSLATION

Benbasat and Zmud (1999, p 13) argued that ‘the IS field does not possess the evidence with which to illustrate the impact of its research …. This is an important question that academics should investigate’. Almost ten years later, we also could not find research that addressed this question. Rosemann and Vessey (2008) make suggestions on how the relevance of IS research can be improved, specifically through using what they call applicability checks when research projects originate. These authors argue that there is “limited demand on the part of practice for the outcomes of IS academic research” (p. 2). However, the only evidence they give for this view is that the numbers of practitioners who subscribe to IS journals or who attend academic conferences such as the International Conference in Information Systems (ICIS) are rather low.

To address our primary question, we turned to a familiar debate in IS to continue our exploration, that of rigor versus relevance (for example, see Agarwal & Lucas 2005, Benbasat & Zmud, 1999). We did not do so to join in this debate ourselves, but to see if there was evidence of what we call effective relevance as embodying some demonstrable evidence of practitioner take-up as against the mere suggestion that the research ‘should be’ or ‘might be’ relevant (as often claimed in the conclusion sections of papers). Despite the lengthy debate of rigor versus relevance there has been little demonstration of effective relevance in this body of literature nor has there been debate about how it can be demonstrated.

The research impact of IS papers has been assessed through bibliometric methods both with regards to the impact of IS researchers within the discipline and also to researchers in other disciplines (Baskerville & Myers, 2002, Lowry et al. 2007). But we are addressing a different question when we ask about the impact on practice, that is, the flow and reception of ideas or knowledge between IS academic and practitioner communities. This issue is one of knowledge translation or transfer which “assumes that practical knowledge (knowledge of how to do things) in many professional domains derives at least in part from scientific knowledge” (Van de Ven 2007, p. 3).

In some related areas where a more distinct artifact is produced, measures of impact such as patentable ideas or start-up companies can be used. In IS, however, the products of research are likely to be less tangible outputs such as methods for IS development or the evaluation of applications, the translation of which from research to practice are more difficult to track.

The problem of the gap between practitioner and academic communities in terms of knowledge creation and transfer was addressed in a special issue of the Academy of Management Review (2001, 14, 2). In introducing this issue, Rynes et al. (2001, p. 340) note that “a substantial body of evidence suggests that executives typically do not turn to academics or academic research findings in developing management strategies and practice”. Some observers have suggested that academics and practitioners inhabit basically different communities, with different frames of reference and different ways of sense-making (Shrivasta & Mitroff, 1984). Further, Rynes et al. (2001) note the paucity of empirical work on the topic of knowledge transfer between academics and practitioners, particularly in the organizational sciences.

There are many ways in which knowledge transfer from research to practice can occur, through textbooks, practitioner-oriented books and publications, teaching, consulting, executive education, and personal links. In this exploratory study, however, we have chosen to study knowledge transfer by investigating how academic research results flow to trade journals and practitioner magazines. We recognize that this is only one of the approaches that could be employed. In defence of our choice, ideas in practitioner journals have been shown to be an important means for the diffusion of knowledge (Rogers, 1995, Van Steijn & Rip 1988) and there is a substantial literature that points to the flow of ideas and knowledge through communication channels as crucial for innovations and innovative behavior (see Rogers, 1995). To give one example, Nederhof and Meijer (1995) argue that
Trade journals are the most single important source of knowledge for farmers and horticulturists. Further, Spencer (2001), in looking at the extent to which corporate and academic researchers in the flat panel display industry exchanged knowledge, noted the importance of publishing in practitioner journals if knowledge transfer is to occur.

To sum up, in our study we chose to explore whether the impact of IS research on practice could be demonstrated by looking at the use of IS academic research in outlets with a professional readership. We explain our approach to achieve this goal in the next section.

3 EXTENDING OUR EXPLORATION: SEARCHING FOR IMPACT OF IS ACADEMIC RESEARCH IN PRACTITIONER JOURNALS

We chose to explore the impact of IS research in practitioner journals by extending traditional bibliometric analyses, as these methods can be applied in a systematic fashion. The method that we adopted was to examine the extent to which a selection of high-profile ‘practitioner’ journals referenced IS research in 2006. This method involved four inter-related steps, none of which were carried out without difficulty, and all these required some degree of iterative exploration and judgment. The four steps were as follows:

1. Choice of the sources of IS research that were to be included.
2. Choice of the high-profile practitioner journals that were to be examined for evidence of references to IS research; that is, referencing the sources selected in (1).
3. Choice of a database that could provide evidence of the linkages between the IS research in (1) to the practitioner journals in (2).
4. Analysis of the linkages between IS research and the practitioner journals in 2006, using the database from (3).

Each of these steps is described in more detail below:

3.1 Choice of sources representing high-quality IS research

We decided to use the ‘basket’ of journals selected by the Association for Information Systems (AIS) as being representative of high-quality research devoted specifically to the information systems field. This basket comprises (in alphabetical order) European Journal of Information Systems (EJIS), Information Systems Journal (ISJ), Information Systems Research (ISR), Journal of the Association for Information Systems (JAIS), Journal of Management Information Systems (JMIS) and Management Information Systems Quarterly (MISQ). Unfortunately, JAIS had to be omitted because it is a relatively recent addition to the Web of Science/ISI database and citation data for it could not be obtained. Although data was difficult to obtain, our understanding is that only MISQ (with around 3000 subscribers) and ISR (with around 2000 subscribers) have substantial subscriptions for their paper editions (of the basket of six, only JAIS is electronic only). Table 1 shows details of the five journals included in the analysis.

3.2 Choice of high-profile practitioner journals and magazines

Table 2 shows the practitioner journals and magazines selected for inclusion in our analysis. These are hereafter referred to as practitioner journals for the sake of convenience. The sample is a judgment sample from journals of interest to IS that met the following criteria:

- They appear in the chosen database (the Web of Science/ISI);
- They are mainly aimed at practitioners;
- They have relatively high circulation counts, and thus a potentially large readership (figures taken from Ulrich’s Periodicals Directory 2008).

Some judgment was required to identify journals that are aimed at least in part at practitioners. Ulrich’s Periodicals Directory makes a distinction between ‘scholarly/academic’ journals and trade journals, but it was found not to be useful for our purposes, as its categorization appeared to be problematic. For example, *Communications of the ACM (CACM)* is shown as an ‘academic/scholarly’ journal in Ulrich’s Periodicals Directory, but the Association for Computing Machinery (ACM) itself refers to this publication as a ‘magazine’. Rather than using Ulrich’s, therefore, we examined the home pages of journals that could be expected to reference IS research. We made a decision as to whether a journal could be classed as having a practitioner audience by considering its stated aims on its website. The circulation count was also taken into account, as this is evidence of reaching an audience beyond academia.

Only journals with a circulation count of 5000 or above were included. The result of this process was the journals shown in Table 2.

3.3 Choice of Citation Database

The two primary databases utilized in our analyses were the *Web of Science* (2008) and *Scopus* (2008). The Web of Science refers to services offered by Thomson Scientific and was previously known under the label of the Institute for Scientific Information (ISI). This database was used as the primary source as it is well-known and used frequently for bibliometric and citation analyses. It was supplemented by data from the Scopus database for some analysis where Scopus provided the data in a more convenient or complete form.

The Thomson/ISI database has some drawbacks. Clarke (2008) has pointed out some deficiencies with respect to IS, including the omission of about 60% of the core body of IS publications, patchiness of data and some serious anomalies. The database also requires some expertise to use and has some peculiarities. Specific journals can be hard to find, even using the international standard serial number (ISSN), which was found to be the most reliable search criterion. Some journals are only in the Social Science Edition (e.g. *ISJ* and *ISR*), some only in the Science Edition (e.g. *EJIS*) but some are in both (e.g. *MISQ*).
In a final step we used Google Scholar (2008) for some further tentative analysis. Google Scholar is an experimental service, still in ‘beta’ release in 2008, but has a more extensive collection and the powerful Google search engine (Clarke, 2008). Unless otherwise noted, however, the data used is from the Web of Science.

3.4 Analysis

Each of the five leading IS journals were examined in turn and the number of citations by the selected practitioner journals in 2006 were noted, using the Journal Citations Report facility in the Web of Science database. Note that all ‘articles’ shown in the database were included, even though these will include some editorials, reviews and similar material. Table 3 shows the results of this analysis.

It can be seen that there are relatively few citations of IS research in the practitioner journals, both in absolute terms and as a percentage of the total number of citations of the IS research articles. As an example, for MISQ, the table shows that there were a total of 49 citations of MISQ articles in the selected practitioner journals in 2006. However, in 2006 the total number of times that MISQ articles were cited by all journals in the Web of Science database was 3186. The last line in Table 3 shows the percentage of citations for the journal that were in the selected practitioner journals compared with the total citations for that journal. So, for MISQ, just 0.02% of its citations were in the selected practitioner outlets. In total, there were only 80 citations in the practitioner journals in 2006 that formally referenced any work in the leading IS research journals. These 80 citations represented, on average, less than 0.01% of the total 9183 citations to the IS research journals.

An alternate way at looking at the data is to study the two right-hand columns. Many of the practitioner journals do not contain a large number of formal references, so these columns give an indication of how often IS journals are cited by the practitioner outlets relative to their overall citations. Thus, we can see that in 2006, CACM made 1658 citations of other work, with 38 (2.29%) being to the basket of IS journals.

Table 3 Number of citations of leading IS journals (all years) by selected practitioner journals in 2006

Our analysis is not complete as it does not include all IS research articles or all practitioner journals. However, we have selected leading research outlets and practitioner journals where IS work could be expected to appear, so, if anything, this result may overstate the proportion of IS research being cited in practitioner journals, as against citations in other research outlets.

As the number of cited papers is rather small, we provide an example of which papers are cited in practitioner journals in Appendix A. This appendix shows the articles from MISQ cited in CACM in 2006 (18 articles using the Scopus database). Of these 18 articles only 4 were published after the year 2000, so they are hardly ‘cutting edge’. What is happening? It may be that the articles in CACM are
using the IS journals to provide evidence of scholarly merit rather than reporting on new and exciting work.

As we have minimal existing data to use as a benchmark, it is difficult to say if this result for IS is markedly different from that of other academic disciplines. However, Nederhof and Meijer (1995) report that in the humanities, a large part (sometimes more than 50%) of the research products is directed at external knowledge transfer, while in some science fields, such as experimental psychology, a more ‘modest’ percentage (12%) of the output is directed to a non-scientific public (Nederhof et al., 1989). Obtaining extensive data for more directly comparable analysis was beyond the scope of our study. We did, however, look further at one of the practitioner journals, CMR, which publishes across a range of disciplines. In 2007, CMR had in total 1277 citations to works in other journals. Analysis classified 242 of the citations as being to research journals, with a breakdown by journal discipline of: 162 Management; 30 Marketing; 23 Psychology, 11 Sociology; 10 Economics, 6 Information Systems, 5 Planning; 3 Law and 2 International Business. IS does not show up well in this comparison.

Given these rather disappointing results, we continued the exploration along some other lines, as shown in the next section.

4 EXTENDING OUR EXPLORATION FURTHER: SEARCHING FOR LOOSER LINKS

The analysis above indicates a rather small proportion of our research flowing directly through to practitioner outlets from our leading journals. However, we explored further, looking for looser links such as what we refer to as additional flow-on effects and non-obvious connections. By additional flow-on effects, we refer to the dispersal effects that occur when articles that appear in practitioner outlets which make reference to IS research journal output are themselves referenced by other practitioner journals. Of course, the latter may not reference those aspects of the intermediary article that discuss the original IS research, so the effect might be very limited. By non-obvious connections we refer to influential IS research that may appear in practitioner outlets without the connection to the underlying IS research being obvious: that is, it may not appear in formal citations.

Each of these aspects is explored in turn, using the same practitioner journals as included in the analysis above. CACM and Harvard Business Review (HBR) are worthy of particular note when looking for flow-on effects. Both reach many readers, as evidenced by their high circulation counts. CACM is the practitioner outlet which cites the largest number of papers in our basket of IS research journals. Polites and Watson (2008) showed in a social network analysis of CACM citations using 2003 data that CACM was the top-ranked journal in a network of 120 IS-related journals in terms of both prominence and centrality. CACM was shown to occupy a central bridging position in the network between the more technical computer science journals and the more business-oriented IS journals. HBR has a very large practitioner base and the potential to reach a significant body of managers whom we wish to influence.

Table 4 shows the result of a similar analysis performed with the practitioner journals to what was performed with the selected IS journals. It indicates that there are indeed such flow-on effects. The practitioner journals are cited comparatively more often in other practitioner journals than are the IS research journals.

CACM is noteworthy. In 2006, CACM articles were cited 130 times, mostly in CACM itself, but there were another 33 citations in other practitioner journals. Further, CACM by itself is the practitioner journal most likely to cite IS research articles (almost half of the citations to them in 2006). As suggested earlier, CACM does appear important to the practitioner influence we wield.
Table 4: Flow-on effects from practitioner journal (all years) to other practitioner journals in 2006

The effect with *HBR* is even more marked. It had a total of 4,913 citations in 2006, with 138 in practitioner journals. However, it does not itself cite other sources in its articles and we cannot, therefore, claim any obvious additional flow-on effects though there may be non-obvious connections. This might require an analysis of the content of *HBR* articles. We cannot assume, however, that any influence to practitioners is benign to IS, as the article by one of its editors (Carr, 2003) evidences. It is beyond the scope of our paper to take our analysis very much further. However, this exploration excited us to see whether there is influential IS research underlying publications in large circulation practitioner journals, which may not have not been identified in the analysis above. To do this analysis, we used Google Scholar, which has more extensive references, and more relaxed criteria for including reference material. For example, citations need not be to an *ISI* listed journal and therefore potentially include papers in the *International Conference of Information Systems* as well as *JAIS*.

Doing searches with Google Scholar and a combination of search terms including “Communications of the ACM”, “Harvard Business Review”, “information systems” and “information technology” yielded some interesting results. A number of the searches converged on the same few papers in *CACM*, *HBR* and *SMR*, all of which have very large citation counts. Table 5 shows these papers and their Google Scholar and ISI citation counts. In further research the efficacy of using Google Scholar to develop this work could be investigated. It is very likely to be most popular in the future among IS academics, if perhaps not librarians.

Table 5 shows four papers that have particularly high citation counts. Although appearing in practitioner journals, they score highly even compared with the most highly-cited IS research articles. Lowry et al. (2007) identify the Delone and McLean (1992) article on the “quest for the dependent variable” as the most highly cited article from leading IS journals, with 481 citations. Only this paper and that of Moore and Benbasat (1991), with 312 citations, are shown as having higher citation counts than the Davenport and Short (1990) article in the *Sloan Management Review*. This observation indicates that Davenport and Short not only achieved high research impact in our normal use of the term, but they are also likely to have had high effective relevance because of their reaching out to a large practitioner audience, both directly through *Sloan Management Review*’s readership, but also through flow-on effects to other practitioner outlets.

Interestingly, Davenport and Short (1990) did not cite any leading IS journals as a source of ideas. Rather they appropriated ideas from industrial engineering (citing *Industrial Engineering*) and reported directly on what had been observed in case studies in 19 companies. Earl (1994, p. 6) refers to the concept of business process redesign as belonging to the “managerial journalism domain” with Davenport and Short’s seminal article in *Sloan Management Review* as being in a journal that provides “an interface between business schools and practitioners”. In view of the impact on subsequent
streams of research on business process redesign, business process modeling and the like, and the applicability of these ideas in practice, this “managerial journalism” is perhaps not such a bad thing.

Table 5: Influential IS ideas in practitioner journals

5 FURTHER REFLECTIONS

Our analysis, emphasizing the impact of IS research in terms of references to IS output reflected in our major research journals, has not shown clear links between IS research and practice, though some tentative strands have been suggested. We discuss the results in terms of our research questions, taking the second question first. We also provide suggestions for future work and action.

5.1 Can we demonstrate knowledge transfer between IS academic research and practice?

The approach in our study has not proved fruitful in showing knowledge transfer between IS academic research and practice. That is, analysis of citations of articles in leading IS journals in a sample of practitioner journals showed that a small number of IS articles were referred to the practitioner journals – less than 1% of total citations.

It is acknowledged that there are weaknesses in the approach we have used. Only a sample of practitioner journals was used and a number of the outlets we studied restrict the number of citations that authors can make. Further, by relying on citations alone we have not investigated the depth or extent to which the cited paper influences the ideas in the citing outlet. This latter weakness is one that is shared by other citation count methods that are used to assess impact, although our discipline frequently employs them as a base for assessing “research impact” and journal quality.

We suggest, however, that our study has considerable merit in that it provides a foundational step for an unexplored problem. When we began our study we could find no systematic studies of how knowledge transfer in IS could be assessed. Exploring the use of a citation count method is an obvious place to start, as this method can be applied consistently, the data is readily available and it is an approach we are familiar with for the assessment of research impact. Even the null result in our study is valuable as it means that future studies can build on it in unexplored directions.

We have made a tentative start on suggesting other avenues to explore in showing that there can be spreading effects from a publication in a practitioner journal to other practitioner journals. Further avenues to explore include more in-depth analysis of practitioner material to identify research work that has been used as a source of ideas. Further work could also widen the scope of the enquiry from practitioner publications to other transfer mechanisms such as textbooks and research monographs. Enid Mumford, for example, claimed that her work in companies could best be described in books and monographs rather than journal papers (see ISJ, 2006 for a full discussion of her work and Mumford and MacDonald, 1989, as an example). Further, articles on websites have potentially a high impact.
CIO Magazine (URL www.cio.com) is read by practitioners whom we wish to influence and so mention of our work in such sites does suggest impact. Practitioner-oriented IS publications are also crucial, such as MIS Quarterly Executive.

Other transfer mechanisms to be explored include student learning and development. Clearly IS academics influence practice through the employment of its graduates in relevant practice. However this is not evidence of our academic research making impact. Nevertheless many successful PhD students decide to continue their careers in practice rather than academia. This needs to be recognized as a positive outcome. Bjorn-Andersen (2008) argues that more than 50% of students at Copenhagen Business School not only take this route but this was their intention originally and these include some of the most talented researchers.

We now turn to our first research question.

5.2 Does IS academic research have consequences for practice?

We can give only tentative responses to this question because of our findings for the first question. We were unable to demonstrate, using the approach we adopted, that there were significant knowledge flows from IS academic research to practice. Because this result may be due to the limitations in our approach we do not want to speculate too far on the answers to the first question.

Our study did suggest, however, that ideas from IS may not be as readily passing on to a managerial audience to the same degree as in some other disciplines. A very preliminary analysis of SMR publications showed that academic works from Management, Marketing and even Psychology and Sociology were being cited to a greater degree than work from IS. This phenomena needs further study. Possible reasons include editorial policy or a lack of suitable contributions from IS researchers. A more worrying explanation would be that IS academic research does not have relevance to the SMR audience. We leave investigation of this phenomenon to further work. Concern over this issue continues in other fields and movements such as that towards “engaged scholarship” (Van de Ven 2007) and design science (Hevner et al., 2004) may go some way to addressing these concerns.

5.3 Suggested action

The finding that is clear from our study is that there is relatively low proportion of academic IS work cited in the practitioner outlets we studied, although some work appearing in practitioner outlets has itself been very well cited in absolute terms. We therefore suggest:

- **Targeting the indicators:** Authors of papers in research journals might write more articles for trade magazines and similar and communicate the research in a more easily digested form whilst referencing the original research articles. Such trade magazine output should be recognized as worthwhile in the IS research community.

- **New Magazine:** CACM has signaled a change in focus (ISWorld listserv, 2 April 2008) that may well reduce IS publications and flow-on to practice. We therefore suggest a new magazine, similar in format to the present CACM, but solely IS and perhaps produced by the Association for Information Systems (AIS). Such an outlet could, for example, include interviews with practitioners illustrating the usefulness of our research as well as evidence of it in its articles.

In conclusion, it is somewhat surprising that prior work investigating whether the impact of IS research on practice is in fact real, rather than imaginary, appears to be non-existent. Our paper makes a contribution in again calling attention to this important topic, and indicating some means by which further investigation can proceed. Our initial study is limited to bibliometric analysis but provides a base for further research.

We need to show that our research has high impact on practice, and therefore we need to work on this problem as a community to affect those indicators that show academia and the outside world that the
IS discipline has made and continues to make a positive and major impact on organizations, people and society.

A WIKI-BASED APPROACH TO ENTERPRISE ARCHITECTURE DOCUMENTATION AND ANALYSIS

Sabine Buckl, Florian Matthes, Christian Neubert, Christian M. Schweda
Technische Universität München, Chair for Informatics 19 (sebis) Boltzmannstr. 3, 85748 Garching, Germany, {buckl,matthes,neubert,schweda}@in.tum.de

Abstract

Enterprise architecture (EA) management is a challenging task, modern enterprises have to face. This task is often addressed via organization-specific methodologies, which are implemented or derived from a respective EA management tool, or are at least partially aligned and supported by such tools. Nevertheless, especially when starting an EA management endeavor, the documentation of the EA is often not likely to satisfy the level of formalization, which is needed to employ an EA management tool. This paper address the issue of starting EA management, more precise EA documentation and analysis, by utilizing a wiki-based approach. From there, we discuss which functions commonly implemented in wiki-systems could be used in this context, which augmentations and extensions would be needed, and which potential impediments exist.

Keywords: Enterprise Architecture, Wikis, Information Modeling.
1 MOTIVATION

In recent years, companies had to face various challenging environmental influences, amongst others forcing them to ensure and further develop the alignment of their business and the corresponding IT support (see e.g. Laudon et al. 2006). Therefore, the management of the enterprise architecture (EA), which is commonly regarded as means to support this task, currently gains increasing attention in many medium-sized to large enterprises, reflected by a rising awareness for this field in academia (Langenberg and Wegmann 2004). Although a multitude of approaches to EA management with different backgrounds exists, ranging from practical origin (cf. Dern 2006, Niemann 2008, and Keller 2007) via standardization bodies, as e.g. the Open Group (TOGAF, cf. Open Group 2009) or the Object Management Group (CWM, cf. OMG 2001) and tool vendors (cf. Matthes et al. 2008), to academia (cf. Fischer et al. 2007, Frank 2002, Lankhorst 2005, or Ross 2006) no commonly accepted best-practice yet exists.

In spite of the number of different origins, all approaches center around the focal term architecture. According to ANSI/IEEE Std 1471-2000 architecture is defined as ‘the fundamental organization of a system, embodied in its components, their relationships to each other and the environment, and the principles governing its design and evolution.’ (IEEE 2000, S.3) Applying the aforementioned definition to the context of enterprises, the EA refers to the fundamental organization of an enterprise, embodied in its components (e.g. organizational units, stakeholders, locations, business processes), their relationships to each other (e.g. supports, hosts, is responsible for), and the principles (e.g. profit, continuity, innovation) governing its design and evolution. Additionally, the term management according to Mary Parker Follet refers to ‘the art of getting things done through people’ (van Aken 2005). Thereby, a typical management process is organized as a cycle containing the following phases: Plan –Do – Check – Act (Deming 1986, Sheward 1986). Put in the context of EA management, the Plan phase includes the development of future planning scenarios of the EA as well as the decision-making. The selected scenario is realized in the Do phase, followed by the analysis and evaluation of the implemented EA during the Check phase. The following iteration cycle is prepared in the Act phase via the identification of potential process improvements.

The goals of the ANSI/IEEE Std 1471-2000 are inter alia the documentation, communication, and analysis of architectures. Based on the definitions given above, the main tasks of EA management are:

- **Documentation:** In order to support the plan phase of the management cycle, the current (as-is) situation of the EA has to be documented. Thereby, elements on different layers ranging from business & organizational to infrastructure aspects (see Figure 1) have to be considered to provide a holistic view on the enterprise. Prior to gathering the data about the current situation, an information model\(^1\) of the architecture has to be developed, which defines the elements and relationships in-between constituting the EA. Besides the current situation, information about future states according to the plans has to be documented. Complementing the current and planned states of the EA an ideal target (to-be) state should be envisioned, which can be derived from the long-term vision of the enterprise.

- **Communication:** Gathering information from the different layers in the plan, do, and check phase, as introduced above, requires the involvement of a multitude of stakeholders, e.g. business process owners, project managers, business architects, etc. Although working for the same company, the terminologies used by these stakeholders differ widely. This communication issue is often referred to as the communication gap between business and IT (Lankes 2008, Schekkerman 2004). This gap is likely to hamper effective communication and

---

\(^1\) The information model is sometimes also referred to as meta model. We prefer the term information model, which we regard to be more unambiguously (cf. Buckl et al. 2007b).
collaboration in the EA management process. Visualizations are a commonly accepted means to bridge this gap. Another challenge is connected to the aspect of historization and traceability of management decision (Buckl et al. 2008).

- **Analysis:** Concluding the management cycle, the current, planned, and target architecture of the enterprise have to be analyzed and evaluated in the check phase to support decision making and identify potential improvements (Johnson et al. 2007). The analysis results are finally used to improve the procedure of EA management itself in the act phase.

![Figure 1: Layers and cross-functions, which form a holistic view on the enterprise](image)

The *traditional* way to address the challenges of documentation, communication, and analysis in the context of EA management, as described above, is to select an EA management tool available (cf. Matthes 2008), and to use the inbuilt information model and methodology. Due to the high investments of such an approach, we propose an alternative lightweight wiki-based approach to EA management in this article, which we deem to be suitable especially for emerging EA management endeavors. Starting with a discussion about the application of wikis in related contexts, as e.g. software engineering, in Section 2, Section 3 explicates on the state-of-the-art in starting EA management endeavors. Thereby, we emphasize on the main tasks of EA management as introduced above. Following Section 4 introduces the wiki-based approach and discusses how it can be used to facilitate the challenges arising in the context of documentation, communication, and analysis of EA related aspects. The proposed approach is thereby complemented by methods for extracting structured information from wikis, by which we hope to promote a smooth transition from beginning small-scale EA management initiatives to mature enterprise-wide endeavors through leveraging information reuse. Finally, Section 5 concludes with a short outlook on upcoming or interesting research concerning the topic and indicates points of interest, which could be subject to further research initiatives.

## 2 SELECTED WIKI USAGES AND EXTENSIONS IN LITERATURE

A number of attempts have been undertaken to use wikis in enterprises as a tool for documentation and communication. Quite a lot of these attempts have been reported in papers on knowledge management (KM). Although EA management, as introduced above, can be regarded as an issue of knowledge management, we do not detail considerations on wikis from a pure KM perspective as found in literature. Instead, we discuss usage approaches and tool extensions directly focused on the three main tasks according to the IEEE, namely documentation, communication, and analysis.

The first approach is taken from the field of software engineering, which is strongly concerned with architectural topics and focuses on the tasks of documentation and communication. In a research project executed at Carnegie Mellon University a wiki-system was used to collaboratively create and
maintain the documentation of the architecture of a single software system under development (Bachmann and Merson 2005). A key finding of research was that the structure of the documentation emerging in a wiki was different from the structure typically employed in a document-centric setting. The documentation in the wiki ended up at a different level of abstraction concerning architecture elements, i.e. complex elements were split up into single and separately maintained pages of which each documented a small portion of the element. This effect, which normally does not occur in document-centric settings, was considered helpful to reduce contention between the parties employed in documenting. This tendency of the information contributors to change the level of abstraction, if they regard an entity to be too complex to describe it in a single text, further promotes documentation maintenance. This leads to a more current documentation, although issues of assigning responsibilities for keeping pages up-to-date were experienced. The wiki-system was also found useful in promoting reuse of documentation fragments, e.g. by linking related pages or embedding visualizations such like class diagrams (Bachmann and Merson 2005). Nevertheless, the latter aspect was not free of problems, as the wiki-system did not provide means for collaboratively editing visualizations. Thus, they were created offline and embedded as images – a fact greatly hampering their maintenance.

An application showing, how wiki entries created and maintained by an appropriately large number of users, can be used as a basis for collaboratively and iteratively building a documentation schema for a field of interest is given in Hepp et al. (2007). Thereby, the authors show how basic wiki concepts as the URIs, referring to described entities, the links between the entities, and the versioning history can be used to derive a basic and simple schema of the documented concepts. While Hepp et al. outlines, that the approach taken might be greatly augmented e.g. using semantic wiki technologies, one of the core findings also holds for simple wiki-systems: increasing stability of entity descriptions indicates the evolution of, what the authors call, wiki consensus on this entity’s meaning.

In Auer and Lehmann (2007) an approach to lift hidden semantic treasures out of simple wiki-systems is presented. In the approach especially wiki templates, as commonly used throughout the wikipedia, play an important role. These templates can be seen very similar to predefined forms, which were initially intended to provide consistently formatted graphic elements for certain content in specific articles. The articles using the same template can mostly be regarded to describe entities of the same type, e.g. all articles, which use the template Settlement, describe settlements. As a consequence, Auer and Lehmann the authors of the article developed an algorithm capable of searching a wiki (in this special case the wikipedia) for the occurrences of specific templates, which were then subsequently parsed and translated to a more formal representation. Having had on the one hand astonishing success with the extraction, some caveats with the approach could be identified, especially concerning the design of the used templates. Some templates are made up in a way, that (semantic) information and presentation information are not strictly separated. Additionally, for the same concept several templates might exist. As a consequence Auer and Lehmann (2007) provide guidelines for designing semantically rich templates, which we will refer to in the presentation of our approach.

3 STARTING AN EA MANAGEMENT INITIATIVE – STATE OF THE ART

In our research project Software Cartography, we gained insights regarding the first steps taken to establish an EA management endeavor in different global acting companies, e.g. Allianz, BMW, MunichRe, Siemens, T-Com. Accordingly, a typical emerging EA management initiative typically starts with the documentation of the as-is situation of the EA. Thereby, seldom a strict and predefined information model is utilized at the beginning of an EA management initiative. Thus, the documentation of the EA is often left to text or spreadsheet documents without a formal structure. This method is often useful to gain first insights on the EA and, more important, to satisfy information needs without having to first explicate and formally describe them. Additionally, the method is commonly regarded as more appropriate for starting with EA management, as the creation or selection
of an EA information model can be considered a labor intensive task, which often employs various review-cycles.

Nevertheless, when the EA management endeavors become more mature and multi-partied, commonly an object-oriented information model for the EA concepts is used. The same is true with the rising demand for aggregated information representations such as e.g. computed metric values (see Lankes 2008), which are mostly grounded on object-oriented information models. Numerous of these models currently exist, heavily researched in the academic community (see e.g. Braun and Winter 2005 or Lankhorst 2005), by tool vendors (cf. Matthes et al. 2008) as well as standardization bodies (e.g. the Object Management Group or The Open Group), and developed by the companies practicing EA management (see e.g. Halbhuber 2004, Lauschke 2005, Brendebach 2005). This fact is further promoted, as no common and fully accepted standard information model has yet been published – with some researchers, tool vendors, and EA management practitioners claiming, that such a model suitable for any company and any way of performing EA management does not exist (Buckl et al. 2007a or Kurpjuweit and Winter 2007). Whereas Kurpjuweit and Winter propose an stakeholder-centered approach to information model creation, Buckl et al 2007a and Buckl et al. 2008 presents a concern-centered approach.

With the growing complexity of the body of management and the rising number of people to be involved as information suppliers, spreadsheets and text documents do not scale appropriately, negatively influencing the overall acceptance of the initiative, e.g. due to arising problems of maintaining the consistency (Fischer et al. 2007). A way to bring EA documentation and communication efforts to the next level is the introduction of an EA management tool, into which the previously gathered data shall be imported. This step can be considered as a turning point in two ways: Firstly, up to that point EA management and especially the documentation efforts do not comprise a major investment and are thus likely to emerge as bottom-up initiatives. In contrast switching to a tool not already present in the enterprise commonly cannot be done without having management support as this poses a great investment for the company. Secondly, the tabular and textual documentations rarely adhere to an explicaded and formal structure. Bringing this information into an EA management tool can be regarded a quite complicated task, as the majority of tools uses an object-oriented information model for the governed information (cf. Matthes 2008 et al.). Therefore, the structure behind the information, previously gathered in spreadsheets and text documents, has to be explicaded and mapped to the structure provided by the future EA management tool.

The process of mapping a grown structure, which evolved in a process potentially without centralized control, to the structure as incorporated in the tool, can be regarded to be challenging (see Matthes et al. 2008). This is on the one hand true, if the tool comes shipped with a predefined and fixed model, to which all the concepts have to be mapped. More often than not the predefined information model demands some concepts to be maintained, about which up to that point no information was gathered. On the other hand, if the tool provides adaptability of the underlying information model, the issue to tackle does not become smaller. A variety of different stakeholders throughout the enterprise wants or needs to be involved in creating and developing a company specific information model, which supports the analyses needed to perform enterprise-specific EA management tasks. Beside the different concerns raised by the different stakeholder, also definitional issue are likely to arise, because terms as application are widely used and are thus strongly overloaded concerning their meaning.

4 A WIKI-BASED APPROACH …

Based on the findings of the work of Bachmann and Merson 2005, we discuss how a wiki-based approach facilitates EA management endeavors. Thereby, we structure our discussion along the three main tasks – documentation, communication, and analysis – and show possible impediments for effectively using wikis in these areas.
4.1 Applying tags to objects is a prominent method for categorizing concepts especially in the Web 2.0 environment (cf. http://del.icio.us). Also many wiki-systems utilize this mechanism, to allow their users to contribute classification information, which constitute bottom-up taxonomies, so called folksonomies. Further, widely used wiki-systems (see e.g. http://www.wikipedia.org) employ the mechanism of templating to provide pre-formatted and structured building blocks for wiki-pages. We subsequently discuss how these two techniques can be used to facilitate the creation of an EA information model consisting of classes and properties.

4.1.1 Collaborative tagging

Golder and Huberman (2005) introduce a classification for different kinds of tags, which are used throughout a collaborative tagging environment. Based on this classification, we discuss which types of tags can be used to facilitate the collaborative creation of an EA information model. These are on the one hand the what-it-is-about tags and what-it-is, which can be regarded to be quite identical in the context of EA documentation. Such tags commonly form the overwhelming majority of tags used in collaborative tagging environments. On the other hand, the who-owns-it tags, which are used especially for tagging blogs, can also be used in EA documentation, although ownership has a different notion there. Owning a concept means to be responsible for this specific concept. Such information should better not be expressed via tags but using properties as described in the next subsection. Therefore, we do not expect ownership tags to be very frequent in EA documentation wikis. A last type of tags, the refining-categories tags are not used on their own, but together with tags of other types for refining their semantics and creating subcategories. These tags can provide information valuable to EA information modelling, although we do not expect them to be more frequent as in general tagging environments.

The tag types discussed above can be considered very useful for finding and refining classes in a similar way as e.g. in object-oriented design. There, the creation of classes is simply spoken related to grouping objects, which share common properties, and finding an abstract label for describing the group. Nevertheless, especially in complex and evolving environments, as e.g. an enterprise such a classification might not easily be found. Therefore, collaborative tagging can provide a useful contribution, when EA concepts, documented in the wiki, are applied tags, e.g. "business application" or "server". Other tags as “important”, which are widely used in tagging environments, are nevertheless not directly related to classes in the information model, but merely have a user-related semantics. They can notwithstanding be used for our approach, cf. Section 4.2.1.

4.1.2 Open templating mechanism for property modelling

Wiki templates, as discussed above, provide a mechanism for defining values for a set of fixed properties of a certain type of object, e.g. a settlement. Nevertheless, as neither a set of fixed types, which could be used for defining templates, nor a fixed set of properties exist, the templating mechanism cannot directly be applied here. Therefore, we propose an adapted form of the mechanism, which we call open templating mechanism. In the context of the mechanism the template itself is reduced to a simple table, in which the user can add rows and thereby properties as well as corresponding values. As a consequence, the user can freely introduce properties and apply values to them. Because of the nature of wiki-systems these values are only textual, i.e. no data types are

---

2 We use the terminology of the Essential Metaobject facility (EMOF), see OMG (2006). Therein, no distinct concept for modeling relationships exists; instead they are represented as connected properties.
assigned to the properties. This might cause several problems discussed below. Nevertheless, semi-complex data structures (e.g. arrays, sets) can be utilized to bundle composite values.

In order to prevent anarchic evolution of templates, a recommender mechanism is added, providing properties, which are potentially relevant to the object currently described. The relevance therein is not computed from the overall frequency of that property but from a correlation analysis between the property and the tags, which are applied to the described object. Thereby, it is determined how frequent given property and tag are used in conjunction compared to the number of usages in general. We regard this method to be appropriate for quickly and easily finding the important properties. In order to display the recommendation of the system, again a visualization resembling a tag-cloud could be utilized, in which the properties most correlated are displayed as more relevant.

4.1.3 Potential Impediments

Collaborative tagging and open templating might be well-suited for the above context; nevertheless some impediments might hamper the development of a semi-structured EA documentation. Subsequently, we outline two of them, which can negatively influence user acceptance. This acceptance is generally considered a critical success factor for tool-supported, bottom-up knowledge management endeavours.

A phenomenon repeatedly reported in the context of classification attempts, is what was called the base level in Tanaka and Taylor (1991). When asked to classify an object, people tend to use terms, which are neither strongly generalized nor specific according to their distinct knowledge backgrounds. The chosen intermediate level between generalization and specificity is called the base level of the particular person. As a consequence of the base level being specific for every person, the expertise in the domain, from which objects have to be classified, greatly influences the specificity or generality of the used classification terms. This effect might especially apply in the area of EA management, where stakeholders from many different areas are contributing to a holistic documentation of the EA. Therein, they are likely to classify according to their domain expertise, leading to issues, which potentially impede the development of a common and consistent information model.

Wiki-entries and therefore also the values contained in templates are mainly textual. While this can be seen as an important success factor for wiki-systems in general, the fact has some negative influence in information modelling. The properties' values in the templates are pure text values, even if they represent information about date or numbers. As a consequence, no type and consistency checking can be performed – endangering the overall quality of the data collected. In addition, when a full migration of the semi-structured wiki-based EA documentation to a fully object-oriented model should be performed, the data types of the properties have to be determined. While possibly some of this determination may be performed automatically, no one expects that to be possible in all cases. This is especially true, if properties representing relationships between objects are considered.

4.2 ... to EA information communication

The different stakeholders of EA management endeavors have distinct information demands and perform specific activities during the management processes. According to the information demands, these stakeholders can be assigned to groups – a functionality, which many wiki-systems provide out-of-the-box. The specific activities can be connected to roles in the wiki, such that access rights can also be granted based on the role-description taken by a person. The formation of virtual communities of practice of different stakeholders as wiki-groups can be leveraged to facilitate communication among these stakeholders by means of collaborative bookmarking or watch lists.
4.2.1 Collaborative bookmarking

In contrast to collaborative tagging, the collaborative bookmarking does not assign classifying tags to the objects, but assigns contextualizing tags, which have no general meaning, but provide sense for the user (or user group), from which the tag originates. Golder and Huberman (2005) provide a classification for these types of tags into self-referential and task-organization tags. Self reference tags are used to express a relationship of the tagged object to the user. These relationships do mostly not refer to formal and organizationally established responsibilities, but refer to intrinsic areas of interest of the specific user. Task organization tags, as e.g. "TOBEREAD" or "TODO", are commonly used in tagging environments to keep track of open activities or inform fellow users of open tasks. Both types of contextual tags do not contribute to the creation of an EA information model, but are important means for information distribution among a certain group, e.g. used as hints during the collaborative creation of an EA documentation artefact.

In order to clearly separate the different types of tags – the classifying ones needed for EA information modelling, and the contextualizing ones needed for EA information communication, we propose an additional concept, which might be helpful in this context. The user should be given the possibility to choose, whether a given tag is visible in public, to a selected user group only, or private, according the aforementioned virtual communities of practice, which the user participates in. This also gives rise to the idea to extend the tag recommender system, such that a user is recommended tags in respect to the groups, he belongs to. Such a recommender system can be helpful to prevent the evolution of numerous synonymic tags in the wiki. The tags recommended are therein sorted by relevance and displayed in an appropriate way, e.g. in a tag-cloud.

4.2.2 Watch lists and change feeds

As the documentation of the EA can be regarded an effort of strongly collaborative character, group related notification in case of specific changes and communication of ongoing documentation initiatives is often considered to be important by practitioners for a number of reasons:

- The person responsible for certain parts of the EA can get a notification, if the documentation of one of these elements is adapted, e.g. to perform quality assurance.
- The head of a group of people employed with documenting parts of the EA can keep track on the progress made in the documentation endeavour.

Watch lists and change feeds, as implemented in many different wiki- systems, may be appropriate to address the notification demands as sketched above. Nevertheless, further demands for notification may exist, e.g. a user might want to get a message on pages, which have not been changed for a certain period. These messages might give indications on parts of the EA documentation becoming outdated or parts being not well established. While such a feature is not commonly supported in simple wiki-systems, the information on the last update of a page is stored and could be easily used to satisfy the notification demand as outlined before.

4.2.3 Potential impediments

Each of the communication facilities outlined above has some subtle complexities assigned, which may lead to sub-optimal usage in an EA communication environment. The collaborative bookmarking might fall for his apparent similarity to the collaborative tagging facility. While the latter is intended to evolve a bottom-up classification schema for concepts, the former can be used as mnemonic for a user or to guide the attention of a user group. Nevertheless, one cannot expect the users of the wiki-system to keep this strict separation alive. Hence, the classification schema might get “contaminated” with contextualizing tags, which have no meaning to the public. The opposite effect might also occur – users might classify objects in the wiki private, such that the information model cannot benefit from.
The watch lists might fall for legal problems, as they could be misused as means to observe and track employee behaviour in the wiki-system. Beside this problem, the watch lists facilitate a one-way usage paradigm, where users only aggregate and consume information, but do not directly contribute to the information and documentation base. Finally, watch lists might, similar to task organization tags, be helpful for directing user attention. Nevertheless, an excessive supply of such list is most likely to distract the attention of the users.

4.3 ... to EA analysis

The documentation of the EA as incorporated in the wiki-system has to be analyzed in various ways to support the EA management process. Different wiki-systems provide functionalities, which are useful for performing EA analyses. These functionalities range from versioning, which is a common feature for most wiki-systems, to textual querying, which is supported by some semantic wiki-systems (e.g. the semantic media wiki – see http://www.semantic-mediawiki.org). By textual querying, semi-structured information from wiki-pages is queried against, and the results of the query are presented in a tabular report.

4.3.1 Versioning

Most wiki-systems provide versioning of pages, i.e. the history of past versions of the page is stored in the underlying database of the wiki. Thereby, two important aspects of EA analysis are facilitated. At first, the description of the EA or parts thereof is historized – a feature, which is often requested by EA practitioners to ensure traceability of management decisions and project changes. In contrast, many of the current tools for EA management (see Matthes et al. 2008) do only rudimentarily support versioning. Secondly, if mechanisms as collaborative tagging and open templating are used to develop and evolve an information model for EA management, versioning of wiki-pages also contributes to a historization of information models.

The possibility to distinguish between minor and normal changes of wiki-pages additionally allows to clearly separate maintenance activities in the documentation from situation, where substantial change in the underlying architecture is documented in the wiki. If the wiki-system further supports to give comments on the changes, especially for the normal ones, this functionality can be used to relate a documented architectural change to the causing EA project. This traceability of the projects, which drive the managed evolution of the EA, is often regarded to be important for EA planning and analysis (Buckl et al. 2009). Finally, the option to mark a change as minor allows reducing the amount of information, which shows up in watch lists, such that the user’s attention is not distracted by these maintenance activities, but is guided towards real architectural changes.

4.3.2 Textual querying

Textual querying allows accessing both the textual and the semi-structured parts of wiki-pages in a more convenient way. In particular, tabular views on the structured information can be created via queries, which can be used to get an overview on specific concepts, e.g. all objects tagged with “business application”. In this overview, also different kinds of sorting can be applied and comparisons of objects of the same type are performed easily.

A tabular listing of “business application” concepts might additionally be helpful in guiding the evolution of the information model, as maintained in the wiki-system. While at the beginning of a collaborative documentation endeavour, frequency counts and correlation analyses might be appropriate methods for determining the importance of a tag and the corresponding properties used in the open templates, the evolving information model may at some point become overloaded and partially anarchic. By comparing the property supply for a certain type of object, a domain expert for EA modelling can decide to make some of the properties mandatory, leading to increased consistency.
of the information model. Having taken such a decision, the tag-cloud recommender functionality as introduced above, could be adapted to incorporate the effects of the decision, e.g. by colour coding certain elements or enlarging their font-size. This could be used to leverage the documentation of specific concepts, which are especially necessary for a distinct EA management endeavour.

4.3.3 Potential impediments

The basic facilities for comparing selected versions of a wiki-page are often somewhat limited in respect to the semi-structured information supplied by open-templating mechanisms. Therefore, especially functions for executing comparisons within the templates can be considered beneficial, so that the user can see a tabular report on the values supplied for properties in the selected versions. For such a comparison, it would also make sense to compare more than two versions of the object – a feature also not commonly supported in wiki-systems.

The synopsis of different objects of the same type or versions of the same object over time can, as alluded to above, be used to facilitate decisions on the EA information model. Nevertheless, if a decision on certain properties is taken, e.g. making them mandatory, the bottom up development of the EA information model is disturbed, which might cause a decrease of user acceptance. Hence, any top-down adaptation to the community developed model should be carefully assessed to prevent a downturn in user motivation.

Textual queries are only the first step on the way to conveniently present semi-structured information to a broader user community. Going beyond simple tabular reports, graphical visualizations of the EA or parts thereof are regarded as an important instrument (Lankes et al. 2005) to both support and promote the EA management effort as well as to increase the awareness for that topic among the company's employees. Such visualizations, called Software Maps in the context of documentation of the EA, can according to the approach presented in Buckl et al. 2007b be created from information about the EA, if all concepts displayed are sufficiently documented. This should be the case, if open templating mechanisms are employed in the wiki to support semi-structured information provision.

Here, we see a potential synergy effect, if the wiki-system can provide access to automatically generated visualizations displaying concepts within the EA, which have been described sufficiently detailed. Such visualizations, if comprising which information has to be maintained for a specific concept in order to be displayed therein, could then leverage the maintenance of that data. Thereby, users of the documentation wiki are encouraged to supply additional information about the EA constituents, which they are responsible for, to make sure, that these objects are displayed in the visualizations of the EA.

5 OUTLOOK

In this article, we presented an approach to use wiki-systems for documenting, communicating, and analyzing the EA. Furthermore, we elaborated on different aspects of wiki-systems, which might be helpful in this context. Nevertheless, the approach presented has yet not been validated in practice. We assume, that especially medium-sized companies may benefit from the presented techniques for starting EA management, while larger enterprises are likely to stay to the more formal and structured tools.

Further aspects of interest regarding the approach are e.g. scenarios to use rating functions on wiki-pages to allow users to provide feedback in a structured and uniform way. Concerning these functions a multitude of implications, e.g. on user motivation would have to be considered. Additionally, these ratings could provide valuable input to the analysis of documentation templates, although a clear correlation between a low rating and the respective template used is not likely to be easily determinable.

Abstract

This paper examines dimensions of social capital in the distributed collaborative development of the
UK particle physics Grid. It is shown that the GridPP project effectively draws upon social capital
rooted in the tradition and culture of particle physics experiments, characterized with trust, equality,
shared vision, collaboration, and pragmatism. These factors contribute to overcoming the challenges
in the creation and sharing of knowledge in the development of the Grid, a cutting-edge technology
that has to be delivered as a working system with limited time and resources. This case sheds lights
on, and provides a good example of, the importance of social capital in distributed systems
development.

Key words: Distributed System Development, Social Capital, Knowledge Processes, Grid
1 INTRODUCTION

As systems development activity becomes increasingly globalised and distributed, projects face great challenges in developing and maintaining knowledge and expertise. The need to mobilize knowledge capabilities is particularly acute when the task itself is highly complex, uncertain, and involve innovative technologies. In this paper we use the concept of social capital to examine the knowledge processes in the development of the UK particle physics Grid. Perceiving the construction of the Grid as a grand systems development challenge in technical, organizational, political and human terms, we would like to go beyond the usual software-centric view of system development, and focus on how a collaborative project, GridPP, dynamically mobilizes social capital to sustain the distributed system development process.

The UK particle physics Grid is part of an initiative which aims to produce not just a working system but a new generation of computing technology that will potentially have significant impact on scientific research, and may foreshadow the “next generation Internet” (Abbas 2004; Carr 2005). It is being developed as a large scale distributed collaboration, by particle physicists who come from a community with very distinctive work practices and culture (Knorr-Cetina 1999; Traweek 1988). They have a record of success in developing innovative computing solutions of which the World Wide Web is the most notable example (Berners-Lee 1989).

The rest of the paper starts with a literature review which connects distributed system development and social capital. The case is then introduced, followed by a brief outline of the methodology. Section five provides an analysis of the case using the three dimensions of social capital (Nahapiet and Ghoshal 1998). Section six further discusses the implications of mobilizing social capital for knowledge processes in distributed systems development, and concludes the paper.

2 DISTRIBUTED SYSTEM DEVELOPMENT AND SOCIAL CAPITAL

With the current trend of globalization where the IT industry is becoming more and more globally interconnected (Herbsleb & Moitra 2001), information systems development has increasingly become a multi-site, multi-cultural, globally distributed undertaking (Herbsleb, Paulish and Bass, 2005). Today there are more software projects running in geographically distributed environments and the so called “global software development is becoming a norm in the software industry” (Damian & Moitra 2006). One of the advantages of distributed system development is the fact that it provides opportunities for developers in dispersed locations to build and share their knowledge collectively. An example of distributed systems development is open source projects, characterized with a highly distributed environment, collaborative and rapid development among virtual teams and rapid evolution as the environment changes (Lee, Banerjee, Lim, Kumar, Hillegersberg and Wei, 2006). Similarly, the globalization’s effects on outsourcing of software production and systems development have made outsourcing take up global dimensions, and thereby become an international complex undertaking which requires a tremendous amount of support and interaction (Yalaho 2006).

As distributed system development emerges as the new paradigm in developing large-scale systems (Damian & Moitra 2006), there are still challenges and complexities involved in managing the development, such as cultural issues, communication issues and technical issues that need to be addressed (Herbsleb & Moitra 2001). Various studies have looked at aspects of managing virtual teams across time and space. Sarker and Sahay (2004) for example, identify problems experienced in distributed systems development, including those arising from geographical separation, different cultural contexts and different information systems development practices. Powell and associates (2006) similarly look at the relationship between team commitment, member effort, and trust in virtual teams as compared to collocated teams. DeLuca and Valacich (2006) examine the effectiveness of using asynchronous and synchronous media in virtual teams. In this paper, we draw upon the concept
of social capital to investigate how GridPP mobilizes its collective knowledge to overcome difficulties and challenges in its large scale distributed systems development project.

The concept of social capital has been traced back to Durkheim (Portes 1998). Bourdieu (1986) identified the value of social capital in the context of unequal power relations reproduced in societies. He defines it as “the aggregate of the actual or potential resources which are linked to possession of a durable network of more or less institutionalized relationships of mutual acquaintance or recognition” (ibid. p. 248). Coleman (1988) distinguished social capital from physical capital, embodied in material form, and human capital, embodied in the skills and knowledge acquired by an individual, and sees social capital as existing in the relations among persons. Later, Putman (1993; 2000) exported the concept out of academia and into a wider media. If Bourdieu and Coleman represent a sociological perspective on social capital, Putman took a political science perspective, whereas Fukuyama (1995) integrated the concept with trust in an economic framework, and defines it as “features of social organization such as networks, norms, and social trust that facilitate coordination and cooperation for mutual benefit” (p. 57). Fukuyama’s work is considered representative of the “economic imperialist version of social capital” (Fevre 2000, p.103), which is based on a rationalistic model of individuals. In organization studies, the concept has also gained considerable currency and has been applied in a wide range of topics ranging from workers’ career advancement to firm strategies in a network (Adler & Kwon 2002). Adler and Kwon (2002) define social capital as “the goodwill available to individuals or groups. Its source lies in the structure and content of the actor’s social relations. Its effects flow from the information, influence, and solidarity it makes available to the actor.”

From the perspective of organizational advantage, Nahapiet et al. (1998) establish the linkage between social capital and collective knowledge in the organization. They argue that social capital facilitates the creation of new intellectual capital by affecting the conditions necessary for exchange and combination of existing intellectual resources, in the form of explicit and tacit knowledge and knowing capability. The linkage between knowledge processes and social capital has also been explored by information systems researchers. For example, Urquhart, Liyanage, and Kah (2008) suggest that the weaker the social capital, the harder it is for the knowledge and human capital to grow in a community. In this paper, we take the view that knowledge is socially constructed (Berger & Luckmann 1966), and that social capital draws our attention to the importance of social relationships, identities and values such as trust which facilitate the knowledge processes. Knowledge is co-constructed in a dialectic between individuals within the context of social structures (Berger et al., 1966). Individuals express themselves through language (broadly defined) which others must interpret to create new knowing (which may or may-not align with the previously known). It is for this reason that we adopt the perspective of social capital to explore practices of knowledge-construction and sharing of individuals and collectives, yet appreciating that knowledge cannot be objectified, it is always “known”. Documents and information can only be potential for knowing, rather than knowledge itself.

Nahapiet et al. (1998) conceptualize three dimensions of social capital: structural, cognitive, and relational dimensions. Structural dimension refers to the overall pattern of connections between actors – that is, who you reach and how you reach them. Drawing upon the term “relational embeddedness” by Granovetter (1992) which describes the kind of personal relationships people have developed with each other through a history of interactions, e.g. respect and friendship, the relational dimension of social capital refers to those assets created and leveraged though relationships. Key facets in this dimension include trust and trustworthiness, norms and sanctions, obligations and expectations, and identity. Finally, the cognitive dimension refers to those resources providing shared representations, interpretations, and systems of meaning among parties (Nahapiet et al. 1998, p. 244), for example, shared language and codes, and shared narratives. The distinction between the three dimensions of social capital is for analytical purposes and they are inevitably overlapping and interrelated. Within this paper we employ these social capital dimensions as analytical devices to explore the case of GridPP, and through this explore the social construction of knowledge within this community.
3 CASE DESCRIPTION

The LHC Computing Grid is building a large-scale computing infrastructure for the high energy physics community. The Large Hadron Collider (LHC) particle accelerator at CERN, the European Laboratory for Particle Physics, is designed to collide Hadron particles at energies close to those of the Big Bang in its search for the elusive ‘Higgs-Boson’ particle (believed to be responsible for matter having mass). These collisions will produce data within the LHCs four experiments (ATLAS, LHCb, ALICE and CMS). The number of collisions, and the subsequent data produced by the experiments, is vast, thus finding the Higgs-Boson has been likened to searching for “a person in a thousand world populations”, or for a “needle in twenty million haystacks. The LHC envisages producing 15 million gigabytes of data a year - equivalent to a DVD every 15 seconds or 1% of global information production (Lee et al. 2006). To store and analyze this data the LHC requires the equivalent of 100,000 PCs spread across the globe and working as a Grid (Economist 2005).

A technical perspective sees a grid as a computing platform for coordinated resource sharing and problem solving suitable for data-intensive and compute-intensive applications (Foster et al. 2001). In this way a grid connects and coordinates diverse and heterogeneous computing resources across space and different domains, presenting itself to users as though it was a single resource. A central concept for grids is that of the virtual organization (VO), and resource management is based on permissions for access to shared resources that members of a VO can make use of, disregarding actual hardware locations. Thus the four LHC experiments are examples of VO, and allow physicists from around the globe to access data and run analysis “jobs”.

The LCG has been broken down into various elements, and distributed among various countries. The UK contribution to the LCG is GridPP, a collaboration of 19 UK universities, the Rutherford Appleton Laboratory, and CERN. The GridPP project started in 2001 and has been involved in developing applications, middleware and providing technical infrastructure and storage and processing units. The LCG has a hierarchically tiered structure, with Tier 0 at CERN, Tier 1s consisting of the national IT centres in each of the major countries involved in the project, and Tier 2s being the regional centres in each country.

4 METHODOLOGY

GridPP’s unique nature provides a revelatory case of distributed systems development practice (Venters & Cornford 2006). Drawing from the interpretive research tradition in information systems the focus of this study is on sensemaking and the symbolic world of those studied (Walsham 1995). The research team includes a senior experimental particle physicist to ensure that the research is not undermined by a lack of understanding of physics.

Data collection began in August 2006, following earlier pilot work, and has included participant observations of weekly project management board meetings and deployment team meetings, quarterly GridPP collaboration meetings in the UK, international meetings of the LCG, site reviews carried out by GridPP, observation of various forums and conferences in which GridPP participates. The research team has had full access to the GridPP main documentation, and we subscribe to its main mailing list and the deployment team mailing list. At the core of this research are over fifty semi-structured qualitative interviews of between one and one-and-a-half hours, undertaken at various universities across the UK and during two week-long periods at CERN in Geneva. Table 1 provides details of the

---

1 Grids are distinguished from existing distributed computing in that scientists/users do not have to negotiate their use of different sites or resources separately and deal with security restrictions of individual sites, nor have to find out the precise location of their data. They need only one user-account to access a wide range of resources – processing and data – as permitted by being a member of a VO.
research activities undertaken. Interviews were audio-recorded, transcribed and then organized for analysis using the Atlas.Ti software. We found the software useful in handling the amount of data we had, but we didn’t want our thinking to be restricted by software. Rather than developing a theory from the data, our data analysis was closely integrated with theoretical development in an iterative and incremental process, one feeding into the other. Data analysis was closely integrated with theoretical development in an iterative process, one feeding into the other.

We can identify three stages of data analysis. The first round was open coding of the data, labelling aspects of the project, their practices, and emerging ideas from the phenomena. This is similar to axial coding in grounded theory (Glaser & Strauss 1967). But these relationships were not understood as indicating causality. In this process, some codes were merged, some became more general or more specific. Not all code families were included in our analysis, as some were considered interesting phenomena but not directly related to the key concepts. This was an iterative process until the key conceptual constructs were sufficiently refined. It should be noted that we also verify the findings from the interviews with a survey, which largely confirm all the themes that we derive from coding the interviews. In the end the analysis reported here is the result of the iterative reflections and ongoing discussions within the research team and with GridPP members, rather than a narrow machine-derived account. All the quotes given here are taken from interview transcripts, and our ideas have also been reinforced by informal conversations and participant observations.

5 SOCIAL CAPITAL & SYSTEM DEVELOPMENT IN GRIDPP

In this section we examine how collective knowledge is cultivated and mobilized in GridPP. The dimensions of social capital (Inkpen & Tsang 2005; Nahapiet et al. 1998) are drawn upon to explore various practices employed by members of GridPP in the distributed and collaborative project.

5.1 Structural dimension

5.1.1 A network structure and decentralized management

Figure 1 shows GridPP’s management structure which may be better described as a network than a hierarchy. The Project Management Board (PMB) is the heart of the network centrally coordinating the project. It provides quarterly reports to the Collaboration Board, consisting of representatives from the 19 institutes. The participating institutes enter the collaboration not under any legal obligation, but bound by a Memorandum of Understanding, which specifies the amount of resources and the level of
service that each site is committed to provide, and the funding and support they will receive from GridPP in return. This document serves more as a “gentlemen’s agreement” and thus there is no authoritative hierarchy between GridPP and the institutes, thus there are not top-down command lines between them. Decisions have to be made on a democratic basis and implemented by influence and persuasion.

The PMB, apart from the project leader, deputy project leader, and the project manager, consists of representatives from a number of internal and external committees, boards and functions. In a sense, the figure also indicates the external and internal environment in which GridPP operates. Due to role differences, some members of the PMB are more closely connected to the main GridPP activities than others. An important thing to note is that each of them serves as a node on this network, while connecting the GridPP to a variety of nodes on other networks that they represent here.

Associated with this networked structure of the project, members of GridPP are generally given huge reign of freedom to carry out their work, usually without clear instructions or strict supervision. When we asked them how they know what they need to do in their day-to-day job, most of them replied that they would look around and find out what needs to be done, as well as responding to arising problems and crises. “This environment is based on, if you want, charismatic leadership and people doing things relatively independent but also having the freedom to do them, and not having to report every two minutes on what they are doing.”

Due to the complexity and prototypical nature of the Grid, knowledge has often to be acquired in processes of exploration and experimentation. Moreover, as the technology is being developed and changing rapidly and constantly, it is difficult to keep documentation up to date. We did not observe a lot of effort in codifying and documenting of the Grid project in a structured way. As a result, most knowledge is embodied within the individual experts (Blackler 1995). Since most people in technical roles are on a contract of two to three years, there is a risk of losing expertise due to turnover. Nevertheless, the extensive communication channels within the community foster the social construction and reconstruction of knowledge through socialisation (Berger & Luckmann 1966). This focus on communication will be explored in the next subsection.

5.1.2 Extensive communication channels

Members of GridPP maintain a general understanding of the project, especially aspects related to their specific roles, through continuous and extensive communication flows in the community. Particle
physics collaborations are managed by what Knorr-Cetina (1999) refers to as “a fine grid of discourse”, channelling individual knowledge into the collaboration and providing it with a sort of “distributed cognition”. This web of communication includes a complex network of boards, committees, and working groups which are regularly holding meetings. One of the most important methods is the online virtual meeting. During these meetings wikis, webpages and blogs are used as stores of previous communication. There are also various mailing lists where there is constant exchange of questions and answers and where solutions emerge. Members of GridPP subscribe to mailing lists relevant to their own job functionalities to keep up with what’s going in the project.

More importantly, understanding and know-how of various aspects of the project are embodied in the key members of the project and carried to different clusters or groups of agents by these people sitting in various boards and a large number of meetings. Besides this formal management structure, most members of the GridPP agree that very often the more important things happen informally under face-to-face circumstances, e.g. over coffee breaks and meals, or (being a British community) “in the pub”.

Such extensive communications embody mutual monitoring and proactive sense-making. This resonates with communities of practice in which knowledge is shared through their collective communication and shared sense of identity (Brown & Duguid 1991; Wenger 1998; 2000). The structure of the project, reflective of the experimental nature of the field, provides a context in which knowledge is socially constructed (and so shared) through socialisation (Berger et al. 1966). The focus of work is thus upon exploration and sensemaking, rather than upon the following (or construction) of formalized, codified “designs” or “plans”.

5.2  Cognitive dimension

5.2.1  Shared goal

While GridPP does include some people from other fields, the majority (and all senior members) are from this “elite science” (Traweek, 1988) which is highly competitive to enter. One consequence is that members of the collaboration are strongly characterized by a shared common goal which is not to build a grid; but to enable the discovery of new physics and to probe the origins of the universe. This concept of a “shared goal” is frequently mentioned, and can be seen to bind efforts, solicit devotion, and bridge differences. A PMB member attributes GridPP’s organisation to “their history and the desire to sort of jointly achieve things”. For example, despite severe competition between experiments, they will willingly work together on grid development because it is required to do new physics: “I said I was proud of being a particle physicist, this is ‘cause particle physicists always get the job done; by and large because they are driven by one fundamental thing. They want their experiment to work when the beam gets into the accelerator, okay? And that transcends everything else they do.”

The common goal of serving Physics is an important source of motivation and commitment. As a recent physics PhD graduate pointed out: “They don’t work for money of course because particle physics doesn’t have a lot of money. They work because of their passion to do science. So they, we, strive to deliver the best result, to collaborate in the best way because we serve the same ideas and the same, the same passion.” Moreover, the shared vision provides a strong sense of direction, urgency and progress.

5.2.2  Shared culture

A shared culture in GridPP emerges from the physics background of most participants. The Grid project arose from the need for a tool to analyze data from the LHC; from the organizational memories of previous successful and innovative experiments; and from a history of cutting-edge computing. Moreover, it also emerges from a tradition and culture of strong commitment with a long term vision, pragmatic problem-solving and developing tools through improvisation and bricolage, as well as
respect for individual creativity and technical expertise. As one interviewee pointed out, “The particle physics community and the goals and the culture has had an enormous influence on GridPP... So it’s not that particle physics is telling us what to do, it’s just that we know it. It’s the culture.”

With decades of experience running experiments, it is not surprising that GridPP is set up in the structure of a particle physics experiment and largely managed in the same way. The established traditions and accumulated experience means working in large scale globally distributed collaborations is almost “second nature”. A member of the PMB commented “I think historically particle physics has this background in teamwork and this way of working you know, a very strong background in that. […] When I started off in experiments, there were about 20 people in an experiment, and now there’s 500 in the current experiment, ATLAS probably 2,000. So that […] we’ve all worked through this, of adapting to that sort of way of working, which is the sort of thing of course the Grid introduces, international projects, um, large scale resources, worldwide. So it’s sort of second nature I think…”

5.2.3 Norms

In face of the high level of complexity and uncertainty that GridPP faces, compound with limited time and resources, the way they do computing has to be very pragmatic and often on the basis of trial-and-error. In a project with such as a multitude of hardware and software elements, no one person can have a clear idea of the whole system; requirements cannot be pre-specified in detail; architectures are often conditional conjectures, and technical decision-making is emergent and empirical. As a result, GridPP has to be constantly adapting to changes, and practices in GridPP have been described as “ad hoc”. The PMB focused on accommodating change as their minimal planning process. “So we set up this project map and …the formality of change forms. So this was to formalise our freedom to change the project … yes, we had a set of milestones but you know, we had a mechanism to change them because we have to be responsive.”

Pragmatism is one the norms dominant in the particle physics community. Which is not only reflected in computing, but has roots in physics experiments as well: “not just in GridPP but in building hardware and building detectors - all sorts of setbacks occur and you have to find solutions. Certain technology doesn’t work, the company cannot provide what you want. So I think there’s this background in problem solving and project management and the sort of pragmatic approach”. This caused friction with the computer scientists working in the project, most of whom aspire to a more methodological approach. A technical expert commented, “…the people who come from a physics background are ultimately more pragmatic in computing. […]If it requires you to wrap sellotape around it to get it to work, then they will wrap sellotape around it. The people who come from a computing background tend to […] have slightly purer model of how the computing should work...whereas the physicists are happier with an ad hoc solution just to get the job done and push them through.”

5.3 Relational dimension

5.3.1 Sense of belonging

With members of the collaboration based in disparate institutes, it is important to develop an emotional bond among individuals for the project to function collectively. “We have to work very well together as a team, in order for GridPP to be successful. And because as you will appreciate it’s quite a complicated structure, there are multiple channels of communication, some of which are duplicated, some of which are contradictory, and there are all sorts of ways in which information flows. And anything that you can do to oil the cogs of the machine is going to help. And one of the things that are going on very well in GridPP is the cohesiveness of the deployment team. And I think for us to socialize together is a very important thing”. “Going to the pub” together when they meet, for
example, is one aspect of it. “It fosters a bond between people and helps... it helps a lot I think because many aspects of working in this project are frustrating because it's so large. And so if you can go out together and you can identify the problems and let out steam about them, I think that's actually a very important social function of these meetings.”

These emotional communications help to alleviate the anxiety they have to face, including the pressure of the LHC switch-on and that of showing the UK in a good light among the worldwide particle physics communities. The collaboration is committed, engaged, and is always “just about” on top of things. They seem to be constantly fire-fighting, discovering problems, managing crises, and negotiating solutions. Yet there is a high level of confidence despite the sense of urgency and disorder on the surface. Almost everybody in the collaboration that we interviewed holds a firm belief that the Grid will work; it may not work perfectly, but it will work.

5.3.2 Trust

Deriving from the shared tradition and shared goal is a high level of trust among people and institutions. One senior member of GridPP calls it “a culture of trust and equality”. The notion of trust also came out very clearly in our interviews: “it's very important for the physicists because there's so many things that they have to do in order to be able to interpret something that's been true in the data, that they have to trust what other people have done. And this is even more so when you have such big detectors as the LHC ones.”

In GridPP, trust not only lies with people’s intelligence and ability to deliver work, but more importantly, with people’s commitment to their job and with readiness to make extra effort to ensure things get done. “There will be problems coming out in all areas and you'll have to trust that people will step up to the plate and you know, do the dirty work as well as doing all the glamorous work you know, and things like that.” Trust seems to be what characterizes high energy physics as a community. “So actually the trust between the different high energy physics computing centres is much larger than what, in most of our member countries, are the legal constraints.”

6 DISCUSSION AND CONCLUSION

How does the mobilization of social capital contribute to the social construction of knowledge (Blackler & Mcdonald 2000; Berger et al 1966) within GridPP? Table 2 illustrates the implications of social capital in facilitating innovation and knowledge socialisation. A flat structure of organizing combined with minimal direct management provides a positive environment for creativity, exploration, and experimentation such that individuals can socialise knowledge. This structure similarly allows peripheral participation by non-experts so they may learn and enter the community (Wenger 1998; Lave & Wenger 1991). However, to be productive, there needs to be guidance of a clearly articulated common goal; in this case to advance the science of physics. Such a shared vision can be viewed as a bonding mechanism that helps different parts of a network integrate knowledge (Tsai & Ghoshal 1998), and provides an important sense of identity for the group (Lave et al. 1991).

Although there are extensive communication channels in GridPP, limited effort has been put on structured codification of knowing as information (Nonaka & Takeuchi 1995; Nonaka 1994). While mailing lists, wikis and blogs provide potential for knowing, they are used in a highly unstructured manner and are not seen as an important collective resource of knowledge. What compensates the lack of a codification approach to knowledge (Hansen, Nohria & Tierney, 1999) is the emphasis on socialization and personalisation within GridPP (Hansen et al. 1999). Most of the members travel frequently to attend meetings, conferences and workshops, and make deliberate efforts to talk to people face-to-face. The construction of social connections within the project provides personal directory (Wegner 1987) to knowing - i.e. “who knows what”. This process of socialization must however be sustained through the relational dimension of social capital, as illustrated by the ongoing
maintenance of trust and a sense of belonging. As the development stage of the grid draws to an end, and emphasis is shifted to maintenance and improving reliability of the Grid, such mobilization of social capital through formal and informal forms of interpersonal communication is gradually being balanced, but never replaced, with a systematic and impersonal arrangement of communication and technical support.

To conclude, the paper has drawn upon the concept of social capital to examine challenges faced in distributed systems development. The analysis on the empirical study of a complex project of system development allows us to reflect and explore dimensions of motivating, organizing, and coordinating distributed members of a systems development project and their implications for processes of collective knowing. Our findings are aligned with existing perception of social capital in the literature. Social capital has been found to enhance division of labour by reducing costs of coordination, induce and speed up sharing of tacit knowledge, and encourage co-operations, which in turn fosters firms’ innovative capability, competitiveness and ultimately economic performance (Maskell, 2000). In an era where distributed projects have become increasingly prevalent, our case generates implications for the importance of mobilizing social capital in distributed systems development processes, especially in terms of providing shared goals and culture, supporting individual creativity and building trusts in the community.

Abstract

This paper examines the views of travel consumers that search for information online in relation to the specific benefits and concerns identified with user-generated content (UGC). Real contrasts in relation to views about UGC content were identified in the literature. For instance, UGC is perceived as being ‘credible’ or ‘not credible’ as an information source depending upon the view of the user. The paper reports research that examined the use of UGC by online travel consumers, sourced from an Australian tourism organisation’s online subscriber database. The study highlighted a similar range of areas that were seen as benefits and concerns in the use of UGC to support travel decisions as identified in the literature – and also similar contrasts. The most notable of these is the level of trustworthiness and reliability that is associated with the postings – they can be trusted because they are ‘real’ experiences by ‘real’ people who are independent – but can also be not trustworthy because the content that is posted may be faked by someone with a vested interest. Similar paradoxes existed elsewhere. One of the theoretical contributions of the paper is the derivation of a matrix for classifying recommendations associated with online UGC.

USER-GENERATED CONTENT (UGC) IN TOURISM: BENEFITS AND CONCERNS OF ONLINE CONSUMERS

1 INTRODUCTION

Consumers are increasingly using different strategies to find information on the Internet about products or services they are intending to purchase. Senecal and Nantel (2004) discuss literature that relates consumers’ choices in relation to such information sources to the type of product or service being sought, noting that goods can possess either search or experience qualities. Information about goods with search qualities can be determined prior to purchase – that is, much can found out about the product or service beforehand. Information about goods with experience qualities cannot easily be determined before purchase, and it is for these types of goods that consumers will often rely heavily on product recommendations from others. Travel products and services fall directly into the category of being experience goods (Bei, Chen and Widdows, 2004). Senecal and Nantel (2004) suggest that consumers who had previously consulted a product recommendation were more likely to purchase that product than those who did not. However, in the absence of recommendations, consumers looking to purchase conducted even more searches for information (Smith, Menon & Sivakumar, 2005). Consumers were more influenced by recommendations associated with an experience product (for example, wine) than for a search product (e.g. calculator) – hence, it would be expected that this also applied to the tourism area. One of the more recent sources of online information for consumers is user-generated content (UGC), where travellers are able to examine text, images, and videos that have been posted online by fellow consumers.

The specific aim of this paper was to capture the perceptions and views of travel consumers that search for information online in relation to the specific benefits and concerns that they might have when dealing with different types of travel recommendations – more particular UGC. Hence, the paper makes a contribution to the existing literature by reporting the perceptions of online travellers and how they view websites that publish information originating with other users. A further contribution of the paper is the derivation of a matrix for classifying recommendations associated with online UGC.

2 FINDING TRAVEL INFORMATION ONLINE

High credibility is often placed on word-of-mouth (WOM) information as it is believed that the person providing the WOM information has nothing to lose and is therefore more likely to offer honest advice (Chatterjee, 2001). Furthermore, well-reasoned, logical and persuasive reviews can positively influence the likelihood of purchase by people who read them (Park, Lee & Han, 2007). However, when negative word-of-mouth is provided with the specific goal to vent frustration or anger, its influence on the receiver tends to be reduced, as the information is not perceived to be constructive or useful (Wetzer, Zeelenberg & Pieters, 2007). In a travel sense, consumers often spread WOM due to extreme feelings associated with a product ‘experience’, such as pleasure or sadness. In some instances, sharing the pleasure of the travel experience is seen as being part of the positive experience (Litvin, Goldsmith & Pan, 2008). Amongst the vast array of information sources consumers can turn to when planning travel, word-of-mouth is one of the most influential. Prospective travellers often rely heavily on advice from friends, family and other peer groups, particularly when planning travel to a destination not previously visited (Litvin et al., 2008). Research indicates that, due to the lack of commercial self-interest associated with WOM recommendations consumers tend to trust and be more influenced by this type of information than by more commercial sources such as travel agents or accommodation operators. This is because the provider of the information is not generally aiming to make a financial gain from sharing their experiences and views with others (Litvin et al., 2008). One of the aims of this article is to examine whether these circumstances translate to the online environment.
2.1 Recommendations in the Online Environment

In the online world, recommendations sources can come from other consumers, human experts or expert systems (that will recommend a particular product or service based upon a consumer’s profile – and are often known as recommender systems) (Senecal and Nantel, 2004). Consumers can use the Internet to mimic sources of information that they would have traditionally received from ‘real world’ sources. Some examples include (Peterson and Merino 2003; Litvin et al.,2008):

- Visiting websites to access information, instead relying on the traditional mass media advertising and/or information normally acquired from a salesperson
- eWOM (electronic word-of-mouth) instead of traditional WOM
- Accessing online independent sources (such as government tourism bodies) instead of their offline counterparts.
- Email- allowing the receipt of subscribed newsletters or as a communication form that facilitates globally correspondence and information exchanges

These days, many websites allow consumers to add their own content in the form of general text comments (weblogs or ‘blogs’), travel reviews, pictures and/or video. This content is known as User Generated Content (UGC). UGC sites can equate to electronic WOM marketing, whereby somebody who has an opinion about a product or service shares their views, beliefs and experiences with other people (Ahuja, Michels, Walker & Weissbuch, 2007). Fernando (2007) suggests that UGC is the opposite to traditional forms of media and marketing since content is generated by the consumer rather than by the marketer. Tools such as blogs and social networking sites (such as Facebook) have meant that consumers are better informed than ever before – not only being able to add their own comments, but also being able to find other information and articles and ‘tag’ them with their own keywords for search purposes (Buhler, 2006). Social networking sites typically operate by inviting people to join and contribute to a network. As this process snowballs the networks can grow. These communities rely upon UGC for their ongoing operation (Trusov, Bucklin and Pauwels, 2008). Dwyer (2007) suggests that websites containing these new media (such as message boards, chat rooms and now blogs) provide two types of networks – social networks and informational networks. In this article the authors adopt the more general view of UGC, that it can provide a means of social interaction for users but it is also an important source of information.

In the online context, eWOM occurs when consumers create their own information on the Internet to share their experiences and views about products they have purchased (Park et al.,2007). There is typically far more information available to the consumer in the online environment from eWOM than from traditional WOM (Chatterjee, 2001). Park et al.(2007) found that the purchasing intentions of consumers increased in line with the number of reviews that indicated that the product or service was popular.

The provision of forums that capture consumer comments potentially allow a business to receive genuine feedback on their products or services. It also provides them with another avenue in which to provide their own feedback and/or reassurance to those customers. However, there are also a number of forums that are not sponsored by businesses – such as general social networking websites like Facebook. These forums do not always attract comments from ‘typical’ consumers – in fact, as with traditional WOM, it is more likely that consumers who have had extreme (very favourable or very unfavourable) experiences are more likely to provide online comments or reviews. However, these sites could be regarded as being more neutral than those sites sponsored by businesses (Litvin et al.,2008).

In the tourism context, the Internet is an important source of information for travellers. For instance, a majority of US travellers use the medium to search for travel information (Litvin et al.,2008). As with other forms of online information, UGC related to travel can be posted on specific travel-related websites or on more generic social networking websites. This content reflects the experiences of the tourist at specific destinations (Pan, MacLaurin and Crotts 2007) or with other travel products.
2.2 Trustworthiness of user-generated content

There is no universally accepted definition of ‘trust’. Chen (2006) discusses two schools of trust. The first school regards trust as a belief or expectation about another party’s trustworthiness. The other school regards trust as a behaviour that reflects a reliance on others and some uncertainty (and vulnerability) from the person who is ‘doing the trusting’. The difference is in how trust is actually measured in a research context. Chen (2006) adopts the latter view of trust and identifies three dimensions of trust: the level of competence, the level of benevolence and the level of integrity. However, this view generally relates to the relationship between the consumer and provider – so in this instance, where we are examining the trustworthiness of UGC – it is more appropriate to adopt the first school, where we consider the trustworthiness of the party providing the UGC comment.

Criticism regarding the power of UGC to persuade travelers about travel related decisions is based on the potential for ‘fake’ content to be posted by travel operators posing as independent reviewers. This effectively defeats the purpose of enabling UGC to influence travelers in their decision making process as the content added is no longer independent, objective or credible (Bray & Schetzina, 2006). One of the concerns raised about the use of UGC sites when planning travel is how the consumer can be assured that the reviews they are viewing are in fact independent and hence trustworthy (Gretzel, 2006). One of the major concerns here is that businesses might use employees to ‘act’ as consumers to post positive comments on behalf of the business or to post negative comments about the competition (Litvin et al., 2008). Senecal and Nantel (2004) note that many consumers are sceptical about any form of communication that is perceived to be skewed towards the interests of the source of the information. Park et al. (2007) suggest that online consumer reviews are often considered more trustworthy and credible than information provided by suppliers of products and services, assumedly because consumers are considered to provide more honest information. Websites that are independent, third-party type sites tend to be considered more preferable by consumers when compared to those that are clearly operated by a business with a vested interest (Senecal & Nantel, 2004). Thus, the forum in which recommendations are presented is quite important. A possible downside of UGC, is that while traditional forms of WOM tends to come from people who are known to the consumer (i.e. friends, colleagues etc), online reviews are typically passed on by total strangers, resulting in some concern over the credibility of the source of review (Park et al., 2007, Litvin et al., 2008).

Table 1 provides a summary of the potential benefits and concerns of consumers in relation to online recommendations as identified in the literature. These are divided into three major categories; those that relate to the content of the recommendation, the source of the recommendations, and the nature in which recommendations might be encountered in the online environment. Obviously, these categories are linked (for instance, where commercial sources are seen to post fake content to bias the behaviour of potential travellers). The Content category relates to extreme or emotional postings versus well-argued postings and the possibility of fake content. The Source category relates to the notion that eWOM provides more recommendation sources and the credibility levels of independent and consumer recommendations versus those of businesses with vested interests and comments posted on social networking sites. The nature of recommendations refers to their influence due to the nature of tourism as a product and the ability of tourists to filter the wealth of information available online. The categories are groupings which have emerged from the literature and should be viewed as a starting point for this type of classification.

What we find most interesting here is that there seem to be real contrasts in relation to views about UGC content. For instance, it can be viewed as being ‘credible’ or ‘not credible’ as a source and there are both benefits and concerns about the content that is posted. This reflects the different opinions that users, and even contributors, have depending upon their different views and experiences. In a study of the content of travel blogs, Pan et al. (2007) divided a number of blog comments into ‘positive’ and ‘negative’ statements and found that there were both types of sentences across most of the categories (the ones with the most comments being attractions, amenities, history, food and beverages and natural
environment). In most cases the number of positive comments outweighed the number of negative comments (overall there were around three positive comments for every negative comment).

Table 1: Benefits and Concerns of Online Travel Recommendations

3 THE STUDY

In this study we are predominantly interested in the views of consumers that use the Internet to assist with travel plans in relation to their opinions about UGC. However, linked with this is the idea that they need to place their use of UGC in context with other travel information and services that are available to them online. Thus, our more general research question relates to whether the benefits and concerns of online travel recommendations (as identified in Table 1), translate specifically to the use of UGC for travel purposes. In particular we will be looking to see if the benefits (in relation to well-reasoned reviews, plentiful sources of information and credibility) and concerns (such as extreme opinions, fake content, unknown sources and low credibility) actually do exist.

To explore consumers’ views on UGC in relation to travel planning, a quantitative study was conducted using an online survey of consumers who were known to use the Internet to gather information when planning their travel. The survey was developed based on a review of existing studies, as outlined in the previous section. It contained four key sections, the first of which gauged participants’ previous exposure to sites containing UGC related to travel. Section 2 assessed the influence of UGC sites on participants’ actual travel planning and trip behaviour. This section included two open ended questions that asked respondents to express what they liked about UGC postings regarding travel as well as any concerns they had about this type of information. Section 3 gauged the types of UGC considered most useful along with opinions about how UGC should be used.
by hospitality and tourism providers in conjunction with their existing online marketing strategies. The final section asked for the demographic characteristics of participants.

Following a pilot test of the instrument with a sample of real travelers, the final survey was conducted online in December 2007. A web-link to the survey was included in an invitation, sent via email, to participate in the research promoted through Tourism New South Wales’s database of email subscribers known as E-Scapes. At the time of dispatching the email invitation to promote the survey, there were approximately 110,000 subscribers listed on the database. An incentive prize was included with the email received by subscribers to encourage responses. Recipients of the email who chose to participate in the survey, on a voluntary and anonymous basis, simply clicked on the web-link provided and responded to the survey questions online.

Data was collected over a two-week period and the survey took approximately 10 minutes to complete. All data received was contained within a downloadable spreadsheet from the survey software that was then converted into SPSS (Statistical Package for the Social Sciences) for further analysis.

By the survey closing date, 13,281 people had participated in the study. This represents a response rate of approximately 12 percent. It should be noted that not all respondents answered every question in the survey, as they were given the option not to answer questions if they so chose. Furthermore, some questions were not asked of all respondents (e.g., names of UGC sites they had used) where their previous responses to questions indicated a question was irrelevant. A typical example of this is where respondents were asked a series of questions related to their opinions of UGC. These questions were only shown to respondents that had indicated they had used UGC websites. These factors should be taken into account when noting the total number of responses reported in the various tables in this section. Approximately 700 responses were not considered useful due to a lack of data, so in effect the usable number of responses was 12,544. The survey contained many questions and 64% of those who commenced the survey actually completed it.

3.1 Respondent Profile

A demographic profile of survey participants is provided in Table 2. The questions related to age, gender, country of origin, place of origin and income level were asked towards the end of the survey. The number of respondents that completed these questions (around two thirds of usable responses) closely matches the overall completion rate of the survey as indicated in the previous section (64%).

The age profile of participants in this study reflects the overall profile of the E-Scapes database. Approximately 51 percent of people were aged 30-49 years. A further 23 percent were 50-59 years. In terms of gender, the skew towards a higher proportion of female participants (61%) is reflective of the overall profile of the database. The profile of responses to the survey appears, therefore, to be able to be generalized to the population of travelers included in the database.

3.2 Benefits of and Concerns with UGC

In order to ensure a consistent meaning for UGC, respondents were presented with the following description at the beginning of the survey:

_A growing number of web sites are incorporating features which enable the user, such as you, to contribute their own content enabling people to communicate about special interest topics or products or services through the Internet. Such content is commonly referred to as ‘user-generated content’._

Proceedings ECIS 2009
In relation to travel and tourism, some examples of user-generated content include:

- ordinary people like yourself sharing their opinions about travel destinations, attractions and accommodation properties through blogs (weblogs) or other discussion forums
- travellers submitting photos or videos to the internet to share their travel experiences with other online users (including family, friends or total strangers who may be interested)
- consumers posting reviews of accommodation properties to sites such as tripadvisor.com
- people using social networking sites such as myspace.com, facebook.com or youtube.com to share travel information.

Respondents were asked if they had visited any Internet sites that had contained UGC (5,724 indicated that they had). To understand the issues that were of potential concern to travellers, the survey asked these respondents two open-ended questions:

- ‘What do you like about sites that contain user-generated content related to travel?’
- ‘In relation to making travel plans, is there anything about UGC that concerns you?’

Thus, these questions related to the opinions of users about websites with UGC content and did not involve any analysis of UGC content itself, such as those carried out by Dwyer (2007) and Pan et al (2007). A total of 2,546 respondents (44% of those that had visited websites with UGC) listed ‘likes’ about UGC content and 1,238 (22%) respondents indicated they held some concerns about UGC. This may relate to Pan et al’s (2007) study which found that positive comments within a blog outweighed the number of negative comments. The responses received to these questions were analysed in the qualitative software package XSight, which enables comments to be classified under key headings that reflect particular ‘likes’ and ‘concerns’ which arose.

Table 2: Profile of Survey Respondents
4 RESULTS

4.1 Benefits of UGC sites

Respondents to the survey were asked (in separate questions) to identify their ‘likes’ and ‘concerns’ in relation to UGC websites. The answers to these questions provided the authors with an opportunity to match these responses with the benefits and concerns of online travel recommendations as listed in the literature (and summarised in Table 1). As mentioned earlier, the ‘likes’ and ‘concerns’ were classified according to various headings and subheadings. Table 3 shows the ‘likes’ classified into their main heading groups.

Table 3: Classification of ‘Likes’ in relation to UGC websites

Many of the comments that were made fitted across a number of categories list in Table 3. Where this occurred the comment was classified according to its primary emphasis, or the first occurrence of the classification in the comment. The main classification of comments occurred as follows:

- **Trust in the Source**: a number of different types of comments were classified under this heading. Typically, comments that highlighted the ‘credibility’, ‘accuracy’ or ‘authenticity’ of UGC content and the ‘balanced’ nature of UGC fitted into this category. In addition, comments that related to the type of person making UGC comments fitted here, such as UGC was generated by ‘real people’, ‘independent people’ or ‘everyday people’. Finally, there were comments that related to the authenticity of the experience of the people posting comments – they had ‘been there, done that’, they were ‘genuine experiences’ and so forth. Comments in this section were also highlighted by words such as ‘honest’, ‘candid’, ‘frank’, ‘truthful’, ‘unbiased’, ‘unsolicited’ and so forth.

- **Traveller opinions**: these were typified by comments that related to the ‘range’ or ‘variety’ of opinions available in UGC and how they could be ‘compared’. One interesting aspect of this category is that a number of respondents (59) actually suggested that the fact that there were both ‘positive and negative’ comments was a good thing as it allowed for comparisons of experiences.

- **Relevance to user**: comments were classified into this category when respondents indicated that UGC assisted in helping with their ‘own travel plans’, was ‘personalised’ to their interests or was posted by ‘like minded people’. Comments in this latter category were posted by a number of elderly respondents and also those that were looking for travel experiences suitable for families.
• Recommendations: these comments involved respondents identifying that UGC content provided specific recommendations for potentially new (sometimes ‘off beat’) experiences, or offered tips, hints or advice on what to do or expect in different situations.

• Amount of information: comments in this category referred to the quantity of information available in UGC. These comments were highlighted by words such as ‘comprehensive’, ‘lots’, ‘more’, ‘detailed’ and reference to the ‘large number of opinions’.

• General comments: no specific comments about UGC were made in this category. These were just comments by respondents that referred to UGC as being generally ‘interesting’, ‘useful’, ‘helpful’, ‘informative’ or just providing ‘information’.

• Ease and speed of Use: these comments referred to UGC websites as being ‘user friendly’, ‘easy to use’, ‘accessible’, ‘saving time’ or ‘convenient’.

• Specific comments: most of these comments related directly to the use of UGC for booking accommodation or the fact that traveller pictures are posted on UGC websites.

• Don’t like/ unsure: Interestingly, 68 respondents chose to use the ‘likes’ of UGC content to say that they did not like UGC websites or that they were unsure what UGC actually is.

• Currency: these comments related to UGC content being ‘current’ or ‘up to date’.

• Share experiences: a small number of respondents suggested that they liked UGC because they could share their experiences with each other.

• Other: these comments did not fit any of the above categories.

Table 4 shows a comparison between the benefits of online travel recommendations that were identified in Table 1 and the results of the UGC study. Overall, most of the benefits that were mentioned in the literature were well-represented in the study, the most evident being comments related to credibility. The only ‘benefit’ that did not stand out in the study was that there were not a lot of comments by respondents that suggested they were persuaded by well-reasoned or logical reviews.

4.2 Concerns about UGC sites

To understand the issues that were of potential concern to travellers, the survey asked respondents an open-ended question - ‘in relation to making travel plans, is there anything about user-generated content that concerns you?’ A total of 1,238 respondents indicated that held some concerns about UGC. Refer to Table 5 for a summary of these responses. The responses received to this question were also analysed in a qualitative software analysis package (XSight). Table 5 lists the key concerns used to classify respondents’ comments about UGC.

</table>

Table 5: Classification of ‘Likes’ in relation to UGC websites

Under the heading of trustworthiness/ reliability the key concern identified by respondents is that UGC sites provide an opportunity for businesses to masquerade as independent travellers and post their own ‘fake’ entries. The second identified concern related to the extent to which comments made on UGC sites are trustworthy, accurate and credible for reasons other than the potential for business to tamper with UGC. Other respondents noted that it can be difficult to base one’s own travel decisions on the types of comments made on UGC sites as other travellers may well have different preferences to their own. Linked to the issue of the identity of travellers, a number of people also noted that it was hard to make a judgement about the value of UGC comments when the profile of the person submitting the information is generally unknown. These comments were classified under the heading of ‘Lack of relevance to the user’. Further concerns identified related to the tendency for people to contribute commentary to UGC only when they had very positive or very negative things to say (i.e. UGC can tend to be biased rather than represent the ‘average’ travellers experience). Some respondents indicated that UGC sites can be used by ‘habitual complainers’ to vent their negative views without providing a realistic assessment of the overall travel experience. These comments were classified as ‘extreme opinions’.

Table 6 shows a comparison between the concerns of online travel recommendations that were identified in the literature (refer Table 1) and the results of the UGC study. As with the ‘benefits’, a large proportion of the comments related to the trustworthiness or reliability of UGC – in this instance it was being viewed as a concern. Within that category, there were numerous comments related to all of the areas that were identified in the literature – concerns about fake content (28% of all respondents), the source not being known to respondents (4%) and comments related to concerns about the credibility of content (14%). There were also concerns about the usefulness of comments that were classified as ‘extreme opinions’ – the main problem identified with these was that they were too biased or that the websites were just being used as a ‘complaints forum’. There was one issue of concern that emerged from the study that was not evident in the previous literature – the practice of comments being posted that were not relevant to the user. In these instances there were concerns that the content was being posted by travellers with different personal preferences, that they were only subjective or personal opinions anyway, or were just out of date. This contrasts the ‘benefit’ identified (refer Table 4) which suggested that UGC helped tourists manage the wealth of data as it was relevant to their needs.

4.3 Summary

The literature highlighted a series of ‘paradoxes’ in relation to the benefits and concerns associated with online travel recommendations. This study was able to match and in some instances further enhance the findings from the previous literature. The paradox appears to be that for just about every benefit (‘like’) that is identified by survey respondents there is a matching ‘concern’ that is also identified. In fact, the study revealed that a number of respondents mentioned ‘extreme opinions’ as being a ‘like’ of UGC, whilst it was mentioned by others as being a concern. Of course, many respondents mentioned the credibility of UGC as being a benefit, whilst it was also mentioned as being a concern. Respondents also referred to UGC content being ‘relevant’ as a benefit, whilst others suggested that a concern was that it was not relevant to them.

The reader is referred to Table 7. Of the 1238 respondents that had listed a concern about UGC, 1179 (95%) also listed a ‘like’ about UGC. In fact, of the 1179 respondents that listed both a ‘like’ for and a ‘concern’ about UGC content:

- 274 suggested a ‘like’ related being able to ‘trust the source’ as well as a concern about the ‘trustworthiness/reliability’ of the source in the same response! In both instances (‘likes’ and ‘concerns’), the proportion of respondents that fitted into this category was higher then the proportion of general respondents that identified trust as only a like or concern. Whilst this seems quite strange, the range of comments that were made in this category for both ‘likes’ and ‘concerns’ makes it quite feasible. For instance, here are some examples of responses:
  - Like: real photographs; real experiences; Concern: fake content
  - Like: frankness of comments; Concern: commercial interest posting comments
  - Like: honesty of comments of travellers; Concern: comments might be ‘made up’ by businesses

- 28 respondents suggested that they ‘liked’ traveller opinions on UGC, but had concerns about the validity of extreme opinions.

- 16 respondents that suggested in the UGC benefits that the information in UGC was relevant for them also suggested in the concerns that it could also not be relevant!
Table 7: 'Likes' of and 'Concerns' about UGC content by respondents that expressed both

5 CONCLUSION

This study suggests that there are still many questions to be answered about the role of UGC. The literature highlighted a number of areas that were seen as strengths and concerns in the use of UGC to support the travel purchase decisions of consumers. The results of the study suggest that the most notable of these is the level of trustworthiness and reliability that can be associated with the postings – they can be trusted because they are real experiences by real people who are independent – but can also be seen as untrustworthy because the content that is posted may be faked by someone with a vested interest. Similar paradoxes exist in relation to the range of traveler opinions available (a benefit) versus the extremity of opinions that can be posted (a concern) and whether or not the content can be specifically applied to a traveller’s own situation (where those that thought it could be applied saw it as a benefit and those that thought it could not be applied viewed it as a concern). For the most part, the results of the study tended to reiterate the benefits and concerns that were highlighted in the literature. It is envisaged that until there can be improvements made in determining the reliability of the source of UGC, less use of UGC for postings involving extreme opinions and the provision of improved filtering capabilities for travelers to identify information that is relevant to their needs that these paradoxes will remain.

The authors wish to thank and acknowledge the Sustainable Tourism Cooperative Research Centre (STCRC) and Tourism New South Wales (TNSW) as the funding sponsors of this research.

DECISION MODELS AND THE USE OF WIRELESS TECHNOLOGY

Gregory Gimpel, Copenhagen Business School, Center for Applied ICT, Howitzvej 60, 2000 Frederiksberg, Denmark. gg.caict@cbs.dk.

Abstract

Many nations boast high broadband internet penetration. In many of markets, consumers can choose among competing technologies to connect to the internet. Much research in the IT diffusion domain has been useful for examining the adoption of individual technologies. This paper explores technology adoption in an environment in which different technologies fill a similar need by focusing on wireless internet access. This paper uses a series of focus group interviews to analyze the use of cognitive referencing in the form of reference prices, situational (status quo) framing, and mental accounting as potential determinants of technology adoption. The findings of this study suggest that adoption decisions are reference-dependent and that researchers should consider users’ referents when studying adoption in the wireless broadband market.

Keywords: Pricing, technology choice, diffusion theory, adoption, standards, wireless, broadband, qualitative research
DECISION MODELS AND THE USE OF WIRELESS TECHNOLOGY

1.0 Introduction

In Europe, the USA, and parts of Asia, internet penetration is high, with substantial consumer use of broadband technology. A plethora of companies offers internet access through a wide variety of different technologies. Wireless data technologies for laptop computers, such as 3G and WiMAX, are new market entrants that offer a fundamentally different delivery method than the more widely adopted fixed-line access points. This paper examines influences on the consumer decision process that affect the adoption of information and communication technology (ICT) through the study of wireless internet for the computer.

Researchers often employ traditional theories of technological adoption when investigating the adoption of ICT. While these methods have proven useful when studying individual technologies, exploring different models can also enhance the understanding of new technology usage. The current broadband market offers existing technologies that compete with new technologies, all of which access the same internet. The users in this study did not evaluate choices in isolation, but weighed alternatives against their current internet technology.

This paper explores the adoption of technology in a situation in which different technologies fill a similar consumer need. More specifically, it explores the determining factors for the adoption of one internet service technology over another; the choice of fixed-line versus wireless technology in particular. Denmark, the world leader in broadband penetration according to an Economist Intelligence Unit study (2007), serves as a market exemplar for Western nations, and was consequently chosen as the location for this study.

In a market offering a plethora of technological choice, why does such a large portion of the population use such a small number of technologies? What goes on in people’s minds during the process to decide which type of information technology to buy? Wireless broadband is a relatively new offering. This paper investigates diffusion models in an environment of competing options by asking the question: what is the best model for predicting and understanding consumer adoption of high-speed wireless internet?

This paper uses focus group research to fill apparent gaps, as pointed out by the calls for alternative perspectives on technology adoption (Benbasat & Barki 2007; McMaster & Wastell 2005; Venkatesh & Davis & Morris 2007) and by the call for the exploration of the consumer decision-making process beyond construct-based research (Blechar & Constantiou & Damsgaard 2006). Following the example of Eynon (2005), this paper utilizes focus group methodology to explore user attitudes about the adoption of internet ICT. The analysis builds upon bounded rationality, prospect theory, and mental accounting. It also expands on the more recent work of Blechar et al. (2006) who applied reference pricing to wireless ICT.

The contributions of this study are two-fold. First, it adds to user behavior research in wireless services by elaborating on the process by which end users make communication technology purchase decisions. Second, it illustrates the insights gained by applying cognitive decision making models to a situation of technological choice.

This article is structured as follows: the next section provides an overview of major broadband access technology. The following section offers an overview to reference pricing and the cognitive psychology theories on which referential decision making is built, as well as the role pricing plays in ICT diffusion. The proceeding segment details the research methodology used to conduct the focus groups and analyze the data. The subsequent section presents the findings. After the presentation of data, the results segment compares research outcomes to theoretical arguments, addresses the implications for service providers, and discusses the propositions and research instrument.

Proceedings ECIS 2009
2.0 BROADBAND OVERVIEW

Many technologies enable connection to the internet at high speeds. While they all provide internet access, the various technologies deliver the service in distinctly different ways and offer different performance traits. Fixed line technology requires a user to access the internet from a specific location. Portable broadband frees users to move their computers within a limited geographic area. Mobile internet enables free movement between access points without interruption.

Table 2.1 Summary of common technologies and their distinguishing features (Corning 2005)

This research makes the explicit distinction between using a Wi-Fi router to relay a fixed line connection for a few meters and using a subscription Wi-Fi hotspot service. This study considers a home Wi-Fi router as fixed-line technology because users must decide which access technology to connect to the router when making an ICT adoption decision. See Figure 2.1 for an illustration of the distinction made for Wi-Fi in this study.

3.0 THEORETICAL INSIGHTS AND PROPOSITIONS

This section begins with the call for different theoretical approaches to the study of technology adoption within Information Systems research. It provides an overview to the theoretical basis for the argument that reference prices influence the decision of whether or not to use a technology. Second, it provides an introduction to the behavioral economics literature that paves the path for the proposition that a status quo bias impacts the willingness of a person to accept a new technology. Third, it lays the theoretical grounding for user preference of simple, flat-rate payment plans that can affect the selection of one internet service over another.
Much of the recent IS adoption literature uses theories such as the Technology Acceptance Model (Davis 1989), Theory of Planned Behavior (Ajzen 1991), Unified Theory of Acceptance and Use of Technology (Venkatesh & Morris & Davis & Davis 2003) and other theories that focus on individual-level adoption. For example, researchers recently applied the Theory of Planned Behavior by expanding it to new types of IT systems (Dinev & Qing 2007) and to the acceptance of broadband among different groups (Hsieh & Rai & Keil 2008). Other studies use UTAUT to study computer applications in non-Western countries (Al-Gahtani & Hubona & Wang 2007) or to investigate the adoption of e-commerce in developing nations (Uzoka 2008).

Research continues to advance the Technology Acceptance Model, the most often employed and influential IS theory (Benbasat et al. 2007; Lee & Kozar & Larsen 2003; McMaster et al. 2005). Recent applications include wireless data networks (Yoon & Kim 2007) and mobile communications (Zhang & Mao 2008). Despite greatly advancing IS research by focusing a formerly scattered field of study (Lee et al. 2003), some argue “TAM has fulfilled its original purpose and that it is time researchers moved outside its confines” (Benbasat et al. 2007). While TAM is appropriate in an organizational context, it lacks other vital considerations necessary to explain user behavior (Lopez-Nicolas & Molina-Castillo & Bouwman 2008). Perceived usefulness and ease of use may not be sufficient criteria to study emerging services such as wireless because the impact on everyday routine may be more influential than the technology itself (Bouwman & Carlsson & Molina-Castillo & Walden 2007). TAM is binary, considering only the choice whether to adopt or not adopt one technology in isolation. It ignores context and contingency. Therefore, it does not adequately consider the complexity of the actors’ decision (Bouwman et al. 2007; McMaster et al. 2005).

This paper breaks from the study of technology in an isolated environment to address the gaps pointed out by Benbaset and Barki (2007), McMaster and Watsell (2005), and Venkatesh et al. (2007) in their calls for alternative theoretical perspectives that expand the study of technology diffusion to include contingent models. It also answers Blechar et al.’s (2006) call to explore adoption decisions beyond construct-based research.

Because people cannot gather or analyze every bit of information, they simplify and seek satisfactory, not necessarily ideal, solutions. Building on this concept of Bounded Rationality (Simon 1955), Prospect Theory, a behavioral economics approach to decision-making in the presence of choices and risks, argues that outcomes are contingent upon comparisons to a referent. People judge value by gains or losses relative to a reference point, not in terms of absolute monetary value (Kahneman & Tversky 1979). For example, people perceive a $5 price change on a $25 item as greater than a $5 change on a $500 item, even though the differences have the same financial value (Thaler 1980). Constructive preference, in which people determine their preferences when presented with a choice rather than drawing upon a priori preferences, suggests that the context and the framing of the choice affect the decision. A goal of the decision-making process is to maximize the ease of justifying a decision (Bettman & Luce & Payne 1998).

Constantiou, Damsgaard, and Knutsen (2007) argue that price is the most important attribute for basic and advanced users of advanced mobile features. Similarly, a study of Wireless Application Protocol details how users compared it against PC-based internet services (Hung 2003). Blechar et al. (2006) introduce reference pricing to the use of advanced mobile services by arguing that mobile phone users compare phone-based data services to computer-based internet services. The reference situation of the internet, perceived as nearly free of charge for similar services, made nearly any price for m-services to expensive in the consumer mind. Therefore, the redundancies between mobile services and PC-based internet could constrain mobile services adoption if users perceive the personal computer as higher in quality relative to mobile devices (Blechar et al. 2006). The importance of reference pricing in a situation of constructive preferences leads to the following proposition:

Proposition 1: the reference price of fixed-line internet creates a situation that biases the consumer against adopting wireless internet service for the laptop.
Because preference construction is contingent on the framing of the problem, the method of elicitation, and the context of the choice; contrast effects play a strong role in decision making by influencing the reference point that is used to gage value (Tversky & Simonson 1993). The perception of quality differences between a new option and the referent affect the likelihood of switching (Constantiou et al. 2006). Since losses loom larger than corresponding gains, loss aversion suggests that disadvantages are more salient than advantages (Tversky et al. 1993). In an identical situation, a different decision can be reached depending on whether the choice is framed to indicate a gain or a loss (Kahneman et al. 2003). Perception is reference-dependent and people notice and evaluate changes as percentages rather than the whole value, creating a phenomenon in which people assign a higher value to something that they view as theirs to be lost; while they assign a lower value to something they see as a gain. Take for example the person who is unwilling to pay more than $35 for a bottle of wine yet is unwilling to sell a bottle he already owns for $100. The loss aversion associated with this “endowment effect” contributes to status quo bias (Kahneman & Knetsch 1991). Loss aversion during the discernment process leads to the second proposition of this paper:

**Proposition 2:** status-quo bias adds a perceived switching cost that increases the difference between the referent and the alternative, diminishing the perceived gain from the adoption of a new broadband technology.

Consumers use “mental accounting” to frame purchasing decisions by assigning them to an expense category. They use these mental distinctions as a frame of reference to measure changes to reference prices. Decisions about which category, and whether to combine categories, impacts the perceived value of the choice. Loss aversion strongly influences how people organize financial transactions in their mind. Accordingly, “consumers don’t like the experience of ‘having the meter running.’ This contributes to what has been called the ‘flat rate bias’ in telecommunications. Most telephone customers elect a flat rate service even though paying by the call would cost them less” (Thaler 1999).

Research into the implications of the bundling wars that have begun with the telecom business explores the effect complementarity has on perceived value and how customers assess a bundle’s transaction value. Mental accounting plays a key role in assessing the transaction value and how context and perceived price affect the choice of mental “category” consumers use to budget a bundled offering (Sheng & Parker & Nakamoto 2007). The influence of mental accounting in purchase and usage decisions leads to the third proposition set in this paper:

**Proposition 3:** consumers prefer flat-rate plans over pay-per-use billing as a way to simplify mental accounting

**Figure 3.1  Theoretical model of decisions in the presence of choice and derivative research propositions**

4.0 METHODOLOGY

This section describes the research methodology used in this study. It begins by detailing the selection of the research instrument and details the study design, recruitment of participants, data collection methods, and data analysis technique.

4.1 Instrument Selection

This study explores how consumers make the decision whether or not to adopt wireless broadband for their laptops. It asks the research question: “what do people think about when deciding to buy
broadband internet?” The attitudinal-based nature of the research question and propositions makes the focus group interview the logical choice of research formats (Kitzinger 1995; Krueger & Casey 2000; Morgan 1997).

The processes of attitude formation and decision-making are inherently unobservable. When researching such topics, focus groups provide access to data that cannot be easily obtained by direct participant observation or open-ended interviews (Morgan 1997). Krueger and Casey emphasize the suitability of focus groups to “uncover factors that influence opinions, behavior, or motivation” (Krueger et al. 2000).

The group interview research technique can be a self-contained methodology that can generate principal data that can be the basis for a complete study (Morgan 1997). The data gained from a particular study provide theoretical insights which possess a sufficient degree of generality or universality to allow their projection to other contexts or situations which are comparable to that of the original study (Sim 1998).

4.2 Study Design

This study consists of multiple focus groups in order to be able to analyze data across groups to find patterns and themes (Krueger et al. 2000) and to reduce the effect of individual group dynamics on the overall dataset (Morgan 1997). The formation of three separate groups serves to achieve the data saturation recommended by Morgan (1997) and by Krueger and Casey (2000).

The number of participants represents a strategic balancing act between manageability and achieving significant idea diversity among group members (Morgan 1997). This study opted for small groups, with 6, 5, and 4 participants respectively. In order to compare and contrast data across groups, the interview questions were created prior to the focus groups (Krueger et al. 2000). The questions progressively narrow the topic of discussion specifically to gather data relevant to validating the propositions.

4.3 Participant Recruitment

Recruitment strategy and the study design encouraged openness of sharing and to facilitate interaction among participants. As recommended by Barbour, the goal was to achieve a balance between diversity and homogeneity (Barbour 2005). In order to ensure sufficient heterogeneity of ideas within each group, the selection criterion was “college-aged persons living or working in Denmark.” This basis is general enough to include a large population, yet create a sense of similarity among the group interviewees, as recommended by the literature (Kitzinger 1995; Krueger et al. 2000; Morgan 1997).

Within the mixed gender participant set, some were students, others were students with jobs, and some had completed their education and were in the Danish workforce. Thus the screening criteria also had the advantage of diversity, which according to Kitzinger (1995) maximizes the exploration of different perspectives within a group setting.

The study selected young adult participants for several reasons. The study aimed to reduce extraneous variables and prior studies show that age affects individual technology adoption (McFarland 2001; Morris & Venkatesh 2000; Yang & Jolly 2008). The selected group has lived their entire lives since the introduction of mainstream personal computing and related technologies (Prensky 2001). They make heavy use of ICT; particularly internet use, and they have therefore incorporated it into their daily lives. They consider technology to be part of the landscape (Oblinger 2003) and they consider computers as commonplace, not as technology (Frand 2000; McMahon & Pospisil 2005). Networked for most their lives (Prensky 2001), they are generally unaware of the pre-internet era (Rickard & Oblinger 2003). Equally important, they are consumers whose entrance as decision makers into the marketplace closely coincides with the wide-scale launch of wireless internet services.
4.4 Data Collection

The focus groups were convened during late April and early May 2008. After the meetings, field notes were typed recording salient points and researcher impressions of the discussions. The conversations were recorded in order to maintain accuracy during the analysis phase of the project. In keeping with the effort to make participants feel comfortable about sharing their opinions, the research plan followed the privacy guidelines recommended by Krueger and Casey (2000).

4.5 Analytical tools

The analysis used both the field notes and transcripts. The data were analyzed at the group level and on a comprehensive (study-wide) level. ATLAS.ti was used to code the data. At times many statements contained similar information; and other statements were short statements that required the context of the surrounding conversation to convey a point. The quotations included in the next section of this paper serve as demonstrative exemplars.

5.0 FINDINGS

This section details the information provided by the focus group participants. It begins with an overview and then elaborates by providing specific statements and quotations.

Based on past and present experiences, the focus group participants weigh many factors when evaluating broadband internet service. Service characteristics such as speed, security, stability, provider reputation, data transmission consistency, and convenience all play a role in the decision-making process. For all participants, price plays a pivotal role in deciding which broadband service to adopt. Rather than purely considering the monetary amount charged, they view price as the financial value derived from the amount paid for the service relative to the performance received. The overall pricing function includes the evaluation of different service characteristics such as performance metrics and provider reputation. Thus, they compare the price of one option to another, both in terms of the monetary amount and the price to performance ratio. While some consumers seek the ultimate price-performance ratio, there is a propensity for the monetary amount to supersede other attributes once the consumers’ minimum needs have been satisfied. Therefore, generally speaking, the performance portion of the function begins to weigh less heavily once a minimum threshold is satisfied.

All of the participants subscribe to fixed-line internet technology, and all use Wi-Fi access at least part of the time. The use of Wi-Fi to deliver the internet from a fixed line access point creates the reference perspective that internet access is portable. While such internet access cannot be accessed continuously over a large geographic area, it does enable access in a wide variety of locations. Some participants expressed an interest in mobile internet that they could use on moving trains, etc. Others saw little difference between mobile service and the portable service they currently experienced with a Wi-Fi link to a fixed line connection. Some subscribe to Wi-Fi hotspot services as either a paid subscriber or as part of an internet collective, but all participants primarily use Wi-Fi as router connected to the same fixed line access that the users can plug into if they choose. Therefore fixed line access serves as the reference point against which wireless alternatives are compared.

Although all participants used fixed-line for primary access, the cost basis varied widely. Some purchased internet as part of a service bundle along with VoIP or television service. Others had home internet service paid by an employer so that they experienced no out-of-pocket expense for the service. Others received internet from the building in which they lived. Often the internet was included as part of the rent, essentially creating a reference price of zero. A participant explains how this frames the decision process:

“And that might be a competition to wireless because people will have internet with their rent, as it is right now. So they don’t need that wireless or that extra internet. It’s not like
they say ‘either we’re going to have wired that we pay for or we’ve going to have wireless.’
It’s ‘we have a wired are we going to pay for wireless as well?’”

Others lived in buildings in which their choice of fixed-line provider was determined by the building, and therefore had only wireless technologies as alternatives. In a similar instance, a participant must choose between two fixed-line options available at his building. A participant whose rent payment includes internet service also belonged to the Webbies collective. Webbies members receive a wireless router that permits any member to connect to any other member. The participant states: “And this way, I also have almost internet everywhere with my cable. …It’s free and a lot of people have it.”

When asked about willingness to switch providers in order to adopt a new technology, some participants express a willingness to switch providers. Others express a status quo bias in which they are hesitant to change providers when such change was necessary to adopt a better internet technology. If participants associate inconvenience with switching, they would stay with their provider. Participants explain that this hesitation stems from a broad aversion to changing relationships with companies.

Others explain their hesitation to switch companies because of the time it takes to complete the switching process. One participant shares that uncertainty plays a part in creating his status-quo bias:

“It’s changing the paperwork and the bank details and whatever it is. But it’s also the fact that you know what you have. You know that it works or that it doesn’t work or that whatever else you don’t know about the other company.”

All of the participants’ primary internet access services employ flat-rate billing plans. The participants expressed a general preference for flat rate pricing plans and an aversion to per-use billing structures. Those who have internet-enabled phones use the data service infrequently because of the high cost of sending and receiving data. One participant uses three services with his laptop: fixed-line, Wi-Fi hotspot, and 3G. The fixed line and hotspot subscriptions are flat rate and used frequently; however, the expense of 3G causes him to use it “only as little as possible, for essential things.” Participants explained that choosing fixed rate plans simplifies their personal budgeting process and also makes it easier to decide whether or not to use the internet:

“…if there is a new opportunity to get like TV access or somebody tells you to go watch this or do this, I don’t have to worry about whether it is worth it to do that transaction; whether I want to spend the extra money on the download. I like the that flexibility of being able to do whatever I want”

Prior to broadband, internet service price varied upon use. When asked about the advantages of dial-up verses high speed fixed-line internet service, in addition to performance differences, focus group participants brought up the differences in billing strategies between the two technologies with statements like:

“When you used the modem, you know in the back of your head, that it costs for every minute. Now it doesn’t matter, really.”

### 6.0 RESULTS

This section is divided into two parts. The analysis compares the findings to the expected outcomes based on theoretical arguments and suggests a diffusion approach for wireless internet service providers based on the study findings and existing literature. A discussion of the propositions and evaluation of the focus group methodology concludes the segment.

#### 6.1 Analysis

The participating consumers view internet service options as access technologies. They have already integrated the internet with their daily lives. They are accustomed to fixed line and wireless ICT.
Therefore, people view the choice among alternative types of technology as a relatively routine purchasing process and thus employ standard cognitive choice models.

When buying broadband service, people exhibit isolation effects. In the case of the focus group data, all broadband technologies take the user to the internet, enable VoIP, data transfer, etc. As a result, the focus group participants pay attention to the factors that differentiate the choices, the most concrete of which is price. Therefore, their ISP choices are generally a function of price. The disregard for components shared by the alternatives conforms to the findings of Kahneman and Tversky (1979).

The interviewees base value on price, not just absolute prices of one offering versus another, but as an assessment of the price relative to various key features. Therefore, if one service costs twice as much, but offers performance perceived to be twice as “good” then the offers would be equal in the consumer mind. At that point, the consumer would evaluate the offering that came closest to his or her subjective performance requirements, in a rough but somewhat rational manner. As a result, the participants evaluate the offerings using their past and current experience to frame their decision, as postulated by Kahneman and Tversky (1979). They make their decisions by evaluating differences from their fixed line reference point, supporting Kahneman’s (2003) findings that people use analogical reasoning to make choices.

Focus group participants using home broadband access reimbursed by an employer or included in the rent or tenant fees perceive the reference price of broadband services as free. These consumers experience no marginal cost for adopting their current internet service, but would experience an incremental cost if they decided to use a different internet service. Therefore, any alternative choice, including wireless broadband, would be infinitely more expensive; which provides support for the argument by Blechar et al. (2006) that mobile service users make reference to existing service delivery platforms when making their usage decisions.

Participants use price analysis to view possible outcomes as a gain or loss to a reference point so they can employ a partially rational decision process. This approach to balancing accuracy and effort conforms to the findings of Bettman et al. (1998) who write that people reach a subconscious compromise between the desire to make the right decision and the desire to minimize the cognitive effort required to make the decision.

A notable situation exists when comparing current fixed line and wireless broadband service. Except for mobility and installation convenience, every metric considered by focus group participants is inferior to the fixed line frame of reference. As predicted (Kahneman 2003; Kahneman et al. 2003), the loss of functionality is weighed more strongly than the gain of another function. This also supports Constantiou et al.’s (2006) argument that quality perception may cause a status quo bias against mobile services.

The presence of an affinity for flat-rate billing and supports Thaler’s (1999) argument that “mental accounting matters.” Participants feared that pay-per-use plans could become very expensive, as postulated by Thaler’s assertion that loss aversion contributes to a flat rate bias in telecommunications decisions (Thaler 1999). Furthermore, the adoption of a flat-rate plan frees the internet user from evaluating whether or not each internet activity is worth incurring a separate expense, in accordance with Bettman et al.’s argument that one goal of the decision making process is to maximize the ease of justifying the decision (Bettman et al. 1998). In the case of broadband internet, an unlimited use plan eliminates the possibility of “buyer's remorse” after spending money to visit a website, download a file, or view a video.

6.2 Discussion

This discussion provides an overview of the findings and a summary of the contribution to theoretical literature. Second, it addresses the relevance to the business community. Finally, it reviews the methodology chosen for the study.
The data support the propositions derived from existing literature. In general, as put forth Proposition 1, participants use reference pricing as a primary decision-making tool. Although opinions vary, a general status quo bias influences purchase decisions, supporting Proposition 2. Mental accounting contributes to a flat rate payment bias in telecommunication services, as predicted by Proposition 3.

The findings contribute to the body of literature that studies technology adoption beyond individual-level technology studied in isolation. The study adds to the body of knowledge about consumer decision-making processes outside construct-based research. It adds to user behavior research in wireless services by elaborating on the process by which end users make ICT purchase decisions. It illustrates that insights can be gained when cognitive decision models are applied to technology choice.

In addition to theoretical contributions, the findings resulting from this focus group study have several business implications for companies with heavy investment in wireless internet technology. With heavy sunk-cost investments in licensing and infrastructure roll-out, much is to be lost if wireless broadband does not gain mass adoption. There are many challenges to the adoption and diffusion of wireless broadband: inferior perceived performance, high price, and reference situations that weaken the wireless value proposition. These reference situations concern the demand for mobility framed by Wi-Fi and by current usage habits.

Study data suggest wireless providers should use flat rate pricing and create an offering that disassociates mobile broadband from fixed-line internet so that users (i) assign the cost to a different mental account and (ii) view it as different enough to weaken a performance comparison between the technologies. Once customers begin using wireless internet, they may experience the “endowment effect” (Kahneman et al. 1991) which will cause the users to perceive giving up wireless internet as a loss. In such case, status quo bias will make them less likely to discontinue service. As Kahneman (2003) indicates, people opt out of the framed situation much less frequently than they opt in to an alternative.

The study creates an opportunity to review the selected methodology. In this case, the focus group format provides a method to learn the thought process of the test subjects. The interplay of the different participants during discussions provides rich data for analysis. The open-ended nature of the format allows participants to introduce new ideas into the group and therefore provides insight not attainable through surveys. During the first focus group, for example, participants introduced a topic that received significant attention and generated much discussion. This topic appears as a question within the interview guide used with subsequent groups. Additionally, a theme recurred within the first focus group that seemed a worthy topic of research. Therefore, a new question explicitly asked subsequent focus groups about their perceptions regarding the theme, enabling more elaborate data collection.

The small sample size of this study precludes developing a probabilistic model from the data; however, the focus group findings are useful for theoretical generalizability (Barbour 2005) and conceptual transferability (Krueger et al. 2000). The selection of participants with common characteristics rather than random sampling provides insights, but it limits the transferability of the findings to the general population at large.

7.0 CONCLUSION

This study uses focus group data to explore the differences as perceived by high-speed internet users that would influence the adoption of wireless broadband. By exploring what consumers consider when making technology purchase decisions, the data support the importance referencing pricing plays in technology adoption. It lends additional support to the existence of status quo biases in purchase decisions; and it strengthens the argument that consumers prefer flat-price service plans in telecommunications because of bounded rationality and the derivative concepts of prospect theory and mental accounting.
A significant implication of this paper is furthering the proposition that much consumer adoption of new technology can be explained with general decision models by providing strong evidence that these models play a primary role in adoption decisions. The implications are important both to further research as well as to industry. Focusing exclusively on technology diffusion models when conducting research or developing business plans or marketing strategy may ignore real and present influences that affect the acceptance and uptake of innovation.

While this study provides support for and insight into applying cognitive decision models to technological adoption, the study has limitations that warrant further research. For example, additional qualitative studies could enrich the findings of this study by exploring the underlying reasons why some consumers exhibit stronger status quo bias than others. Additionally, quantitative research with larger samples could validate the findings of this study. One potential study would focus on the young demographic featured herein because their technology literacy differs from the population at large. Continuing to study this demographic is relevant to adoption theory and business practitioners because the participants may view different technologies as their referents; and thus their status quo may be different from that of older individuals. At the same time, a sample of the population at large would serve to test the overall validity of the findings. Similar results between the groups would validate this study. If differences between younger and older demographics prove significant, then it might support a call for different approaches to the study of technology adoption based on generational considerations.

Abstract

Ambient intelligence systems facilitate job performance by medical staff in health care services. Several papers detail scenarios in which these technologies may support clinicians in their daily work processes, but their specific characteristics suggest such technologies also could be useful for surveillance and subsequent control of employees. Until now, only little attention has focused on resolving such issues. On the basis of 16 in-depth interviews with medical staff from three German hospitals, this study identifies a reserved attitude and several acceptance problems among interviewees. The qualitative data indicate 10 hypotheses, tested using a questionnaire study of 215 nurses in training from Germany and India. The investigation of the quantitative data relies on partial least squares modeling to identify and categorize problems with user acceptance of ambient intelligence and mobile systems on various levels. The results of this mixed methods study mainly indicate that German participants assess ambient intelligence much more critically. Consequently, specific strategies for implementing such technologies should be adopted.

Keywords: Acceptance Problems, Ambient Intelligence, Health Care, Mobile Technologies, Partial Least Squares (PLS) Modeling, User Acceptance
1 INTRODUCTION

Ambient intelligence and mobile technologies offer various possibilities for enhancing the efficiency and effectiveness of medical treatment in hospitals. Through the use of sensors for example, such systems provide context-aware support. In the health care domain, ambient systems also might support an operating team by determining whether any instruments have been left in the patient (Macario & Morris & Morris 2006). Such avoidable errors lead to approximately 17,000 deaths per year in Germany, and technologies can help reduce the risk of complications for patients.

Yet ambient intelligence also is bound to provoke public scepticism. For example, the use of radio frequency identification (RFID) tags has invoked concerns about potential invasions of customer privacy, which could result in boycotts of the devices (Spiekermann 2008). Acceptance problems also should be anticipated because an ambient system offers new possibilities for monitoring and controlling the staff in a work environment, which may create anxiety and privacy concerns. These issues also apply to medical staff in health care services. Especially in Germany, people seem quite sensitive to the potential threats of such technologies (Bick & Kummer & Rössig 2008).

Taking the specific characteristics and acceptance problems associated with ambient intelligence into account means questioning the usefulness of common acceptance models (Spiekermann 2008). New technologies imply additional risks for users and thus require adapted acceptance models, especially in the health care domain, where the traditional Technology Acceptance Model (TAM) is inadequate (e.g., Lapointe & Lamothe & Fortin 2006).

Few studies have investigated physicians’ acceptance of modern information and communication technologies in general or mobile technologies in particular (Raitoharju 2007). To bridge this gap, we investigate acceptance problems specific to ambient intelligence and mobile technologies by nurses in Germany and India, who are potential users. Germany provides a viable setting because of its negative experiences with adopting ambient technologies (Bick & Kummer & Rössig 2008); India is an emerging country that is closely connected to information technology and is culturally different from Germany. The Global Leadership and Organizational Behavior Effectiveness (GLOBE) study (House & Javidan 2004) supports this assumption. Our study considers any differences in the adoption or application of these new technologies across the two countries. To clarify acceptance problems, we follow a mixed methods approach in an effort to overcome the shortcoming of traditional acceptance models in health care settings. Specifically, we attempt to analyse hospital workers’ fears regarding their acceptance of ambient intelligence and identify any differences due to national culture.

We begin by outlining in detail the scientific background and identified research gap. We then present our research design, followed by the results of our investigation. In the conclusion, we outline some opportunities for further research.

2 STATE OF KNOWLEDGE

In this section, we define the term ambient intelligence, explain its application to the health care domain, and offer an outline of acceptance research in hospitals.

2.1 Ambient intelligence in hospitals

The term “ambient intelligence” was introduced by the Information Society Technologies Program Advisory Group (ISTAG) of the European Union to refer to environments equipped with advanced technologies and computing, which create an ergonomic space for occupants (Bohn et al. 2005, ISTAG 2003, Regmaglino et al. 2005). Weber, Rabaey, and Aarts (2005) similarly define ambient intelligence as the “vision that technology will become invisible, embedded in our natural surroundings, present whenever we need it, enabled by simple and effortless interactions, attuned to all our senses, adaptive to users and context-sensitive, and autonomous.”
As a complex service, the level of support demanded in the health care industry differs from that in other sectors, and research in this area must take specific working conditions into account. Medical staff occupy various positions, including surgeons, physicians, radiologists, and surgical and ward nurses. They often share available desks, computers, and devices and are extremely mobile. A nurse, for instance, usually walks more than a kilometre per shift (Morán et al. 2006), and they often work collaboratively in teams, rarely on individual tasks. Because their work focuses on the physical domain of the patient, digital content should provide back-up support in decision processes. Nurses also move constantly among locations and are frequently interrupted, so mobility and flexibility are necessary and fundamental elements. Ad hoc problem solving also has critical importance for the entire staff (Bardram & Baldus & Favela 2006).

Ambient intelligence might support medical services in several areas. In combination with mobile technologies, ambient intelligence can improve patient identification processes, such as by employing RFID tags that contain relevant information about the patient and thereby prevent mistreatments due to errors during treatment (Andersen & Bardram 2007).

2.2 Acceptance of mobile and ambient technologies in hospitals

Research in the field of user acceptance attempts to explain how and why users adopt new technologies. Several streams of research can be distinguished. In the domain of health care, most studies use the Technology Acceptance Model (TAM) by Davis (1989), the Theory of Planned Behaviour (TPB) by Ajzen (1991), or combinations of the TAM, TPB, and Innovation Diffusion Theory (IDT) by Agarwal and Prasad (1998). Extensions to these approaches include TAM2 (Venkatesh & Davis 2000), and combinations of various approaches have resulted in the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al. 2003). Although these various approaches offer some degree of generalisability, they generally have been developed for contexts such as desktop computers or standard applications. No studies investigate the acceptance of ambient intelligence technologies in health care, and few studies analyse the acceptance of mobile technologies in this domain (Raitoharju 2007); those that do focus on physicians rather than nurses. Only Wu, Wanga, and Lind (2007) investigate the acceptance of mobile health care systems based on an integrated model of TAM and IDT in Taiwan.

The Technology Acceptance Model establishes perceived ease of use and perceived usefulness as determinants for predicting acceptance of a technology in a given setting. In TAM2, cognitive and social influence factors also influence perceived usefulness (Venkatesh & Davis 2000). Ong, Lai, and Wang (2004) extend the TAM with perceived credibility, or the degree to which a person believes that the use of a particular system will be free of privacy and security threats. These constructs are relevant in many information systems studies, but in health care environments, the influence of perceived ease of use on other constructs is not significant (Chismar & Wiley-Patton 2003, Spil & Schuring 2006). Furthermore, perceived ease of use does not offer a significant predictor of the intention to use a technology in a clinical domain (Chau & Hu 2002, Hu et al. 1999, Jayasuriya 1998). In a study of the dynamics of IT adoption in a major change process in health delivery, the Technology Acceptance Model emerges as inadequate (Lapointe & Lamothe & Fortin 2006).

Thus, it appears that ambient intelligence features specific characteristics that enable new functions and are connected with new acceptance problems (Spiekermann 2008). For example, the possibility of surveillance, which creates suspicions of invasions of users’ privacy, leads to acceptance problems, none of which appear in common acceptance models. These acceptance difficulties have not been investigated, so established acceptance models cannot analyse ambient intelligence acceptance in health care contexts. Against this background, we endeavour to investigate which acceptance problems are most relevant for ambient intelligence and mobile technologies in hospital settings. We first investigate which acceptance problems exist in this domain and whether they influence intentions to use the technology.
3 DESIGN AND METHODOLOGY

This study uses a mixed methods design. First, we conducted in-depth interviews to identify various acceptance problems. Second, on the basis of these interviews, we developed a questionnaire that we distributed to nurses in training from Germany and India. The data collection then involved three specific stages: In the first, exploratory stage, we reviewed existing literature to identify various issues that might influence health care domains in which handheld devices could be used. The main purpose of this stage was to identify important factors and create a suitable interview instrument. The second stage involved actual data collection through interviews. Finally, in the third stage, we administered the questionnaire that we developed through the previous stages.

3.1 Explorative research design

We chose a qualitative research design to identify acceptance problems with the use of ambient intelligence technologies in hospitals. Semi-structured interviews, which are flexible and open by nature, provided a suitable means for contrasting areas of application, as described in prior literature. The study took place in the surgery departments of three German teaching hospitals. To provide a high degree of contrast, we chose hospitals that differ in size and organisation, though the number of beds in the investigated clinics is similar at approximately 30 beds each. Participants were physicians and nurses in different leadership positions. This selection criterion reflects the assumption that people in higher positions have better knowledge about relevant tasks and can better evaluate the involved staff. In addition, the interviews in every hospital involved persons in special functional capacities, so that we could understand the individual organisational circumstances. The interviews took place in the work environment, conducted by two researchers with experience in qualitative research. They lasted between 40 and 50 minutes on average and were digitally recorded, with the participants’ permission, and later fully transcribed. The transcripts also were coded separately by the two researchers. The full results of this research have been published previously (Bick & Kummer & Rössig 2008).

3.2 Quantitative research design

In this section, we detail the research components and hypotheses, research scope, and methods for analysing the data.

3.2.1 Scenario, constructs, and hypotheses

A developed scenario describes acceptance problems and benefits in three major areas. Because the scenario needed to be easy to understand, we used no special terms and confirmed its comprehensibility with a pretest. The scenario indicates:

A system automatically controls the staff of a hospital in the medication process. The patient and medicine are tagged by sensors. The medical staff uses a mobile device that provides information about the required steps for treatment and automatically documents the work. During the medication process, sensors on the medicine and patient automatically check their mutual suitability. When errors in the treatment are recognised by the system, an alarm occurs, and the error is recorded.

The benefits and potential risks (including the possibility of surveillance) of the system were emphasised. The questionnaire features three major fears, identified in the explorative study. In contrast with perceived credibility (Ong & Lai & Wang 2004), which has a mostly positive connotation, fears represent negative influence factors and have concrete negative associations with technology conditions, the work, and surveillance. The corresponding question items were developed on basis of the interviews. The questionnaire also includes key constructs from TAM, perceived usability and intention to use the system. The personal opinion of the potential user about a fictitious scenario thus represents acceptance, for which the original question items from TAM are applicable. Relevance and voluntariness also emerge as important for acceptance, according to the interviews, and
appeared in TAM2 as potential influences on perceived usefulness. To measure these constructs, we use the corresponding questions from TAM2 (Venkatesh & Davis 2000). However, the pretest indicated that perceived usefulness and relevance and intentions to use the system and voluntariness cannot be separated because they display low discriminant validity, so we merged these constructs. The final set of constructs consists of the following:

- **Fears of new technologies**: This construct consists of fears arising from the extended use of technology, such as trust in technology, the fear that technology will replace the personal component of treatment, and rejection of technology in general.
- **Fears about work**: This construct includes worries about changes to work processes. Therefore, it comprises the fear of losing one’s job and working longer, as well as the perception of the system as a burden and fears of a reduction in decision making rights.
- **Fear of surveillance**: The extended possibilities of data collection and analyzing are integrated in this construct, which consists of fears of being exposed and monitored during work. Each item entails five question items.
- **Perceived usability**: This construct measures whether participants regard the system as useful and relevant.
- **Intention to use the system**: This construct measures the intention to use technology voluntarily for work purposes.

Perceived ease of use (Venkatesh & Davis 2000) does not appear in the scenario, because it is not possible to measure and because previous studies show it is not relevant in the health care environment. However, the fear of technology construct measures, in general, whether people expect that using the system will lead to problems. Table 1 summarises the tested hypotheses.

### 3.2.2 Research scope

The objective of the quantitative research design is to evaluate the hypotheses with a paper-based questionnaire. The questions were measured on a seven-point Likert scale (Dawes 2008). A pretest of the questionnaire with professional nurses in Germany resulted in minor changes to the questions. A total of 224 participants (111 from India, 113 from Germany) completed the questionnaire in the main test, and 215 were appropriate for use in the study (9 were incomplete). The participants were undergraduate nurses in India and Germany with at least one year of experience, which ensured they were acquainted with the working environment of a hospital. These participants provide a contrast with the interviewees in leading positions in the preliminary qualitative study. Furthermore, we assumed nurses would be a relatively homogenous group compared with physicians and focus more often on medication processes as a main part of their daily work. The use of students as participants might limit the generalisability of the results, and transferring the qualitative developed items from Germany to India could limit the results as well. To reduce this concern, the items were translated into Hindi as well as English and then retranslated into German. Any differences prompted minor changes,
with the translation process repeated. A researcher also discussed the questionnaires with a small group of participants to ensure their understanding. In both countries, the data collection followed the same procedure: The researcher explained the aim of study to a class of nurses in training, emphasising the voluntariness of participating and ensuring the anonymous character of the results. The questionnaires then were distributed and collected. The average ages of the participants were 21.80 years in Germany and 24.49 years in India. The difference results from the different educational systems in these countries. Most people in India have more working experience before they go to nursing school. In Germany, 81.25% of the participants are women (18.75% males), and in India, 73.82% are women (27.18% males).

3.2.3 Data analysis method

To investigate the hypothesis, we used partial least squares (PLS) modelling. An advanced statistical method that belongs to the structural equation modelling (SEM) domain, PLS allows for the empirical analysis of a measurement model and a structural model. The structural model consists of a network that links the latent and manifest variables, and the measurement model connects the constructs with a set of indicators (Wold 1974, 1982). In contrast with traditional statistical methods such as factor analysis, regression analysis, and path analysis, PLS assesses the measurement model embedded in the structural model and thus uses an iterative algorithm that estimates indicator loadings on the construct and then among the constructs (Fornell & Larcker 1981).

We select PLS to test the hypotheses because its required sample sizes are relatively smaller than those for other SEM approaches. Moreover, PLS can test theories in an early stage of research. Various information systems studies use the same method to analyse data (Keil et al. 2000, Venkatesh 2000, Venkatesh et al. 2003). We adopt SmartPLS 2 (Ringle & Wende & Will 2005).

4 RESEARCH RESULTS

The qualitative research in Germany enabled us to identify the constructs and select the items. We next explain the measurement and structural model in detail.

4.1 Measurement model

The investigated model is reflective, so the latent variables are operated by the measurement models and explain the indicators. The strength of the measurement model is determined by its reliability and validity. We calculate the reliability of the single measure, composite reliability of constructs, variance extracted by the constructs, and discriminant validity (Fornell & Larcker 1981, Hair et al. 1998).

To assess the reliability of the single measure, we note the correlation of the indicator and the construct. The factor loading measures reliability as a score that should be greater then 0.7. Factor loadings less than 0.5 are not acceptable and therefore are excluded from the analysis (Chin 1998). If a factor is excluded for one country, we also exclude it for the other country to ensure comparability. In the final model, all the factor loadings of the indicators are greater 0.5, and most are higher than 0.7, so the constructs achieve reliability in both countries.

Table 3. Validity findings of the measurement model.

All the Cronbach’s Alpha values are greater than 0.7. An acceptable internal consistence requires composite reliability greater than 0.7 as well. The average variance extracted (AVE) should be greater than 0.5. To assess the discriminant validity for each value of the latent construct, we determine whether the AVE is greater than the maximum squared correlation between this construct and other constructs (Chin 1998, Fornell & Larcker 1981). As we show in Table 3, all AVE values are greater than the corresponding maximum squared correlations with other constructs, so the tested models in both countries achieve this requirement, and we can assume the discriminant validity of the results.

Table 3. Validity findings of the measurement model.
Not all the facets from the model developed in Germany appear in the data from India. As a result, we deleted these indicators from both models, because the model is reflective (Chin 1998). Nevertheless, these findings are important in that they show that the constructs differ across countries. In our model, we focus on describing only the intersection of both models as a comparable core.

### 4.2 Structural model

Variance-based approaches to structural equation modelling and PLS tend to bias the results. Indicator loadings in the measurement model are estimated as too high, and the path coefficients in the structural model are estimated as too low (Chin 1998). This bias can be avoided with either an adequate sample size—at least 10 times higher than the most complex construct’s number of indicators or the largest number of paths leading to a latent construct. In the model, the most complex model consists of five indicators, and the four paths for intention to use the system are the most (Figures 1 and 2), so we require a minimum sample size of 50. Even though both sample sizes achieve this requirement, it is only a rule of thumb; critics argue that this rule does not take statistical power into account. Significance tests that lack statistical power are limited because they cannot discriminate reliably between the null hypothesis and an alternative hypothesis. Thus, the possibility exists that not all significant paths in the model will be identified. Furthermore, the statistical power should be greater than 0.8 (Cohen 1988, Hair et al. 1998). Using G*Power 3.0 for a moderate effect size of 0.15, an α of 0.05 for four predictors (latent variables), and a statistical power of 0.8, we need a sample size of at least 85 (Faul et al. 2007). Because both samples are greater than 100, the statistical power is acceptable (> 0.87), bias problems can be overcome, and the squared multiple correlation R² in the upper 13% will be detected as significant.

After computing the path coefficients in the structural model, we used bootstrapping to obtain the corresponding t-values. All hypotheses correspond to paths in the structural model. Each hypothesis test uses a path coefficient (positive or negative) and the statistical significance of the t-values. In the t-tests, we assess the 0.05, 0.1, and 0.01 significance levels (Efron & Tibshirani 1993). In Figures 1 and 2, we outline the path coefficients, t-values, and significance levels.

![Figure 1](image_url)  
*Structural model: German data.*  
(****p < 0.001, **p < 0.01, * p<0.05; hypotheses in bold are supported)*
As in the regression analysis, the $R^2$ indicates the explanatory power of the latent endogenous variables. For example, Chin (1998) regards 0.67, 0.33, and 0.19 as substantial, adequate, and low values, respectively. We use these same values to evaluate the findings. To assess the relevance of the prognoses ($Q^2$), we adopt the Stone-Geisser criteria with a blindfolding procedure (Tenenhaus et al. 2005). This approach eliminates values in the empirical data and approximates them with the resultant PLS findings. The procedure ends after all values have been replaced. Using squared errors and approximated values, $Q^2$ can be assessed; values greater than 0 suggest the constructs have relevance for the prognoses. In both models, the values for $Q^2$ are greater than 0.

(Table and text continue)

5 DISCUSSION AND IMPLICATIONS

The concerns about technology, as identified in the qualitative study, have significant influences on perceived usability and intentions to use the technology in Germany. Moreover, all of the hypotheses receive support from the study findings (Figure 1). However, only four—H1, H2, H8, and H10—have significant influences in India (Figure 2). The unease associated with technology in Germany and India also affects users’ fears of surveillance and work degradation. In other words, people who do not trust technology and do not want to increase the extent to which they use it in their work also express a fear of being under surveillance and believe that their work conditions will worsen with the introduction of such technologies. This critical point shows that acceptance issues cannot be described sufficiently by the components of classic acceptance models such as TAM2 (Venkatesh & Davis 2000). New technologies such as ambient intelligence, which imply additional risks for users, require adapted acceptance models that take these risks into account. The high correlation between fears illustrates a close connection among the various risks posed by new technology. Therefore, attempts to reduce the fear of new technology may reduce other fears and perhaps increase acceptance levels.

The fear that a user’s work will be degraded because of the introduction of a technology has a significant negative influence on the perceived usefulness of ambient intelligence in both Germany and India. This negative influence confirms that people tend to consider technologies less useful when they anticipate negative consequences for themselves. In the Indian data, this fear explains only a minimal lessening of perceived usefulness ($R^2=0.084$) and has no direct affect on the intention to use the technology. However, in Germany, fears of technology and anxiety about work degradation have
considerably negative influences on both perceived usefulness and intentions to use the technology. However, the surveillance aspect has a positive effect on perceived usefulness and intentions to use a technology; that is, participants appear to understand the positive aspects of surveillance and regard them as useful. However, H1 and H5 imply that technology is very closely related to two other fears with negative implications. In another interesting finding, we note that in India, the only significant influence on the intention to use the technology is perceived usefulness. The correlation between usefulness and intention to use the technology is also much higher in India. In contrast, German respondents indicate that all their fears have an impact on their intention to use the technology. Thus, it seems relevant to take the perceived risks in Germany carefully into account.

6 CONCLUSION AND FURTHER RESEARCH

The main objective of this study is to determine whether special fears about technology influence acceptance of ambient intelligence and whether national culture also might affect attitudes of potential users. The results significantly support the hypotheses. In Germany, we identify three major concerns, each of which affects the perceived usefulness of and intentions to use the technology. However, in India, the findings suggest that only those fears related to the working environment are critical for ambient intelligence acceptance. These results imply that ambient intelligence prompts much more criticism in Germany than in other countries. It is important to allay such scepticism by supporting the implementation process better. Strong relationships among the different fears about the technology indicate it also is important to try to avoid them by adopting a holistic approach. According to the German study, surveillance can have a positive influence on the acceptance of such technologies. In contrast, the Indian findings suggest that only those fears related to work are critical for implementation, which might be enhanced through better communication with the staff.

As mentioned, our study suffers from several limitations. First, the participants are comparatively young and had minimal experience because they were still in training, so our results might not be generalisable to a wider audience. Second, our qualitative development of items in Germany and their transfer to the Indian health care system might lead to bias in the results. The transferability to other application areas (e.g., collaboration, patient monitoring) and other groups of medical staff also cannot be assumed. Third, the results are not necessarily representative of the investigated cultures. Fourth, intention to use a technology serves, in this study, as an indicator of acceptance, but a bias between intentions and actual use is likely.

In a next step, these results could provide the basis for implementing an ambient intelligence system and performing a case study. Research into the changing level of acceptance over time and comparisons across different application areas and users also would improve our understanding of related ambient intelligence acceptance problems. We suggest that the relationships between the cultural dimensions, according to the GLOBE study, and the level of acceptance should be analysed in detail. Finally, other countries could be integrated in further research projects. The acceptance of special technologies is highly relevant because of their enormous benefits. As the comparison between India and Germany demonstrates, certain countries participate in the use of ambient intelligence more readily than others, because they are more open to using new technologies in their working environments. A better understanding of the special fears and risks associated with ambient intelligence thus is required to motivate people with more critical attitudes to participate in the use of such technologies.

Why Information Technology Is Not Being Used for Financial Advisory

Schwabe, Gerhard, University of Zurich, Binzmuehlestrasse 14, 8050 Zurich, Switzerland, schwabe@ifi.uzh.ch

Abstract

Swiss banks have returned to their roots and pay an increasing amount of attention to differentiating themselves from others through good financial advisory services. This has led to a loudly publicized standardization of IT-advisory processes, but not to an increasing use of supporting IT tools. This paper uses interviews with Swiss advisors, sales managers and IT managers, as well as focus groups of users and a survey with users to identify reasons for non-usage. The analysis is based on a framework combining principal-agent theory, IT-business alignment, technology acceptance and information behaviour. We provide evidence that the key problem explanation is the incentive system of the advisors and that poor usability of the software and lack of engagement by sales managers also contribute to the non-usage of most tools.
1 INTRODUCTION

The breaking down of the asset management market has led to a rediscovery of the traditional banking wisdom and banking business. Giving credit to companies and advising clients in their investments are increasingly seen as an attractive and sustainable source of income. As for them cost leadership is not regarded a promising strategy in the long run (Buhl, Kundisch & Steck 2002), an increasing number of financial service providers has turned to financial advisory services as a competitive differentiator. Buhl & Kaiser (2008) argue that such a differentiation may be accomplished by individualizing advisory, i.e. by aligning the advisory activities to the customer needs. Taking into consideration the complexity of advisory, they also conclude the need of extensive IT support for improving advisory services regarding efficiency and effectivity.

Switzerland is one of the leading worldwide destinations for wealth management and enjoys the reputation of being a worldwide leader in financial advisory processes. In recent years, leading Swiss banks have placed considerable effort into restructuring their advisory process in order to further improve their quality. However, studies repeatedly reveal that customers are notoriously dissatisfied with advisory services; we were able to confirm this in the context of a larger study on the investment advisory process (University of Zurich & Solution Providers 2009). In this study we also investigated the advisory's IT support, i.e. the tools advisors have available to better serve their customers, particularly in face-to-face meetings. Our observations regarding IT in advisory were based on a broad definition of IT support - we were interested in the categories of available advisory IT (apart from the widespread tools for customer relationship management (CRM) virtually every bank employs): means of IT-enabled communication (such as email, chat, instant-messaging), IT tools for information access (stock prices, ratings), tools for decision support (simulation and visualizations of scenarios) as well as IT-support for customer self-advisory (such as tax calculators).

We were puzzled to see that almost no banks used IT during the actual advisory meeting, although there were tools available. We even looked over the Swiss-German border and noticed that advisors of Deutsche Bank also did not use IT during the advisory meeting even though Deutsche Bank had won an award for its advisory software (Voss 2005). In the course of pilot interviews it became clear that this phenomenon could be explained not only by simple “usefulness” and “ease of use” as suggested by the popular Technology Acceptance Model (Davis 1989); rather, advisory IT appeared to inject itself into a complex web of interests and accepted behaviour of key bank stakeholders.

We therefore decided to look at these issues from a stakeholder’s perspective. Four groups of stakeholders were analyzed: the advisors in the banks, their clients, the sales managers responsible for the advisory process, and the IT managers responsible for building tools for supporting the advisory process. All their comments in the interviews were scanned for clues on “Why is IT not used for financial advisory services”? Consequently, the objective of this paper is to provide insight into the reasons why financial service providers fail in tapping the full potential of IT for improving advisory, especially in meetings with customers. Building on different well-established theories we thereby strive to contribute to a better understanding of the behaviours of actors and their effects in an organizational context.

The rest of the paper is organised as follows. The subsequent section reviews relevant literature and identifies useful theories to guide our search for an answer to our research question. The third section offers an overview of our research design, describing the collection and analysis of the data. The findings, presented in section 4, illuminate the problem in the eyes of each of the stakeholders. Section 5 synthesizes and critically discusses the findings, culminating in a preliminary answer to our research question. The final section closes with limitations of our research and the need for further research to support our claims and to deepen the understanding reached thus far.
2 LITERATURE REVIEW

There is no generally agreed upon definition of financial advisory. Fischer & Gerhardt (2007) provide a general definition that describes a financial advisor as “a person or organization that offers its professional financial expertise to individuals who seek assistance or want to completely delegate their investment decisions” (p. 9). From a financial service provider's perspective, the advisory process may be seen as the structured arrangement of advisory activities, with the objective to standardize and control these activities. For investment advisory, these activities may be arranged into a process with multiple phases of customer interaction, such as customer contact (collecting basic customer information), actual advisory (developing investment strategies based on the customer's situation and requirements, mostly in face-to-face meetings), realization (implementing strategies into specific product portfolios) and periodic customer support (updating the customer's requirements and optimizing strategies/portfolios). Similar definitions and arrangements of advisory activities can be found both in literature (e.g., Homburg, Schäfer & Schneider 2003, Kallhardt 1997, Lippitt & Lippitt 1984) and practice (e.g., the four steps advisory process of UBS).

We chose to base our research on financial advisory on the perspectives of the main actors involved in an advisory process. This approach reaches beyond organizational boundaries (looking at advisors and customers), organizational levels (covering both advisors and the managers responsible for the advisory process) and functions (IT and business). Accordingly, the areas traditionally covered in different IT and business subdisciplines are combined (see Figure 1). On the operational level, theories and models explaining the behaviour of the actors are selected. For clients, this is “information behaviour” and for advisors, the corresponding “advisory behaviour.” On the management level, the corresponding management disciplines provide models; for sales managers, the discipline is “marketing”; for IT management, the discussion on “technology acceptance” leads to the field of “usability.” Further, theories and models of the relationships of the actors are used: The relationships between clients and financial advisors, as well as financial advisor and the sales manager, can be analyzed by “principal-agent theory.” Any changes have to overcome the conflict using “Change Management” models. The relationship between sales managers and IT managers is covered in more detail in the “IT-business alignment” literature.

Clients: Typically, the customer’s buying cycle (Muther 2001) is not as systematic as the bank’s selling cycle. For financial advisory services, the customer’s buying cycle can be best understood using models from information behaviour (e.g., Wilson 1999). They explain how clients search, select and use information, as well as show the settings that they prefer. These models are particularly useful in explaining situations where a client has to uncover information needs s/he is not yet aware of (Belkin et al. 1982). Advisory service is typically a powerful strategy in such situations (Schwabe et al. 2008), fulfilling pragmatic information needs.

Figure 1: Integrated Non-Usage Framework

---

1 http://www.ubs.com/1/e/ubs_ch/wealth_management_switzerland/relationship/advisory_approach.html
**Client – Advisor:** The relationship between client and advisor has the features of a principal-agent conflict (Eisenhardt 1989, Golec 1992): The advisor (= agent) is paid to work for the client (= principal), but s/he may have hidden characteristics (e.g., lack of knowledge about the market) and hidden intentions (e.g., optimizing fees for the banks instead of the investment profit of the client) and may engage in hidden actions (e.g., selling assets without the real consent of the client). S/he may not want to use IT, which, for example, may make investment solutions more transparent and thus may allow the client to better monitor the advisor’s behaviour.

**Advisors:** We are not aware of any published empirical models on actual advisory behaviour. There are, however, ample normative models on how advisors should behave during the advisory process. These models originate from advisory service process design and banks promoting their advanced advisory process (see definitions above), from the finance literature, e.g., promoting a theoretically sound portfolio choice (Markowitz 1991) and from IT tool descriptions suggesting a suitable advisory approach (Buhl, Kaiser & Winkler 2007, Eberhardt & Zimmermann 2007).

**Advisor – Sales manager:** The relationship between advisor and sales manager can also be regarded as a principal-agent conflict. While the sales manager is responsible for designing an advisory process optimizing the bank’s long-term income, an advisor may focus rather on maximizing her personal short-term income through fees. Furthermore, it may be in her personal interest to bind the customer to herself as a person rather than to the bank as a whole. This may foster hidden intentions and lead to hidden actions. The advisor again may have no interest in implementing IT that could make her intentions more transparent or may prevent her from engaging in hidden actions. Swiss banks have implemented standardized advisory processes to address this known problem. Implementing supporting IT could greatly enhance their capability to enforce these new processes.

The literature on change management may enhance our understanding of why sales managers have failed in implementing advisory IT. In the context of the advisory process the sales manager owns, an understanding of conflicts of interests as well as an active design and change of incentive systems is of particular importance. As advisory technology supports client-advisory collaboration in an organizational context, the literature on groupware adoption is the most applicable regarding change management issues. In her seminal work on the failed diffusion of a Lotus Notes based knowledge management system, Orlikowski (1992) shows how the highly competitive culture of a consulting company (“up or out”) contradicts the sharing approach that lies at the heart of the knowledge management system. Top managements’ efforts to enable and persuade the consultants to use the software remained fruitless in this context. Grudin (1988) uses the example of shared calendars to demonstrate that implementation of groupware requires a critical mass of users to make them useful for everybody. Only peer pressure (Grudin & Palen 1995) may convince users to compromise their own interests (e.g., in privacy, flexibility, or, more generically, in hiding their characteristics, intentions and actions) for the sake of everybody else’s benefit (improving the coordination and increasing the efficiency). Generally, the organizational implementation of software is difficult if one group of actors has the costs and another group of stakeholders reaps the benefits (Grudin 1994). Furthermore, successful changes require a shared vision and the affected users have to be enabled to perform the change. Ward and Daniel (2006) establish the managers’ responsibility to actively manage IT benefits on the basis of a sound understanding of the stakeholders’ interests and the needed business changes.

**Sales manager:** Sales management strives for a competitive advantage (Porter 1985). The implementation of IT is interesting from the sales manager’s strategic perspective if it serves as strategic differentiator (Ward & Peppard 2002). From an operational point of view, IT can serve as a means of monitoring the advisors to avoid hidden actions and to enforce quality standards.

**Sales manager – IT Manager:** The alignment of IT to the needs of the business remains on the top of a CIO’s agenda (McGee 2008). Successful companies establish joint decision making on the business demand for IT support (Weill & Ross 2004). Ward and Peppard (2002) recommend including the management levels of IT and business, as well as the user levels in determining the demand and the steering of IT projects. IT managers are requested to actively market their products in business (OCG
2007), and sales managers and users need to actively participate in IT projects, even though it may not be their primary interest.

**IT Manager:** The IT managers strive to provide acceptable software. Davis’ (1989) model on technology acceptance (TAM) proposes that this mainly depends on usefulness (i.e. the functionality it provides) and the ease of use. Newer literature from HCI expands the idea of “ease of use” to the concept of “usability.” Apart from having pragmatic qualities of the software (e.g., whether the user finds the information s/he is searching for within reasonable time), the rising popularity of computer games has stressed the importance of the hedonic qualities of IT (Heijden 2004), i.e. how enjoyable IT use is.

The TAM has been frequently used, but also been frequently criticized and expanded upon. Newer models like the Unified Theory of Acceptance and Use of Technology (Venkatesh et al. 2003) include contextual constructs of performance expectancy, effort expectancy, social influence and facilitating conditions. The Model of Information System Success (DeLone & McLean 2003) describes the relations between information, system and service quality and use of information systems, correctly declaring that the net benefits of such systems are dependent from usage and user satisfaction. Current technology acceptance models explain the adoption behaviour of individuals, teams in special settings (Powell, Piccoli & Ives 2004) or whole organizations (Bajwa et al. 2007). They are not yet specifically tailored to explain adoption of dyads or to link individual adoption to organizational adoption.

In summary, there are considerable general building blocks that can contribute to an understanding of why IT is not used in the advisory process. However, we have also identified a few holes. What is still missing is (a) a model that is specifically tailored to financial advisory issues and (b) a combined and coherent full picture that identifies the key factors and also explains the interplay of these factors.

## 3 Research Design and Data Collection

The question of why IT is not used for financial advisory processes surfaced in the course of a larger study on the quality of financial advisory services (University of Zurich & Solution Providers 2009) in which IT use was only one question. We were thus fortunate to have a very rich set of data to contextualize the observed IT use. The larger study combined an adapted and enhanced Servqual model (Zeithaml et al. 1990) and an information behaviour model (Wilson 1997). Following the Servqual gap model, we contrasted the perceptions of bank customers, advisors and the sales managers responsible for the advisory process. Typically, these were senior executives, one or two organizational levels below the company board. We then added the IT management perspective, addressing the person responsible for advisory IT, typically a senior IT manager. The questionnaires were based on the Servqual items for the five dimensions of service quality (reliability, assurance, tangibles, empathy, responsiveness) and extended by items for the advisory process dimension (effectivity and efficiency) as well as IT-related questions. In this paper we focus on the results of the IT items and of the items on Servqual’s assurance dimension (i.e. confidential behaviour of employees), which add to the discussion on the importance of trust regarding information asymmetries.

All four stakeholder groups received the same core set of questions and each received a set of additional questions targeted at their special competence. The most extensive enhancement was on the client side where we applied a survey of their information behaviour, building on Wilson’s model (Wilson 1997) and asking which sources they preferred for their information search, how they judged them in comparison and why they chose to do so.

The data collection took place in two waves. From December 2007 to February 2008, four researchers performed a total of 21 “mystery shopping episodes” that were performed in Switzerland (16) and - for the purpose of comparison - in Austria (3) and Germany (2). The episodes entailed consulting talks with retail banks (12), private banks (6) and one provider of bank assurance. Each session typically lasted from 60 to 90 minutes. Targeting the affluent banking customer segment in our study, the researchers requested advice about the investment of sums of 50,000 to 500,000 Swiss francs, which generally classifies a customer as “affluent” by a bank. For details see Nussbaumer et al. (2009).
In the second wave of data collection, which lasted from June to October 2008, we focused on financial service providers in the Swiss banking region\(^2\) to obtain a more homogeneous sample (European banks, for example, show substantial differences regarding legal regulations on advisory). A total of 21 advisors from 19 banks, 28 responsible sales managers from 27 banks and 12 IT managers from 12 banks were interviewed. As we strove for deeper insights, the questionnaire consisted not only of quantitative questions from Servqual, but also open-ended questions for each of the dimensions. This paper draws mostly from these open-ended questions. A typical interview lasted 60 to 90 minutes. All sales manager interviews were transcribed\(^3\), and in two cases where interviews could not be conducted, the respondents answered the questions electronically. We have audio recordings plus written notes for the interviews with the other stakeholders.

For the customer perspective, we applied electronic questionnaires and involved customers in a written discussion as part of two focus group sessions. The workshops lasted 150 minutes each. A total of 28 clients participated, almost all of which belonged to the affluent customer segment. We furthermore collaborated with a very popular investment journal (Cash\(^4\)) to apply purely quantitative questionnaires on advisory quality and information behaviour in September/October 2008 (for details see University of Zurich & Solution Providers 2009). A total of 136 users responded to the survey, with the vast majority again being from the affluent customer segment. The online survey was based on refined questionnaires that were used for the focus groups. The applied triangulation of methods (Flick 2000) allowed both finding support for existing working hypotheses and seeking for a deeper understanding in areas less well understood.

The subsequent paragraphs describe in more detail the data that were actually used for explaining why IT was not used in the financial advisory services. The overall research question of “Why is IT not used for financial advisory services?” can be split into three subquestions: (1) “Is IT not used in financial advisory services?” establishes the basis for our argument, (2) “What reasons are given by the stakeholders?” establishes the multiple-perspective view for which we argued in the literature review, with (3) “Which of the reasons appear credible?” we interpret the findings.

The research on “Is IT not used in financial advisory services?” primarily draws on our observation in mystery shopping. We can further support the analysis with (a) the outcome of two student research projects (à Porta 2008, Hämmerli 2008) covering another 10 advisors, and (b) results from the interviews with advisors.

The research on “What reasons are given by the stakeholders?” draws from the interviews with the advisors, sales managers and IT managers, as well as from the workshops with clients. All the gathered data was scanned for remarks that could indicate a reason. Any applicable remark was noted and later synthesized in an overview map (see Figure 2). Most remarks came from the IT sections of the questionnaire, but a significant number was also mentioned in other sections. For a few observations we have further support from the quantitative sections of the questionnaires. Most importantly, we can give quantitative evidence on the clients’ expectation of IT and the other stakeholders’ views on this.

The research on “Which of the reasons appear credible?” is mainly interpretative. We particularly focussed on contradictory claims and their support by theory.

4 FINDINGS

4.1 Is IT not used in financial advisory services?

The advisors did not use IT in any of the observed 21 mystery shopping episodes. We had purposefully added Deutsche Bank to our sample because Deutsche Bank had received an award for its financial advisory solution; however, it was also not used there. Further, a student of ours interviewed 7 advisors in his Bachelor Thesis (à Porta 2008) – all of whom critically discussed IT usage in advisory meetings and emphasized customer expectations. Another student modelled the advisory process in three banks as a part of a small research project (Hämmerli 2008). He was able to identify one advisor who frequently used a computer during the actual face-to-face session. He claimed to benefit from the efficiency of the structured process and the increased shared understanding facilitated through the visualization of an investment choice on the screen in the advisory meeting. Interestingly, this advisor belonged to a retail bank (where efficiency is more an issue than in private banks). This lone exception can be seen as proof that an efficient and effective use of IT is possible in advisory meetings, but it does not change the overall picture. We therefore conclude: IT is not used during advisory meetings.

This picture changes if one includes back-office use. The advisors who prepared for the meeting (a minority) obviously had gathered information from the banking system; however, they printed the information and brought it to the meeting. Both interviewed advisors and sales managers stated that CRM systems were used to collect information on their interaction with customers and special systems were used to enforce compliance (e.g., to money laundering laws). Yet the systems appear to remain invisible during the actual advisory meeting. The following types of information systems are rarely or never used in the advisory process: decision support systems, e.g., allowing the customer to visualize and simulate investment options, and systems for self-advisory, e.g., over the Internet.

As we were not able to identify any publications on the diffusion of advisory IT into advisory meetings, we relied on our own Swiss data. We thus concluded that some IT systems are used during advisory services, but never during the actual advisory meetings. The subsequent sections provide reasons for why no systems are used during the actual advisory meeting and why only the mentioned types of systems are used in the advisory process at all.

4.2 What reasons do the stakeholders give?

Figure 2 gives an overview of the reasons for non-usage, as given by the interview partners. If a stakeholder group places the responsibility with themselves, the reason is put above the boxes. If it is in the eyes of stakeholder A and it is stakeholder B that is responsible, the reason is written on an arrow pointing from A to B.

The advisors’ perspective: Advisors state that they do not feel confident in using IT with customers. They fear the loss of competence in the eyes of the customer if they run into problems with using the IT system while the customer is present. The older generation has a lack of IT-affinity. Additionally, they are not convinced of the functionality provided by the tools and their usability. In many places, the IT-tools are poorly integrated and therefore require the advisors to switch tools during the process. In the survey they state that they have been properly trained in the usage of the tools; however, participants stated that isolated training of tool usage was insufficient for them to be applied in the advisory process, let alone in an advisory meeting, and that they should rather learn how to embed tool usage into the actual process and its diverse activities. It is thus not surprising that the benefits of using IT tools in the advisory process remain unclear to the advisor. In the interviews it became clear that the degree of standardization of established advisory processes is rather low – in most cases neither the detailed activities of the processes, nor the usage of accordingly supportive tools, is specified or enforced by management, respectively. Also, the involvement in standardizing the process is perceived as being very low, since the management specifies the processes and implements them top-down.
However, advisors in the few banks that have established rather stringent advisory processes and integrated some IT tools conceive them to be very supportive.

**Figure 2: Overview of arguments**

The advisors claim that customers do not want IT in the advisory processes. Advisory service is said to be a very personal and trust-oriented business; IT would endanger this set-up, or – as one advisor reported – it would “destroy the magic” of advisory.

**Clients:** From the clients’ perspective, the picture is clear: There is no IT provided during the advisory meeting and therefore they cannot use it. Yet, their view of the usefulness of IT for advisory processes differs from the other stakeholders’ perceptions. When asked whether they expected IT support in very good advisory processes, the clients evaluated all offered IT support tools positively, i.e. above 5 on a Likert scale of 1= “I absolutely disagree” to 7= “I absolutely agree”. IT-support for communication (E-Mail, Instant Messaging…) was rated (5,01) as lowest, and IT-support for access to latest information (e.g., stock prices, ratings, tests) as highest (5,86). IT for self-advisory was rated 5.35. Most surprisingly, even tools for decision support (simulations and visualizations of scenarios) that can realistically only be applied in a meeting, were rated as 5.68. All ratings on what clients think are significantly above the expectations of advisors and sales managers. A much lower rating of the IT support they have experienced so far indicates that there is a significant gap. Thus, we can conclude that clients are more positive on IT support than advisors and sales managers think they are.

Trust is also not the important facilitator that advisors claim it to be; rather, the opposite is true. The surveyed clients reported a rather low level of trust towards their advisors (mean agreement of 4.72 to the statement “The advisor’s behaviour is trustworthy.”). As a client noted in a focus group, there is information asymmetry in the advisor-client relationship and this asymmetry reduces trust. Thus, clients do perceive the principal-agent conflict. This explains why IT is important in the clients’ views since it reduces information asymmetry.
Sales managers: The sales managers responsible for the advisory process were mainly marketing oriented people. In their eyes, IT - e.g. for transaction processing - is not a means of differentiation. They also do not think that IT tools supporting the advisory process (like tools for CRM or decision support) may add to a competitive advantage. Thus, for them IT is rather a “hygiene” factor: Banks have a disadvantage without it (since today, for example, transactions are processed fully electronically), but they do not have an advantage if they have it (since other banks have implemented such IT as well). IT managers mostly share this view.

The interviewed sales managers pointed out that IT use might not be in the advisors’ interest, since advisors prefer to tie the customers to themselves rather than to the company (and its information system). In Switzerland, it is not unusual for advisors to take their clients along when they switch companies. The more interesting their clients and the tighter they can bind them, the higher is the advisor’s market value. They do not like the controlling function of the IT. These sales managers’ comments show that there is indeed a principal-agent conflict between advisors and their sales managers.

Sales managers confirmed that advisors are afraid of losing face with their customers when they run into trouble with IT. They are aware of the fact that advisors use only mandatory functions. They enforce the use of tools only in two areas: IT that ensures compliance (such as laws on money laundering) and the customer relationship management system, i.e. systems that indeed can be seen as hygiene factors. For other systems, they have the same laissez-faire attitude as regarding their advisory process. Managers – especially in private banks – only hire experienced advisors. As they tend to be older and have built up experience in advising without IT support, they have difficulties appropriating IT.

Both the sales managers and the IT managers agreed that IT-business alignment remains a problem. IT is rarely included in the design of advisory processes and decisions on applying tools. Thus, the developed tools do not fit newly designed advisory processes. In the eyes of the sales managers, clients do not want IT in the advisory process. In this regard, they disagreed with some IT managers.

IT Managers: Several IT managers did see that customers want to use IT in advisory, and they also saw some benefits. They were able to more precisely estimate the clients' expectation in regard to decision support systems and information systems than advisors and sales managers. They also confirmed lack of usage by the advisors and voiced frustration about the unused expensive tools. In their relationship with the sales managers, they complained about low and late involvement in decision processes regarding the design and support of advisory processes. Internally, they had a lack of roles and processes to develop and implement innovations.

5 DISCUSSION

Some of the statements of the stakeholders reinforce one another; others are obviously contradictory. In this section we discuss the credibility of the statements in the light of other statements and the literature. Further, we link arguments to identify chains of reasons and identify root causes of non-usage.

The most striking difference is the question of whether clients want visible IT support. If they didn't want IT, it would be a plausible root cause for non-usage. While advisors and their sales managers claim that customers dislike visible IT support in the advisory process, IT managers have a more positive attitude towards such IT. Most importantly, clients themselves voiced interest in support, the highest interest being in pure information access, but there is also considerable interest in decision support and self-advisory systems. Thus, we conclude that the responding clients and IT managers are more credible and that a significant number of clients would welcome visible IT support.

The most obvious cause for lack of usage would be lack of software quality. In this regard, advisors pointed at many specific quality issues where quality seemed to be a great challenge. Particularly, the widespread poor integration into processes and low usability were major issues. The IT managers cannot push process integration ahead because they are not involved in the decision processes for advisory design. The IT-business alignment is regarded as poor from both sides in this area. An indicator of
poor IT-business alignment can be found in the valuation of IT support for advisory. It is not regarded as a means of differentiation. Therefore, it is applied only in areas where it increases efficiency (CRM) or where the bank has to document compliance with regulations. Thus, we conclude that one root cause for the lack of adoption of advisory support is its low potential for strategic differentiation. This leads to a low priority of such projects, poor IT-business alignment and an isolated IT department that can neither embed advisory support sufficiently into the advisory process, nor train users adequately.

The usability problems remain in the domain of the IT managers. There is great potential for improvement, as usability is particularly important for dyad users. Only well-designed software could ease the fears of the advisors for losing control or losing face. Furthermore, including the lessons from hedonistic software design could protect or even increase “the magic” of advisory meetings. Schwabe et al. (2008) have demonstrated for the domain of tourism, how this can be done using large screens. Yet, we are not convinced that poor usability is the root cause for the low uptake of advisory software. IT managers have bought many expensive off-the-shelf tools that have not been adopted either. We have the example of Deutsche Bank that did not use their award-winning tool. Researchers have developed advisory software with an emphasis on usability (e.g., visual product editors such as the multi-touch table developed by the Swiss Design Institute for Finance and Banking5). And we have the example of the one advisor who successfully used a standard banking system in the advisory session. Thus, we conclude that poor usability contributes to non-usage and gives advisors a welcome excuse, but it is not a root cause.

This leaves us with the two principal-agent conflicts. There is an information asymmetry between customers and advisors. This asymmetry is to the advantage of advisors and therefore they will not use IT tools without other strong incentives. Especially private banking advisors have the incentive to bind the customers to themselves. Any information that the bank has on the customer, and any binding of the customer to an information system are detrimental to this interest. Since the clients rather distrust their advisors, they have a high demand for transparency, participation and control of the advisory process. Novak (2009) discusses the design of such (collaborative) approaches to better involve end-users in advisory settings. Still, the sales managers have to enforce standardized advisory processes (and not only their design) to allow establishing a mandatory usage of more tools. They would have to apply strong change management techniques to align the interests of the customers with the interests of the advisors. However, they do not see the priorities, as IT is no strategic differentiator.

Thus, our overall conclusion is that the advisors are the main obstacles to visible IT use in the advisory process. The key to the solution is, however, in the hands of the sales managers. They do not view IT for advisory as a strategic asset, and thus neither enforce the use of IT in the advisory process (with a few exceptions), nor sufficiently collaborate with IT managers.

There are two scenarios that could change this situation: An entrepreneurial bank could demonstrate that IT can serve as a differentiator and thus force the other banks to follow suit. In the discussions, particularly the IT managers saw a realistic chance of this happening. The second scenario is a consequence of the current financial crisis. After the experience with investment bankers, banks may not tolerate uncontrollable “entrepreneurs” in their own organization any longer. They may want to enforce their processes and reap efficiency and service benefits of IT tools in the advisory process.

6 LIMITATIONS AND FUTURE WORK

Our research is targeted at a deeper and multi-faceted understanding of a yet poorly understood phenomenon. We had to make some compromises in order to reach this target within reasonable time.

5 http://www.sdfb.ch/de/aktivitaeten/projekte/strukturierte Produkte
While we were able to talk to sales managers, advisors and IT managers of all major Swiss banks, we cannot be completely certain that we have reached a representative client sample. As banks are very reluctant to provide direct access to their own customer pool, we had to accept the compromise of a public survey. The survey was launched over an electronic website; thus users may have had an IT-bias. However, as the majority of the Swiss population uses the Internet, this should not be major problem. The focus groups may also have had more IT-affinity than the average affluent client, as they were recruited from our alumni organisation and from a consultancy company. We were therefore very careful with using their interpretations in this paper and for the important parts relied rather on the client survey.

A second limitation is the emerging nature of our research question: We wanted to observe the current use of IT for advisory in the mystery shopping and talked to the stakeholders about the actual use of IT and ended up with a paper on non-usage. Thus, we rarely explicitly talked to the stakeholders about non-use but rather drew conclusions from their reactions on our questions of their usage behaviour. This approach did not allow us to discuss specific non-usage issues and we therefore could not reliably count frequency of answers.

A third limitation is the diversity of the banks covered: The arguments given by a stakeholder in one bank may be specific to this bank and may not hold true for the situation in another bank. We were surprised about the coherent picture we received by adding arguments from stakeholders in different banks. But we still had to do some interpretation and sense making in order to reach the clear picture presented in this paper.

The next steps for research in this domain could go in two directions. Firstly, we need a deeper understanding of the dynamics between the stakeholders. For this purpose, observing stakeholders within one bank could be a viable approach. Secondly, there is room to validate the barriers to the adoption of advisory systems and the causal relationships proposed in the discussion section in a quantitative study.

7 ACKNOWLEDGEMENT

We would like to thank Solution Providers, particularly Ralph Mogicato, as well as Ingrid Slembek for supporting us with the interviews and providing critical input. Furthermore, we are grateful for the inputs given by the interview partners in all major Swiss banks.

Abstract

Nowadays Knowledge is regarded as a strategic resource in organizations, and thus the leverage of knowledge is a key managerial issue. Knowledge creation, sharing and dissemination are the main activities in knowledge management. This study examines the influence the social and technological factors such as learning culture and IT use, could have on knowledge sharing of King Fahd University of Petroleum and Minerals (KFUPM) students. A cross-sectional survey was used as a methodology for data collection and 137 valid responses were collected from all the three categories of students that include graduates, undergraduates and preparatory students. The study shows that there is a significant positive relationship between the student learning culture and IT use on student knowledge sharing. The study limitations, practical implications, along with directions for further research are discussed.

Key words: knowledge sharing, learning culture, IT use, knowledge management

1. INTRODUCTION

Knowledge is recognized not only as the most important resource in organizations (Liao et al. 2004) but as one of the primary sources of competitive advantage (Stewart 1996). Knowledge is critical to the long term sustainability and success of any organization (Nonaka and Takeuchi 1995). The importance of knowledge is eminent to both public and private organizations, particularly educational/learning institutions such as universities (John 2001). The leverage of knowledge is a managerial and strategic issue. As reservoir of knowledge, higher learning institutions are no longer just providing knowledge to students, but also managing and blending together as well as sharing such knowledge among the students. Thus, knowledge sharing is inevitably challenging and important concept in higher learning institutions.

Knowledge creation, sharing and dissemination are the main activities in knowledge management. Being part of knowledge management (KM) process (Kim and King 2004), Knowledge sharing (KS) is the exchange of experience, events, thoughts or understanding of anything. In general, people expectations from knowledge sharing are to gain more insights and understanding about concepts or practical applications, thereby improving learning and expertise. Thus, knowledge sharing can be considered as a significant ingredient for mutual learning and intellectual development to students.

To stay competitive in the education industry, institutional members must promote knowledge sharing (Kumar 2005). Conversely, the competitive nature of learning institutions, among others, may hinder the knowledge sharing among the students. Thus, studies on both barriers and enablers of knowledge sharing in learning institutions may be relevant not only for adding to the literature, but to the policy makers of such institutions. Literature search shows that limited studies where available on the factors that promote and limit knowledge sharing among students.

With the increasing investment of Information Technology (IT) in educational institutions, one expects such investments to have positive impact on the way knowledge is disseminated. Possibly, the level as well as the use of Information Technology (IT) may support knowledge sharing capabilities (Ipe 2003) in institutions of learning. However, investment in technology may not be the only factor that could enable
knowledge sharing. Other factors, social and cultural, in particular are worth considering. In this respect, support of one another, learning culture, might in a collectivistic society, like Saudi Arabia, promotes the willingness of students to share knowledge among themselves (Maccoby 2003).

Literature search shows that limited studies where available on the factors that promote and limit knowledge sharing among students. Similarly, the literature search revealed that, to date, no such study was undertaken in Saudi Arabia. Hence, the focus of this study is to examine the relationship of some dimensions of learning culture and Information Technology (IT) on students’ knowledge sharing.

This study is unique and original, not only for being one of the first in Saudi Arabia, but for being one of the few that examines how both technological and social and cultural factors together serve as antecedents of knowledge sharing. Next, the research objectives and significance of the study will be presented. Then, section two examines the relevant literature. Section three discusses the research methodology. Section four provides findings and implications. Finally, section five concludes the paper and recommends future research directions.

1.1 Objectives of the Study

In a bid to assess the impact of learning culture and use of information technology on students’ knowledge sharing in KFUPM, the study specifically aims at:

1. Determining the impact of learning culture on the students’ knowledge sharing.
2. Evaluating the role of IT on students’ knowledge sharing.
3. Assessing the level of knowledge sharing and learning culture of the KFUPM students and
4. Assessing whether knowledge sharing and learning culture differ among demographics of KFUPM students.

1.2 Significance of the Study

Literature search revealed that, to date, no research has been conducted on the role of learning culture and use of IT in promoting knowledge sharing in the Kingdom of Saudi Arabia. Thus, the result of this study may be relevant to various stakeholders in the Kingdom. To the government authorities of education in the Kingdom, the understanding of how knowledge is been shared (Brown and Duguid 2000) is important in attaining the government strategic plan of transforming the country to knowledge-based economy. Hence, the findings of the study with respect to the level of the knowledge sharing will be of great significance to this end.

The management of KFUPM may also find the results of the study of immense practical benefits because there is a need, in the first place, to know those factors that impact knowledge sharing among students before embarking on any strategy and program of supporting knowledge management in the university. From an academic perspective, this study's insights will add to the existing literature on the impact of learning culture and IT use on knowledge sharing in general; and in Saudi Arabia in particular where none exist. Therefore, the study is of significant value to practitioners and scholars alike.

2. LITERATURE REVIEW

2.1 Knowledge Sharing

Organizational success in today's dynamic and fiercely competitive environment depends largely on the ability to leverage knowledge to develop competitive capabilities to aid in developing new products, services and processes that outperform those of rivals (Kogut and Udo 1992, Nickerson and Zenger 2004,
Szulanski 1996). Knowledge is regarded as a fluid mix of framed experiences, values, contextual information, and expert insights that provide a framework for evaluating and incorporating new experiences and information (Davenport 1997). Many other definitions are abound (Davenport 1997). With respect to categorization of knowledge, there is no consensus in this regard. Researchers have identified different types of knowledge (Nonaka and Takeuchi 1995). The most common classification, however, is between explicit and tacit knowledge (Nonaka 1994).

While it is easy to transmit explicit knowledge through formal language, it is much difficult on the other hand to convey tacit knowledge (Nonaka and Takeuchi 1995). This is because explicit knowledge can be made readily available in the form of files, library collections, or databases (Nonaka and Takeuchi 1995). However, tacit knowledge is difficult to express in words or to codify in documentation. It mainly resides inside individuals’ brains (Hlupic and Rzevski 2002). It is the personal knowledge that is embedded in individual members and used by them in performing their work (Argote and Paul 2000).

It should be noted that knowledge is not an end in itself, but rather means to an end. Thus, only by harnessing and exploiting the collective wisdom and knowledge of their members can organizations adapt and develop innovative processes, products, tactics and strategies (Alavi et al. 2005/2006, Maccoby 2003). A technique widely championed by organizations in order to achieve this end is knowledge management. Knowledge management demands that knowledge should be obtained, produced, shared, regulated and leveraged by a steady conglomeration of individuals, processes and IT (Benbya and Belbaly 2005). Knowledge sharing, as a dimension of knowledge management, is in turn defined as the provision or receipt of task information, know-how and feedback regarding a product or procedure (Cummings 2004).

Knowledge sharing can also be seen as a social interaction culture, involving the exchange of employees’ knowledge, experiences, and skills through the whole department or organization. Knowledge sharing comprises a set of shared understandings related to providing employees access to relevant information and building and using knowledge networks within organizations (Hogel et al. 2003). It is the voluntary dissemination of acquired skills and experience to the rest of the organization (Ipe 2003).

At the individual level, knowledge sharing is referred to as the talking to colleagues to help one get something done better, more quickly, or more efficiently (Lin 2007). Sharing of knowledge at the individual level is the most critical to an organization, even though it may exist at other levels of an organization that include team and organizational levels (Lukas et al. 1996). Individuals can realize synergistic results greater than those achievable individually by sharing their knowledge (Cordoba and Isabel 2004).

Moreover, knowledge sharing occurs not only at the individual level, but at the organizational level as well (Lin 2007). For an organization, knowledge sharing is capturing, organizing, and transferring experience-based knowledge that resides within the organization and making that knowledge available to others in the organization (Lin 2007). A firm can successfully achieve promotion of knowledge sharing culture not only by directly incorporating knowledge in its business strategy, but also by changing employee attitudes and behaviors to promote willingness and consistent knowledge sharing (Connelly and Kelloway 2003, Lin and Lee 2004).

There are several antecedences, organizational and otherwise, to knowledge sharing. These factors include the organizational structure, organizational culture, leadership, information systems (Davenport and Prusak 1998, Bock, et al. 2005, Ardichvili et al. 2006), avoidance of embarrassment (Burgess 2005), obligation, trust, and identification (Faraj and Wasko 2002), individual ability (e.g. subject expertise, tenure) (Wasko and Faraj 2005), greed, self-efficacy (Lu et al. 2006), extrinsic rewards, fear of punishment (Burgess 2005), expected rewards, expected associations, expected contribution (Bock and Kim 2002), perceived costs, extrinsic benefits, intrinsic benefits (Kankanhalli et al., 2005), anticipated extrinsic rewards, anticipated reciprocal relationships, sense of self-worth (Bock et al. 2005) among
others. The outcome of knowledge sharing that includes productivity, task completion time, organizational learning (Argote 1999, Argote et al. 2000, Cummings 2004), enhancing innovation performance and reducing redundant learning efforts (Scarborough 2003) have been examined by a number of studies. Conversely, the absence of knowledge sharing is likely to undermine knowledge management efforts (Calantone et al. 2002).

### 2.2 Learning Culture

Both private and public organizations are increasingly recognizing the importance of culture as an essential prerequisite for readiness and willingness to learn (Calantone 2002). Simply, culture can be referred to as a system of shared values and assumptions. It influences employee interaction, organizational functioning, and even decision making in organizational settings (Lukas et al. 1996). Culture is of great importance to the learning organizations including universities (Carleton 1997). It influences or inhibits, directly, the quality of learning (Szulanski 1996), which is of utmost concern in institutions of higher education.

According to Johnston and Hawke (2002), learning culture can be defined as the existence of a set of attitudes, values and practices within an organization which support and encourage a continuing process of learning for the organization and/or its members. A learning culture is said to exist in an environment where teamwork, collaboration, creativity, and knowledge processes exist that have a collective meaning and value (Joo 2007). For an organization to improve its performance, it requires a learning culture (Kumar 2005). Hence, development of learning culture is becoming a dominant theme in the strategic plans of many organizations today (Walsham 2002).

Developing a learning culture could help in gathering, organizing, sharing, and analyzing the knowledge of individuals and groups across an institution in ways that directly affect its performance (Kumar 2005). Learning culture benefits a whole organization and certain teams within the organization and it is essential in moving an organization to a learning one (Cohen 1990) which usually support knowledge sharing. Researches that focused on factors affecting knowledge sharing have identified the relevance of learning culture, among other variables (John 2001). In higher educational institutions, in particular, learning culture is needed for the institutions to create and disseminate knowledge that is necessary for the development of such institutions. Development of such learning culture in learning institutions may also create opportunities in accessing and sharing the right knowledge at the right time and in the right location to stay competitive in the global educational environment (Kumar 2005). Hence, it can be hypothesized that:

**H1:** The level of learning culture has positive effect on students’ knowledge-sharing behavior.

### 2.3 Information Technology

The role of the information technology (IT) in sharing knowledge has been a center of debate (Maccoby 2003). While some investigators are of the opinion that knowledge management (KM) initiatives could be successful without using IT tools (Mohamed 2006, Hislop 2002), other researchers have, however, identified IT as a variable that could impact knowledge sharing (Huysman and Wulf 2006) for the fact that technology is one of the important pillars of knowledge management (Maccoby 2003). Haldin-Herrgard (2000) maintained that a great deal can be done through modern IT to diffuse explicit knowledge. It is also becoming easier nowadays to capture tacit knowledge with the aid of retrieval technologies (Kumar 2005).

A study by Pai (2006) that examined the relationship between the effectiveness of IS strategic planning (ISSP) and knowledge sharing found that top management support for ISSP has a strong significant effect
on knowledge sharing behavior. A separate study in South Korea by Kim and Lee (1996) also found, among others, that both employees’ usage of IT applications and friendliness of the IT systems significantly impact employee knowledge-sharing capabilities. It can, therefore, be expected that individuals with more usage and favorable perception of IT may demonstrate more knowledge sharing behavior (Kumar 2005). Hence, it can be hypothesized that:

**H2:** The level of students’ utilization of IT has a positive effect on students’ knowledge-sharing behavior.

Based on the study objectives which were substantiated by the reviewed literature, the hypotheses of the study are eventually developed. These hypotheses are translated into the theoretical model depicted in Figure 1. The model presumes that learning culture and IT use have an impact on students’ knowledge sharing in KFUPM.

### 3. METHODOLOGY

#### 3.1 Data Collection and sample

In a bid to examine the impact of learning culture and IT use on students’ knowledge sharing in KFUPM, the study undertook a survey questionnaire method. The survey instrument reflected the conceptual framework depicted in Figure 1.

![Conceptual Model](image)

*Figure 1. Conceptual Model*

To ensure generalization of the study findings, the questionnaires were administered based on stratified random sampling to KFUPM students. A total of 200 surveys were hand-delivered to the graduates, undergraduates and preparatory students from all the academic departments in the University. A total of 142 questionnaires were returned; of which five incompletes were discarded. The final number of usable questionnaires was 137, representing 68.5% response rate.

#### 3.2 Measures

All the constructs of the study were measured from items adapted from previous studies, with some alterations to account for the peculiarity and setting of the study. To improve the reliability and validity, multiple-item measures were used for all of the variables. Responses were recorded along a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree) for all the items in the questionnaire. Learning culture was measured using 6 items adopted from Cordoba and Isabel (2004). The six items were meant to be grouped into meaningful cluster(s) by conducting factor analysis. Students’ IT usage was measured using 6 items from Kim and Lee (1996) and 1 item specifically designed for this study was added. Finally 6 items were adapted from Kim and Lee (1996) as a measure of students’ knowledge-sharing.
4. STUDY FINDINGS AND IMPLICATIONS

4.1 Profile of the Respondents

The survey questionnaires were distributed to each of the three categories of students, graduates, undergraduates, and preparatory students. Preparatory students are those students that are undergoing one year course toward starting their main bachelor degree. Undergraduates are those that are pursuing their four year bachelor degree courses. Both the preparatory and the undergraduate students are from different regions of the country, which makes the sample relatively homogeneous. On the other hand, graduate students are those students pursuing their postgraduate programs that include MBA, MS and PhD. The unique characteristic of the graduate students of the university is that they include students from different countries, not only from Saudi. The cosmopolitan nature of this category of the students may reflect the perception of students across different societies, hence enabling the study findings to be more generalized.

It can be inferred from Table 1, that 30.15% of the respondents were graduate students, 63.97% undergraduates, and the remaining 5.88% preparatory students. With respect to the GPA, it can be seen that only about 15% of the respondents have GPA of more than 3.75 and 16% with GPA of 3.51 - 3.75. On the other hand, over 50% of the respondents’ GPA is between 3.00 - 3.25 and less than 3.00. This seems to be quite representative of the population.

4.2 Reliability and Validity of Variables

Several major steps were carried out to enhance the reliability and validity of the variables. Factor analysis was first made for this purpose. Reliability was then utilized to check the internal consistency of the scales involved in the study. Coefficient alpha analysis was used to determine the extent to which items making up each measure were homogenous and loaded on the same scale (Allen and Yen 1979). Cronbach’s alpha has been suggested to be the preferable measure of index reliability. The scales used in this study were checked for their internal consistency.

Content Validity which determines the adequacy of the sample characteristics in describing the study measures (Nunnally 1978) has been established in the study. This is because the questionnaire used in this study built upon existing research where the scale items were found to be valid. For the construct validity, one technique widely used to assess such validity of an instrument is factor analysis (Kerlinger 1973). Various items that represent each dimension were analyzed to see if they are properly assigned to the appropriated scale (Carmines and Zeller 1980). Two criteria were used to identity the factor scales. First, all scale items that loaded less than 0.40 were removed. Second, a construct with the highest eigen value
would be represented by a factor. For the learning culture, all the items were found to be correlated with the factorial groups produced with the factor loading more than 0.40. Out of the 6 items, two factors emerged as can be seen in Table 2. The correlation result between these factors shows that the two factors are significantly correlated at 99% level of confidence. Thus, one factor was selected that represent the learning culture construct and named learning culture in KFUPM. This factor is the one with the highest eigen value of 2.844 and the percentage variance explained of 47.403 as depicted in Table 2.

Table 2. Correlation of Learning Culture Factors

From Table 3, it is evident that the Cronbach’s alpha of the construct, learning culture in KFUM is 0.777. Since according to the guideline of Nunnally and Bernstein (1994) the value of 0.7 or above is an acceptable reliability coefficient, hence the construct has exhibited adequate reliability. With respect to the Students’ IT usage, the result of the factor analysis indicates that one item has less than 0.40 factor loading. The item was hence dropped. The remaining five items eventually yielded a single factor with 0.678 Cronbach’s alpha. Though the Cronbach’s alpha not up to 0.70, the factor could still be considered reliable since it very close to .70 (Koch et al. 2005, Graham and Nafukho 2007, Chang and Lin 2007). Some of the items used for measuring IT use are those provided by the university (KFUPM) such as the WebCT, and other systems that are specifically designed by the university authority to promote learning. Other IT items used by students for knowledge sharing and learning include the email tools available in KFUPM Intranet and the Internet. Similar to IT usage, one item of the knowledge sharing has less than 0.40 factor loading value. The item was dropped and the remaining 5 items yielded one factor. The Cronbach’s alpha reliability for these five items was 0.744, which can be considered quite reliable (Nunnally 1978).

4.3 Study Findings

Recall that the first and the second objectives of the study are to determine the impact of each of the learning culture and IT use on students’ knowledge sharing respectively. Since the appropriate analysis that assesses the influence of independent variable(s) on dependence variable is regression analysis, two simple regression analyses were run to test the two proposed hypotheses. The choice of the simple regression analysis in assessing the impact of both learning culture and IT use on the dependent variable is that each of the two variables has a single dimension. Moreover, The R² of both learning culture and IT use models explains knowledge sharing behavior of students in KFUPM. From the results of the regression in Table 4, it can be deduced that the learning culture in KFUPM, which has a positive
coefficient Beta, as hypothesized has significant relationship with students’ knowledge sharing. Hence, the first hypothesis is fully supported that learning culture has positive impact on the students’ knowledge sharing in KFUPM.

Table 4. Summary of Regression Analysis

Similar finding was achieved from the regression analysis result in same Table 4 of the positive influence of IT use on the students’ knowledge sharing in KFUPM. The second hypothesis is equally supported. Furthermore, the $R^2$ of the two regression models, which are 0.487 and 0.151, indicate that 48.7% and 15.1% of the overall student knowledge sharing is explained by the learning culture and IT use independent variables respectively.

a. Predictors: (Constant), Learning Culture in KFUPM, Information Technology
b. Dependent Variable: Knowledge Sharing
Furthermore, the result of regression in Table 5 shows which Information Technologies items more used for knowledge sharing. It can be inferred that the coefficient (beta value) of the item "It is easy for me to use the university's information systems without extra training" is higher showing this IT items contributes more to knowledge sharing and the least item that impact knowledge sharing is "I regularly use the KFUPM's databases (e.g., library e-database, etc)".

Table 5.  Summary of Regression Analysis

To answer the research question of the level of knowledge sharing and the learning culture of the students, one-sample t test analysis was undertaken. Since the scales for knowledge sharing and learning culture are all on 5 point Likert scales, the test value of 3 was used and the result in Table 6 shows that all the means are significantly different from neutral value 3. These findings indicate that the students are more inclined toward satisfaction than dissatisfaction with both the knowledge sharing and the learning culture.

Table 6.  One-Sample Test of Level of Knowledge Sharing and Learning Culture

The last research objective aims at examining how the learning culture and the knowledge sharing of the students differ according to the demographics. The results of the ANOVA in Table 7 below report such relationships. The results indicate that the level of the knowledge sharing among students is not significantly different with respect to both the students’ GPA and their category because the p > 0.05. This implies that the students share knowledge irrespective of their GPA or their category. However, with respect to the learning culture in KFUPM, ANOVA results in Table 6 show that the level of learning culture in KFUPM is significantly different among students with different class of GPA, though no significance difference exists between different categories of students.

4.4 Discussions and Implications

The findings of the study of the impact of both learning culture and IT use on knowledge sharing among students has important implications to the management of KFUPM as well as other sister institutions. The reason is that because in their effort to enhance knowledge sharing which is inevitable in promoting learning (Graham and Nafukho 2007, Haldin-Herrgard 2000) the management of KFUPM and other higher institutions should opt to at least instill the culture of learning as well as invest more in IT and ensure more usage of IT by their students.

The finding of learning culture as a contributor to knowledge sharing shows that knowledge sharing factors do not depend solely on technology. In fact, the study finding that learning culture accounts by about 48.7% to knowledge sharing against IT use that accounts by only 15.1% is of practical implication and implies that effort toward promoting learning culture may be more viable in promoting sense of knowledge sharing between the students. To achieve this, there is need to organize some orientation courses, seminars among others to instill the etiquette of positive learning culture in the students. It can be envisaged that it may be wise to consider integrating learning culture in the course syllabi design. In the same vein, the finding with respect to the demographics that level of the knowledge sharing of the students is the same irrespective of their GPA and their category implies that, when designing a knowledge sharing program it can be standardized to all students in the university.

5. CONCLUSIONS AND FUTURE RESEARCH

Based on the study results and discussion, it could be concluded that the usage of IT and learning culture are significant variables that affect student knowledge sharing in higher institutions, and KFUPM in particular. The presence of learning culture as the major contributor shows that knowledge sharing factors do not depend on technology alone. It is suggested that in a bid to improve student knowledge sharing, the appropriate authorities and decision makers need to commit efforts and programs that could enhance learning culture and IT usage among students. In spite of the originality of this study for being one of the few that examined the influence of social and technological factors together, learning culture and IT use, on student knowledge sharing in the Kingdom of Saudi Arabia, it suffers from some limitations that are common to many other researches.

One of the chief limitations is that the sample size is relatively small and needs to be increased. To account for the sample size limitations of the study, further studies can consider respondents from several universities, possibly including female respondents, to ensure more generality of the findings. In addition to the learning culture, further studies can expand this study to include other factors that may impact students’ knowledge sharing. Also, the impact of IT on collaborative learning is another area where further research could be viable.

Abstract

The uncertainties of information system development (ISD) provide many routes that end in poor project outcomes. These uncertainties produce opportunities for IS researchers who are continually exploring the complexities of information system development. In this paper, which is a work-in-progress, we are focusing on the implementation of enterprise systems in three universities in Malaysia.

We adopt a socio-technical process model which provides us with a vehicle to describe an in-depth analysis of the phenomena under examination. By examining the notions of technology and knowledge transfer in ISD, this paper explores the intricate relationships and interactions between its human and non-human actors in the attempts to construct various network alliances. We end with some suggestions for research and practice.

Keywords: information system development (ISD), universities, transfer of technology and knowledge, socio-technical modeling, actor-network theory (ANT)
1 INTRODUCTION

Researchers in enterprise system implementation in universities show indicates that one of the main motives for their implementation is to replace legacy systems (Wagner et al. 2006; Pollock & Cornford 2004; Wagner & Newell 2004; Scott & Wagner 2003; King et al. 2002; Oliver & Romm 2002; Allen & Kern 2001). The systems which were once the backbone of the organization have with time become obsolete. Organizations today require more robust contemporary systems that are able to cope with ever changing and intensifying market competition. Replacing a legacy system is not just a matter of changing components. It may also require a complete overhaul of the organization itself. That is why it is common to see failures in enterprise system implementation in universities due to the complexities of the specifications, functional inadequacies and lack of political support (Pollock & Cornford 2004; Wagner & Newell 2004; Scott & Wagner 2003). However, not all project failures are due to organizational complexities. Understanding organizational compatibility with project managers and vendors plays a vital role in ensuring smooth project implementation.

In general, the data analyzed in this paper was derived from three Malaysian universities where each of these organisations had technological and personnel connections with the others. While the discussion will concentrate on the enterprise system implementation project in one of the universities, some of the discussion will apply to the other two. Our study was guided by the following research questions:

1. What are the key actor networks in the development process and how do the networks develop and interact diachronically?
2. What are the implications for research and practice resulting from our findings, particularly for similar institutions?

The structure of the paper is as follows. Part two provides a summary of the main features of actor-network theory. In part three, an overview of the research methodology which includes the case description, data collection method and data analysis is presented. This is followed by the presentation of the findings in part four. Part five revisits the research questions in an attempt to better understand the phenomena. The paper ends with conclusions that have emerged from the study.

2 PREVIOUS RESEARCH

2.1 Actor-network Theory (ANT) and the process of translation

According to Latour (1993) the world is full of hybrid entities which contain human and non-human elements (Tatnall 2003). The development of these hybrid entities is facilitated by the heterogeneous nature within the information system environment. ANT is unique as it is engaged in both sides: ANT attempts to discuss the heterogeneity of elements in forming a network while also examining the asymmetry of its elements. In relation to generalized asymmetry, Latour (1993, p. 95) has described it as a rationale of symmetric treatment in observation on the relationship between technical computer systems and social organizations where all human and non-human elements are treated equally and are labelled as actors or actants.

---

1 In this paper, implementation refers to an on-going process which includes the entire development of the systems from original suggestion through to the installation of the system (Lucas 1981) and development refers to a stage within the implementation process.
The next concept we will use is the actor-network. This is considered as the most crucial part of ANT and looks at the process of building a network of actors. This process involves several main activities including interactions, negotiations and translations. In our research we will focus on the process of translation and in this paper we will concentrate on Callon’s four phases of the translation process (Callon 1986). The first phase is the problematization. In this phase an issue or a problem will be identified and the role of each actors affected by the issue is defined. In this phase, some actors will establish themselves as indispensable to the solution of the problem (McMaster et al. 1997). They consider themselves to be the ‘obligatory passage point’ (OPP).

This process of translation is continued with the phase of interessement. According to Cordella and Shaikh (2003), translation is a circular process of interpretation of interest. Interessement is a group of actions by which an entity attempts to impose and stabilize the identity of the other actors it defines through its problematization (Callon, 1986). The moment that an actor accepts the interest defined by another actor is called enrolment (Callon, 1986). This point of enrolment can only be observed through time and it is crucial for a researcher to identify each of the different stages or phases of network building. According to Hanseth et al. (2004), during this process, programs-of-actions are inscribed where roles, competencies and responsibilities are delegated between the actors within the network. This is further elaborated through the concept of circularity of the translation process which, according to Cordella and Shaikh (2003), ensures that the interest of all actors within the future network is properly inscribed within the network. According to Latour (1992), inscription (the fourth phase) is a process of creating technical artefacts that ensures the protection of an actor’s interests (Sarker et al. 2006). In layman’s terms, this process can be considered as the signing of a memorandum of understanding (MoU) that binds the party to a specific objective or in ANT terms, interest. For example, a centralized enterprise system can be seen as an inscription of the interests of management who commissioned the project. However the system can become subverted to the interests of other groups in the process of its development.

3 RESEARCH METHOD

3.1 Case descriptions

This study takes place in three universities in Malaysia that are similar, yet possess unique features. It is their similarities and uniqueness that have made this research challenging and produced a number of surprises.

![Figure 1 Inter-organization transfer of technology and knowledge](image)

*Figure 1 Inter-organization transfer of technology and knowledge*
Case 1

This is the youngest of the three universities and was established in 2002 when they implemented the integrated management system (IMS). With a current enrolment of 3,000 students and 1,000 staff, the need to maintain and further improve the IMS was essential and ongoing. The implementation of the enterprise system was an integral part of the university’s strategic planning and was initiated during the university’s infancy. This has ensured the smooth internalization of an electronic working culture. The head of ICT in Case 1 was later employed as the project manager in Case 3.

Case 2

Established in 1922, this is the oldest education institution in Malaysia and under the mandate of the university act, it became a full university in 1997. The problems that arose from the islands of legacy systems created the need for a more integrated information system. Today, this dynamic and mature university comprises 16,000 students in addition to a compliment of 580 faculty and 764 management staff. The experiences and the expertise over the years have produced more stable and fully tested business processes. The implementation of such a large enterprise systems in this culturally-developed organization was completed seamlessly in 2005.

Case 3

This university was also established in 2002, and represents an amalgamation of nine institutes which were previously managed individually. The diverse operational processes among these previously independent institutes brought about a call for an integrated management system (IMS) similar to that adopted in Case 2 to enhance their operational efficiency. With 13,000 students supported by 2,000 de-centralized staff members, the establishment of a single integrated database was thought to produce a more efficient management of resources. This two-year project launched in February 2007 has experienced the greatest number of problems encountered in any of the above noted IS development projects. For our study we will focus on one component of an integrated management system, an integrated finance module.

While the above description has emphasized the unique nature of each individual case, the one element that is common among all three cases is the ‘system’ (Figure 1) which has been developed on the same base system (V0 above). Depending on the timing of their implementation, any new system enhancements or modifications are integrated into the latest version. This refers to V1 and V2 in Figure 1. The system for Case 2 was developed based on Case 1’s latest version. The system for Case 3 was built upon the latest version of Case 2. Whilst Case 2 is more mature in terms of its operation compared with Case 1, the base system for Case 3 was deemed to be more up-to-date and more comprehensive. However, the project manager in Case 3 resigned in August 2008, just seven months after her appointment. The project is currently being managed by the information technology department (ITD) of Case 3. As of the last visit management has no intention of appointing a new project manager.

Table 1. The interview schedule – Cases 1, 2 and 3

Proceedings ECIS 2009
Table 1 represents the list of interviews conducted during the field work in July 2008 but during the second round of interviews in March 2009, we have managed to gain responses from other actors related to the cases especially with the ex-project manager of Case 3.

The research will attempt to analyze the socio-technical relationship during the process of ERP system implementation. Therefore, the interviews were conducted with as many ERP system stakeholders as possible in order to gain an in-depth understanding of the process. Interviews were tape-recorded and verbatim transcripts were produced.

### 3.3 Data analysis

Since this paper is a work-in-progress, the analyses of the data are only based on the available transcripts to date. Further interviews and data gathering will be undertaken in due course over the next year. The analysis began with developing a project timeline analysis for all the three cases. Initial analysis of the project timelines shows interesting yet diverse issues between the three cases. Upon reading and re-reading of the interview transcripts, a matrix of project critical events together with direct quotations was produced. During this process it became apparent that the relationship between the cases was also significant in regard to the personnel involved (their knowledge) and the vendor and its technology (the base system). Hence, this is the focus of the paper.

Next, we focused on identifying critical events that occurred during the relationship. Since the focus of the paper will be on Case 3, attention was paid to the antecedent conditions of the other two cases in relation to the third one. Based on these historical experiences, a more in-depth understanding was achieved. Finally, we applied the notion of translation within ANT to explain the dynamics of the interactions and relations during the enterprise system development. According to Monteiro and Sahay (2000), applying ANT in IS research requires the identification of key actors, interests and scenarios and to follow them through time and this is what we are attempting in this paper.

### 4 FINDINGS

Generally, the analysis of the findings in this paper will be based on the socio-technical process model which links antecedents, event processes and context to outcomes (Lyytinen & Newman, 2008).

#### 4.1 The story of an enterprise system implementation through a socio-technical process account – Antecedent conditions

At the time of writing, Case 3 was already one and a half years into the two-year project period and approximately only thirty percent of the finance system has been developed and deployed and as of March 2009 the project period has lapsed. But still the finance system is only thirty percent developed and used. Why have they not been able to complete the other seventy percent of the system? What went wrong in this project? This paper is not an attempt to solve the problem but to better understand the phenomena of the case under study. The notion of transfer of technology will be used to further examine this case study. By adopting a process study model, this paper will use four sections: antecedent conditions, the process, context and the outcomes.

The complexities of an information systems development are not only due to the technicalities of the system itself but most of the time are also due to the intricate relationship between its socio-technical elements. In this paper, the understanding of the antecedent condition of the related actors is crucial. But understanding the history of the organization alone will not be sufficient. We assert that due to the complexities of IS development, an in-depth understanding of the history and background of the vendors (software developers) and the project managers are also crucial to our story.
4.1.1 The university as a unique organization.

The main characteristic of the organization that should be considered in IS development is the establishment of the university which is itself an amalgamation of nine institutes. But as a result of being "nine under one roof", many management problems surfaced. One of the most important issues within the organization was the streamlining of the business processes:

"...the implementation of the finance system is to make sure that the processes are standardized throughout the campuses..."

Senior General Manager (Finance) – Case 3 (17/07/2008, p. 1)

The legacy system of the university did not provide solutions to their problems. With more dispersed campuses and a higher number of students, having a non-integrated system created chaos. Within these campuses also, there were different ways of doing things with very different management styles. In addition, different work styles between the top management and the middle management posed challenges to achieving a successful project.

4.1.2 Vendor (system developer) as one of the important components of IS development

The process of identifying a suitable vendor to supply and deliver an enterprise system is one of the most crucial parts of any project. Usually, the assurance that is given to the clients in providing a complete and usable system develops high expectations among the clients. In this particular case, the assurance or guarantee from the vendor to provide a workable system stems from their previous experiences in the same industry. A successful implementation of prior projects (Cases 1 and 2) provided that confidence. Based on the previous projects, there are several criteria that needed to be fulfilled to ensure project success. The most critical was the transfer of knowledge between the vendor (system developer) and the technical team of the organization. A dedicated technical member attached to a module ensured knowledge was captured and utilized. As the prior client in Case 2 mentioned:

"...the good thing about the project is that our ICT team have efficiently captured the development knowledge that enable us to stand on our own... even our ICT team have understood the debit and credits of accounting transaction and the links in the systems..."

Project Manager (Finance) – Case 2 (08/07/2008, p. 10)

He adds;

"...even after the UAT [User Acceptance Test] there are still minor changes to ensure the completeness of the system and we have to thank the ICT team... they are able to adopt the knowledge and settle some of the problems themselves."

Project Manager (Finance) – Case 2 (08/07/2008, p. 10)

A successful transfer of knowledge ensures an uninterrupted progress of system development. Another important criterion is the user’s capabilities to provide complete and stable business processes. A well-developed business process that is derived from years of operational experiences ensures a smooth development for the vendors. The only development issues would be the integration aspect of the systems which was resolved through continuous coordination and integration meetings and discussions. But in contrast to these positive aspects, the inability of the vendor to comprehend or adapt to different organizational cultures has created some uncertainty towards the current project.

4.1.3 Project manager as the key player in IS development

The project manager often plays a very important role in IS implementation. Due to their complexities, managing such a vast enterprise-wide project requires the multi-tasking capabilities of a project manager. Wide knowledge and experiences in both technical and human aspect of the projects are vital
in ensuring project success. In this case, the 20-years of experience of the project manager in IS implementation gave confidence to the clients. In addition, most of her experiences were based within the educational environment. Prior to Case 3, the project manager handled a similar implementation (i.e. Case 1) as well as a more recent one which was an e-management system. Holding the post of Head of ICT, she initiated the implementation of an enterprise system using a rapid application development (RAD) strategy.

“...so far [an] IT project fails because it takes too long to finish the development.”

Ex Head of ICT – Case 1 and Project Manager - Case 3 (24/07/2008, p. 1)

She further explains:

“...to be successful, this system owner... should understand the nature of system development and rapid approach because they can’t expect the software to be perfect at the 1st time when it is installed. Because of the rapid development we just deploy the 1st draft so that the user can start using it and start improving it based on their actual requirement... the system owner must be aware that they are evolving in the system development, it is part of the software development, it is not like having a complete software, this is a process of software development that the system owner must be involved 100% in the development and improvement of the software...”

Ex Head of ICT – Case 1 and Project Manager - Case 3 (24/07/2008, p.1)

According to her, there are several pre-requisites for a successful RAD implementation. The skills and knowledge together with the commitment of the system developer (vendor) are essential. However, to date, she was not able to replicate her previous success in Case 3 by applying the same concept and strategies acquired in Case 1.

4.2 The story of an enterprise system implementation through a socio-technical process account – The crisis identification

![Figure 2 The 'intention baggage’ or project actors antecedents](image)

Figure 2 provides a summary of the historical background of the projects. Each of the actors identified in the projects have brought their own intention baggage or expectations to the projects. We have

---

2 Because of space considerations we were not able to include the full process model description based on Lyytinen and Newman (2008). This will be explored in a future paper.
already noted that after two years of the development project only thirty percent of the finance system is developed and deployed. What has gone wrong? In the first part of this paper we have discussed the antecedent condition of the situation under study. It is pertinent to understand the history of the case before any further analysis is made. There are several important issues that need to be explored.

The need for such a system was identified due to the complexities of the new organizational structure. The implementation of an enterprise system will create a more streamlined and standardized business processes. The vendor (software developer)’s prior development with other clients provides a basis for an educational system’s best practice. This project tried to build upon the existing best practice and further improve the systems. For the project manager, the rapid application development (RAD) approach, proven to be successful in previous projects, was to be replicated in this project with the same intention to reduce the development time of the project.

While the intention of the clients remains intact, the actors within the project organization have caused the crisis in the IS implementation.

4.2.1 Misunderstanding of project complexities

The adoption of rapid application development (RAD) approach by the project manager together with the ‘adapt and adopt’ method by the vendor have caused chaos within the project development team. The overall project period was two years. It seemed appropriate initially. But when the project manager came in and tried to develop and use the student intake modules within six months, the user went ‘haywire’.

Although the approach was agreed unanimously in the steering committee meeting, it created doubts in the mind of the user. This was further worsened by the fact that the project manager worked on the project on a part time basis and not full time as in her previous projects. Crucially, her control over the project was further impeded because she was not able to create a coalition with the chairman of the steering committee and the IT director. Since there was no alignment of interests between the project manager and the top management, the pre-requisites for a successful RAD approach were missing. The project manager failed to create a coalition with the chairman of the steering committee and the IT director in contrast to her previous experience. This could be due to the fact that the top management did not see the importance of the approach itself or the top management had a ‘laid back’ working style or they were not powerful enough to handle the dominant middle manager.

“…the chairman of the steering committee is not very powerful due to the fact that he is not able to control the group by giving leeway to them.”

Vendor (system developer) – Case 3 (01/08/2008, p. 3)

The intention of the vendor (software developer) to just employ the ‘adapt and adopt’ approach was also scrapped when fifty percent customization of the so called base ‘best practice’ system was agreed upon. In an unfavourable comparison with the vendor’s other clients that manage to adopt the approach, the non-standardized business processes in Case 3 created the need for such major customizations. Currently, the reengineering of the business process is being carried out in parallel with the business requirement study (BRS) sessions.

4.2.2 Misalignment of project expectations

The project manager’s critical misinterpretation was the simplification of the business process. While mainly concentrating on ensuring a smooth flow during the student intake, no attention was given to the more critical back-end process of the related modules. This was critical for the finance modules when her attention was given only to the process of issuing invoices to students rather than looking at the overall accounts receivable modules. This surfaced when the user (finance) was asked by the project manager to sign off the user acceptance test (UAT) for accounts receivable only after the student registration.
The failure of the project manager to assess the organization capabilities to comprehend such a tight deadline created major issues. This meant that the users were not able to develop complete and stable business processes through a formal process of re-engineering. As agreed by the users, a thorough re-engineering exercise of the current business processes seemed crucial due to the fact that Case 3 was an amalgamation of nine institutes with different organizational processes. To make things worst, the scepticism over the system escalated when the user’s requirements did not match the vendor’s existing ‘best practice’ systems. This has instantiated the need for a customization and to date, according to the vendor, fifty percent customization has been carried out.

The departure of the project manager from office after only seven months has strained the relationship between the user and the vendor. There are many reasons speculated for her leaving. According to the vendor, the dominance of the user over the project steering committee is crucial to understand her departure. Lack of support from the chairman of the steering committee and the IT director can also be seen as a motive for leaving the project. Primarily, the task of a project manager is a boundary person or a ‘buffer’ between the user and the vendor. Thus, the absence of the project manager has caused a direct impact on the vendor. Any system modifications have to be completed by the vendor. Unlike the vendor’s previous clients, the successful transfer of knowledge from the vendor to the IT team has enabled the clients to modify the used systems rather than relying to the vendor alone.

5 DISCUSSION

We begin by revisiting in turn the two research questions raised at the beginning of the paper:

1. What are the key actor networks in the development process and how do the networks develop and interact diachronically?

In this particular IS implementation case study, it can be clearly identified that there were attempts in creating alliances or networks to achieve the project’s objectives. In this case both the intended network failed due to the involvement of the various actors and consequently the pre-existing organizational network became stronger and more robust.

The problematization phase was seamlessly completed by the project manager in that she was able to create the need for a rapid system development methodology for the Case 3 IS implementation project.

Top management, the users, the IT department, the vendors and the project itself were identified as the key actors within the IS implementation. The project manager established herself as the obligatory passage point (OPP) for the project implementation. Everyone agreed on the need to develop and use the related modules within six months of the implementation process and according to the project manager this could only be achieved through RAD methodology. The intended networks are portrayed in figure 3.

Over time, the consensus that was achieved during the steering committee meeting on the application of RAD seems to have deteriorated. This was due to the project manager’s failure to understand the complexities of the organization and its unique history and features. Through her experiences she recognized the pre-requisites of a RAD approach but failed to acknowledge the organizational resource capabilities that have created chaos in the project. All her planned devices in ensuring interessement within the built network collapsed. Her plan to create a coalition with top management to ensure control over the project was diminished by the user/ middle manager’s dominance over the chairman of the steering committee. In addition there is no evidence showing she had achieved a good relationship with the IT director, further reducing her control over the project.

The project manager’s lack of judgment over the organizational readiness towards new approaches severely impacted the overall project management thus resulting in her failure to create the network, leading to her departure from the project. The project manager, during the interview session, foresaw that the project would eventually fail. This resulted from her failure to create a partnership with the steering committee that could have then supported her.
Further attempts to form a network between the vendor and the user within the organization took place. The vendor faced no issues during the problematization phase since the users identified the challenges of business process disintegration and non-alignment due to the merger. The latest version of the base system, the vendor, the user, the steering committee and the project manager were identified as the actors related to the problems and the vendor with its prior experiences and expertise established themselves as indispensable to the solution.

The base system, which was initially seen by the user as a perfect match to what was missing in their daily operations, was later viewed by the actors as incomplete and not full-proof. Negotiations and re-negotiations over the need to conduct a comprehensive business process re-engineering or major customizations over the based systems created tensions between the vendors and the users. Furthermore, the absence of the project manager in the complex relationship has reduced the indispensable position of the vendor in favour of a user-dominant network. The legacy left by the project manager on rapid development methodology has also impacted the overall development plans negatively.

The users were now more focused on modifying and enhancing the current system rather than concentrating on the undeveloped modules (Figure 4). The users established themselves as indispensable to the need for creating a more complete, full-proof and fully tested system.
Imposing themselves (i.e. the customer is always right) over the vendor to ensure compliance has to a
certain degree achieved enrolment. With their strong control over the steering committee and lack of
intention to appoint a project manager, the users are confident that they will complete the system
although it will take more time.

In summary, both failures to complete the process of translation are due to the strength of the existing
networks formed within the organization between the top management, the middle managers and the
IT director. This created a problem for the vendor and the project manager when they tried to impose
their wills in order to establish alliances.

2. What are the implications for research and practice resulting from our findings?

This work-in-progress paper provides multiple pictures of actors in action. As discussed earlier, each
of these actors had their own implicit intention or expectations towards the project. These intentions
and expectations were being translated into actions during the project executions. However, the
process of translating intentions and expectations into executable actions must be done with extreme
care and justification. In our case, there are several instances where the converted intentions are not
doable and are thus rejected. The IS development project site resembled a war zone where all the
players had strategies and an action plan. Therefore, when the project manager came into the project
site, based on her previous experiences, she had strategies that she thought no one could challenge.
She possessed technical skills as well as soft-skills. But everything was based on her experiences.
When she laid out her plans to the steering committee, they were identical to her previous projects and
did not take into consideration the uniqueness of the clients and her own capability as the project
manager. As clients they agreed with a strategy that provided them with the most up-to-date system
that can be developed and used as fast as possible.

Due to her inadequate judgement over the client capabilities, frustrations were revealed in all the key
players. The project manager also became frustrated since she was not able to realize her plans and left
the project. According to the project manager, the failure to create relationship with the steering
committee was due to the fact that they (the steering committee) saw her as an outside person (part of
the vendor) rather than a team member within the project. The users were frustrated due to the fact that
they could see what is going wrong but were not able to communicate with the project manager who
was too preoccupied with her own strategies.

Lastly, the vendor, who was frustrated as a result of the project manager’s concept of ‘ongoing
modifications’ that cause them to waste most of their time modifying old systems rather than
developing new systems. From the recent interviews conducted with other actors who dealt with the
project manager, she was not comfortable in her role. Clearly, the research will find resonance with
those studying enterprise system implementations and practitioners will recognise the problems arising
from a failure to establish usable networks with the client. In our further work we will explore these
issues in greater depth.

6 CONCLUSION

This paper is a research-in-progress and the dynamic of the enterprise system implementation project
in Case 3 has produced the continuous emergence of major events. To date, the two-year project
period has lapsed with little improvements to the percentage of completion for the finance system.

At thirty percent completion, the vendor pulled out of the project site with the argument that the
project period had come to an end. Prior experiences of both the vendor and the project manager are of
little help in this case scenario since they are not able to replicate their history. i.e. What worked in
Cases 1 and 2 seemed of little help in Case 3. The dominant network that existed before the project has
inevitably been reinforced by events. We will continue to monitor the major events of case three when
we analyse the interviews from the March 2009 visit and will provide updates to our story of
technology and knowledge transfer in this university setting.

Abstract
This paper examines the adoption of software product line engineering to implement digital differentiation of physical products. The introduction of such software-based variety can typically be challenging for firms innovating within the realm of a manufacturing paradigm. In particular, the mutual dependency between the organization design and product design of new product developing firms may counteract attempts to induce change through software product line engineering. On the basis of innovation theory and the notion of isomorphism, the paper presents a case study of digital differentiation at one of the world’s largest automakers, GlobalCarCorp. Relating to the literatures of software product lines and product families, the contribution of the paper is a lens through which to understand the role of isomorphism in implementing digital differentiation in new product development. In addition, practical implications are derived from this in-depth study.

Keywords: digital differentiation, IS implementation, software product lines, innovation, innovation management, isomorphism.
1 INTRODUCTION

The digitization of physical products is radically challenging the innovation processes of established firms. On one hand, it multiplies the space of digital options for not only incrementally improving existing offers but also to launching radically new services on the market (Jonsson et al. 2007). On the other hand, seizing emergent digital options is difficult because current product innovation practices may not involve necessary IT capabilities and organizational agility (Sambamurthy et al. 2003).

In the innovation literature, the tension between options provided by a new technology and institutionalized practices established over longer periods of incremental innovation has received significant attention (Abernathy 1978; Abernathy and Utterback 1978; Anderson and Tushman 1990; Hargadon and Douglas 2001; Tushman and Anderson 1986). In particular, the notion of dominant design captures how institutionalized innovation practices typically congeal over time as a template for product innovation within an industry (Teece 1986). Dominant designs help firms organize their innovation processes so that they capitalize on their intellectual, relational, and technical resources. In particular, successful firms orchestrate a reciprocal relationship between organization design and product design. Baldwin and Clark (2000) refer to this relationship as the fundamental isomorphism between task structure and design structure.

While the fundamental isomorphism between organization design and product design is important to exploit a dominant design, it lowers a firm’s capability to respond to technological discontinuities (Anderson and Tushman 1990). The introduction of digital technologies in physical products represents such a discontinuity for manufacturing firms. While existing processes embed an innovation logic fine-tuned for a tangible, hardware-based business, embedding software into existing product architectures introduces an alien innovation logic requiring new architectural knowledge (Andersson et al. 2008). A pressing issue is therefore how to handle these parallel logics when organizing innovation processes.

This paper focuses on the adoption of software product line engineering for implementing digital differentiation of physical products. This focus directs the attention to two literatures on modularity, currently divided along disciplinary lines. First, the body of literature on software product lines is concerned with strategies for managing software families in a way that facilitate flexibility and modularity (Clements and Northrop 2001; Pohl et al. 2005). This software engineering-literature has its origins in Parnas’ (1976) work on software families, and has evolved as a result of the growing complexity of handling and exploiting software innovations. Second, the product family literature is concerned with platforms as a means for achieving product differentiation without compromising mass production advantages. This body of literature has emerged within the context of the product innovation literature, addressing the concerns of manufacturing companies in areas such as the automobile industry (Karlsson and Sköld 2007), camera industry (Robertson and Ulrich 1998), and office material industry (Cooper et al. 2001).

The contribution of this paper is a lens through which to understand the mutual dependency between organization design and product design in implementing digital differentiation in new product development. Drawing on innovation theory and the notion of isomorphism (Baldwin and Clark 2000), we present a case study of such differentiation through software product line engineering at one of the world’s largest car manufacturers: GlobalCarCorp. The following research question is addressed: How can software product lines be implemented to leverage digital differentiation in firms innovating in a manufacturing paradigm?

The remainder of the paper is structured as follows. Section two reviews the extant literatures on product families and software product lines. Section three outlines the theoretical framework including the notion of isomorphism. While section four presents the research methodology, section five outlines the case of software product line engineering at GlobalCarCorp. Analyzing the case, section six outlines implications for theory and practice, while the last section concludes the paper.
2 RELATED LITERATURE

Throughout this paper, we refer to digital differentiation as a software-enabled process that identifies, implements, evaluates, and maintains distinctive characteristics of a physical artifact relative to other artifacts of the same class. For the purposes of this paper, we review two streams of literature that relate to digital differentiation but yet are divided along disciplinary lines. First, reviewing the innovation literature, product differentiation has been an established topic for long. The research on mass customization (Pine II 1993) as well as product platforms and families (Halman et al. 2003) are of specific relevance in the context of this paper. Second, research on software-based differentiation has emerged within the software engineering community, typically oriented towards methodologies for managing variety in specific software families (Clements and Northrop 2001; Clements and Northrop 2003; Pohl et al. 2005).

2.1 Product Family Research

Product differentiation has been addressed quite extensively in the innovation literature (Aaker 2003; MacMillan and McGrath 1997; Pine II 1993; Robertson and Ulrich 1998). Conceptualized as product family, platform, or line research (Halman et al. 2003; Robertson and Ulrich 1998), one of the main themes of this literature has been the challenge of achieving a differentiated offer to customers without increasing cost and development time proportionally. The implementation of differentiation attributes on a common architecture promises to maintain or increase the market share and keep customer attention (Aaker 2003). The typical approach to this challenge is the development of a common architecture, which allows for the delivery of well-adapted products while maintaining a high degree of commonality of components (Lundbäck and Karlsson 2005). In this regard, mass-scale advantages can be combined with customization (Pine II 1993).

Managing product families can be challenging. As an example, Karlsson and Sköld (2007) note how multi-branded strategies typically involve counteracting forces linked to commonality and differentiation. On one hand, the commonality force directs attention to identifying a common solution for a set of brands identified as a product family. On the other hand, differentiation within this family is important as to avoid brand “cannibalization”. It has been observed that careless search for commonality opportunities through common architectures may cause negative revenue effects (Kim and Chhajed 2000).

2.2 Software Product Lines

In the software engineering community, software product lines have emerged as an increasingly important research theme (Clements and Northrop 2001; Pohl et al. 2005). The introduction of digital technology in physical products enables new forms of differentiation that do not rely on hardware changes. In this regard, costly development of new tools and models for each product change is virtually avoided. Firms introducing software product line engineering are promised to achieve product differentiation in a more cost effective way (Kreuger 2002). Indeed, it is argued that the use of software product line engineering not only results in lower costs, shorter lead times, and increased variety, but also in higher quality of software products belonging to the same family (Ereño et al. 2006).

Reflecting its software engineering origin, the literature on software product lines is design-oriented in its emphasis on better methodologies for managing software families. As outlined by Clements and Northrop (2003, p23) “a software product line is a set of software intensive systems sharing a common, managed set of features that satisfy the specific needs or mission and that are developed from a common set of core assets in a prescribed way”. To this end, domain engineering (Pohl et al. 2005), or core asset development (Clements and Northrop 2001), is the process where identification of common and variable features of a product family is accomplished.
Pohl et al. (2005) distinguish five iterative steps of domain engineering to ensure variability of the common assets: product management, domain requirements engineering, domain design, domain realization, and domain testing. First, product management sets the direction of the project and manages consumer goals throughout the software development process. The objective is to develop the product roadmap to the extent it is possible in a given point in time. The second step is to determine common requirements of the domain. The following two steps involve designing a solution, which is later implemented. The last step of this iterative process is to test the domain solution. While these steps resemble any single system development process, the emphasis on identifying commonalities within the software family and the options of variability makes software product line engineering promising for accomplishing software-based differentiation.

3 THEORETICAL FRAMEWORK

The literatures on product families and software product line engineering are important backdrops in our quest of understanding digital differentiation of physical products. However, in these streams of literature, little attention is paid to the relation between organization design and product design. Given the received innovation literature on dominant design (Anderson and Tushman 1990; Teece 1986; Tushman and Anderson 1986) it would be useful to further investigate the institutional challenges evoked in introducing digital differentiation in the new product developing process in firms designing and manufacturing physical products.

Isomorphism is an established concept within institutional theory (DiMaggio and Powell 1983; Meyer and Rowan 1977; Scott 1995; Zucker 1977). In this paper however, we draw on Baldwin and Clark’s research (2000) on design and industry evolution. In particular, we apply their layers of structure (LoS) model and its relation to fundamental isomorphism as a lens with which to understand the role of institutional arrangements when transforming innovation processes assembled for hardware-based differentiation into processes suited for digital differentiation. The LoS model distinguishes three different layers of structure important in product innovation: artefact, design, and task structures. On the most basic level, the artifact structure refers to the tangible instantiation of a particular design. In other words, the artifact structure is what can be seen, heard, touched, and used. It simply performs functions that create value for its user. Encompassing its architecture and functions, the design structure is a description of the artefact. In this regard, it is not only the technical blueprint of the artefact but also defines the adaptability of the design to changing circumstances and markets. Typically, physical products embed a modular architecture, enabling flexibility because of its implementation of independence between structural elements of the design (Baldwin and Clark 1997; Sanchez and Mahoney 1997; Ulrich 1995). Lastly, task structure refers to the set of activities needed to be performed to realize a design. The task structure implies organizational design elements including communication channels, information filters, and standard operating procedures (Henderson and Clark 1990).

In this paper, we are particularly interested in the relation between task structure and design structure. The received innovation literature describes alignment of these structures as imperative to enable successful new product development (Henderson and Clark 1990; Sosa et al. 2004). Referring to this relationship as the fundamental isomorphism, Baldwin and Clark (2000) not only underline the tight coupling between the two structures but also suggest the challenges involved when initiating change in either structure. In what follows, we apply the LoS model in general and the concept of isomorphism between design structure and task structure in particular for understanding digital differentiation through software product lines at a global automobile manufacturer. The next section describes our methodology.
4 RESEARCH METHODOLOGY

4.1 Research Setting and Design

Our case study research was conducted at one of the world’s largest automakers, referred to as GlobalCarCorp throughout this paper. At GlobalCarCorp, R&D operations serve many brands. The multiplicity of brands creates incentives to identify and develop product platforms for making differentiation economically feasible.

In 2005, one subdivision of GlobalCarCorp in Sweden received global responsibility for R&D on instrument clusters. This responsibility came in a transition period of instrument cluster design. Digital technologies were introduced into the design of instrument clusters including speedometer, tachometer, and other types of driver information during this time. This change in technological basis introduced a range of digital options for new types of differentiation within product families. Given its traditional hardware basis, however, digital differentiation also breaks with extant task and design structures.

Designed as case study research (Eisenhardt 1989), our 12-month study was initiated in November 2007 and was specifically focusing the 3-year process by which digital differentiation was implemented through software product lines at GlobalCarCorp. Exemplifying process research rather than variance research, the intention has been to identify and predict “patterned regularities over time” (Markus and Robey 1988).

4.2 Data Collection and Analysis

The data collection can be described as an iterative process. It consisted of three phases, as described below. Concurring with the typical case study, data collection also included multiple data sources including semi-structured interviews, meeting notes, workshop documentation, and email correspondence.

The first data collection phase included meeting attendance as to frame the area of concern. Analysis of meeting notes generated five areas of significant interest (development methods, organization, digitization, differentiation, and architecture), which, together with relevant literature, guided the remainder of the data collection process.

The data collection of the second phase mainly included recorded and transcribed semi-structured interviews. All in all, 25 interviews, ranging between 40 minutes and two hours, were conducted. The interviews were based on an interview template developed on the basis of the themes identified in the first phase. Respondents ranged from managers to developers, and they covered expertise such as software, architecture, graphical interfaces, ergonomics, design, and market. The semi-structured interviews improved the understanding of the organization’s task and design structures and how these changed with the introduction of the SoftCluster tool. Statements from respondents concerning one or many of the five significant areas of interest were especially focused on.

The third phase was confirmatory in character. After completing the first two phases, process charts of the software development and differentiation process were developed. These process charts were discussed with GlobalCarCorp employees as to verify and extend our preliminary understanding of the case. The findings were assessed in view of relevant literature. Then, the theoretical framework was applied to extend our ideographic understanding beyond the specific case setting.

Exemplifying engaged scholarship (Van de Ven 2007), workshops were organized with the project team over the last two phases to feedback new perspectives on their work practice based on prior research and empirical findings.
5 SOFTWARE PRODUCT LINES AT GLOBALCARCORP

In 2005, GlobalCarCorp designers working with instrument clusters introduced the idea of implementing software product line engineering. There were three main reasons for doing this:

- Controlling and managing software variants became significant as GlobalCarCorp decided to leverage from its portfolio of multiple brands.
- GlobalCarCorp initiated an economics of scale strategy with the intention to use the same hardware for many products, while accomplishing differentiation through software.
- The digitization of the car necessitated increased software development professionalism.

While the instrument cluster traditionally consists of hardware with little, or no, modification possibilities, the digitization of interfaces in the instrument cluster opened up new possibilities to present information in flexible and differentiated ways (see Figure 1). For instance, context-aware information presentation can be used to reflect the current condition of the car or immediate traffic situations. It also allows the introduction of new functionality and differentiation features in the instrument cluster.

Figure 1. Instrument cluster with fully reconfigurable display

GlobalCarCorp identified five product families to manage instrument cluster variants for over 80 car models, amounting to approximately 3.8 million cars each year until 2012. In addition, the new strategy involved separating hardware and software development. GlobalCarCorp intended to increase flexibility in the selection of hardware and software suppliers.

Different hardware requirements and cost requirements guided the process. Each cluster family was divided in different levels: base, mid, and high, representing levels of appearance and features. In other words, the complexity of handling software variants was considerable. Because of this complexity, GlobalCarCorp decided to adopt a tool that would facilitate the process.

5.1 The SoftClusterTool

The SoftClusterTool is a comprehensive XML-based tool for differentiation of the software architecture of instrument clusters. The tool enables the development of one basic software module for all types of displays in a specific product family. By using an editor, a HMI (Human Machine Interaction) engineer can differentiate the common cluster through changes to the XML-files controlling static data such as font, language, colors, layout, and graphics, or the dynamic data produced by functional units of the car. Examples of functional units are the FM tuner, phonebook, and thermometer, as well as units related to the condition of the car.

5.2 Implementing the New Process

Before adopting the SoftClusterTool, HMI engineers were responsible for the HMI portion of the instrument cluster on the basis of input from the design department and managers of functional units. HMI requirements and the overall cluster design would later be implemented by the selected instrument cluster supplier (see Figure 2). In this regard, the supplier was responsible for implementing and delivering the integrated cluster, including both hardware and software. Once implemented, GlobalCarCorp tested and evaluated the cluster. Changes and updates were then
collected and submitted to the supplier as change requests. This process was unique, although similar, for all brands within GlobalCarCorp.

A common problem of the traditional design process was differences in requirements interpretation between GlobalCarCorp designers and the supplier. In other words, there were often a gap between the final implementation of the supplier and GlobalCarCorp’s original intention. In addition, new requirements emerged over time, including seemingly minor issues such as change of a word, bitmap or a color. Since every update required contacts with the supplier, the process was both time consuming and costly. In fact, as a designers noted, late change requests were anticipated by the supplier and essentially an important element in their business model.

![Figure 2. GlobalCarCorp’s old task structure for instrument cluster design](image)

In view of the problem with change requests, the tool was adopted in 2005. The intention was to in-house the software for realizing digital differentiation, also called HMI software, side of realizing instrument clusters. Rather than having the supplier implementing change requests related to HMI software updates, the new process, enabled by the tool, attributed the instrument cluster suppliers the role of a component supplier only. Without prior experience of software implementation, new roles and tasks had to be defined at CarCorp.

Given that the software implementation previously was done by the supplier, cognitive ergonomics and interaction design competences had been prioritized within CarCorp’s HMI design group. In view of the new tool, people with programming skills in general and XML competence in particular were necessary. In addition, a new role was defined to cater for the idea of using the tool and the new process for accomplishing digital differentiation between brands in GlobalCarCorp’s product families. Before separating software and hardware, as was done in the new process (see Figure 3), each brand-specific cluster had a responsible manager.
Due to the significant effort put into developing the SoftClusterTool, however, little focus was nevertheless on adjusting the organization and process to harvest the anticipated benefits of the tool. The traditional way of developing information cluster with significant focus on hardware components and their design structure and coupled task structure remained at GlobalCarCorp.

One example of this prevalence of institutionalized practices was the lack of standard operating procedures for gathering and communicating software differentiation requirements from GlobalCarCorp stakeholders. In this regard, programmers were required to work proactively to acquire relevant information. This was both time-consuming and challenging because the programmers had to know exactly who to contact and what information to ask for. As a result, programmers often had to make decisions outside their obligations to meet deadlines and the overall productivity pressure. Essentially, they had to develop informal ways of gathering requirements, drawing on requests from people they already knew or were referred to by other employees. Ideally, such requests would involve perspectives from employees working on branding, interaction design, functional units (e.g., radio, antenna, or navigation) or cluster hardware. Without any general process in place, however, programmers of the HMI group often faced conflicting requirements and had to rely on individual judgment.

Before adopting the SoftClusterTool, the task of a HMI engineer at GlobalCarCorp was separated from other modules of the instrument cluster. Many decisions were made by the supplier, including the important task of pooling and integrating different requirements. While programmers face the consequences of the new tasks that the SoftClusterTool implies, other stakeholders at GlobalCarCorp were not fully aware of the new way of gathering requirements. Consequently, they drew on work processes already established before introducing software product lines. The anticipated benefits of the SoftClusterTool therefore remained to be seen.

6 DISCUSSION

Operating in a manufacturing paradigm, product innovation in the automotive industry is typically geared towards integrating different hardware components, or modules, into a fully functional product. As an important element in such integration, requirements engineering with regard to the different
modules and their interfaces is a core competence (cf. Sanchez and Mahoney 1997). Following the
digitization of the car, however, automotive design increasingly includes separating the software
elements from hardware ones. Following this design change, the relationship between the supplier and
the automotive firm is changing. Using our theoretical framework (Baldwin and Clark 2000), the
design change occasioned a change in the layers of structure of designing instrument clusters at
GlobalCarCorp. The digital options generated were challenging in view of the established
isomorphism between the established design and task structures.

The case presented in this paper illustrates the adoption of software product line engineering in
instrument cluster design at a global automaker. In particular, we examine the introduction of a tool
that was designed not only to enable flexible catering for change requests related to software but also
to allow for digital differentiation over product families. The SoftClusterTool was an attempt to
harvest commonality benefits on the hardware side of instrument cluster design, while achieving
differentiation between GlobalCarCorp brands with software. In this regard, the adoption of software
product line engineering was an attempt to implement a vision of digital differentiation.

Referring to task structure as the set of activities needed to be performed to realize a design (Baldwin
and Clark 2000), it is clear the adoption of the tool at GlobalCarCorp rendered some important
implications associated with the established isomorphism between design structure and task structures
in instrument cluster design: the redefined supplier role and the decoupled development of hardware
and software. In what follows, we explore these implications in view of the LoS model in order to
understand the innovation challenges faced by producers of physical products when attempting to
seize digital options.

6.1  Isomorphism and Parallel Task Structures

As noted in our case, the old task structure of instrument cluster design was highly dependent on
suppliers. While GlobalCarCorp specified, tested, and evaluated the implemented product before
assembly into the car, some core activities in the task structure were performed at the supplier
including hardware-software implementation and the coordination of hardware and software
requirements. Given that this division of work tasks was not only institutionalized in GlobalCarCorp’s
supplier relationships but also reflected in the dominant industry structure, the new design structure
occasioned by software product line engineering was challenging. Indeed, the debundling of hardware
and software design instantiated through the SoftClusterTool created a new situation for both
GlobalCarCorp and suppliers. At GlobalCarCorp, however, the task structure changes needed for
mirroring the design structure changes have not yet been fully completed. At the end of the study, it
could be noted that no real isomorphism existed between the design structure and task structure. As a
tangible example of this, the final products, the instrument clusters, currently lack digital
differentiation characteristics between brands (which was one of the main objectives at the outset). In
other words, despite a change in the design structure and the implementation of the SoftClusterTool,
prevailing task structures counteracted these initiatives.

There were three important aspects of digital differentiation and the established isomorphism between
task structure and design structure at GlobalCarCorp. First, one tangible change amounted to the
newly employed programmers, who were supposed to implement requirements submitted by
stakeholders throughout GlobalCarCorp. Because stakeholders such as brand managers, interaction
designers, and functional unit managers were unable to systemically supply such software-specific
requirements to SoftClusterTool users, however, they had to take on tasks for which they were not
responsible. This caused frustration among a key group of people involved in the digital differentiation
initiative.

Second, as a multi-branded firm, GlobalCarCorp viewed digital differentiation and software product
lines as elements in a strategy intended to combine commonality and differentiation. Given that such
strategies traditionally applies to the hardware side of the car (cf. Sköld and Karlsson 2007), the
corresponding strategy on the software side was completely new. It shifted major tasks of the domain
engineering process (Pohl et al. 2005) to GlobalCarCorp from suppliers. In this regard, complexity has increased and new patterns of requirements coordination and integration were needed. Even though GlobalCarCorp recruited programmers with XML knowledge, the new engineers could not fully accommodate the responsible task of handling the domain engineering process. Because GlobalCarCorp had no prior competence in the area, the new employees could not foster new requirement gathering processes with other stakeholders in the firm who still relied on the established hardware-related isomorphism between design structure and task structure. As an illustration, the differentiation plan (Sköld and Karlsson 2007) for the five different cluster families only included strategies for hardware differentiation.

Third, the institutionalized boundary relationships between suppliers and GlobalCarCorp were blurred. The old task structure had been instantiated and fine-tuned over many years. With the new initiative, a portion of that process remained, namely, the hardware and pre-installed software, while the differentiation software responsibility was taken on by GlobalCarCorp. This required new boundary-spanning behavior, where the old task structure needed to be split into two parallel ones (cf. Figure 3). In essence, the hardware set the rules and the software had to follow. As illustrated in Figure 3, the hardware was first developed and then software was added. This resulted in an inflexible way of handling software updates. While software is more flexible than hardware with regard to updates, adoptions, and adjustments, this sequencing downplayed the flexibility introduced by the SoftClusterTool. This advantage dissolved in the already introduced hardware constraints. It simply was not possible to make software updates as frequently and swiftly as the tool rendered possible due to lack of supporting task structures.

7 IMPLICATIONS

We report a case study of GlobalCarCorp’s proactive attempts to introduce software product line engineering for combining commonality and differentiation in instrument cluster design. Using Baldwin and Clark’s (2000) LoS model and the notion of isomorphism, we analyze this case for understanding the mutual dependency between organization design and product design in implementing digital differentiation in new product development. Our study has significant implications for the innovation literature on product families (e.g., Halman et al. 2003; Karlsson and Sköld 2007; Robertson and Ulrich 1998) and software product line engineering (Clements and Northrop 2001; Pohl et al. 2005).

In sum, in spite of attempts to introduce a new task structure around digital differentiation software in cluster design, our evidence pinpoints the difficulty for a manufacturing organization to establish software product line engineering processes that break with the fundamental isomorphism between task structure and design structure (cf. Baldwin and Clark 2000). Because the established isomorphism is based on a hardware paradigm that will remain in firms producing physical products, attempts to establish new design structures and task structures for the software portion of the sub-system are challenging. As illustrated in the requirement elicitation problems at GlobalCarCorp, the new task structure will be severely challenged by the dominant design and task structures related to hardware. This insight is a contribution to the software product line literature (Clements and Northrop 2001; Pohl et al. 2005), which tends to disregard surrounding processes, including hardware-related ones, when outlining their recommendations on how to accomplish software variety. In a similar vein, in its orientation on physical products only, the product family literature (Halman et al. 2003; Karlsson and Sköld 2007; Robertson and Ulrich 1998) cannot either cater for this observation. The innovation literature on product families tends to oversee the increasing digitization of physical products, thereby disregarding the new and relevant relationships emerging between differentiation across the digital and physical realms.

We believe that more research is needed in this domain in order to handle the innovation challenges and opportunities that manufacturing organizations face in a time when their manufactured products...
are becoming digitized. After all, a new set of core competences seems to be needed when seizing emergent digital options.

Abstract

There is a wealth of knowledge linking Information and Communications Technologies (ICTs) to human development, but Africa’s leaders have not used it well to develop its human capital. The continent has the lowest global levels of ICT diffusion and human development. This paper proposes a way of developing Africa’s vital access to knowledge through ICT, by reviewing and using the human development record of South Africa to develop a research framework for a human development – based ICT development strategy. The framework comprises a research-based bottom-up participative action program that responds directly to the specific information needs of the country’s socio-economically marginalized communities, the so-called “Bottom of the Pyramid” (BOP), by ensuring their maximum participation in the research and development process. The proposed framework draws liberally from the vast accumulated knowledge about human development and its principal tool, the ICTs, especially from Asia where similar development activities are delivering impressive results. The multi-cultural and multi-lingual characteristic of South African society, including its recent socio-political history, presents numerous challenges for balanced human development, but also unique opportunities to build an effective model for improving the usefulness of ICTs for human development in the country and by extension, in Africa as a whole.

Keywords: Human Development; ICT for Development, South Africa, Bottom of the Pyramid
1 INTRODUCTION

Soweto, South Africa, 2008: “Bra” (brother) Peter Wembe is a 64 year-old Soweto based jazz musician known as “Piwe” by his friends. He obtained a Bachelor of Music degree from a leading South African university in 1985. He lives with his wife, two unemployed daughters and a musically talented 15 year-old grandson Nelson. Nelson’s father, said to have been a budding musical genius himself, died of HIV/AIDS soon after Nelson’s birth. Piwe’s main source of income is an informal “Spaza” shop, a modified shipping container out of which the family sells basic groceries, cigarettes, soft-drinks and pre-paid telephone cards to the local community. The total family income from this informal business ranges from R2000 to R3000 per month (approximately US$2 per person per day). This income is supplemented by a few local jazz concerts each year, a few “Corporate Gigs” during end of year festivities, occasional international musical tours arranged by international jazz music celebrities who appreciate Piwe’s style and talent, and a small income from royalties on past recordings. Nelson attends an “informal” school near his home, but has largely lost hope of academic achievement. He rehearses diligently in the hope of emigrating to Europe or the USA as a professional jazz artist. Nelson has appeared on several local television talk-shows and documentaries promoting local young talent, but his contribution to the family’s income is minimal. The Wembe family have basic ICT literacy, an old personal computer with dial-up connection to the Internet, and they dream of establishing a small music studio from which they can produce and market their own commercial recordings. They also worry constantly about security, and their foreign-sounding surname which may provoke xenophobic violence against them, as has happened to many similar families in other informal residential enclaves throughout the country in May 2008 (HSRC 2008, UN 2008). Piwe is a third generation South African, his grandfather was an early migrant mine-worker from the then Belgian Congo.

The semi-fictitious story of the Wembe family is based loosely on a living family residing in Soweto at the time of writing this paper. Their names, ages and other identification features have been changed, but their lifestyle, their daily challenges and their hopes and fears are representative of the majority of South Africans residing at the bottom of South Africa’s social pyramid (BOP) (IFC, 2007), also called the “Second Economy”, a description coined by South Africa’s former State President Thabo Mbeki (du Toit and Neves, 2007). Their story puts a human face to this development discourse, and provides a useful foundation for addressing their needs to access information and knowledge via the global ICT infrastructure that will enable them to help themselves out of the vicious poverty cycle that afflicts so many South Africans.

The Human Development concept was introduced by the United Nations Development Programme (UNDP) in 1990 to replace GDP per Capita as the main measure of national development. UNDP publishes annual Human Development Reports (HDR), with each year focussing on a different theme of concern to humanity as a whole. The theme for HDR 2004 was “Cultural liberty in today’s diverse world”, a theme that harmonizes well with South Africa’s currently fragmented multi-cultural society. This paper draws extensively from the most recent HDR 2007/2008 (HDR 2007) which focuses on climate change and the search for human solidarity to combat the global threat, but also provides an extensive database of human development indicators. A full history and description of the concept is beyond the scope of this paper, however an excellent description of the evolution of the concept has been prepared by Stanton (2007). A broad definition of human development favoured by the OECD is “the process of enlarging people’s choices. Their three essential choices are to lead a long and healthy life, to acquire knowledge and to have access to the resources needed for a decent standard of living” (OECD, 2003). The human development index (HDI) is a composite index used to gauge development across these three choices (HDR, 2007).

The authors of this paper share the opinion that the most important human development choice is the choice to acquire knowledge. Without this choice, all the other human development choices will be undermined by the lack of historical and current knowledge of how they can best be achieved.
Information and Communications Technologies (ICT) are the most efficient knowledge dissemination tools today. They enable unrestricted information flows that support the creation and use of global knowledge for the full range of human development, bridging cultural, gender, geographic and even knowledge divides. ICTs have been closely linked to all the Millennium Development Goals (MDG), (Gilhooly, 2005), and their importance to global development has been stressed by Payaril (2005) who observes that “the divide between the income rich and the income poor, the technology have-s and the technology have-nots, the information rich and the information poor, has become the most serious political economic problem facing the world today”. This paper draws on the accumulated knowledge of both human development and ICTs, with specific reference to the South African experience, typified by the semi-fictitious Wembe family. In the next section, the human development challenges in South Africa are discussed. This is followed by discussions of ICT development in South Africa. Finally a brief outline of the proposed framework for ICT development at the BOP is provided in Section 4. The conclusion provides a speculative discussion of how the Wembe family and BOP compatriots could benefit from the proposed research.

2 HUMAN DEVELOPMENT IN SOUTH AFRICA

South Africa has the largest economy on the African continent with purchasing power parity gross domestic product (GDP PPP) of nearly US$470 billion in 2007, closely followed by Egypt with US$404 billion, and nearly twice that of Nigeria, the most populous and third largest economy on the continent. Despite this, South Africa faces one of the severest human development challenges on the continent. The human development statistics that follow quantify South Africa’s human development challenges, drawing statistical data from the UNDP Human Development Report (HDR 2007), the IMF World Economic Outlook for 2008 (IMF, 2008), Statistics South Africa (Stats SA, 2007), the South African Development Indicators (2008), and ICT-specific data from the International Telecommunication Union’s (ITU) World Telecommunications ICT Indicators 2007 (ITU, 2007).

2.1 HDI Indicators

South Africa (HDI rank 121 in 2005) was one of 17 countries that suffered a reversal in human development between 1980 and 2005. After steady growth from 1980 to a peak of 0.745 circa 1995, a major decline ensued which resulted in the HDI reversing to 0.674 by 2005, the third steepest global decline after Zimbabwe and Swaziland. The country’s HDI global rank fell 36 places from 1990 to 121st in 2005 (HDR, 2007). Figure 1 compares South Africa’s HDI to the averages of each major development region.

![HDI Trends: South Africa compared to major world regions](image)

*Figure 1 HDI Trends: South Africa compared to major world regions
Source: UNDP HDR (2007/2008)*
2.2 The Choice of a Long and Healthy Life

The choice to lead a long and healthy life is one of three main indicators making up the HDI (HDR, 2007). A key indicator is life expectancy at birth amongst citizens of a country, with subordinate indicators that include the impacts of specific disease pandemics. The key contributor to South Africa’s steep HDI decline shown in Figure 1 was the nation’s failure to control the spread of HIV/AIDS. In 2006, South Africa had the 6th highest prevalence with an infection rate of 18.8%, outranked only by the country’s neighbours Swaziland (33%), Botswana (24%), Lesotho (23%), Zimbabwe (20%), and Namibia (20%). As a consequence of the HIV/AIDS pandemic, South Africa’s life expectancy at birth declined to 53.4 years by 2005, a rank of 145 out of 173 countries, and the national probability at birth of surviving to age 65 years fell to 33.9% for South African males, placing South Africa 160th out of 173 countries in this longevity indicator (UNDP, 2007). For greater clarity on these vital HDIs, Figure 2 compares South Africa with Thailand, Colombia, Turkey and South Korea, selected for their demographic and economic similarities, and for their geographic representation.

![Life expectancy at birth; Probability of surviving beyond age 65 (males)](image)

*Figure 2* Life expectancy at birth; Probability of surviving beyond age 65 (males)

2.3 The Choice of Knowledge Acquisition

The choice of knowledge acquisition is another key indicator that makes up the HDI. It is assessed with regards to literacy rates and school enrolment ratios (HDR, 2007). South Africa’s national educational achievements have been disappointing. The PIRLS (2006) and TIMSS (2003) international education assessments comprising 40 and 46 countries respectively, ranked South Africa last amongst the participating countries with average achievement scores 61%, 57% and 51% below the global averages for reading literacy (PIRLS 2006), and mathematics and science (TIMMS 2003) respectively. Compounding these disappointing results is their racial characteristic. Data derived from South Africa’s 2001 census shows that 16.5% of Black South Africans (pre-colonial indigenous South Africans) had no formal education, compared to 3.1% White South Africans (of European only ancestry), 6% Indian South Africans (ancestry traceable to the Indian sub-continent) and 8.7% Coloured South Africans (descendants of mixed race unions irrespective of ancestral origin) (Stats SA, 2007). At the higher end of education, 12.8% of White South Africans had a diploma or first degree as their highest educational achievement, compared to 1.8% of Black South Africans, 5.9% Indian South Africans, and 1.7% Coloured South Africans. Figure 3 illustrates the educational divides between South Africa’s official race groups. The post-apartheid South African government has retained the
apartheid legacy of race-based classification as a means of monitoring progress in reversing apartheid era racial segregation and discrimination.

![Figure 3](image_url)

2.4 Access to Resources

The choice of having access to the resources needed for a decent standard of living is the third indicator that makes up the HDI (HDR, 2007). National poverty and wealth, the distribution of both, and inequality extremes are the popular measures of this choice. South Africa has the highest GDP in Africa, but also one of the highest levels of economic inequalities in the continent and the world. A popular measure of economic inequality is the Gini coefficient. A nation or community that shares its wealth equally amongst its members has a Gini of 0, while one in which all wealth is consumed by one person has a Gini of 100. UNDP HDR 2007/2008 reports a Gini of 57.8 derived from year 2000 surveys, while the South African government reports a Gini of 69 for year 2005. The rising level of economic inequality is recognised by the South African government and its development partners as one of the most challenging aspects of human development. Due to historical reasons, the country’s inequalities have a strong racial characteristic. Statistics derived from South Africa’s Development Indicators 2008 (PCAS, 2008) show that Black South Africans who constitute 80% of the population live off an average gross national income (PPP) of approximately US$2500, equivalent to that of Bangladesh and Haiti, while their White compatriots enjoy an equivalent income ten times higher, equivalent to high income economies like New Zealand (HDI rank 19) and South Korea (HDI rank 26).

South Africa’s unemployment levels are similarly skewed along racial lines, with 30.5% unemployment amongst Black South Africans, compared to 4.5% for their White compatriots (Stats SA, 2007). Inequalities of this magnitude are a source of conflict and social instability. Stewart (2000) concludes that in every major conflict, group perceptions and identities are enhanced by sharp differentiation in political participation, economic assets and income, and social access and well-being. These inequalities present a strong environment for conflict. Cramer’s (2005) analyses of conflict and inequality quotes Plato (circa 400 BC): “We maintain that if a state is to avoid the greatest plague of all - I mean civil war, though civil disintegration would be a better term - extreme poverty and wealth must not be allowed to arise in any section of the citizen-body, because both lead to both these disasters” to argue that the debate is as old as mankind’s strive for peaceful societies. By relating Cramer’s (2005) and Stewart’s (2000) analyses to South Africa’s inequalities and various media reports of historical and current conflicts throughout the world, troubling parallels emerge.

As, Cramer (2005) and Stewart (2000) argue, South Africa’s deep inequalities may not provoke internal instability, but conditions exist for this to happen. The outbreak of xenophobic violence in
May 2008 (HSRC, 2008) represents a disturbing harbinger of this possibility. In a related development, an important outcome of the World Summit on the Information Society (WSIS) was the establishment of a global research unit and think-tank of how ICTs can be used prevent conflict, and to help societies to recover from it after an outbreak (Mansell and Nodenstreng, 2007). The Switzerland based ICT4Peace Foundation is the UN specialized organ coordinating the global search for ICT applications that prevent and reduce the threats of conflict (Stauffacher et al., 2005).

### 3 TECHNOLOGY DIFFUSION - ICT

In this section, South Africa’s ICT development is compared to those of Colombia, South Korea, Thailand and Turkey, four countries with demographic and economic similarities with South Africa over the last 20 years. Table 1 illustrates these similarities, and shows that South Africa led the group in both economic and ICT indicators in 1980 and 1970 respectively, but lagged in both by 2005. South Korea’s impressive growth record has been attributed to aggressive mass education and rollout of ICTs, typified by the country’s early 1980’s policy to provide a telephone line to every family in the country (Reynolds et al. 2005). This policy has served South Korea well. The fixed line telephony infrastructure was the key to the country’s recent dominance in broadband access and Internet usage, the provision of cost-effective xDSL services on existing copper cable telephony infrastructure. South Africa has been slow to leverage the installed telephone cable capacity for broadband and other ICT services derived from it, even after studying and supporting the concept of Local Loop Unbundling (LLU) that is critical to its success. (DoC 2007).

Table 2: Basic ICT Statistics in the four benchmark countries. Data derived from ITU ICT database 2007 (ITU, 2007).

Table 2 provides basic ICT data for the four benchmark countries in years 1995 and 2005. Except for mobile telephony, South Africa’s ICT growth was lowest in the group. One disturbing feature of the data in Table 2 is that South Africa’s penetration of Internet users, fixed line telephones, and personal...
computers aligns with the country’s racial demographics. It is mainly White South Africans and a small but growing number of Black “First Economy” South Africans who enjoy the services of these knowledge-rich ICTs. The “Second Economy” population depends almost entirely on costly mobile telephone services for their information needs. Recent research by Skuse and Cousins (2007) concluded that the success of mobile telephony in South Africa had introduced an unexpected negative outcome: chronically poor mainly rural communities developed dependencies on the mobile telephone services, while their high usage fees effectively deepen chronic poverty.

High ICT user prices have been recognised by all South Africans and their international development partners as significant barriers to national development, as noted by South Africa’s Minister of Communications, Dr. Ivy Matsepe-Casaburri in her budget vote speech (Budget Speech, 2008). Figure 3 quantifies the depth of this barrier to development, and verifies the concern expressed by Parayil (2005).

3.1 South African ICT Policy and Regulatory Environment

Historically inherited race-based inequalities clearly dominate nearly all South African discourse on human development and its complex multiple facets. The national ICT policy and regulatory processes have not been immune. Costly and often damaging compromises between the need to ensure Black South African ownership and management of the critical ICT industry within the framework of national Black Economic Empowerment (BEE) policies, and the need to develop the nation as a whole have had to be made. A recent study by the Centre for International Development at Harvard (CID), a partnership that includes the National Treasury of the Republic of South Africa, poses the research question: Is Black Economic Empowerment a South African Growth Catalyst? (Or Could it Be…) (Andrews 2008). Andrews’ conclusions note numerous disappointing outcomes of the BEE policy, but remain positive that it could be a growth catalyst. One key conclusion proposed is that government should focus its BEE policy on the middle and bottom of the economy, the primary focus and helm of this paper.

A classic example of the conflict between implementation of the BEE policy and national poverty alleviation through ICT development is the recent case of broadband wireless spectrum allocation. On 17th June 2008, South Africa’s state regulator ICASA published a strict BEE policy for awarding the valuable 2-3 Ghz spectrum (ICASA, 2008). This required applicants to prove 51% Black South African ownership with an emphasis on women, unspecified Black South African participation in management and control, and skills development in line with national BEE policies (ICASA, 2008).
Just 3 days later on 20th June 2008, the USA Federal Communications Commission (FCC, 2008) published its approach to allocating this same spectrum. The FCC planned to license a single nationwide operator that would be obliged by regulation to reserve 25% of its network capacity for free pro-poor broadband access, 50% coverage of needy Americans in the first 4 years, rising to 95% by the time the license expires after 10 years (FCC 2008). The contrasts are stark. South Africa, a developing country chose to use invaluable broadband wireless spectrum as a political tool to reverse historical injustices, while the United States of America, arguably the biggest economy on earth, chose to use the same technology to bridge its socio-economic divide. A useful research question could be: of the two approaches, which one was more likely to reduce South Africa’s severe socio-economic inequalities and promote Black South African participation in the economy?

The complex uniquely South African dilemma of balancing historical injustices with future growth is beyond the scope of this discussion; however, valuable insights can be obtained from numerous studies and analyses. For example, Hodge (2008) provides a detailed fifteen-year review of South Africa’s telecommunications policy, observing the numerous failures to solve the pro-poor access and price conundrums. Horwitz and Currie (2007) provide a critical appraisal of the country’s ICT policy dynamics, highlighting in some detail the conflicts between liberalization, privatization and BEE ownership, and the costly errors that resulted from these conflicts. Fleming (2002) explores the role of ICT in developing the democratic processes in South Africa, and Brown and Brown (2008) propose a radical shift in South Africa’s definitions and perceptions of ICTs so as to enable policy-makers to focus more on their human development utility.

4 A RESEARCH FRAMEWORK FOR BOTTOM OF THE PYRAMID ICT DEVELOPMENT IN SOUTH AFRICA

The brief quantitative review of human development in South Africa presented in preceding sections of this paper justifies an urgency to take corrective action. Action research has been recognized as a means of ensuring relevance and applicability of ICT research to practice (Baskerville and Myers, 2004). A research framework for carrying out an action-based study is outlined in this section. The components of the framework are neither original nor unique. They draw liberally from the vast quantity of knowledge about ICT and development that has been accumulated throughout the nearly 250-year evolutionary history of electronic ICTs. They also benefit from the experiences of fully developed countries, newly industrialised countries, developing countries, and failing or failed states. An extensive database of knowledge about ICTs for development, and the successes and failures of different nations has been compiled to support the research framework. The major departures from traditional approaches to ICT research and development are:

- The primary focus is on the complex components of human development: the information and knowledge needs of South Africa’s socio-economically marginalized communities, and of the people tasked with supporting their development efforts. Prior research has shown the weaknesses of approaches that are techno-centric, where the focus is on technology rather than people (Roode et al., 2004).

- The complexity of human development demands that multidisciplinary and multi-institutional approaches be adopted. Each human development challenge, be it economic deprivation, knowledge acquisition, health related challenges, or inequitable distribution and high prices of ICTs are intricately intertwined. Fragmented approaches to reducing these challenges have generally been total or partial failures in most African countries. The low comparative levels of human development on the continent are clear proof of these failures. An alternative integrated approach is proposed in the framework, one in which research and development in all human development challenges are conducted simultaneously, and the ICT support solutions built from the results of this research, rather than taking a technological determinist view of ICT (Licker, 2001);
A balanced “Evolutionary” and “Clean Slate” approach to technological innovation for BOP-ICTs will be used. The challenges facing human development at the BOP have an uncanny resemblance to the challenges facing the evolution of the Internet (Schwarz da Silva 2007, Sung-Su Kim et al, 2008) - evolutionary tweaking versus radical redesign to overcome significant current problems. In this research framework, a balance between using traditional ICT networks, evolving networks in the form of Next Generation Networks (NGN) that tend to cater exclusively for the needs of the economically endowed, and totally new innovations for pro-poor ICT applications will be developed. The research emphasis will be on the information and knowledge needs, not on the technological means of delivering them, as advocated in techno-centric approaches (Roode et al., 2004);

A “bottom-up” approach will be used. The research focus will be on people residing at the BOP, the full range of sociological factors that influence their human development, their capacities to adopt, afford and use advanced ICTs, will be the innovation drivers. A strategy to integrate the “bottom-up” solutions with current and planned “top-down” development solutions will be a key factor of the framework. Purely top-down approaches to ICT strategy development are known to have limited success (Segars and Grover, 1999).

In developing the research framework, the complexities of creating and managing a multidisciplinary multi-institutional research and development team have not been underestimated. They have been accommodated in the research schedule with allowances for continuous review and adjustment. Thus far, the research process has been initiated, the initial proposal has been drafted and initial communications and canvassing support from potential researchers and funding agencies has begun. Intricate details of the emerging framework are beyond the scope of this paper, however, an outline is provided in Annexure 1. It is anticipated that a Steering Committee will have been formed by mid June 2009, and will be tasked with setting up the required management and research teams, their operational structures, and initiating the four phases of research activities over the planned duration of three years. A key outcome of the research will be to chart the path for continuous ICT for BOP development in South Africa, accounting for changing socio-economic environments and technologies (Avgerou, 2008).

5 CONCLUSION

This paper provides a short background on the key factors that should guide a human development-oriented ICT development strategy in South Africa. The challenges are immense, but they can be eased significantly by focusing attention on South Africa’s BOP market, or the “Second Economy” as it is popularly known locally. A concerted single-minded search for ICT solutions for this population group that are both effective and affordable is not beyond the national capability, especially with the support of modern ICTs. A detailed description and discussion of the proposed research framework aimed at addressing these challenges is beyond the scope of this paper, but expected and speculative outcomes can be discussed in relation to the fictitious Wembe family used to introduce the paper:

Soweto, South Africa, mid-2012: “Bra” Peter Wembe is now 69 years old. He travels less now, but enjoys the growing success of his grandson Nelson, whose growing international reputation as an avant-garde jazz saxophonist with a distinct African flavour reminds many global jazz fans of jazz legends like Charlie Parker and John Coltrane. The family has a more comfortable income: they extended their “Spaza” shop to include a jazz café with live music at the weekends, which is becoming a popular tourist destination. The café is managed by Peter’s daughters, and doubles as an Internet café during the day. They use a low-cost broadband service to source goods and services for their business. This service helped launch Nelson’s international career: he promotes his and Granddad’s original music compositions and performances through online streaming to the global jazz marketplace, and receives a growing number of lucrative live concert contracts as a result. They still dream of a recording studio, but this is getting more remote as real-time online opportunities emerge. Their
primary broadband access is derived from the excess capacity of the neighbouring supermarket’s fibre optical connections and servers. The supermarket was allowed by new regulatory provisions to follow the UK’s “Tesco Telecoms” model of reselling excess capacity to the local community (Tesco Telecoms, 2003). Peter’s Internet café servers provide fixed VoIP services to the homes of twenty neighbours who pay a fixed monthly fee of R50 for unlimited national voice services. An extended family relative maintains these and other similar services in the community. Peter thinks he could derive more revenues by reselling broadband, but that is in the pipeline waiting for his granddaughter to graduate with an IT diploma from the local polytechnic. Life for the Wembes has improved since the arrival of fast internet.

RECOGNIZING WORK PRIORITIES AND TASKS IN INCOMING MESSAGES THROUGH PERSONAL ONTOLOGIES SUPPLEMENTED BY LEXICAL CLUES

Tagg, Roger, Gandhi, Prashant and Srinivasan Kumaar, Raaj, University of South Australia, School of Computer and Information Science, GPO Box 2471, Adelaide SA 5001, Australia, roger.tagg@unisa.edu.au, prashant.gandhi@gmail.com, skraaj@gmail.com

Abstract

Email has been recognized as one of the chief sources of the current epidemic of information overload. The work described in this paper is part of an ongoing project to re-focus the attention of information workers on “what needs to be done” rather than “what someone wants us to read”. The approach is to base a software agent that pre-processes incoming email on the user’s “personal ontology”. The ontology used in this work contained two facets, namely Work Topics and Task Types, and also included lexical “clues” whereby, if such a word or phrase is found in the text of a message, the system can infer with a certain probability that a particular ontology concept (class or instance) is relevant. The paper describes the prototype tools developed and some initial trials. Further trials and improvements are planned.

Keywords: Information Overload, Task Orientation, Ontology, Lexicon.
1 INTRODUCTION

The concept of information overload has been recognized for more than a decade (e.g. Whittaker et al 1996). Suggested causes range from trends in the organizational climate towards mistrust, risk aversion and micro-management, e.g. (Allen and Wilson 2003) to the availability of too much information and of the IT facilities themselves, e.g. (Alberts 1996).

Many authors, e.g. (Mulder et al 2006) have stated that email is the biggest contributor to information overload. A workshop discussion in (Whittaker and Sidner 2005) reported, for example, that in the previous three years, the number of email messages has increased eight fold. Some organizations have instituted email-free days (Wakefield 2008) and some individuals have given up email as a main channel of communication, e.g. (Suarez 2008).

The search to find ways to use IT to relieve information overload is becoming more urgent with every year that passes. Without relief, information workers will find that they have less and less time to carry out the functions for which they are actually employed, and decisions they make may be adversely affected (Sutcliffe 2006). The authors of the current paper, following a series of earlier experiments (Tagg 2007) under the theme “Virtual Private Secretary”, have over the year 2008 developed a prototype that aims to address individual overload, primarily that arising from email. The principles of our prototype are that:

- It should be activity-oriented, i.e. it should be concerned with what we as individuals most need to do, rather than what email senders want us to read.
- It should reflect the collaborative nature of most information work, but from a federal, bottom-up viewpoint rather than a top-down “one group, many members” perspective.
- It should make use of the information that a computer system can provide about an individual’s work topics, contacts, priorities etc.
- It should not be so complex that an ordinary user will be deterred by the effort of setting up and maintaining it.

The remainder of this paper is organized as follows. We first describe our rationale for the approach we have taken and the stages of the work we undertook. Next, we give the details of our prototype system for recognizing work priorities and tasks, and some comments on the evaluation we performed. Following this, we discuss our approach for users to maintain their personal ontology including the lexical clues. We then outline some of the related work that is addressing similar objectives to ours, and this is followed by some discussion and comparison. We then conclude with some suggestions for future work.

2 RESEARCH DESIGN

2.1 Justification for using a prototyping methodology

According to Clay Shirky, reported in (Wagner 2008), Information Overload has been with us for so long that it should be seen as a fact of life, rather than a new problem; instead, the real problem is that our filters are no longer adequate. The work described in this paper, therefore, concentrates on one activity where, in the authors’ experience, better filtering seems to be particularly needed; namely that of incoming email messages.

The literature shows a wide range of theories for reducing information overload, ranging from intelligent software agents to organizational restructuring, personal goal re-appraisal and even speed reading. However so far there has been little evidence of success. One symptom is the lack of major improvements (Hall 2004) in task management facilities in everyday tools such as MS Outlook, or in
web browsers. We have therefore taken the approach of building a number of prototypes, based on relatively heuristic algorithms, to see what working with such prototypes feels like to users. A similar approach has been taken by other researchers in this field, for example the group at Xerox PARC (Bellotti et al 2007).

2.2 Review of alternative approaches to a prototype email pre-processor

Current commercial tools, such as Outlook, typically offer an email filtering facility using rules, with a wizard that helps the user express the desired rule. However Ducheneaut & Bellotti (2001) suggest that rule-based filters are not very widely used, suggesting that this feature is either not useful or is difficult to use. The same authors argue that filtering is mainly useful for filing schemes based on the identity of the sender, and offers weaker performance when required to deal with more complex categorization. Crawford, Kay and McCreath (2002) suggest that the process of composing rules is, for many users, cognitively demanding.

Another approach has been to extend the idea of spam filtering, where an approach based on Bayesian classifiers and machine learning is usually used. The application of this approach for categorizing emails into multiple categories (rather than just spam / not spam) can be found in studies conducted by Maes (1994), Segal and Kephart (1999), Mock (2001), and Crawford, Kay and McCreath (2002), amongst others.

Some other approaches address the recognition of tasks and priorities, rather than the categorization of emails. In current practice, the receivers of emails are highly dependent on the senders. Outlook, for example offers “follow up” and “high priority” flags; the sender can also send a formatted “task” as a message – though this does not seem widely used. Bellotti and her colleagues (2007) have approached tasks partly through recognizing threads of emails, coining the term “thrasks”. The more mundane reality, though, is that most users have to fill a form manually in order to turn a message into a task that would appear in a “to do” list.

Although historically, many proposed methods for email pre-processing have been based on Machine Learning, we have not followed this approach. Our reasons were:

- Machine Learning techniques depend on acquiring sufficient training data in order to build a competent classification system. The “slow start” problem, by which classifiers slowly build-up their competence as more examples are provided, may be more intense when a user has, say, tens of different categories rather than “spam/not spam”. A significant amount of training data, with user supervision, would therefore be needed in order to acquire strong classification results from the beginning.

- Making use of a personal ontology takes account of what is known in advance about the user’s work structure. Ontologies have recently gained increased attention within other research areas, and we believe that their application to email pre-processing is worth further exploration. However we recognize that, because user’s work structures change over time, a hybrid approach will be the most effective in the longer term.

2.3 History of previous prototypes developed within the authors’ research group

VPS (Virtual Private Secretary) is an ongoing project within this university’s Information Systems Laboratory, having started in 2005. Some of the earlier efforts on this project are described in (Tagg 2007). An overall view of the architecture of the current and planned components of the VPS project is shown in Figure 1. The upwards blue arrow represents the direction in which we think the user’s task interface ought to develop.
The numbers in the diagram refer to some of the prototypes developed within the VPS project up to the end of 2007:

1. An email pre-processor “TaskMail” that reformats emails, which contain one or more key words in a defined set, as tasks in a “to-do” list with links to the message body and any attachments.
2. A middleware architecture for aggregating tasks from different source applications such as Workflow, Project Management and ERP (Enterprise Resource Planning).
3. A “myTasks” portal that gives a unified to-do interface to tasks that come from different sources (e.g. workflow, project management, ERP system) via a unified TaskXML (Tagg 2007).
4. An Outlook add-on for importing tasks formatted in TaskXML into the Outlook task facility.
5. A “drag and drop” ontology editor called EzOntoEdit that allows users to import ontologies (OWL or CSV formats) into a personal OWL file and amend it graphically wherever possible (Einig et al 2006).
6. The VPS email categorization agent that is described in this paper, which uses the personal ontology maintained in 5 above.

In addition to the above, we also attempted in 2005 to support “sender-assisted” categorization, by means of a generator of “contact us” pages based on the personal ontology of the recipient, senders of messages being required to enter certain fields that give message context.

A further project in 2007 added into EzOntoEdit the facility for including “clues” in the user’s ontology. A clue is defined as a lexical string which, if detected in an incoming document, indicates (with a certain probability) that the document is relevant to a particular ontology category.

### 2.4 Attempting to ease the burden on the user in maintaining a personal ontology

However initial evaluation of the clue-enhanced EzOntoEdit ontology editor suggested that users would probably be discouraged by the effort required to fill in the forms needed to specify these clues. We were also concerned about the user’s workload in reacting to changes in the pattern of his or her work.
We therefore investigated the use of an automated text analysis tool, Leximancer (Smith 2003) which has been used in a number of domains to suggest both “Themes” (what a document is about) and “Concepts” (words or phrases most strongly associated with a Theme).

We applied Leximancer to collections of emails in two different ways:

- Documents created by concatenating all the emails - received or sent - that had been already archived by a user, into each of around 20 major categories;
- A single concatenated document of all the emails in the same user’s inbox that had not yet been archived.

The first approach aimed to detect significant differences in the frequency of words or phrases in the different categories, while the second approach tried to deduce themes *ab initio*; the desired number of themes being set as a parameter. While the results made some sense, we judged that:

- The influence of the chosen stop word list was very high.
- The effect of email senders including the text of previous emails in a thread was variable and unpredictable.
- Files of concatenated emails behaved quite differently from the single longer documents for which Leximancer had been designed.

We therefore decided to abandon this approach for the time being. This research is described in more detail in (Tagg, Lalwani and Srinivasan Kumaar 2008).

### 2.5 Research design approach eventually taken

We therefore split our work for the remainder of 2008 into two parts:

- To build a new prototype email pre-processor, this time one that separated the ontology classes and instances (in two dimensions, “work topics” and “task types”) from the lexical clues used; and
- To develop a better, more user-friendly approach to capturing the lexical clues from the user’s normal activities.

We would later bring these two parts together and test their effectiveness in predicting the work topic and “taskiness” – following a term coined in (Macbeth 2008) - against the manual judgment of users.

### 3 THE VPS CATEGORIZATION AGENT

#### 3.1 Mode of operation of the prototype

The mode of operation of our prototype is described in Figure 2 below. The letters show the high-level sequence of operation.

- Ontology maintenance (A1-A3) is discussed in section 4 below.
- The OWL ontology is converted to Oracle (B) for the agent’s internal purpose, although the definitive version is maintained in OWL XML format.
- Messages arrive in the user’s mailbox asynchronously (C), however …
- The email agent only reads the inbox at set intervals (D), during our trials, this was 5 minutes.
- Pre-processing (E) involves stripping off message bodies and attachments into separate web-accessible files, and tokenizing the message body and other fields.
- The context recognition stage (F) uses the ontology to tag the messages in one or more “work topic” or “task type” categories, the default being “uncategorized”.
- The user views the categorized task list, derived from a Tasks database (G1) in a “MyTasks” portal, with links to the original message text bodies and attachments on a web server (G2).
Our approach to categorization is a very simple and heuristic one.
1. Scan an incoming document for occurrences of any of the clue strings (words or phrases) in the user’s ontology.
2. Apply the concept of Indication Strength, which is the subjective probability that presence of the clue’s string indicates relevance to an ontology concept.
3. The Weighted Indication Strength (WIS) for each matched clue is then calculated based on multipliers that reflect the number of occurrences of the clue. These range from 1.2 (or a 20% raise of the indication strength) for 2 occurrences of the clue, to 1.75 for 10 occurrences or more.
4. Aggregate all the clues that refer to the same ontology category (class or instance) and add their WIS values.
5. If the total of the WIS values matches or exceeds the threshold value (default is 1.0), insert a row in the “categorized” table, and include URI links to the original message and any attachments.
6. Repeat for each category that is indicated by clues in this document.
7. Repeat for all documents received since the last clock event (currently, at 5 minute intervals).

The procedure is performed twice; the first time with respect to Work Topics, the second with respect to Task Types. The Task Types we used were as in Table 1 below. In our trials, we removed the middle “invitation” priority level for simplicity, and reallocated the Task Types as shown by the arrows.

<table>
<thead>
<tr>
<th>Priority</th>
<th>High</th>
<th>Invitation</th>
<th>Low</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>“Definite task”</td>
<td>“Conditional task”</td>
<td>“For information only”</td>
</tr>
<tr>
<td></td>
<td>“Reply only” (explicit request)</td>
<td>“Questionnaire” -&gt;</td>
<td>“Private communication”</td>
</tr>
<tr>
<td></td>
<td>“Vote”</td>
<td>“Conference invitation” --&gt;</td>
<td>“Uncategorized”</td>
</tr>
</tbody>
</table>

Table 1. Task Types used in the prototype.
The user’s ontology can be amended between clock events, and if it has changed, the new ontology will automatically be used the next time the in-box is processed.

The myTasks portal displays a scrollable table of inferred tasks, sorted either by Task Type within Work Topic, or vice versa. By default, only the high-priority tasks are displayed, but the user can choose to look at the low-priority list if he or she has time to do so. There is also an option to display the original email message body for a task on a table that has been highlighted by the user.

3.2 Evaluation of the prototype

In the time available we were only able to test the system against one user’s manual categorization. However this was done twice, once for an early version of the prototype and again for a later version when the task inference had been improved (by adding to the ontology some clues indicating template-based task-requesting emails that were repeatedly received). Both trials involved around 100 emails forwarded from the user’s live inbox. For Work Topics, performance was consistent in both versions with precision over 80% and recall 67%. Task Type categorization was less successful – precision was only 43% in the first trial and 62% in the second; recall was around 55% in both.

On reflection we felt that we still need to improve the ability to accurately infer tasks from the text of emails. Three particular problems appeared to contribute to these results

- a proportion of definite tasks were not recognized as such, due to the seemingly inexhaustible circumlocutions in the English language of asking for something to be done
- we did not have in the prototype a means of recognizing dates, which appear to be a good indicator of taskiness
- our “Conditional Task” category was too wide and did not distinguish between conditions that were quite likely to be true and those that were extremely speculative.

3.3 Results of an informal questionnaire carried out during the project

Halfway through the project, we demonstrated the prototype at a “project fair” to a mixture of students, academic staff and project sponsors from industry, and asked them to complete a questionnaire; 43 people responded, out of 70-80 people attending. We do not claim that this is a representative sample of users in the wider world, but we were interested to gauge initial reactions from people who saw our prototype working.

Over half the respondents reported that they regularly juggled 6 or more work streams. Deadlines were the chief driver to carry out tasks. People received 75% of their tasks through email, and they frequently “batch” tasks so that they get a run of doing similar tasks together. 80% declared an interest in trying a tool such as our prototype, although most said that they would like to keep the ability to look at the traditional email inbox view. The feedback suggested that we need to look more closely at peoples’ personal information habits and preferences.

4 GENERATING A PERSONAL ONTOLOGY AND CAPTURING LEXICAL CLUES IN VPS

This section details the work done on the ontology maintenance side of the project. Most authors, e.g. (Sheth et al, 2003) take the view that building an ontology, especially a complex one, is not a task for the average end user. We therefore need to find a mechanism by which the user can, relatively easily, generate and maintain a simple personal ontology and capture the lexical clues that indicate that a document relates to an ontology category. The EzOntoEdit tool (Eimig et al 2006) mentioned above is oriented to importing a pre-existing ontology from a work group or a domain, then tuning it to one’s personal preference, rather than creating it from scratch.
The problem remains of how to capture the lexical clues. Figure 3 shows a range of modes of capturing clues and the ontology structures to which they relate.

![Building ontology structure manually](image)

**Figure 3. Various Modes of Generating Lexical Clues for an Ontology.**

It has been rightly pointed out that, by adopting an ontology-based approach, we might be simply transferring the user’s workload to manually maintaining his or her ontology, instead of ploughing through a mass of emails.

While totally automatic maintenance of lexical clues seems unrealistic, it might be possible to do regular text mining of samples of recent documents and messages, and for the user to interpret those results. However our own experiences with Leximancer (Tagg et al 2008) suggested that such a system might turn out to be very complex. Semi-automatic approaches have been proposed, e.g. (Wang et al 2006, Fortuna et al 2006) but there are not yet many reviews of their user acceptability over an extended period. In our study, we decided on an intermediate - but fundamentally semi-manual - approach, assisted only by the importing of “blueprints” or “stereotypes” of the clues used by users doing similar tasks, and by the process of “snipping”.

![SnipCat main window](image)

**Figure 4. SnipCat main window.**
“Snipping” in our prototype is derived from the ideas of (Snip!t 2008) and from MS Internet Explorer 8 Accelerators (Microsoft 2008). A user highlights a word, phrase or name from any document he or she is working on (e.g. an email, Word document, spreadsheet, PDF file etc) and on the “Copy” command that text appears automatically in the prototype’s window. In Figure 4 above, the user has just highlighted and copied the word Andrew; that text appears in the top left window of our SnipCat (short for Snip Categorization) tool.

The Categories window allows the user to browse the ontology hierarchy and highlight the appropriate category. The Location window allows the user to specify where the text should appear; the options are From, Subject, Body and Anywhere. Indication Strength allows for “maybe” clues – the default is a probability of 1 (slider at extreme right). In the top right window the existing clues for the highlighted category Campus Related are shown. If the green tick is clicked, a Clue instance with Andrew, Subject and 0.9 will be added. Note that “Discriminator” is not the same as Clue, since Andrew might have other meanings, for example if it is in the From location.

One can have a clue that points to a whole Class instead of a particular Instance; currently this is done by highlighting the standard Instance None. Likewise, Other indicates assignment of the string to the next higher level Class.

SnipCat also allows for “Bulk Snipping”. If that button is pressed, the user is prompted for the path of a tabular file (currently MS Excel but potentially also a database), the Sheet (or Table) and the Name of a Column. A typical use would be to import list of contacts such as email addresses, surnames etc. These strings are all set up as clues to the ontology concept chosen.

SnipCat also allows for additions to the ontology, but only at the Instance level. Changes to classes currently require the user to switch to the EzOntoEdit tool mentioned in section 2 above, or some other OWL editor.

SnipCat was tried by 5 users. All found the method fairly easy to use, although to really judge whether or not people would use it, trials would have to continue over a long period. There was a wide range of complexity in peoples’ ontologies; the smallest had fewer than 10 classes with 20 instances and 30 clues, while the largest had:

- 6 work topic classes with 24 subclasses and 98 instances
- 8 task type classes, no subclasses and 27 instances
- 261 clues, split into 25% in the location From, 30% in Subject, 16% in Body and the rest in Anywhere
- The distribution of clues by indication strength (probability) was 67% for a probability of 1.0, 25% for 0.7 to 0.99, 8% for less than 0.7.

5 RELATED WORK

In recent years a number of major prototypes, several of them European funded, have been built addressing similar issues. The systems listed below all follow, to some extent, an ontology-based approach.

- DELOS (Katifori et al 2008) incorporates a PIMS (Personal Interaction Management System) based on a Personal Ontology. This group has explored alternative ontology visualization methods. Their ontology is significantly fuller in detail than that described in the current paper, and they recognize that it is critical to find suitable views to prevent the task of maintaining the ontology from becoming too complex. However, they do not appear to use a clear separation of ontology concepts and clues.

- NEPOMUK (Sauermann et al 2008) includes the concept of a Semantic Desktop, driven by a PIMO (Personal Information Model), which appears to be a form of Personal Ontology. A number of standard classes are provided, and users can add more using a tool. However automatic categorization, in particular of emails, does not seem to be included.
Perfect Digital Assistant (PDA) (Schraefel et al 2008) has been developed by a consortium involving MIT, University of Southampton and Nokia Research Centre. As in our VPS project, it aims to simulate the work of a personal assistant. It is built on a RDF representation of personal knowledge, which is partly fed by activity log mining, but does not yet appear to support email categorization.

DYONIPOS (Rath et al 2008) also builds up a user model by mining logs from the whole range of a user’s frequently-used applications and operating system actions. The resulting context “ontology” is expressed as a hierarchical structure of Tasks, Event Blocks and Events. Tasks are recognized automatically while the user is working.

The Semantic LS system (Krishnan et al 2008) is being developed by IIT Kanpur, India but with European funding. It is targeted at a P2P cooperation model, but for a private group rather than an open internet. A DKS (Domain Knowledge Model) is maintained as a taxonomy in OWL. It does not yet address email documents.

The following noteworthy systems, which are not ontology-based, should also be mentioned.

TV-ACTA (Bellotti et al 2007) is a development of work that has been going on at Xerox PARC since around 2001. TV (Task Vista) is a “to-do” list, while ACTA is an Activity Centered Task Assistant that works as an Outlook add-in. The system takes account of repeated “workflow-like” activity patterns. Earlier work (Taskmaster) looked at threads of messages related to tasks.

SCOUT (Sow et al 2006) was developed by a group within IBM. This appears to be primarily rule-based; the “context” referred to is primarily physical location. Their evaluation showed good results, but they only analyzed those messages that were generated automatically by software, which were only a small percentage of the total.

SmartMail (Corston-Oliver et al 2004), is a Microsoft Research development that “presents the user with a task-focused summary of a message. The summary consists of a list of action items extracted from the message. The user can add these action items to their ‘to do’ list.” Natural language processing is used.

Chandler (Chandler 2008) is a cross-platform personal information management tool that streamlines the links between emails, calendar appointments and tasks. It was originally designed by Mitch Kapor of Lotus 1-2-3 fame, and supported by the Open Source Applications Foundation. It appears to be one integrated PIM that is generally available.

It seems clear that the major software vendors are seeking a way forward in this area, but may be averse to the risk of prematurely launching a major enhancement to popular systems such as Lotus Domino/Notes and MS Exchange/Outlook. The typical user has yet to see any significant products addressing any of context recognition, task recognition or reducing the fragmentation that arises from having to use different applications for each different file type.

6 CONCLUSIONS AND FUTURE WORK

Most of the prototypes emerging from the projects listed above have been wider-ranging and are further developed than our own. We have limited ourselves to addressing email overload problems, partly because of resource and time limitations, and partly because we feel that email is the single most pressing problem.

Our own prototypes have many shortcomings; in particular, our ontology structure as it exists today is little more than a taxonomy, and is-a and part-of relationships are not always strictly distinguished. Our recognition algorithm is very simplistic and needs testing with more variations over more data. Its performance in inferring tasks from emails is so far only moderate.

Our evaluation process was very limited, due mainly to the strict deadlines imposed by the student authors’ thesis and project timetables. However it is worth commenting that it seems very difficult to obtain reliable evaluation of how tools - like those proposed here – would be received by real users in overload situations. Many related projects have used teams of student interns, but these may not be
representative. However the administrative and ethical challenges of testing, using active employees in a cross section of industries, seem daunting.

Our contributions have been:

- to investigate the idea of clue-enhanced personal ontologies
- to test the principle of using these for pre-processing (as a personal assistant might do) emails and potentially other documents
- to explore some of the issues in inferring tasks from incoming emails
- to test an alternative approach to capturing clues and instances in personal ontologies

We recognize that we have only scratched the surface of what is needed if these ideas were to become part of a widely usable tool with “critical mass”. Some of our current ideas for future development are:

- General improvements to our personal ontology facilities, e.g. incorporating WordNet
- Building a library of blueprints (both basic ontology and lexical clues) for common human roles
- Recognition of dates in text, especially where these are deadlines and therefore indicate a task
- Recognition of the relevance of a message to a specific activity within a work topic
- Use of the context recognition system as a component in a system for annotating observed activities in a grounded theoretic approach to group work (Blackburn et al 2007)
- Integration of non-email sources of tasks into the task database, e.g. “actions” from minutes of meetings that are stored in shared folders
- Investigation into improving the contribution of email senders towards categorization for the message receivers.
- An investigation of habits and preferences in personal information management for a range of users in different work environments.

However we feel that we have made a start on a potentially valuable approach to context recognition that strikes a balance between, on the one hand, a high-technology approach that is hard to implement and maintain, and on the other a more easily manageable – but possibly simplistic - solution.

THE EMERGENCE OF LANGUAGE CONSENSUS –
INTENSIFYING LANGUAGE INTERACTION IN INFORMATION
SYSTEMS DEVELOPMENT

Corvera Vargas, Marianne, Goethe University, Grüneburgplatz 1, RuW Building, 60323
Frankfurt, Germany, corvera@wiwi.uni-frankfurt.de

Abstract

As language is the venue for the concretisation of concepts and entities in information systems
development (ISD), language unambiguousness is understood as an ideal basis for the success of the
consolidation process in information systems development. In contrast, a fundamental postulation of
language theories is the inherent ambiguity of natural language. Therefore, the analysis of how
language consensus can be reached in an effective manner is of particular interest for collaborative
ISD. We claim that the effectiveness of ISD depends on the ability to manage the question of how
people deal with language in practice and reach consensus in the concrete ISD process. This
requirement leads us to the point of emergence of language: the language interaction setting. Hence,
we analysed the language interaction in an ISD project and identified different language interaction
levels which serve as orientation for specific interventions in an interaction setting, enabling an
intensification of consensus negotiation.

Keywords: ISD, Language Interaction, Emergence of Consensus, Communication.
1 INTRODUCTION

A central challenge in information systems development (ISD) is certainly the question how a coherent and meaningful model can be created out of the consolidation of different requirements and perspectives in the enterprise. As we understand ISD as a language development and formalisation process (Lyytinen 1985), the analysis of the consolidation process on a language level can provide an important contribution to this challenge. We argue that by characterising and analysing the use of language as an instrument for communication and for consolidation of an information system (IS) in the ISD setting, we can obtain helpful advice that enable us to enhance effectiveness in the emergence process of language consensus. Our main questions are: how language consensus in ISD processes is reached and how can we influence this process effectively? These questions lead us to the micro-level of ISD, the point where language consensus emerge, that is, the language interaction setting.

The relevance of the improvement of communication issues in ISD is obvious due to its impact on the ISD profitability. Alarming results of different requirements engineering surveys give an account of the failure arising in a significant percentage of software projects (Keil, Mann and Rai 2000, Standish Group International 2001). Some major reasons for this failures are e.g. the insufficient understanding of the integration in practice (Suchman 1995), information asymmetries, and goal incongruence (Keil et al. 2000). We propose: by improving the communication basis for the different stakeholders involved in the ISD process, we can achieve a better alignment of the IS with the business model of the organisation.

Along with the categorisation by Gregor (2006), the contribution of this article is the development of a theory that helps to explain and predict language interaction in ISD. Therefore, we emphasise on the role of language interaction by matching social interaction and communication theories with language theories. Our results emerge from the triangulation of positivist and interpretive research approaches on a research case (Lee 1991) and brought to light different strategies to deal with communication bottlenecks. At the end, we obtained different language interaction levels, which serve as orientation for specific interventions in an interaction setting, enabling an intensification of consensus negotiation.

We proceed as follows: In the next section, we locate the position of this article within the theoretical background of its field and introduce theoretical assumptions relevant to the contribution of this article. Then, we outline our fundamental theoretical propositions based on social interaction, communication and language theories for the particular ISD setting. After drafting our research approach in section 4, we present the results of the interpretive observation and the observed language interaction levels in section 5. Section 6 gives an overview on the application and embeddedness of language interaction levels in different observation cases and finally, section 7 presents an outlook and limitations of this article.

2 STATE OF THE ART AND PROPOSITIONS

Coming from a functional tradition, the IS research has been challenged by new alternative approaches since the 1980s (Lucas 1975). By the consideration of the contribution of those involved in and affected by the system, the understanding of IS as human activity systems gained significant attention (Robey and Markus 1984, Clarke and Lehaney 2000). A further focus addresses communication-related questions about the processes of social interaction in IS and ISD (Hirschheim, Klein and Lyytinen 1995a) and the existence of a practice fraught with volatility, exceptions, unstructured data and unpredictable requirements (Truex, Baskerville and Travis 2000).

As far as language is concerned, although its relevance seems not fully established, the IS research has introduced different approaches and methods focusing on language processes (Lyytinen 1985, Winograd 1988, Helmut 1997, Holten 1999). The main focus on natural language has been set by
the Language Action Perspective (LAP) (Goldkuhl and Lyytinen 1982, Winograd 1988) which focuses on linguistic communication as the basis for understanding IS as well as on the impact of language action on a system (Winograd 2006). However, the focus on action through language was adopted for the analysis of ISs and less for the improvement of language use in ISD.

Yet, the importance of language for ISD can be discerned as dually constituted:
- Language is an instrument for communication in ISD (Pohl 2007)
- Language is deeply involved in the development and formalisation process representing coherent elements and functions of the future IS (Lyytinen 1985, Hirschheim et al. 1995a)

This is the point where the ISD setting defers from many other interaction and communication settings: language is an instrument and a result at the same time. Therefore, a main assumption of this article is that the ISD setting is a language based setting (Lyytinen 1985, Hirschheim, Klein and Lyytinen 1995b, Holten 2007) and that we need a special focus on this topic.

Regarding ISD as a language development and formalisation process (Lyytinen 1985), a main goal in ISD is the development of a coherent and sound IS model (Thomas and Carroll 1981, McDavid 1996, Holten 2007). The resulting models have to be successfully 1) legitimised on a language and knowledge level (Boland 1979) and 2) consolidated by social action and communication (Hirschheim, Klein and Newman 1991) in a collaborative setting, where multiple stakeholders representing the different fields of the organisation and of the system development are involved (Alvarez and Urlo 2002, Kavakli and Loucopoulos 2003). Translating this assumption to the language perspective implies a somehow performed negotiation about and concretisation of language as a sine qua non during the ISD process. Several contributions have been made discussing the role of fixing the requirements elicitation in natural language (Ryan 1993, Rupp and Sophisten 2002). And even if the requirements are fixed in a formal language, we have to acknowledge the use of natural language because it is the most probable common communication media between the different stakeholders, and the most used communication instrument in practice (Pohl 2007).

The advantages of natural language are its universal use in different knowledge areas, its flexibility regarding abstraction grades and its simple use (Kamsties 2001, Pohl 2007). Nevertheless, there are significant disadvantages of natural language. Its inherent ambiguity (Pohl 2007) – e.g. lexical, syntactical, semantical, referential ambiguity and vagueness – provide space for different interpretations of the same requirements (Berry and Kamsties 2003), leading to an increase in negotiation costs and of the risk of misunderstanding in requirements engineering (Holten 2007).

Holten (2007) applied the language critique of the “Erlangen School” (Kamlah and Lorenzen 1984) in ISs and assumes that the reduction of the immanent ambiguity of language and the construction of language consensus between the ISD stakeholders is reached by the creation of a language community as a group of stakeholders with a consensual understanding of relevant language representations. Consequently, the stakeholders of an IS project ought to reach a shared understanding of and an agreement on the same concepts about the system’s elements and functions.

Consensus as a language matter is also addressed by different researchers and practitioners (Rupp et al. 2002, Holten 2007). Different instruments to support the management of terminology were developed; e.g. the construction of dictionaries or lexica for consolidation of the company’s language (Sommerville and Sawyer 2003, Pohl 2007), the language standardisation instances (e.g. ISO TC37) or the development of terminology management systems or support tools (Holten 2001, Kamsties 2001). Nevertheless, none of them gives advices how consensus emerge at the micro level of the communication process in ISD. To analyse this setting we juxtapose in the following communication, social action and language theories with our understanding of ISD outlined in the next section.
3 THE COMMUNICATION, SOCIAL ACTION, AND LANGUAGE VIEW ON THE ISD SETTING

The analysis of communication is usually discussed in the sense of the classical code model (Shannon and Weaver 1949) and refers to the act of transmitting codified knowledge from sender to receiver. Yet, as already outlined, the successful development of an IS model means more than a transmission of requirements, but its social, action-driven consolidation. Consequently, a more adequate focus on communication is taken by circular communication concepts, assuming that communication success is related to the right interpretation of the utterance by the receiver and including his or her reaction (Sperber and Wilson 1995). Furthermore, Watzlawick (1990) sees communication as a reciprocal sequence of utterances between individuals in an action/reaction act. As communication is “carried out by an ensemble of people acting in coordination with each other” (Clark 1996), we use the term interaction, that refers to reciprocal social action. Thereby every stakeholder in the interaction encompasses his or her own actions with the actions of others. The perspective underlying this analysis is based on the social action theory of Max Weber (Weber 1921/1967): people perform instrumental-rational interaction which defines a social interaction form aiming for the achievement of goals through the use of an artefact. In this setting the goal is the development of an IS, and the artefact is language. As a result, we introduce the concept of language interaction.

The linguistic perspective is endorsed by basic semiotic concepts. Saussure (1974), as the precursor of modern linguistics, introduced the term sign as a two-sided psychological entity. It consists of the relationship between the signified as a mental fact related to objects in the real world (concept) and the signifier as its psychological imprint (sound pattern or term). That means, in language interaction we deal with subjective concepts by using terms as their representations. As the communication takes place over the use of terms, we also need a similar understanding behind, that is, the used terms should relate to the same concepts. Yet, the existence of same concept-term relationships is not self-evident, but as Kamlah and Lorenzen (Kamlah et al. 1984) argue, it can make the communication process more effective. The collaborative challenge in this field is thus the design of the process of language interaction in an effective way (Thomas et al. 1981).

Moreover, we postulate that the relationship between concepts and terms is developed in the particular socialisation process of each individual and actualised in the concrete interaction process. There, meaning is developed and modified through schemes of interpretation (Blumer 1973), e.g. subjective language schemes or assumptions. In Figure 1 we draft the role of language interaction in the ISD setting as used in this research.

![Figure 1: Language interaction in the ISD setting.](image-url)
4 RESEARCH METHOD AND RESEARCH FIELD

Our research is developed against the background of the ontological assumption of the existence of a real world but the epistemological assumption that social action always arise out of a subjective cognition of it (Burrell and Morgan 1979). Moreover, we apply the combination of interpretive and positivist research according to Lee (1991).

According to Figure 2, the first step, the interpretive understanding (1) consists of an interpretive observation of the language interaction in the ISD project. The procedure used by the researcher to develop the interpretive understanding from the subjective understanding (Lee 1991) includes the use of the hermeneutical circle to test the validity of the resulting interpretive understanding according to the research principles proposed by Klein and Myers (1999). The qualitative participant observation consists on the observation of the language interaction in the different face-to-face project meetings. As part-involved researchers, the observation was at all times performed in a two-person team, so that one researcher could concentrate on the observation and the other performed the required tasks. A qualitative participant observation was not only the precondition for the realisation of the research but it is moreover a necessary aspect for the understanding of the language community created by the stakeholders. In the second step, the theory-driven development of the positivist understanding (2), we develop hypotheses about the language interaction levels and its impact on the consensus building by analysing the interpretive results and testing them against relevant literature in the areas of communication, social action and language theories. Based on Schutz (1962), in the second step a testing of the developed assumptions in terms of rationality was performed as our assumptions were compared rationally with other theoretical propositions (Lee 1991), in this case, of language interaction. The third step, the positivist analysis (3), consists of a positivist re-observation of the different communication strategies on the ISD setting to confirm the relevance and the impact of these strategies in a qualitative way.

The observed ISD project aimed at the development of an IS for analysis, storage and retrieval of market-specific and user customised information with an expected user group of >500. The work was divided in two main tasks to be fulfilled: 1) the knowledge reproduction task, where the content of the system should be identified and collected and 2) the development of the IS, including the election of required system elements and functions. Our observation focus was set on 2).

The research began on December 2006 until September 2008. The development of the structure of the IS model was based on the acceptance and adoption of used concepts and terms used by the involved
stakeholders. The meetings took place in different project member configurations. By the drafting of this article, the requirements were being successfully realised.

The researchers had a project-inside role, as they were responsible for requirements engineering. This research position was convenient because although the other project stakeholders were informed about the documentation of interaction for research purposes, the reaction towards the researcher’s role was overlapped with the role as stakeholders in the project. Table 1 shows an overview of the stakeholders involved in the research, the research team is underlined. Additionally, the information of the domain knowledge serves as indicator for the existence of different technical languages between the teams.

## 5 INTERPRETIVE AND THEORY DRIVEN POSITIVIST UNDERSTANDING: LANGUAGE INTERACTION LEVELS

After the first interpretive observations it could be asserted that the stakeholders – using language as an artefact – changed the manner how to deal with language many times and were able to build a common meaning through their interaction. These changes seemed to occur motivated by the necessity to reach an interaction goal and we could observe which impact such changes had on language interaction success.

To classify the areas where changes occurred, we first use the concept of language interaction areas (LIA) as a superordinate concept. Table 2 offers an overview of the observed areas.

<table>
<thead>
<tr>
<th><strong>LIA</strong></th>
<th><strong>Interpretation</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>LIA-1</td>
<td>Existence of phases where the language interaction between the stakeholders strove for a common understanding of terms and concepts and, on the other side, phases where the interaction was built on mutual complementation referring to concept use.</td>
</tr>
<tr>
<td>LIA-2</td>
<td>The language negotiation was in most of the cases not performed on the language interaction surface, but implicitly present in the background of the discussions. Then again, in few cases the negotiation about language occurred explicitly, in the sense of: “what do you mean with the word XY?”.</td>
</tr>
<tr>
<td>LIA-3</td>
<td>Existence of a different use of natural language referring to the elaboration of utterances. There were on the one hand phases were technical language was on the foreground; on the other hand we could observe a high use of colloquial language and narrative elements.</td>
</tr>
<tr>
<td>LIA-4</td>
<td>Besides the oral language, written language was used during the face-to-face language interaction. It seemed to have different purposes, on the one hand, it was used for documentation and in other cases it allowed the visualisation of meaning.</td>
</tr>
</tbody>
</table>

*Table 2. Language interaction areas.*

Within each LIA, the discerned changes of the manner how to deal with language are now referred to as changes of language interaction levels. In the following paragraphs we present the language interaction levels for each LIA as a result of the theory-driven positivist analysis on the interpretive observations. Afterwards Table 3 provides an overview on these language interaction levels.
LIA-1: Symmetrical vs. complementary interaction level

In prior literature the phenomenon observed in LIA-1 was already analysed (Watzlawick 1990, Dennis and Valacich 1999, Holten 2007). We apply Watzlawick's (1990) concept of symmetry and complementarity. Symmetry means an interaction which aims for the building of the same knowledge, complementarity means that one stakeholder's knowledge complement the knowledge of the other. In the case of language, we assert that as long as both stakeholders have the same language basis, the interaction leads to a complementation of knowledge. Otherwise, the interaction leads to the building of a same language basis.

LIA-2: Explicit vs. implicit language interaction level

Based on the results of LIA-2, there are different approaches referring to the manner how language is negotiated constantly in everyday life. As everyday language is learned empratically in the socialisation process (Bourdieu 1990) it has a self evident role on its use (Kamlah et al. 1984, Rupp et al. 2002, Pohl 2007). We use language more than we talk about it. The process of connecting signs with specific concepts is involved in its use in an existing environment of social interaction, and is therefore coined empratically, that is, by its practical use (Kamlah et al. 1984, Bühler 1990). Although an explicit language negotiation may be not usual, it sometimes seems inevitable, as for example in academic fields (Kamlah et al. 1984).

LIA-3: Colloquial vs. technical language interaction level

The questions raised by LIA-3 refer to the level of abstraction of language use. The use of technical language is usually associated with a differentiated and less context dependent vocabulary (Cummins 1979) whereas the use of colloquial language is fraught with narrative contents, less concrete use of terms and context-rich utterances (Cummins 1979). Although the interaction in the level of colloquial language may be an indicator for a weak sign concretisation in the sense of sign unambiguity, it may provide a clearer notion for people with different language backgrounds. These observations are similar with the results of an ISD research performed by Alvarez et al. (2002), which assert that narratives and messy data may provide a deeper insight into the user’s perspective.

LIA-4: Level of language interaction volatileness vs. codification vs. visualisation

The differentiation between oral and written language use, as observed in LIA-4, is of particular interest in communication theory. One important aspect is the question whether the results of language interaction remain fleeting or are perseverant as in the case of written language (codification). The construction of enduring utterances, e.g. in the form of reports and documentations are understood as language actions on time distance (Clark 1996). This implies a further reflection about the expression chosen, which ensures stability and uniformity of what has been written (Hellmuth 1997). Therefore, the change between oral and written language can be classified as more than a change between communication media but as a language interaction modus. A further observation is the use of written specifications, e.g. in form of conceptual models. The ISD has a long tradition of the use of conceptual models as instruments of the visualisation of concepts (Kottemann and Konsynski 1984, Karimi 1988). Therefore, this issue is considered as important as well.
<table>
<thead>
<tr>

Codification: The language used is written and used for documentation.  
Visualisation: The language used has the purpose of provide a visible reference or an overview. |

Table 3. Language interaction levels.

6 APPLYING LANGUAGE INTERACTION LEVELS IN THE CONCRETE ISD SETTING

As a conclusion we present three exemplary cases (EC) where the existence of the developed language interaction levels and its impact on language consensus is analysed, showing the appropriateness of the results already presented. The criteria for the choice of the ECs are on the one side their appropriateness to show some important insights in consensus building and language interaction, which can be the basis for further research. On the other side the ECs show a spectrum of different interaction lengths. EC-1 refers to an observation performed over different meetings, whereas EC-2 was observed over one meeting in a time segment of about 2 hours. EC-3 shows a passage of about 10 minutes and gives an outlook on further research. Afterwards we analyse EC-1 to EC-3 altogether and present further results which can be gained over the analysis of language interaction levels.

Analysis of EC-1:

In prior meetings the stakeholders had elaborated some notions about the structure and functions of the IS. Nevertheless the language interaction in one of the concluding meetings between PMT and RET was still fraught with ambiguity about how these foregoing notions should be articulated and referred to. In the specification process about the structure of the IS, there were many confusing situations in language use. Although the stakeholders had developed notions about the concepts behind entity types, they were not able to refer to them. They used different terms or described them by using colloquial language (LIA-3).

During the subsequent language interaction, the search for a language anchor was so obvious that the point arrived where one of the participants explicitly asked for a time-out to order the different concepts behind the terms (LIA-1). By doing so, he changed the current language interaction from the implicit into explicit language interaction (LIA-2). In the course of the conversation following, a negotiation about which terms should be connected with which concept emerged. In this negotiation, the relevant concepts were solidified and linked to terms; furthermore they visualised the relationship between the different terms (LIA-4). To better concretise the negotiation results, the stakeholders were also engaged in writing the produced terms and the relationships between them down, building thereby a structure (LIA-4).
In the next meeting, where the consolidation of the systems structure had to be accomplished, the PMT presented the negotiated terms and its relationships (LIA-1, LIA-2), indicating the importance of the specified terms for a better understanding within the project.

**Analysis of EC-2:**

The first meeting between the PMT, the RET and the DT was held in order to bring the different perspectives of the stakeholders together and develop a first concept of the IS structure. During the meeting, the discussion on the term *content* seemed to be held in an atmosphere of confusion. Although the stakeholders referred to the same term, they seemed to have different technical perspectives on the question of “how to deal with *content*”. By using the term *content*, the PMT referred to the data display whereas the RET and the DT meant the data structure on an abstract level.

In this first phase of the meeting, the language interaction level of all stakeholders can be classified as complementary interaction. All three stakeholders were trying to build new knowledge without realising that the symmetric interaction could more appropriate (LIA-1). Later on, the negotiation seemed to stay in the level of implicit language interaction, as the concept was embedded into further explanations, but not defined as such (LIA-2). In this phase, the stakeholder interchanged between interaction volatileness and interaction codification (LIA-4), and colloquial and technical language interaction (LIA-3), without visible impact on the consensus building process. After a while, the possibility of everyone talking about different concepts was explicitly mentioned by one of the stakeholders (LIA-2). Then, the other stakeholders agreed on receiving an exemplary content document from the PMT to have a look at the meant *content*, thereby the stakeholders achieved a common understanding.

The change into explicit language negotiation (LIA-2) resulted to better suit the requirements of the language interaction. Even if the change between implicit and explicit language interaction as well as symmetric and complementary interaction seemed to be decisive (LIA-1, LIA-2), we suppose that the changes between interaction volatileness and visualisation (LIA-4) and casual and elaborated language interaction (LIA-3) were not unimportant as they brought the situation to escalate and enabled the change into an explicit language negotiation as a last chance of understanding.

**Analysis of EC-3:**

<td>X</td>
</tr>
</tbody>
</table>

*Table 4. Exemplary case using language interaction levels.*
The dialog in EC-3 (Table 4) makes clear that as T has another concept of Users Profile, both stakeholders have to negotiate about their understanding of terms (LIA-1, LIA-2). Thereby they were able to find out that they have a different understanding of Information Object. It shows furthermore, how a same term related to different concepts can be the source of misunderstandings and how the stakeholders use language visualisation to find a common understanding (LIA-4).

EC-3 also shows how to classify language interaction situations along the drafted language interaction levels and it indicates possible further research fields, e.g. by coding the language interaction we could search for patterns or analyse the data using quantitative research as well.

**Analysis of EC-1 to EC-3**

EC-1 and EC-2 show that the estimation about the adequate point when the negotiation about language should occur is not self-evident. Both cases showed that the adequate point to negotiate explicitly about language seemed to be missed and, as a consequence, the language interaction remained ineffective in a first place.

In addition, EC-1 and EC-3 suggest that the explicit language negotiation can involve important solutions for ISD problems as:
- the concretisation of the concept-term relationship,
- the development of a conceptual model consisting of sign structure and its relationships and
- the development of common and accessible definitions of the concepts and terms used, which can serve as anchor for referring to already reached consensus.

Insofar, the change from language volatileness to language codification and visualisation can also be assumed as being important for consensus building (EC-1 to EC-3), as the conceptual model served as a basis for future communication.

Below the line, we could observe that the categorisation of language interaction in language interaction levels can provide a helpful perspective to understand the consensus building process. The awareness of language interaction levels could give stakeholders simple strategies to react in the different language interaction situations and to influence the interaction course significantly.

**7 LIMITATIONS AND OUTLOOK**

The detected language interaction levels show how language is used over the whole ISD process. This may contribute to a better language consensus building in ISD by providing orientation for specific interventions in the interaction and enabling an intensification of language interaction. Thereby we can gain a deeper understanding about the emergence of language consensus.

Although the interpretive approach and the process of finding the different language interaction levels seems to be the more sensitive link in the chain, we need to go over this step as language emerges in the interaction. There is a necessity of observation and participation as the only way to find out which language negotiation strategies are used in the micro level of communication is to be present there. There we have the chance to develop useful hypotheses to be able to intercede in language interaction by changing the schemes of interpretation of the stakeholders. By analysing the language interaction in ISD settings, we provide qualitative evidence and analytical generalisation of how language consensus is reached in practice. Using the developed interaction levels proved to be helpful tools for the analysis of single observations cases in the field of language interaction in the ISD setting.

Further research, besides the aforementioned research fields, could focus on stakeholder interviews, in order to get more detailed information about the user interpretation of the strategies to reach consensus. Another alternative could be action research, trying to change the current interaction levels intentional and observing its impact on the development of coherent entities in ISD.

Abstract

Implementations of advanced information systems in developing countries are often perceived as a way to economical prosperity and modernity. However, even in the best of scenarios implementing major information systems is far from a risk-free activity. The reality of developing countries adds extra complexity to an already demanding endeavor. This study explores socio-technical aspects of an unprecedented technological journey in the Vietnamese banking industry, and thus responds to calls for more empirical research in this field. In this paper we present contextual issues affecting the studied software package implementation project and propose a theoretical framework for a basic social process we called “gap bridging.”

Keywords: Packaged software, Implementation projects, Developing countries, ICT for Development, Grounded theory, Case study, Empirical studies, Theory building.

1 INTRODUCTION

Businesses in developing countries often adopt advanced information technology (IT) as a way of keeping pace with the developed world. This is both a necessary and a risky activity. While IT investments in developing countries can contribute and foster economic growth and development (Avgerou, 2003, Yoo, 2003), IT implementation projects are intrinsically prone to failure (Lyytinen and Hirscheim, 1987) and these failures are more significant in developing countries (Heeks, 2002).

The socio-technical conditions of developing countries demand special research attention. On one hand, there is an increasing interest in the use and adoption of information systems (IS) in these countries (Walsham and Sahay, 2006). On the other hand, increasing the knowledge of conditions and processes related to socio-technical changes in developing countries through the adoption of technology is significant to both IS research and practice (Avgerou, 2008). Yet, the number of empirical studies on IS implementation in developing countries is limited (Walsham et al., 2007).

In response to this, our study investigates the implementation process of large package-based information systems (Iivari, 1990) in Vietnam. This study presents a theoretical account that emerged from the perspective of Vietnamese client organizations engaged in “an organizational effort to diffuse and appropriate information technology within a user community” (Kwon and Zmud, 1987 p.231).
2 LITERATURE REVIEW

IS implementation is an important research topic that has been studied since the 1970s (Lucas, 1975, 1981, Ginzberg, 1981, Cooper and Zmud, 1990, Lapointe and Rivard, 2007). While “the early implementation research lacked a sufficiently rich technological, institutional, and historical context” it succeeded in identifying critical success factors and providing multiple insights into the development and implementation process (Lucas et al., 2007 p.208). After its initial concerns with success and failure, the direction of research on IS implementation moved to packaged solutions, enterprise-wide implementations and rapid implementation (Lucas et al., 2007).

Packaged IS implementations have been studied since the 1980’s (e.g., Markus, 1983, Lucas et al., 1988). Packaged software presents benefits over custom-made software; however, the implementation of packaged software is not trouble-free (Iivari, 1990) and organizations are likely to find hidden costs (Lynch, 1984), multiple pitfalls (Lynch, 1985, Ben, 2005) and implementation risks in the external business context, the organizational context, the IS context and the project context (Scott and Vessey, 2002).

IS implementation projects in developing countries add risks to four contexts identified by Scott and Vessey (2002), presenting an interesting area of research with many possibilities. IS adoption in developing countries has been mainly studied from the perspectives of technology transfer and diffusion, social embeddedness, and transformative discourses (Avgerou, 2008). However, these studies can also focus on the role of IS in development, cross-cultural collaborations, localization, and marginalization (Walsham and Sahay, 2006).

The change agency aspect of technology must also be considered. The IS implementation process clearly involves organizational change (Zmud and Cox, 1979, Markus, 1983, Orlikowski, 1993, Lyytinen and Newman, 2008). Markus and Robey (1988) suggested that theories about organizational changes caused by technological innovation should be evaluated in terms of causal agency, logical structure and level or unit of analysis.

Following Markus and Robey (1988) causal structure dimensions, our research adopts an emergent perspective, with the logical structure of process theory at organizational level. This exploratory, theory-making, study follows an interpretive epistemology to analyze empirical data from case studies of large packaged IS implementations in Vietnam.

3 RESEARCH METHODOLOGY

Our objective is to generate a substantive theory of packaged IS implementation in Vietnam while allowing the special economic, political and developmental aspects of Vietnam to emerge without the constraints of theoretical preconceptions. We adopted classic grounded theory methodology (Glaser and Strauss, 1967) to derive theory from case study data (Fernández, 2004). Grounded theory (GTM) is an inductive, contextual and procedural method suitable for exploratory studies (Orlikowski, 1993, Myers, 1997) that facilitates the generation of substantive theory based in the discovery of patterns from participants’ accounts and data collected in the field (Glaser, 1998). GTM fits well with case studies (Eisenhardt, 1989, Orlikowski, 1993), provides well established guidelines for data collection and analysis and is likely to produce a theory that is relevant, rigorous and readily modifiable (Glaser, 1978, Fernández and Lehmann, 2005). Using case-based data for theory building studies allowed us to deal with complex processes enacted by multiple actors in a real life situation and to use multiple sources of evidence to derive knowledge (Eisenhardt, 1989).
3.1 Data collection

It was critical to the success of our study to have access to IS projects that were important to local organizations and exhibited organization-wide impact. To gain access to suitable sites personal contacts were needed. The first author attended a banking conference in Vietnam; from contacts made at this conference, we gained access to six cases. To facilitate theoretical emergence, we choose to start with the case of CORE, a significant IT project at BetaBank (pseudonyms) because it was “the most complicated of the real cases” (Yin, 2003 p.74) and thus well suited as a foundation case (Fernández, 2004). BetaBank is a top commercial bank in Vietnam and CORE presented an excellent foundation case given its magnitude, socio-technical complexity. CORE was also the first system of its kind to be introduced in Vietnam and it was under implementation from 1994 to 2004.

Following Yin (2003), we collected data from documents, records, interviews, and direct observations of the systems in use and the actors in situ. The first author spent 4 months at BetaBank. The first month allowed for familiarization with the case through document reading, observations and informal discussions with project personnel. This activity was very important to become familiar with the case and also for the participants to become familiar with the researcher. The following three months were used for formal interviews; yet, access to documents and informal “chats” continued.

Interviews were the primary source of information. Data from 15 formal interviews were collected and analysed. We interviewed different stakeholders including the bank’s board members, IT department managers and IT staff, relevant business department heads and members, project manager and project team and business unit users. Each interview lasted up to two hours, with average of one and a half hours and was recorded and transcribed, producing more than 250 pages of text.

Following the GTM approach, the interview process evolved over time as the themes emerged from data analysis. For example, our earlier interviews were more open and unstructured, but the later ones were guided by the emergent themes and concepts developed from data analysis (Glaser, 1978). Many brief follow-up discussions were also used to gather further information, to explain emerging issues or to clarify aspects or issues found during data analysis. The strategy to develop rapport during the first month was very effective in facilitating the engagement of participants.

3.2 Data analysis

Data analysis activities included open coding, sorting, selective coding and theoretical coding (Glaser and Strauss, 1967, Glaser, 1978). Open coding produced 217 codes related to meaningful excerpts from the data (or instances). The codes were further sorted into categories while the constant comparison of incidents facilitated the generation of theoretical memos, thus raising the conceptual level (Glaser, 1978). By comparing incidents in each category, we generated theoretical properties of the category. The emerging 26 themes included concepts related to gaps, communication, learning, conflicts, goals, delays and performance.

We conducted further theoretical sampling and selective coding within the core themes. Memo writing proved to be helpful in recording the ideas generated during the analysis and theorize on interrelations. Memos also help to guide our research discussions and to reach higher levels of conceptualization. From this iterative process the “core variable” (Glaser and Strauss, 1967) emerged, we called it the gap bridging process, a basic social process (Glaser, 1978) described in section 5 of this paper.

4 BETABANK’S CONTEXT

This section describes factors in the external and internal environment of the bank that we found influential in the case. The external environment presented the following influential factors:

- Laws and regulations. The banking services were heavily regulated by the state laws and regulations. The CORE implementation was affected by requirements that were mostly suitable to
the manual operations of old-fashioned commercial banks. The fast pace of integration of Vietnam into regional and world economies demanded changes in laws and regulations. These changes were often sudden and unexpected.

- **Industry development.** In the late 1980s, Vietnam’s banking system was transformed into a two-tier system, separating the state bank and commercial banks. Consequently, in the 1990s the banking industry in Vietnam was less developed than those in Asian region and industrialized countries. The CORE project was then seen as the pioneer in modern banking technology and most Vietnamese commercial banks were observing how BetaBank implemented CORE.

- **Technological base.** In the early 1990s, most of the commercial banks used either their in-house developed program or package programs. These programs could only be used in a local area network for each branch with its sub-branches. Data exchange between a bank’s headquarter (HQ) and its branches were through file transfer by modem connection over telephone lines. The national telecommunication infrastructure was in poor condition with low capacity and interrupted services.

BetaBank is one of the four biggest local commercial banks in Vietnam with over 5,000 employees and a branch network covering over the country. It provides wholesale and retail banking services to government agencies, corporate customers and the general public. The bank had strong banking services to support foreign trade, FDI, ODA and remittance. The organizational context had a direct effect on the CORE project. The most influential factors in this context included the followings.

- **Business strategies.** Before CORE, each branch operated as an independent bank with its own funds, management and operations. In the early 1990s, the bank’s management started a process of centralization of fund management and increased control over the branches’ operations; as we shall explain, this was a key driver for the CORE project.

- **Business processes.** Most of the business processes at the bank were poorly-documented. Policies relating to business processes or operations issued by HQ were usually ambiguous, causing different interpretations. Business processes were not standardized across the bank; for example, a loan to a small enterprise would be provided differently across branches. HQ was unable to ensure the observance of its policies by the branches.

- **Management control.** As a consequence of a long tradition of branch autonomy, the organizational structure of each branch developed independently and was different from that of HQ. Each functional department (either at branch or at HQ level) had considerable authority and strong views regarding how their specific business should be conducted. The HQ management control was weak, and rewards and penalties were ineffective and seldom used.

- **Corporate culture.** Following the autonomous traditions, BetaBank’s culture was characterized by a focus on local interest and unwillingness to share information and knowledge. The function-based organizational structure contributed to the lack of cooperation and cross-organizational team spirit.

- **IT strategies.** The bank did not have clear IT strategies. The bank had a tradition of in-house IT provision of all IT supports to business areas as required by the business operations.

- **IS/IT management policies and procedures.** Before the project, all the big applications at the bank’s network were developed by the IT department at HQ. Each branch had its own IT group to support the branch’s operations and to develop applications for its own needs.

## 5 THE CORE BANKING SYSTEM PROJECT

In the early 1990s, while BetaBank was working with partner banks in the developed world, the bank realized that they needed to improve its operations through the use of IT. As a consequence, the bank’s top management decided to implement a core banking system (the CORE project). This was the first core banking system (CBS) to be implemented in Vietnam.
The adopted CBS was packaged software developed in USA and used by many commercial banks in USA as well as in some Asian countries. The CORE project went through a sequence of partly overlapping phases (see Figure 1) classified by the critical events and characteristics of the activities undertaken by the organization and project implementation team.

![Figure 1: Phases of the CORE project.](image)

In the **emerging** phase, BetaBank decided to use a CBS for online service and central processing of transactions for the whole bank, including HQ and its 25 branches. CORE was perceived by top management as a mechanism both to modernize operations and to bring the branches under control. The IT department initiated the project and assisted the bank’s management in making important decisions such as choosing the client-server technology and buying a modern packaged system rather than developing in-house. In early 1996, a vendor from Malaysia was chosen to provide and implement a software package solution developed in USA. The functionality of this system was thought to be aligned with the business objective of centralization of the fund management undertaken by the bank.

At the **exploration** phase, a project taskforce was setup to study the base system provided by the vendor and also the bank’s business processes and operations. The taskforce performed a gap analysis and prepared the user requirement document (URD) for customizing the system. The group encountered several barriers, including: their own lack of knowledge and experience in the technology and modern banking practices; lack of cooperation and contributions from other units at the bank; and, lack of business and IT strategies to guide the development of the URD. Hence, their URD was too general and failed to capture the bank’s operations in sufficient details. Based on this deficient document, the bank and the vendor signed a contract to customize and implement the CBS across BetaBank. A flexible contract condition covered unanticipated changes required by state regulations.

The **evolving** phase was the longest and most difficult for the bank and the vendor. The formal implementation team was set up, consisting of IT staff and business staff from HQ and some branches. The interactions between technical changes and business changes made the implementation more complicated. The technical side required an iterative and evolving process of system customization/development, system testing and gathering further user requirements. The business side required changes to the business processes, organizational structure, policies and procedures were proposed, discussed, and implemented. Also, the implementation teams from client and vendor, this phase required the involvements of many other groups, including the bank’s top management, functional departments, IT department, and users at branches. This phase experienced poor planning and a significant lack of formal and suitable methods. The changes were characterized as an emergent process. Conflicts were frequent in most tasks and among different stakeholders involved. Solving conflicts was seen as a time consuming process that caused delays in the project. Fortunately, the learning was most effective for the implementation team and other stakeholders. This phase lasted over three years and ended with the launch of the new system at a single branch at the bank’s HQ.

The forth phase, **rolling**, aimed at the installation and use of the systems in all of the bank’s branches. This was a hectic process with insufficient time to perform complex tasks such as user training, data conversion and launching of the system. This phase started in early 2000 and lasted over 1 year with 24 branches converted from the in-house developed legacy systems to the new CBS. While the
changes to business operations were implemented, the training was ineffective and users were unable
to exploit the benefits from the new system causing delays in benefit realisation, as explained next.

The last phase, achieving, took place from mid 2001 to the end of 2003. During the first year after the
rollout of the system, the bank-wide use of the new system demanded errors corrections, fine-tuning of
the system, and changes to business processes. The bank started to achieve benefits from the new
system, experiencing growth in customers and services offered. BetaBank was able to introduce many
new financial services thanks to the technological foundation of the new CBS.

From the data analysis the initial framework emerged as a pattern that was relevant and core to the
activities of the CORE project. The participants main concerns were able to be explained by a basic
social process (BSP) that we call Gap-bridging (for an extensive discussion on BSPs, see Glaser,
1978). The following section presents this emerging BSP as a theoretical framework.

6 THE EMERGENT THEORETICAL FRAMEWORK

From data analysis following grounded theories methodology, we discovered the emergent theoretical
framework of package information system implementation in the context of Vietnam – the gap-
bridging process (Figure 2.). A discussion on the nature and role of each sub-process is presented next.

6.1 Gap discovering

Gap discovery is a social process that detects discrepancies between the expected reality and the
reality found in action. We observed many instances where the implementation teams discovered
differences between the system purchased and the bank’s needs. One common cause for discrepancies
related to contextual differences between USA and Vietnam, as one team member said:

The development of the software was based on the thinking and logics of the foreign country [USA];
therefore what we needed to do was to customize totally. The technology of had to be changed totally.

The implementation of the CBS started with the gap discovering process, yet, the gap was initially
perceived in technical terms. Another team member defined gap analysis as follows:

Gap analysis is the comparison between the new system and the old [legacy system] to identify what is
the same and what is different.

Yet, our data suggests that gap discovering refers to gaps in the intersection of context and system,
with social and technical aspects. Thus, the gap discovering process serves to initiate the negotiation
process that will enable the resolution of the gap and the progress of the project. This process detects
mismatches between the characteristics of the system and the local context, including environmental,
organizational and user contexts (Figure 3).
Figure 3: properties of the context-system gaps (CORE data analysis).

Environment-system gaps refer to the mismatches between the system characteristics and the environment of the organization in which it is to be used. We found three elements (or gaps) at this level, including legal regulations, business customs and customer interfaces.

At the organization-system level, the gaps are mismatches between the proposed system and the existing structures, politics and culture. Gaps regarding the organizational structure are often easier to detect, they refer to elements such as communication channels, control mechanisms, decision rules and chain of commands (Markus and Robey, 1983). However, gaps related to organizational politics and culture tend to remain latent (undiscovered) for an extended period. Organizational politics refers to the distribution and use of power to influence decisions (Barbara and Sonny, 1985). Power relations among individuals and groups in BetaBank were important to the project and also difficult to discover and solve. The third element, organizational culture, “a complex set of values, beliefs, assumptions, and symbols that define the way in which a firm conducts its business” (Barney, 1986) acted as a retardant of information sharing, acceptance of alien technologies and collaborative behaviours.

Finally, user-system gaps refers to discrepancies regarding system user interfaces and operational procedures that required a certain level of user’s competence, skills, knowledge and certain cognitive characteristics. For example, assumptions about adequacy of training effort were proven incorrect because computing skills and literacy among the bank employees were lower than the vendor’s assumptions. This resulted in frequent user-induced errors, a more protracted implementation cycle, reduced user acceptance, and a more difficult user support task.

The gap discovering process is a cognitive process that converts unknown gaps into known gaps at all three levels. In the CORE project, both BetaBank and the vendor intended to carry out the gap discovering process during the Exploring phase in order to develop a complete specification of user requirements. However, this intension failed due to natural limitations in human cognition. Clearly, to imagine the unknown under the influence of the known and with imperfect information is a toll-order, as a team leader attested:

[The development of URD, because of the thinking of the old ways and not grasping of all the complexity of the project, was very limited. We found that it is really funny when we read that URD now.]

As seen in this indicator, the gaps were obvious, even funny, when observed with the benefit of the experience. Yet, the actual gap discovering was an on-going, incremental, process that went along with the gap closing process throughout the implementation resulting in a more suitable system. As one team member put it:

[The [system] was customized over the years into something totally different from the initial URDs. … When we actually worked on the program, the development of URD never stop. For over 10 years, it is still being developed.]

The delays in the process of customization were caused by several factor including the following: (a) the organization-system gap was very complex and contained tacit knowledge, embedded in the organization’s contexts (at structural political and cultural levels) and in the CBS; (b) the project
implementation teams lacked bank-wide support to investigate the organization’s contexts; and (c) the project team consisted of young, inexperienced, people with limited knowledge of the bank’s existing operations and management. Prior to the CORE project, the implementation team had no exposure to modern CBS or to an IT implementation project; they discovered their way while doing. One team leader stated:

“We did this project for the first time and had no training or education on how to carry out such a big project in a professional way. Mostly, we learned by doing.”

It could be argued that a more comprehensive identification of context-system gaps through the initial implementation team’s investigation could have contributed to forming more clear and realistic project goals and to a more efficient gap closing process. Yet, the observed gap discovering process was an important process leading to gap closing throughout the implementation, and had an important role in influencing the goal forming process.

6.2 Goal forming

The goal forming process consisted of three interrelated sub-processes: the identifying (needs and constraints), the balancing and the evolving processes, which are next explained in more detail. The discovery of gaps often caused the implementation team and BetaBank’s management to struggle with the choice of keeping the bank’s existing business processes or followings the functions and processes in the vendor’s base system. Consequently, one of the emerging themes was need-identifying. This process required the implementation team to clarify expectations and desires of both the bank’s management and the system users in order to achieve more precision in identifying clarify the goals. However, the requirements of these two groups were often tacit and divergent, demanding of the implementation team a great deal interactions to discover hidden details.

Another emerging process was the constraints identifying process, whereby the implementation team realized that not all identified needs could be satisfied with the available time, resources or because of external factors. Only when the identified needs were balanced with the identified constraints, feasible goals could be formed. However, balancing needs and constraints was an imprecise science requiring significant skills and knowledge. During the early stages of the project the goals were vague and not uniformly understood among the project stakeholders. As a result, the project team and management often underestimated the constraints, resulting in unrealistic expectations or unrealisable goals. As the project progressed, the project goals became clearer and more realistic; the efficacy of the goal forming process increased as the team’s capability improved overtime.

Implementation goals are important elements, they guide the change process by specifying what, when and how the system or the organization should be changed. The data showed that evolving goals acted as a guide to the gap closing process, which is discussed next.

6.3 Gap closing

Gap closing is defined as the process of creating organizational fit (Iivari, 1992) between the system and the organization by eliminating the discovered context-system gaps or by reducing the gaps to an acceptable level. This process consists of two sub-processes: changing and conflict solving.

Based on our data, we agree with Orlikowski and Hofman (1997) in that “when organizations are using information technologies to attempt unprecedented and complex changes … the depth and complexity of the interactions among theses activities is only fully understood as the changes are implemented.” The observed change in the CORE project provided evidence for three types of changes: emergent, anticipated and opportunistic.

At a high level of abstraction, the change process consists of technological change and business change, with each following its own process and interacting with the other. The change to the packaged software was initially planned to be done by sequential steps, but the actual method used
was iterative process of requirements, customizations, testing and further requirements. The cycle continued until the users accepted most of the functions in the system.

The lengthy customization process was influenced by the following factors. First, the users, including the end users and functional departments, were not involved in the earlier phases, but they had most important voice in testing and accepting the system. Only at this phase, the users fed their requirements to the customization along their testing of each system function by test cases. Second, the requirements of the laws and regulations were found to be also a significant source of changes to the customization. Considerable delays were caused by ambiguous legal requirements to banking services and accounting procedures discovered during the customization stage and during tests.

The business changes included organizational structure, business processes, management control and IT management. In this domain, the implementation team regularly interacted with different functional departments and top management. The prominent issues here were related to knowledge gaps, management bureaucracy and lack of responsibility and accountability. Several attributes influenced this process, including the following: (a) differences in understanding between groups about certain implementation issues, (b) the difference between the realities embedded in the organization and the software system and the perceptions of the people, (c) the management bureaucracy resulting in a lengthy decision making process that involved many functional departments and different management levels, (d) multiplicity of implicit procedures for different types of issues made the process more complicated, and (e) unwillingness to accept responsibility causing delays in decisions.

Change was often a source of conflicts among the groups involved in the implementation. Change resistance existed at all levels of the organization and appeared in all phases of the implementation process. Conflict existed between the change promoting (i.e., the implementation team) and change resistant groups (e.g., management, functional departments, users and vendor’s team). Changes also brought uncertainties and at times altered the distribution of power and benefits among the groups involved. In pursuing their different self-interests, these groups created conflicts. Lastly, gaps in knowledge caused misunderstandings and opposing views regarding implementation issues.

In the CORE project, conflicts happened in almost all issues emerging from the implementation process. The project implementation team was central in the conflict resolution process, balancing the different goals and interests of top management, users and vendor. Yet, satisfying the parties was difficult, as the following quotations illustrate:

..not all disagreements on the issues was solved satisfactorily. … [W]hen there were requirements from BetaBank, they [vendor] asked why we needed in that way. Both two sides were tense with each other.

… the technology and IT department …tries to keep the functions in the base system as much as possible. The users tried to keep as what they were doing. There were battles between the two. … Even in the board of management, there were fights on these issues.

With unclear responsibilities and accountabilities and a tendency to delay decision, the main conflict resolution method was a compromising process by which the involved parties went through lengthy discussions and negotiations to arrive at short-term solutions. As one informant put it:

[o]ur opinion was that one thing was necessary, we needed to persuade the other side about that, but you could not force them understand in our way. It was also true that they could not force us to understand in their way. It was human aspect.

The continuous nature of the change process coupled with the constant resolution of conflicts fostered the necessary learning in the project for all parties involved. The numerous issues emerging during the implementation required constant discussion and negotiations among the groups, closing the discovered gaps contributed to building critical capabilities in the implementation team.
6.4 Capability building

The implementation team was central to the implementation process. Their capability consisted of knowledge, experience, and skills that contributed to the deployment of CORE. Team capability at any point in the project is the results from a dynamic process involving staff turnover/recruitment and learning process.

Knowledge, experience and skills were limited at the beginning of the project, affecting both the client and vendor implementation teams. The client’s team members were either newly graduates recruited for this project or staff from functional departments with limited working experience in BetaBank. This caused certain level of frustration, as one of the users stated:

[the client team’s] operational knowledge and experience was an issue. When they received our complaints and requests, they could not understand why they should be as we requested.

In addition, the team knowledge of modern banking operations and management and of the capabilities of the CORE technology was also lacking. Fore example, a team member stated that:

All the people in the project team, when joined the project, did not know about the modern banking operations embedded in the new program. We had to investigate the system to understand the technology as well as those embedded business processes.

On the other hand, the vendor’s team was knowledgeable in the technology but had no knowledge, experience and skills in implementing such project in Vietnam. This problem would have affected any vendor as the project was the first implementation of a CBS in Vietnam. Thus, both implementation teams had significantly reduced capabilities at the beginning of the CORE project, the only way out for them was by learning in action.

However, learning during the implementation process was challenging for the individuals and groups involved in the project. They faced work overload, uncertainties, language difference, and staff turnover. To overcome the challenge, the learning process emphasized on learning focus, learning from others and learning by doing, as this quotation indicates:

We did not have education or training [on IS implementation]; therefore we learnt by doing and self adjusting. ... We exchanged ideas, for example, something we did but we heard that people said it was not reasonable and should be done like this or that. We had to think thoroughly what people said was reasonable or not. We adjusted the way of working for my self and for the whole group in the direction that we believed it would be better.

Learning happened during the change process in both technological domain and business domain and also during conflict resolution of the many issues that the client and the vendor had to confront.

Another key element to build the capability of the implementation team was its recruitment process. As the project developed through the phases, the implementation team changed in size and expertise composition. While recruiting more staff contributed to capability building, staff turnovers decreased the team’s capability, as experience and knowledge in the project were lost.

The implementation team was a key actor in the gap closing process. By proposing and implementing changes and solving the conflicts throughout the project, the team not only enabled the delivery of a complex project in difficult circumstances but also became knowledgeable and effective.

7 CONCLUSION

The paper discussed the process of packaged IS implementation in the context of Vietnam and confirmed the importance of the context to the implementation process, indicating areas for attention. This case study contributed to knowledge in the area of IS implementation in developing countries. By using grounded theory with case-based data, the study developed a theoretical framework called “gap bridging” with four sub-processes – gap discovering, goal forming, gap closing and capability
building. We used the framework to explain the roles and characteristics of these sub-processes as well as how they were interrelated. It also provides evidence of issues confronted while implementing and using application packages as means of modernisation of business practices.

However, this is only an emerging framework developed during the first phase of a major study, thus the framework needs more empirical work to further refine and develop its properties and produce a substantive theory. To achieve theoretical saturation, we are currently working with data from two subsequent cases. From the integration of these data with the relevant extant literature, we will propose a substantive theory on package IS implementation in developing countries.

The research in progress reported in this paper highlights an important set of processes that need to be considered when software packages developed and used in the developed world are implemented in developing countries. The topology of context-system gaps and gap discovering process developed in this study may be useful for client organizations in selecting and implementing such application packages. Moreover, lessons learned from the proposed gap-bridging process can be utilized to overcome prominent issues in countries such as Vietnam, and thus facilitating technological adoption in the developing world.

Abstract

This paper addresses Information Systems (IS) standards from a managerial perspective. Standards can be seen as behavior regulations where there is a lack of hierarchical and market steering mechanisms. The use of government standards to harmonize IS is complicated, since in comparison to hardware and software products, IS are specific to the context in which they are implemented. Only hardware and software can be pre-fabricated. Based on a comparative case study of implementations of regulation from the European Commission seeking to harmonize European e-Customs, this paper develops a taxonomy of deviation sources for IS standards implementation divergence – reasons why implementations of IS standards differ. In addition to the previously known deviation sources: a) work process, b) data meaning, and c) data model, we found two new potential deviation sources in mode of transfer, and timing of implementation. Furthermore, all these sources seems to be of the nature that even the slightest deviation in any of the areas leads to the standard failing to meet its objective of increased efficiency with detrimental effects to the competitiveness of European exporters.

Keywords: Standards, Regulation / Deregulation, Implementation, Cross national study
1 INTRODUCTION

The European food industry face a number of major challenges in the immediate future. Consumers and governmental agencies demand increasing control, traceability and security from producer to the dining table (Tan et al., 2006). At the same time, a recent report from the European Commission (Wijnands et al., 2007) reveals that the European food industry is poorly equipped to meet the increasing worldwide competition. It will be severely hit if/when the EU realizes its plans to diminish subvention of the industry. The industry face the seemingly impossible demand of increasing control, traceability, and security while at the same time reduce the administrative burden of these functions for actors in the European food industry and its value networks in order to ensure competitiveness.

Adoption of standards is a major driver for industry productivity (Shapiro & Varian, 1996). Following industry-wide standards decreases the total resources spent on organizational transactions and interactions (Schilling & Steensma, 2001). Network effects of standards use enable increased efficiency as more and more actors adopt a standard. In a number of national and pan-European initiatives (e.g. FoodTrace, Traceback), Information Systems (IS) in various forms have been or currently are being introduced as the answer to the seemingly impossible demand for increased control and decreased cost of administration. In this paper we report on the efforts of harmonizing all European export procedures, using the same standard for e-Customs (here defined as “electronic transfer of information needed for customs processes”) in all European countries.

In the absence of hierarchical or market structures to enforce behaviour, management through standards is a possible way to achieve coordination among independent actors (Brunsson & Jacobsson, 2000). Standardizing through the creation of structures is also one of the most effective managerial toolboxes as suggested in the classic framework for exertion of power (Markus & Bjørn-Andersen, 1987) in the sense that standards are often perceived as less obtrusive than other regulations. But standardizing IS pose a particular set of challenges on the standardizing body due to its socio-technical nature (Hanseth et al., 2006). Introducing the European e-Customs standard as defined by Regulation (EC) No 648/2005 has the outspoken managerial objective to harmonize European customs processes by an IS standard, in order to provide a common interface to companies active in several European countries. However, as we shall demonstrate with our analysis, standardising IS is not as easy as one might expect in spite of the obvious advantages if all actors standardized.

The dairy company “Dairy Corp” has business in several European countries and export their products from two European countries. Both countries’ customs organizations, Custom A and Custom B, have adopted the European e-Customs standard launched by the European Commission. Yet, to report the customs data electronically Dairy Corp has to implement and maintain two separate interfaces to the two e-Customs implementations. Even though Dairy Corp is one of the largest dairy companies in Europe and must be regarded as one of the more frequent exporters in Europe, the cost of implementing and maintaining the new system extensions has been estimated to exceed the benefits in efficiency by e-Customs. When complying with the standard does not mean that the objective of harmonization is met it is a relevant question to ask why. In this paper we address the question why although Customs A and Customs B complies with the same e-Customs standard, the outcome in terms of IS is so different that they have to be treated as completely different systems. We refer to these reasons as the deviation sources of divergence in IS standards implementation. Our objective in this paper is to develop a taxonomy of sources for standards implementation deviation, which is a contribution of descriptive theory according to the theory classification by Gregor (2006).

The relevance of seeking to explain the reasons for standards compliance not fulfilling the managerial objective should not be limited to the context of customs. Research on IS and standards is limited despite the increasing importance in managing and using IS (Lyytinen & King, 2006). In addition, the existing research has mostly investigated content of new anticipatory standards rather than processes and factors that explains why and how standards emerge, are used and with which consequences
Among the explanatory works, standards development is almost exclusively the focus leaving the subject of standards implementation almost unexplored (Egyedi, 2007; Egyedi & Dahanayake, 2003; Söderström, 2004). The exceptions include a few writings on institutional factors of standardizing organizations that eventually leads to implementation problems (e.g. Egyedi, 2007; Damsgaard & Lyttinen, 2001; King et al., 1994). Not at least the past stream of EDI research has highlighted the need for synchronization between standards on IS and organizational level (e.g. Brousseau, 1994), but not specifically addressed the different levels as sources of deviations.

In the next section we will introduce the field of IS standards implementation and the current understanding of why implementations of standards may deviate. Thereafter we present the case of standardization of the European e-Customs, which introduces two yet undocumented sources of standard implementation divergence. Based on existing literature and our empirical investigations, we suggest a taxonomy for sources of divergence in standards implementation. Given the taxonomy we discuss and make tentative suggestions on how these problems can be met. Finally we provide conclusions for practice and academia.

2 MANAGEMENT THROUGH IS STANDARDS

In settings where hierarchical structures that enables enforcing behaviour lacks standards can be used as a managerial technique to regulate behaviour. The regulating mechanism is driven by a number of mutually independent actors identify themselves as a group and adopt a defined way of carrying out specific tasks (Brunsson & Jacobsson, 2000).

2.1 Management through IS standards

IS management has the ultimate objective of ensuring that the IS contribute to the organization reaching its goals (Alter, 2003). Drawing on general IS management research (e.g. Clemons & Row, 1991; Gottschalk, 2000; Kalling, 2003; Mata et al., 1995; Pyburn, 1983) and research on IS and IT governance (e.g. Van Grembergen, 2005; Willcocks et al., 2006; Brown & Grant, 2005), IS integration management may be defined as consisting of two main tasks: a) identify the different basic structural options that exist for IS management, and b) make and implement decisions upon an understanding of how the alternatives relate to organizational objectives. This is parallel to the two tasks of IS standardization: a) defining and developing IS standards, and b) adopting and implementing IS standards (c.f. Markus et al., 2006).

Defining and developing an IS standard is part of the options identification process. Few standards are the result of purely rational economic decisions (Backhouse et al., 2006). It is more than a little naïve to think that power and politics does not play an important role in the creation of standards (Cargill, 1989). However, this paper is not on how the objectives with an IS standards are developed, it is about how the objectives are realized in implementations. Standards implementation is thus part of the second managerial task above. The objective of standardizing is to harmonize and coordinate. Exactly how the harmonization shall be achieved is stipulated in the standards specification, but this might leave too much room for different interpretations leading to different implementations.

2.2 IS standards

IS standards are fundamental specifications that shapes the configuration of IS (Backhouse et al., 2006), and how the IS are used and managed in their organizational implementations (Hanseth & Braa, 2001). IS standards contain inscribed actions and processes that affects the way an organization is operating (Backhouse et al., 2006). The relationship between IS and IT standards can be compared to the discourse on differences between IS and IT in general (c.f. Iivari, 2003; Myers, 2003). IT standards are technical standards that can be defined as an agreed-upon specification for how to communicate and perform actions (Nickerson & zur Muehlen, 2006). Although various IT standards
can be important components of IS standards, just as IT frequently are important parts of IS. IS standards exists on an infological level (c.f. Iivari, 2003) that is based on the conception of information transfer from one human to another (Checkland & Holwell, 1988). An IS standard can thus be defined as a standardization of how information about something should be transferred from one individual to another individual who is in need of that piece of information.

A common distinction between standards is between de jure and de facto standards. Regulations from the EC can be seen as de jure standard, since the regulation works as what in the discipline of law is called “soft laws”, i.e. the use is mandatory but the means of enforcing use are limited. EC regulations can also be described as open standards, in contrast to proprietary standards, since the EC regulations are publicly available to everyone who wants to adopt them. The non-electronic standard that preceded the e-Customs initiative – the Single Administrative Document (SAD) – was adopted by several non-EU countries that had extensive trade with the EU.

2.3 Deviation in standards implementation

Stories of intentional and unintentional standards deviation are frequent in the business press. Microsoft’s use of Sun’s Java standard (Blundon, 1997) is one classical example of an intentional standards extension. Organizations may also choose to only adopt parts of an existing standard - intentional partial standards adoption. The reasons for intentional deviation from the standard might be both strategic and technical (Egyedi & Dahanayake, 2003). The focus of this paper, however, is unintentional standards deviation which is a less explored phenomenon (Egyedi & Dahanayake, 2003).

While IT software and hardware can be duplicated and sold as complying to a particular standard, IS are specific to the organizational or inter-organizational context in which they are implemented (Iivari, 2003). IS can be defined on three different levels: technical, infological, and organizational (Iivari, 2003). Consequently, deviation sources can be found on each of these three levels.

Egyedi and Dahanayake (2003) addressed deviation sources on a technical level. They found that these deviations stemmed from pure errors, ambiguities, and specification to parallel options, and functional deviation. Inter-organizational standards are based on a data model, describing which data should be transferred through the system are intended to eliminate such differences. If ambiguities, inconsistencies, or options exist in the data model, deviation in the implemented IS is possible.

The infological level of IS exists in a language context (Iivari, 2003). This means that the objective of an information system is to supply its user with information to support its activities. The interpretation and meaning of transferred data is another potential source of IS deviation (Gustafsson et al., 1982). In the case of e-Customs, deviations can occur because data fields such as “means of transport”, “description of goods”, and “exporter” are interpreted differently in each e-Customs implementation. An exporter might be the company that produced the goods and who is now sending it to the customer, but it might also be the logistics service provider that actually transports the goods across the border. In some cases it is even the receiving part who actually acts as exporter. The same problems exist for almost all data that is shipped: shall weight of goods be specified with or without wrapping? How does one write an appropriate description? Is the receiving part represented by its name or organizational number, and if so the organizational number in which country? Data transferred in the IS should have similar meanings to its users. Data meaning is another potential source of implementation deviation.

The organizational level of IS refers to a process view of how data is transformed through the systems to its users. IS can be seen as work systems that as one constituent part contains a work process (Alter, 2003). To complete transfer the user has to manipulate the system by a logic that is partly built into the system and partly defined by the implementation context. The process view addresses when to send which data and to whom. It is possible that national customs offices wants some part of the data model to be submitted to VAT-controlling authorities, some data to health authorities, and some data to the authority responsible for controls of dangerous goods. When and where data is transmitted is defined by the IS’ work process, which is a third source of standards implementation deviation.
Although the three levels of deviations described above are important sources for variations in implementation of standard, they are to the best of our knowledge not explicitly described in the literature as sources of deviation; they are only deductively derived as potential sources of errors. In the absence of previous works the deduction of a tentative framework based on closely related research is a possible way forward.

3 RESEARCH APPROACH

This paper presents a comparative case study, following the structured case study approach (Carroll & Swatman, 2000), of implementation of Regulation (EC) No 648/2005 in two European countries.

3.1 Research approach

Our purpose was to develop a taxonomy of sources for standards implementation deviation, which is a contribution of descriptive theory according to the classification by Gregor (2006). The taxonomy also contains an explanatory element since by using it, it is possible to explain why standards implementations differ from each other. But the study is explanatory in a general sense and not in the notation of explanatory case study as used by for example Yin (1994). As descriptive theory we suggest drawing on Gregor (2006) the usefulness of this type of theory should be evaluated by its completeness, distinctiveness, and simplicity. Completeness means that important categories or elements should not be omitted from the classification system, that is, the theory should be able to capture all important resources. Distinctiveness means that boundaries between categories and characteristics that define each category are clear. The empirical phenomena encountered should be possible to categorize according to these criteria without too much difficulty (Gregor, 2006). Simplicity refers to that by making a model or framework too elaborated or comprehensive makes it hard to work with and in the end makes it useless for its purpose.

The words: IS, standard, and deviation can be combined in a way that deviation refers to a discrepancy between what is described in the standard specification and how the IS performs, but it can also mean that two IS are performing differently although they both conforms to the same specification. Given the managerial perspective and the research question regarding the use of standards to regulate behaviour, it is the latter deviation that is of interest in this paper. The cases are thus the two implementations of Regulation (EC) No 648/2005 and the focus is the difference between these implementations which is addresses by a cross case comparison.

3.2 Data collection and data analysis

The essence of the structured case study approach is that it forms an iterative research cycle upon a formal theoretical framework. The framework creates a structure that permits collection of relevant field data and in later stages, the case results enables traceability of conclusions and theoretical generalizations (c.f. Yin, 1994). The framework in this study was based on the three levels of implemented IS (work process-, data model- and data meaning level) and the deduced sources of standards implementation deviation. Empirical data was collected along the three levels of IS in both standards specification and implemented IS.

Existing documentation about the European e-Customs initiative and the implemented systems are extensive and was an important source of empirical data. The standards specification Regulation (EC) No 648/2005 was a natural starting point. Other important documents produced by the EC include Regulations, Decisions, and Communications regarding customs code, as well as e-Customs and the Multi Annual Strategic Plan that sets the strategy for developing European customs. To grasp the implemented systems, user manuals, system documentation, specification of applied data model, and specifications of UN/EDIFACT and XML-schemas for data transfer were investigated. In addition, specifications of technical standards by ISO, DG/TAXAUD, and UN/CEFACT were investigated.
The second empirical level was participations in meetings, workshops, and interviews of IT personnel at Customs A and Customs B. In total 12 meetings and workshops were held on e-Customs with representatives from Customs A, Customs B, the EC and Dairy Corp. These were complemented by 10 semi-structured interviews to understand the specific details of the customs processes. Visits at Dairy Corp’s production facilities and export office complemented with the organizational context.

4 HARMONIZING EUROPEAN E-CUSTOMS

A number of contributing factors have forced the EC to reconsider the customs processes in the member countries. This section presents the story of how the EC seeks to increase control in customs processes and simultaneously lower the administrative burden for exporting companies in the EU by introducing a standard for e-Customs.

The competitiveness of the European food industry is weak from an international perspective. Productivity growth is less in the EU than in the largest competitive economies, the world market share is decreasing, and rate of innovation in the EU is minor compared to innovations in the US and Canada (Wijnands et al., 2007). There are several reasons for the deprived. One contributing factor is the administrative burden caused by comprehensive export processes. This non-productive cost is estimated to be as high as two percent of the total turnover for the average exporting company. The current complexity of export processes is manifested by the sometimes more than 20 km long lines of freight trucks waiting at the Finnish-Russian border or the more than 40 paper documents in four copies that has to accompany a container shipped by vessel (Tan et al., 2006). So far, only 4% of all trade documents exist only in electronic form. (Tan et al., 2006). This is a huge waste of paper (causing CO\text{2} emissions), a huge administrative burden, and in a number of countries, the passing of paper documents from one person to another is a potential for bribing/kick-back.

4.1 Harmonizing regulation and process standardization

Until now national customs authorities has been able to individually decide how they asses risks, control goods and carries out administrative tasks. A pan-European company thus have had to deal with national customs individually, complying to different legislation and processes. With the modernized customs code (TAXAUD, 2004) and the e-Customs standardization (Regulation (EC) No 648/2005) the EC seeks to harmonize all European processes and at the same time increase efficiency by the move to electronic processes.

With the focus on divergence in the standards implementations the objective of harmonization is in focus. Harmonization would imply substantial benefits as companies would be able to merge export departments and reduce the numbers of connections reporting electronically to e-Customs solutions.

4.2 Customs A’s e-Export system

Customs A introduced its first IT-supported export system in 1988. This pioneering system was solely used internally in the local tax and customs office by employees at the tax offices to register export statements in an IT system. From 1990, it became possible for companies to report their export statements into the system via an electronic connection. The possibility to report export statements via Internet using a web-interface or FTP was introduced in 2000, but adoption has been sparse.

In 2002 Customs A decided to reengineer the e-Export system in collaboration with an industrial advisory board. The objective was to achieve at least 95 % electronic export declarations. Two years after the implementation, practically all export declarations were reported electronically. As the EU has refined and elaborated its demands on national customs authorities, these have been successively implemented in similar but not identical e-Export system across Europe. Current alternations concerns complying with Regulation (EC) No 648/2005, which should be implemented by June 2009.
Figure 1 outlines the main steps associated with export declaration and control when exporting from Country A to outside the EU. Before the goods are transported across the border, the exporter has to notify Customs A with what is called a pre-advice message (step 1 in Figure 1). When this message has to be sent is dependent on the status of the exporter. If the exporter is certified by the customs as an approved exporter and use electronic transfer of declaration data, the data can be submitted one hour in advance. Based on the pre-advice, Customs A runs a risk analysis (step 2) and then either a) decides that additional control is required (step 3), possibly with a physical inspection at the loading place or b) releases to goods for export (step 4). Assuming that nothing is discovered in the additional inspection, the goods are finally released for export (step 4) and shipped across the border (step 5).

### Figure 1  **Generic export process in Country A**

Custom A’s e-Export system is a direct computerization of a previous manual and paper-based system. Messages sent have their paper equivalent which are still possible to use for companies who for some reason does not want to submit export data electronically. The paper-equivalent is the SAD. The SAD, specified by the EC in Regulation No 1875/2006 and No 648/2005, is a standardized form for customs data that is accepted in the EU, EFTA-countries and many other countries, including for example Russia. The data model is a field by field translation of the SAD-fields that Custom A was using prior to the computerization. Customs A e-Export system can be reached using standards like UN/EDIFACT messages or XML messages. However, it should be noted that using XML does not mean that the contents is standardized. There are no international XML standards for electronic customs declaration messages. Regarding UN/EDIFACT directory D96.B is used. The messages sent are based on the following UN/EDIFACT documents:
- UN/EDIFACT Syntax Rules
- UN/EDIFACT Syntax Implementation Guidelines
- UN Trade Data Interchange Directory Issue D96.B
- UN/EDIFACT Message Design Guidelines document
- UN/EDIFACT Procedure documents
- EWOS Technical Guide for EDI Message Profiles

Regarding data meaning, Customs A’s e-Export system benefits from being a direct derivation from the SAD, since the need for specifying data meaning was highlighted already when the SAD was introduced. A substantial amount of work was already done by UN/CEFACT, ISO, and the EC/TAXAUD to specify the meaning of data. Also for such fairly interpretable fields such as “product description” there are appropriate guidelines on how to provide and interpret data.

### 4.4 Customs B’s e-Export system

Deviation in the work process means that the basic process logic of how to make an export declaration could deviate. The EU regulation and directives does not contain a generic process model, specifying how an export declaration shall be made in each of the EU countries. However, customs processes are based on a long tradition and have many similarities on a high level: they are based on the same need of controlling what goods are leaving the country and for what destination. In the two countries
investigated, the processes of how to do an export declaration, meaning which steps are required to complete, are basically similar by tradition – not by formal standardization.

Customs B also used the SAD as template for creating the *data model* in their e-Export system. However, besides the mandatory fields the SAD presents a number of optional fields that national customs can demand if they want. In reality, this has resulted in the use of different XML schemas for the data transfer related to export declaration. In our analysis, it is very unlikely that any two European countries would have implemented exactly the same XML schema without directly collaborating on the matter. Consequently, although both e-customs solutions for the two countries are within the general EU regulations, the data transferred differs from country to country.

Regarding data meaning a substantial amount of work is already done by UN/CEFACT, ISO, and the EC/TAXAUD to specify the meaning of data. Already in the work of the SAD many of these issues were brought into daylight and had to be solved. Also for such fairly interpretable fields such as “product description” there are appropriate guidelines on how to provide and interpret data.

4.5 Consequences for pan-European business

The implications for European exporters are grave. For instance, when we look at country A, Dairy Corp has set up a system that links their enterprise system (SAP) to Customs A’s e-Export system. Dairy Corp uploads UN/EDIFACT messages via FTP to the EDI server of Customs A. But Dairy Corp is an approved economic operator in that country, and it is delivering their pre-advice notifications in batch mode every five minutes.

Customs B does not require Dairy Corp to report export declarations electronically, and Dairy Corp has chosen not to. The reason is that the development and future maintenance cost of extending the existing system with a module for handling also electronic export declaration in the second country would far overshadow the efficiency gains. Dairy Corp investigated the cost of developing such a module and were given the offer of about 100 000 Euro. Bearing in mind that it has to be considered normal that factual development cost is most often up to twice of calculated costs and that maintenance costs throughout the lifetime of a system is normally much higher than the development cost, implementing electronic export declarations to Customs B would be a fairly costly development. Therefore, Dairy Corp has chosen not to implement electronic transactions with Customs B.

Accordingly, the consequence for Dairy Corp could be summarized as follows:

- Two different export offices – one for each country
- Two different system modules reporting to Customs A and Customs B respectively
- Additional development costs of >100 000 Euro
- Additional maintenance costs, normally substantially larger than development costs for IT systems

5 ANALYSIS: STANDARDS DEVIATION

The objective of the above described regulations and directives were partly to harmonize export declaration processes in the EU. It should be said that the European e-Customs initiative is far from finalized, but directives regarding export declaration is already being implemented in the two investigate countries. Therefore differences in how these regulations were interpreted, adapted to the national context and implemented can already be seen. Our objective was to describe sources of standard divergence, and as viewpoint to identify divergence we used Dairy Corp that has to deal with both Customs A and Customs B. To assess the usefulness of our initial framework, the question is whether it can explain the differences between the two e-Export systems? Or, in other words, if harmonization in the three stipulated dimensions would imply Dairy Corp being able to deal with the two customs organizations using the same IS? The answer is no. As will be explain in the following the framework has to be extended with at least two empirically derived sources of deviation.
5.1 Extending the framework: empirically identified sources

As far as the authors of this paper has been able to identify, a fourth and a fifth source of deviation is largely ignored in the current regulations and directives. Even if the same data, with the same meaning is transferred there can be deviations in the way it is transferred. We refer to this as the *mode of transfer*. Comparing e-Export A and B we found that the mode of transfer differed in encryption required for submission and in requirement of digital signature. Currently neither Customs A nor B employs encryption, but considering the data submitted this is a must for future developments. In the country of Customs B, legislation demands identification of the person who submits data, therefore Customs B employs digital signature since long. Customs A does not. As will be further elaborated later, this source of deviation may be very difficult to deal with due to the roots in national legislation.

Finally, *timing* is an almost ignored aspect of implementation deviation. On a very general level the EC has set deadline for the phases of e-Customs, but on a practical level national customs are free to implement regulation and updates during a time span. As updates, modification and alternations are frequent during systems development processes and as the systems development process of European e-Customs is likely to be ongoing for a long time, timing of implementation creates at the same time different systems in all European countries.

5.2 A taxonomy of deviation sources in standards implementations

Recapitulating both theoretically and empirically derived sources of deviation we found five distinct sources of deviation: a) declaration process, b) data model, c) data meaning, d) mode of transfer, and e) timing in implementation. The five sources are summarized in Table 1 as *A taxonomy of deviation sources in standards implementations*.

Table 1 A taxonomy of deviation sources in standards implementations

It is noteworthy that all five sources of deviations are so crucial that only the slightest deviation severely damages the harmonization idea. A new step in the work processes, slightly different data models, incompatible meaning of data fields, different encryption techniques, or different implementation dates would from the perspective of Dairy Corp force different versions of e-Customs connections. Although development cost for each deviation might be limited seen in isolation, the complexity of having to maintain 27 e-Customs solutions for the pan-European trader is a substantial overhead cost, which is reducing the competitiveness of EU companies. And it is problematic, since it can be avoided, if government agencies across the EU collaborated to a higher degree on standards. In the next we will discuss possible ways of dealing with deviations in the implementation of standards.

6 DISCUSSION: DEALING WITH DEVIATIONS

Trough the current harmonization-efforts European export declaration processes has becoming more similar. But, as shown above, close is not close enough if the ambition is to substantially lower cost for pan-European business. We will discuss three different ways forward that can lead to the foreseen benefits being met.
The first redesign solution is to seek to achieve what can be called “true harmonization”. True harmonization means that a company can use the same electronic connection, being based on EDIFACT, XML or whatever, to report to all European customs authorities. To achieve this, the level of specification on how to implement the customs side of the export declaration system must be substantially more elaborated. It must cover at least all five sources of divergence as described earlier in this document. Today, the functionality of the export declaration is standardized, but not how it should be implemented - therefore the difference in implementation. We suggest that a substantially more detailed blueprint, which is sufficiently detailed to eliminate all potential sources of divergence in order to achieve true harmonization must be developed, agreed upon and implemented.

A second redesign solution is to keep the current peer-to-peer structure, but create a “complete European export declaration protocol” that contains all data demanded by national customs organizations. That means that a company like Dairy Corp, when exporting through Customs A would submit all data that is needed by Customs A, but also all data that is needed by other European customs. Customs A would be able to receive such a message and extract the information relevant to them. The benefit for Dairy Corp is that they could send the same message to all European customs. The downside would be that they had to send irrelevant data at each submission, but since companies such as Dairy Corp do already have all necessary data in their internal systems, the cost of providing irrelevant data is marginal. There are several upsides for national customs in this suggestion, and the downside is very limited. Being able to distil relevant data from a complete European export declaration would not be a challenging task.

The third redesign suggestion is to allow companies to deal with only one national custom authority. For example, Dairy Corp could submit export declarations to Customs A regardless from which country they export. The problem of implementation differences is thus reallocated from business to customs. However, since it is the authorities who decide the rules of the game it is unlikely that they will take on additional responsibility although from a macro-economic perspective it would mean that fewer resources are being spent on setting up infrastructure for European wide e-Customs. The main reason why this would be less resource demanding is that implementing connections between the 27 member countries is far from the effort needed to interconnect the almost one million exporting companies with as much as 27 national customs each. This third option is in EC writings referred to as centralized clearance. This is a complex enterprise if not limiting the scope to just passing on information, but also include actually making the customs clearance in one single country and then divide fees, reimbursements etc according to predefined schemas. But once established, this would significantly improve the competitiveness of EU companies.

7 CONCLUSIONS

In our investigation we found that differences in the implementation of e-customs systems potentially could originate from five distinct sources. In addition to the previously known deviation stemming from a) work processes, b) data model, and c) data meaning, we found two new potential deviation sources in d) mode of transfer, and e) timing of implementation. All these sources seems to be of the nature that even the slightest deviation in any of the areas leads to the standard failing to meet its objective of increased efficiency.

The idea behind the above mentioned regulations of total electronic data transmission is that it will lead to increasing the security, higher transparency and less fraud while not adding to increasing the administrative burden on pan-European actors. So far the results have been that:

- Security, traceability and control have increased.
- The cost of reaching the new level of security, traceability and control without electronic submission of data seem to be higher in most cases.
- The additional burden on pan-European companies has not yet been lowered but rather increased as a result of the new export declaration processes.
We believe that to a large extent this is due to the current deviations in the implementations of export declaration processes, which are in a clear conflict with the idea of creating one common, inner European market place. With the current situation, if a company is active on one member country and would like to expand business with another production and export facility, everything else being equal, the cost is higher if placing that facility in another country than the country that the company is already exporting from due to the need of creating new export processes and developing a new electronic channel to the national customs.

We believe that this research highlights the importance of taking the step from research on IT standards to research on IS standards. As heavily emphasized in the IS literature, IT has no organizational value in its own right, but only as an enabler for information sharing. What we show in this research is that IT standards compliance is a prerequisite but not sufficient requirement for leveraging the benefits that is expected by standardization. More research is needed to understand the potential and problems with regulating behaviour by IS standardization.

More research is also needed on the complex issue of harmonizing the way national authorities work and interface to global business. Business is steadily getting more and more global while national agencies seem to be lagging behind in adaption. Failure to adapt might have far reaching effects as competition is extending to include competition between value chains, industries and regions.

Abstract

What determines the involvement of users to ‘go with the new workflow’ in the case of workflow management (WFM) deployment, and how is this related to their perceived quality of work? This key question is addressed in this paper. Customized for our empirical case context – a large Dutch social insurance organization that recently deployed a WFM system – we developed a conceptual model based on the models and concepts of DeLone & McLean, Hartwick & Barki, and Kappelman & McLean. Our model subsequently relates user participation, user satisfaction and quality of work, shortly after WFM deployment. The expected relations are tested by survey data collected from 143 end-users. Results of correlation and regression analysis show that (1) the degree of influence is a key determinant for the perceived quality of the system, (2) perceived system quality is a main driver for user satisfaction, and (3) user satisfaction is a main determinant of the users’ perceived quality of work.

Keywords: user participation, user satisfaction, workflow management systems, quality of work, public service organizations.

1 INTRODUCTION

Workflow management (WFM) and WFM systems have been around for a long time (cf. Kobielus 1997, Jablonski 1995, Hollingsworth 1994), but its adoption and deployment remains a relevant topic. An editorial article of Information & Management suggests that WFM has enjoyed regular attention over the years 1998 to 2005 with mostly three articles published per year (Palvia et al., 2007). Most recently, WFM has been extended to the broader concept of Business Process Management (cf. Smith and Fingar 2004, Weske et al. 2004).

The general premise of applying workflow management, is that the coordination of work can become easier, a higher quality of services is delivered, the work is executed more efficiently, and the process becomes more flexible (Reijers et al. 2003). Despite the successes (Fischer 2007), there are also many questions about the implementation of workflow management. Most of the problems appear to be of an organizational nature, rather than technical. Moore (2002) found that excessive activity automation and poor design of work assignment strategies are critical in workflow projects. In an influential study on the effects of workflow systems on organizations, Küng (2000) concludes that workflow design should actually be extended towards job design and organizational design. Most critically, employees outside the IT department should play an active role from the beginning of a workflow project. This essentially implies that user participation and user involvement in WFM deployment will improve its success.

Not much empirical research has been conducted on the success of WFM systems applying survey research among users. There seems to be a white spot with regard to the organizational benefits from WFM deployment in terms of the effects of WFM on the quality of work of end-users. This is
remarkable given the extensive lines of information systems (IS) and information technology (IT) research on the perceived usefulness and perceived ease of use of IS/IT (cf. Markus and Keil 1994, Venkatesh et al. 2003, Konradt et al. 2006, Sabherwal et al. 2006), and the line of social science research on job changes and quality of work in relation to technology and ICT (Zuboff 1984, Benders 1993, Mullarkey et al. 1997, Andries et al. 2002). Apparently, these two lines of research have developed quite separately from each other.

This paper aims to contribute to the different research problems and issues addressed above. By approaching the deployment and effects of WFM in organizations from both an IS/IT and social science perspective, we go beyond the studies that analyse WFM either from a technical, organizational or a job perspective. The lack of empirical research drives our objective to develop and test explicit hypothesis about the relationship between WFM deployment and the users’ quality of work. We firstly do this by building upon the research on upgrading and downgrading of skills and jobs in relation to IS/IT (cf. Grint and Woolgar 1997, De Witte and Steijn 2000, Bresnahan et al. 2002). Secondly, we develop testable hypothesis on the intermediating role of user participation for WFM success and quality of work. All hypotheses are part of an integrative conceptual model that provides an answer to the central question how WFM deployment effects the perceived quality of work of users. A key element of this paper is the data by which our model and hypothesis are tested. Contrary to the ‘common’ structure of most papers, we start by describing the case context of an empirical study on a large Dutch social insurance organization that recently deployed a new WFM system. The the conceptual model and its underlying expectations are tested by data collected from a survey among 143 end-users of the WFM system. After a discussion of the results the paper concludes with some recommendations for further research.

2 THE CONTEXT: WFM DEPLOYMENT AT A LARGE DUTCH SOCIAL INSURANCE ORGANIZATION

The empirical research for this paper is based on a case study and survey within a large Dutch organization for the execution of employee (social) insurances. Since its foundation in 2002, as a result of a merger of five public organizations, the formal mission of this organization is “to stimulate people to work, and if work is impossible to provide a temporary income”. The organization is an independent policy agency that resorts under the Dutch Ministry of Social Affairs. It is a large administrative organization that has a national task to execute several social security laws. The organization controls all administrative and financial processes to execute these laws, and is dedicated to control misuse and fraud. A second task is to realize the reintegration of (partly) unemployed and disabled employees. For this task, it collaborates with private health companies. The organization has 17,292 employees amounting to 14,563 Full Time Equivalents (FTEs) in 2007. The research took place within the so-called Social Medical Function (SMF) domain. The focus of this domain is to examine the medical- and work capabilities and to judge the claims of the clients within the scope of the national laws. Within the SMF-domain the number FTEs in 2007 is 6,359.

In 2005, a project was started to support the front office to integrate existing applications. As part of that project a WMF system was developed. This WFM system was primarily aimed to streamline the core administrative processes of the social security laws within the SMF organization and improve its quality in terms of compliance with rules and procedures that are mostly of a legal kind. The WFM system consisted of a standard software package with custom-build components to support the transition of information and tasks from one ‘resource’ to another. A resource can be a person (i.e. an employee) or a system (i.e. an application). Besides achieving more efficiency and higher quality of services, the goal of the WFM project was to reach uniformity in case handling. To support this, the concept of teamwork was introduced. Teams were created by joining five different types of employees namely team-support employees, process support employees, work/job consultants, insurance medical doctors, and sometimes medical assistants. To ensure that the composition of the team fitted with the system, the size of a team was flexible. It was intended that a proper composition of the team will increase the (user) performance of the new WFM system.
The project organization consisted of a steering group supported by a sounding board and a project quality group. The steering group was responsible for the end result and consisted of senior users, senior developers, a representative of the user organization, a project advisor and the project manager. The sounding board was responsible for the definition of the requirements of the user organization and the acceptation of business products. This group consisted of managers and staff employees of the user organization, one end user, a quality advisor and development manager. It was agreed that members of the sounding board informed the employees they represent. The project quality group was responsible to monitor the quality aspects of the project and the deliveries. Members were quality advisors and domain experts. The overall responsibility of the project manager was to assure that the project delivers the right products within the appointments that have been made.

In 2007 the WFM system was nationally deployed along all establishments of the Dutch social insurance organization. During the implementation phase at all locations, new releases of the WFM system were developed. To set priorities for the releases a user group was installed with members of the different function groups of the user organization. Priorities were discussed with members of the design team. Users could send issues to the user group and received information about its progress. In this phase the users were actually confronted with the new system for the first time. From the start it was planned that the use of the new WFM system was mandatory. During the introduction users received professional training lasting one to two days. After that, training on the job was supported by a trainer and a mentor. In the beginning it occurred that the new system sometimes failed. Besides that, during that period there was a huge workload because of new legislation. Also, there was significant time pressure to reach productivity norms. In some cases, users were allowed to use the old systems if the new system failed – or if it was easier to achieve the production norms.

This case context should be explicitly taken into account, as the survey that is reported in this paper took place 6 to 12 months after the deployment of WFM system. The specific conditions as just described were therefore incorporated in the development of the conceptual model from which expectations about the interrelation between this new WFM system and users’ quality of work and their role as user participation is derived.

3 A CONCEPTUAL MODEL OF USER PARTICIPATION, USER SATISFACTION AND QUALITY OF WORK

3.1 The D&M model

There is an expanding field of research on the measurement and determinants IS/IT in organizations. Several theories and models from several perspectives have been developed in this domain. One stream of research departs from models on adoption and use of IS, with theories such as Diffusion of Innovations (DoI), Theory of Reasoned Action (TRA), the Technology Acceptance Model (TAM), Social Exchange Theory, Theory of Planned Behaviour (TPB) and Task Technology Fit (cf. Van de Wijngaert et al. 2008, Dwivedi 2008). The major stream of research however, is dedicated at exploring the direct determinants and measurements of success (or failure) of IS. Important studies in this area are Delone and Mclean (1992, 2003), Seddon et al. (1999), Smithson and Hirschheim (1998), Grover et al. (1996) and Sauer (1993). For the study reported in this paper, the departure point is the leading, and probably most-cited, model in the research of IS success, namely the updated DeLone and McLean Model of IS Success (see Figure 1).

The original D&M Model was first formulated in 1992 (DeLone and McLean 1992) and updated in 2003 (DeLone and Mclean 2003). In the updated D&M Model the quality of a system depends on three dimensions namely ‘information quality’ (e.g. completeness, ease of understanding, relevance), ‘system quality’ (e.g. usability, availability, reliability) and ‘service quality’ (e.g. empathy, responsiveness). Each dimension will affect ‘use’ or ‘intention to use’, and ‘user satisfaction’. ‘Use’ is a behaviour, whereas ‘Intention to use’ is an attitude. ‘Use’ and ‘user satisfaction’ are interrelated. If there is a positive experience with ‘use’, this will lead to greater ‘user satisfaction’. Similarly, increased ‘user satisfaction’ will lead to increased ‘intention to use’ and thus ‘use’. As a result of this ‘use’ and ‘user satisfaction’, certain ‘net benefits’ will occur. The ‘net benefits’ can be individual or
organizational. The ‘net benefits’ will in turn influence, positive or negative, ‘intention to use’ and ‘user satisfaction’.

Concerning the case context of the study as described in the previous section, the D&M model was adapted in two ways. First there is focus on system quality only, excluding information quality and service quality as other drivers for intention to use and user satisfaction. The reason for this is that interest for the research reported here lies in the evaluation of the deployment of a specific application (a WFM system), and a definition of the perceived quality of work of users as the net benefits. As was mentioned in the previous section, during the introduction users were for the first time confronted with the WFM system. System quality is therefore the most significant reason for (potential) changes in use, user satisfaction and their effects. Although use was mandatory, during the deployment there were several reasons to escape from this rule, e.g. system failure and production norms. The second adaptation was therefore to adjust the D&M model by selecting intention to use, not use, that is both related to user satisfaction and also to net benefits. Because this was a study of the deployment of a new WFM system that was not fully in use at the moment of data collection, its actual use is a less valid measurement since this depends on many other practical factors such as technical implementation problems and other delays. Therefore, the original D&M model that assumes that intention to use leads to actual use, with feedback effects from actual use to user satisfaction and intention to use was not used.

3.2  Extending the D&M model with Hartwick and Barki

It would be prudent to refer to the very early notion of Conway (1968), or more prominently Orlikowski (1992) that an important issue to the use and success of IS/IT is in the interaction between designers and users. In the study reported here the process between designer and user was explicitly included, and the D&M Model was extended by bringing in the concepts of user participation and user involvement. Recalling the case context, this is relevant as during the process of deployment of the WFM system users could bring in issues for new releases through user participation by delegation.
recently were confronted with the deployment of a “new, business oriented, IS application in the near future” (p. 446) in their organization, is shown in Figure 2.

They define user participation as the observable behaviour of system users in the information system development process, i.e. their participation in information system development and implementation activities. Barki and Hartwick (1994) identified three dimensions of user participation: overall responsibility, user-IS relationship and hands-on activity. Overall responsibility refers to user activities and assignments reflecting overall leadership or accountability for system development project. User-IS relationship refers to development activities reflecting user-IS communication and influence. Hands-on activity refers to specific physical design and implementation tasks performed by users. Next, user involvement is defined as a psychological state of system users, i.e. as the importance and personal relevance of a system to use (Barki and Hartwick 1989). The authors differentiate this psychological state from another psychological state, namely attitude. This is generally conceptualized as an affective or evaluative judgment of some artefact and can be measured to locate one’s position on a bipolar affective or evaluative dimension, e.g. bad/good. Finally, they incorporated in their model Fishbein and Ajzen’s Theory of Reasoned Action (1975). From their study (Hartwick and Barki 1994), it is claimed that user participation influences user involvement and that the effect of user participation on intentions and use is mediated by the psychological constructs of involvement, attitude, and subjective norm. User participation and involvement are particularly important for the voluntary users of a system.

For this study the Hartwick and Barki (1994) model is used in particular the three user participation concepts and their relationship with IS success, i.e. intention to use, user satisfaction, and quality of work (as perceived by the end-users). The TRA concepts and actual use concept from their model is not used. As described previously, external factors in this case organization strongly hindered the actual use of the system during the WFM deployment. This makes the TRA constructs (attitude concerning use and subjective norm concerning use) as well as the actual use concept less relevant as concept to be included in our conceptual model.

3.3 Extending the D&M model with Kappelman and McLean

While Hartwick and Barki (1994) relate user participation to the Delone and McLean concept of intention to use, Kappelman and McLean (1991) shows that there is also a relation between user participation and user satisfaction. As stated before, the case context in the study reported here concerns a period where participation and involvement is critical. Therefore it is also important to link user participation to the concept of user satisfaction of the D&M IS Success model. The model that Kappelman and McLean (1991) tested is called the Behavioural-Attitudinal Model and is depicted in Figure 3. The study was conducted at 52 branches of a regional interstate bank holding company, during the installation and conversion of the information processing sub-system at each of the branches. Although the operationalization of user participation was not the same as Barki and Hartwick, the underlying items were based on the same literature (Olson and Ives 1980, 1982).

As in the case reported in this paper users in the Kappelman and McLean (1991) study participated only in the system installation and conversion phase, or what they label as ‘later-phase user participation’. This concept corresponds with the ‘hand-on activity’ dimension of Barki and Hartwick (1994). User involvement in the model of Kappelman and McLean also overlaps with the model of Barki and Hartwick (1994). Finally we adopted the concept of user satisfaction. Kappelman and McLean (date) convincingly showed that user participation does induce user involvement, i.e. that involvement actually intervenes in the participation-satisfaction relationship. Further, they argued that involvement is more important in understanding user satisfaction than user participation.

Figure 3. The Kappelman and McLean Behavioral Attitudinal Model.

As in the case reported in this paper users in the Kappelman and McLean (1991) study participated only in the system installation and conversion phase, or what they label as ‘later-phase user participation’. This concept corresponds with the ‘hand-on activity’ dimension of Barki and Hartwick (1994). User involvement in the model of Kappelman and McLean also overlaps with the model of Barki and Hartwick (1994). Finally we adopted the concept of user satisfaction. Kappelman and McLean (date) convincingly showed that user participation does induce user involvement, i.e. that involvement actually intervenes in the participation-satisfaction relationship. Further, they argued that involvement is more important in understanding user satisfaction than user participation.
3.4 A conceptual model of user participation, user satisfaction and quality of work

The results of the adaptation and extension of the D&M IS Success model are combined and jointly depicted in Figure 4 below. In addition to the previous sub-sections, a number of other decisions were taken in designing the final conceptual model to suit the case study context.

To measure user participation, the concept of ‘overall responsibility’ was replaced by the concept of ‘degree of influence’. As will be described in the next section, the actual measurement was how satisfied users were with the degree of influence offered by the sounding board and user group. Further, user satisfaction is measured with the User Information Satisfaction (UIS) instrument as used by Shaw et al. (2002). With this instrument the perceived service satisfaction and information satisfaction is measured, because this is relevant in view of the D&M IS Success model. The net benefits in this study are defined as the quality of work of the WFM system users. As mentioned in the introduction, WFM systems are designed to coordinate processes and can potentially make work more efficient by improved information and steering of tasks and roles. WFM systems potentially effect the autonomy and workload of users, as well the information they receive. Therefore, it was decided to specifically focus on autonomy, workload and information as the main indicators of the quality of work of the WFM users. Further elaboration of measurements are presented in the next section.

The conceptual model in Figure 4 below depicts the expected relationships. From left to right, between: (1) the three user participation concepts on the one hand, and the three concepts system quality, attitude toward the system and user involvement on the other, (2) subsequently between these three concepts and intention to use and user satisfaction, and (3) between intention to use, user satisfaction and net benefits of the WFM deployment being the three dimensions of quality of work. By colours, Figure 4 also depicts the theoretical origins of the concepts and their interrelationships.

The main hypotheses from our conceptual model that will be tested are:

1. user participation is positively related with system quality, attitude toward the system and user involvement;
2. system quality, attitude toward the system and user involvement are positively related with intention to use and user satisfaction;
3. intention to use and user satisfaction are positively related to net benefits.

4 THE SURVEY AMONG THE WFM SYSTEM USERS

The survey research took place at six offices of the Social Medical Function (SMF) domain and was conducted in May and June 2008. The focus of this domain is to examine the medical- and work
capabilities and to judge the claims of the clients within the scope of national laws. Within the SMF-domain over 7,000 UWV employees are active. Within these locations, the sampling was stratified according to the four main job categories that would jointly become team members as main users of the system. The job categories included team support employees, process support employees, work/job consultants and insurance medical doctors.

The (web-)questionnaire was sent out through internet. As not all team support employees and process support employees had access to the internet some completed the questionnaire from another computer or a hardcopy. A total 143 employees returned a complete questionnaire. The response rate was 30%, not biased according to job category as the main stratification criteria. The sample consisted of 13% team support employees, 21% process support employees, 42% job consultants and 24% medical insurance doctors – which is largely representative for the total organization. With regard to some other background characteristics, the sample can be described as:

- 60% male, 40% female;
- average age is 48.5 years;
- 27.3 percent of the respondents has an university degree;
- respondents have 19 years average work experience at the organization;
- 35 percent stated that they have more than average computing skills, compared to their colleagues.

4.1 Measurements

Below the measurements of the elements of the conceptual model (Figure 4) is described from right to left. The results of construct validity and reliability testing is presented.

Perceived Net benefits (i.e. Quality of Work) – As explained in section 3.4, the focus is on the three main characteristics from the total quality of work concept that are most relevant in relation to the potential effects of the WFM system under study, i.e. Workload, Information of Work, and Autonomy. The characteristics were measured with scales developed by Schouteten and Benders (2004) and Dhondt et al. (2002). Principle Component Analysis (PCA) shows that the 11 items for workload all contribute to a 1-factor solution with an eigenvalue of 5.58. Similar results were achieved for the 6 items for information of work (eigenvalue 2.87), and the 9 items for autonomy (eigenvalue 4.04). The overall accounted variance of the three 1-factor solutions was 50.8%, 47.8% and 44.9% respectively. In addition, Cronbach’s alphas were calculated for the three item sets. Their scale reliability was confirmed as the Cronbach alphas were 0.90, 0.77 and 0.84 for the Workload, Information of Work and Autonomy constructs.

User Satisfaction – To measure user satisfaction the Information Satisfaction and Service Satisfaction scales developed by Shaw et al. (2002) was used. Factor analysis was performed to analyze the construct validity of the group of 9 items. PCA resulted into a 1-factor solution with an eigenvalue of 4.50, accounting for 50.0% of the overall variance. Reliability of this User Satisfaction scale was confirmed by a Cronbach’s alpha of 0.87.

Intention to Use – The ‘intention to use’ concept can be defined by one relatively clear item, i.e. “If the system was not mandatory, I would still use it”, as suggested by Seddon and Kiew (1996) as one of the first scholars with regard to this issue. This single item holds 4 answer scale categories, as most of the other items used for the model.

System Quality – For the purpose of this study, specifically the aspects Usability and Usefulness of DeLone and McLean’s concept of system quality are measured. Usability is measured by 6 items from a (Dutch) questionnaire developed by Tijdens and Steijn (2002) and the classic complexity scale of Thompson (1991). Usefulness is measured by 6 items from the classic compatibility scale of Moore and Benbasat (1991) and the work-with-computer-scale from Tijdens and Steijn (2002). Factor analysis was performed to analyze the construct validity of the total set of 12 items. The one-factor solution from PCA holds an eigenvalue of 6.43, accounting for 53.6% of the overall variance. Reliability analysis confirmed the scalability of the 12 items, as Cronbach’s alpha is 0.91.
Attitude towards the System – Attitude toward the system is measured by four items from a scale developed by Hartwick and Barki (1994). Different from the previous items described, they developed as 7-point items by which users could judge the IS/IT application by contrasting labels as “good/bad”, “terrible/terrific”, “useful/useless” and “worthless/valuable”. PCA showed that the four items clearly load on one factor, with an eigenvalue of 3.21 and an overall variance of 80.2%. As can be expected, the reliability of the scale was also confirmed by a Cronbach’s alpha of 0.92.

User Involvement – To measure User Involvement, five items from Hartwick and Barki (1994) were used. They defined the User Involvement concept by items that express the judgment of the IS/IT application in terms of “important/not important”, “relevant/irrelevant”, “fundamental/trivial”, “essential/non essential” and “significant/insignificant” on a 7-point scale. For this dataset, PCA on the items showed that there is one strong latent factor (eigenvalue was 3.36, overall variance 67.3%). Reliability analysis supported the scalability of the item set (Cronbach’s alpha = 0.88).

User-IS relationship – The User-IS relationship scale, as part of the User Participation concept, is based on the work of Hartwick and Barki (1994) as well. They developed 7 items to measure 7 different types of participation that could be either scored as “no” or “yes”. As these items refer to specific actions that, in many cases, were actually not applied in IS/IT project (for all kinds of reasons), it was decided to sum the “yes” scores of these items instead of applying PCA and reliability analysis which is more appropriate for ‘subjective’ items as opinions and Likert-type statements.

Hands-on Activity – Hands-on Activity concerns a scale that is comparable with the User-IS relationship scale, also developed by Hartwick and Barki (1994). Likewise, the sum of the 8 items they defined was used, addressing 8 different types of hands-on activities to let users participate in the IS/IT development.

Degree of influence – Finally, the Degree of influence as developed by Lynch and Gregor (2004) was applied. Using their four (4-point) items, PCA on the dataset confirmed that these items can be aggregated into one latent factor, with an eigenvalue of 2.67 and overall variance of the 1-factor solution of 66.6%. Reliability analysis confirmed the scalability of these four items: Cronbach’s alpha is 0.83.

5 RESULTS

In Figure 5 below the results of three OLS regression analyses that correspond with the three decomposed parts of the conceptual model is presented. These are labelled as ‘Model I’, ‘Model II’ and ‘Model III’. The one-way-directed arrows in the figure represent the significant (standardized) regression (beta) coefficients (p<.01), while the two-way-directed arrows represent the significant correlations (p<.01) between the independent variables within the subsequent regression models. For all three OLS regression models, the potential problem of multicollinearity was investigated by computing VIF-factors for each predictor in the regression model. Although in some cases correlations between independent variables were relatively high, VIF factors in none of the three models exceeded 5 – a commonly applied rule of thumb.

The results from regression Model I show that primarily User Satisfaction holds a significant relationship with each of the three Quality of Work dimensions. Although Intention to Use is strongly correlated with User Satisfaction, this holds no significant relation with the users’ Quality of Work. This might be partly due to the problems with the actual use of the WFM system at the social insurance organization as we described in section two. On the other hand, this result also supports that satisfaction through ‘actual use’ is an important determinant. It is confirmed that satisfied users significantly experience higher Autonomy, Work-related Information and less Workload. The explained variance (adjusted R$^2$) of the three regression models is 7.4% (F=6.613, df=141, p=.002), 16.4% (F=14.802, df=141, p=.000) and 15.0% (F=13.424, df=141, p=.000) respectively.

With regard to model II, the three assumed determinants of User Satisfaction and Intention to Use are strongly inter-correlated. In joint regression analysis however, only System Quality holds a significant relation with Intention to Use and User Satisfaction. Apparently, the usability and usefulness of the WFM system dominates the actual satisfaction and intention to use of the users at the social insurance,
while their attitude and involvement only supports this, i.e. not significantly driving it. Given the context as described earlier – a new WFM system fully in the phase of adaptation and deployment, combined with limited use of the WFM system – this result is as expected. The explained variance of both regression models (adjusted R²) is relatively high: 47.8% (F=11.976, df=142, p=.000) for Intention to Use, and 45.0% (F=37.843, df=142, p=.000) for User Satisfaction as a dependent variable.

Model III finally, shows that Degree of Influence is the prominent determinant of User Involvement, Attitude towards the System and System Quality. Again, the three predictors of Model III do correlate and clearly coincide, but ‘in competition’ the perceived Degree of Influence is the clearest driver, probably as the participation items of Hands-on Activity and User IS relationship were lacking in practice as well. The explained variance of the three regression model varies: 23.5% (F=15.580, df=142, p=.000) for System Quality as a dependent variable, 23.4% (F=15.445, df=142, p=.000) for Attitude towards the System, and 10% (F=12.660, df=142, p=.000) for User Involvement.

![Conceptual Model](image.png)

Figure 5. The conceptual model tested: reliability of the item scales (stats within the boxes), significant correlation coefficients (two-way arrows between the boxes), and significant standardized regression coefficients (one-way arrows between the boxes) for three sets of dependent variables.

### 6 CONCLUSION AND FURTHER RESEARCH

This paper presents and effort to build upon two research traditions that both deal with the question of how the success of IS/IT deployment can be understood in terms of individuals benefits, more specifically the users’ quality of work. In developing a conceptual model, different models and concepts from the IS-tradition were brought together (i.e. the model IS success model of DeLone & McLean, extended by model elements from Hartwick & Barki, and Kappelman & McLean). In addition, concepts from the social science tradition on quality of work and its relevant dimensions in relation to IS use, more specifically WFM systems were used.
Based on the context of a large Dutch social insurance organization that recently deployed a new WFM system for all their employees, a conceptual model was customized. In this model it is claimed that the quality of work of users is directly related to their intention to use the WFM system and their user satisfaction. Next, it was hypothesised that these two concepts in turn are related to the quality of the (WFM) system, the users’ attitude and their user involvement. Finally, the three types of user participation are included into the model as drivers of the perceived system quality, system attitude and user involvement.

Data collected from a survey among 143 users within the case study organization enabled the construction of valid and reliable measurements and constructs as defined in the conceptual model. Correlation and regression analysis showed that for each of the three sub-models significant relations were found, although not all of the hypothesized relationships were confirmed. It was shown that (1) the degree of influence is a key determinant for the perceived quality of the system, (2) perceived system quality is a main driver for user satisfaction, and (3) user satisfaction is a main determinant of the users’ perceived quality of work. From these results it could be argued that the concept of (perceived) system quality appear to play a central role. On the one hand, system quality is the main determinant of user satisfaction which subsequently holds the strongest relation with the users’ quality of work. On the other hand, system quality is as strongly related to user participation as user involvement. One way to further validate our findings is to estimate the complete model using Structural Equation Modeling (SEM). An additional method to validate our scale construction is to apply factor analyses over all items.

If these (quantitative) results are interpreted against the (qualitative) case context as described earlier in this paper, some further conclusions can be drawn. While the value of the WFM system within the Dutch social insurance organization is recognized, its importance for all processes and tasks has not been proven yet. The disruptions during the introduction of the WFM system caused employees to kept working with the old system to keep up with their targets. This resulted into a lack of use and experience with the new system. Although the benefits and added value of the new system still remain unproven, it can be seen from the survey results that user satisfaction and system quality do matter. If users increasingly value the quality of the new WFM system, their satisfaction and perceived quality of work will increase – and most likely their productivity.

With regard to participation and involvement, it was determined that users at the Dutch social insurance organization were not much directly activated during the deployment of the WFM system. Instead, their participation was mainly organized through delegation, and in addition users were frequently informed during the project. From the analysis it was found that if users experience this degree of influence, this holds a positive relation with the experienced quality of the system, user involvement and attitude towards the system. As this subsequently increases the users’ satisfaction and quality of work, this influence can thus be considered as an important ‘background driver’ for the benefits of the new WFM system. These results support the basic statement that employees should play an active role in WFM projects (Küng 2000). High impact IS/IT application as WFM can indeed upgrade jobs, but only if this is mediated with user participation.

The measurements and analysis of user participation in the context of this case of WFM at a large Dutch social insurance organization also provides new roads and ideas for further research. In particular, finding the ‘right’ type of user participation for the ‘right’ type of user/system combination can be a crucial new research question. It was found that ‘indirect’ ways of participation hold positive relations with user involvement and perceived system quality, while direct participation activities showed no relation with these factors. This is a particularly interesting result for larger organizations. Obviously, with larger number of users the costs of user participation will be higher too, challenging new and ‘efficient’ ways to let users participate during deployment projects. Further research within other organizations is needed to validate if the size of the organization is indeed an important condition for selecting the ‘optimal’ type of user participation (cf. Markus and Mao 2004, Nordheim and Nielsen 2008). Finding the right mix of user participation makes it possible that users go with the (new) workflow, and subsequently experience an improvement of their quality of work as well.

Abstract

Structural changes and increasing market dynamics in the health care sector intensify the hospitals’ need for cost-savings and process optimization. A first step is the documentation of processes in order to clarify the actual needs. As in health care processes are rather complex and often different players with divergent demands are involved, a disciplined approach to effectively and efficiently model processes is required. For this purpose, in this contribution a component-based modelling approach is presented and applied.

Keywords: Business Process Management, Design Research, Health care, Workflow.
1 INTRODUCTION

The health care sector is confronted with unsatisfactory performance in costs (i.e. health expenditure) and quality (i.e. effectiveness of service delivery and medical malpractices) for years (Porter & Olmsted Teisberg, 2004). Affected organisations counteract these deficiencies by various changes on strategic, procedural, technological, and cultural level. Horizontal mergers, outsourcing and shared services, public-private-partnerships, managed competition, integrated and preventive care, new medical procedures and information systems, clinical information interfaces, and digital imaging are only few examples for the dynamic environment and related challenges of health care organisations (Denis et al., 2000; Ginter et al., 2002; Ham, 2003). However, transformation projects often fail or at least do not meet raised expectations due to unexpected influences and obstacles (Berg, 2001; Lorenzi & Riley, 2004). These are in most cases the result from the high complexity of change projects. Complexity is related to the number of elements of a whole system as well as their interrelations (Schneberger & McLean, 2003). Looking at an enterprise or hospital from an intra-organisational perspective, this understanding covers organisational and procedural structures as well as the information processing landscape and the target systems of employees (Mettler et al., 2008). From an inter-organisational perspective, involved stakeholders (e.g. patients, health care service providers, suppliers, administrations, competitors, insurance providers), regulatory conditions, requirements of the market (e.g. collaborative service production), etc. have to be considered (Denis et al., 2000). These circumstances point out the complexity of health care organisations (Anderson & McDaniel, 2000) and respective changes, and clarify the need for transparency, in order to identify potential areas of modernisation as well as to derive concrete actions for a successful transformation.

Prerequisite for transparency is the comprehensive understanding of relevant structures and influences basing on respective documentations. However, looking at current change projects (regardless whether technically, organisationally or strategically motivated), required information is costly gathered primarily within those projects by internally responsible persons or expensive external consultants. Resulting documentations are closely aligned to the goals of the respective project and their quality, to large extents, depends on knowledge and experiences of the modeller. Thus, they are often not reusable for other purposes and integrable to existing documentations. A model-based representation of knowledge provide the foundation for documenting organisational architectures in a standardised, comprehensible, and interoperable way which is the basis for a cross-organisational identification of deficiencies and the design of a targeted state, for communication with involved stakeholders as well as for derivation of the transformation process itself.

Although models are well known and accepted for abstracting real life systems in medical research, they are not yet broadly diffused for documenting business-related knowledge in health care organisations. In contrast to medical or biological models which are widely accepted (e.g. Rector et al., 1997; National Library of Medicine, 2005), business-related models are applied to homogeneous groups of organisations, single organisations or even specific units. While re-use is limited, effort for creating new business-related models is unequally high. In addition, business process models typically involve several people with different perspectives and comprehension (Vassilacopoulos & Paraskevopoulou, 1997). However, there are much more influencing factors that constrict broad diffusion of process modelling, such as the confusing variety of modelling notations for similar purposes, the incompatibility of different tools and the integrability of respective models, the dependency on modellers’ knowledge and experiences, the diverging levels of detail and abstraction, the inconsistent use and poor definitions of organisational terminologies, or the lack of maintenance and up-to-dateness which are limiting re-usability (Chen et al., 2008; Curtis et al., 1992; Christov et al., 2007).

This contribution addresses this heterogeneity and uncertainties by proposing a component-based modelling approach. The composition of predefined Generic Activities (GAs) establishes a common terminology and understanding of what a process is. It aligns the levels of detail and abstraction, and
finally enables compatibility of independently created model parts as well as their combination to complete processes. For that purpose, a proven concept for development of GAs is being adopted from public sector research, and its applicability in the health care domain is discussed.

After the description of the research method in the subsequent section, the conceptual foundations and the procedural model for identifying the demanded model components are presented in section 3. Then, the identified model components and practical aspects of applying GAs for modelling processes of the health care domain are discussed in section 4 by exemplifying a concrete model instance. The main findings and topics for further research are summarised in the last section.

2 RESEARCH METHOD

As the documentation of organisational knowledge is a rather pertinent and practical issue, engaged research is needed in order to provide rigorous solutions for this relevant problem. A theoretical basis that serves both relevancy and rigour of research and requires engaged research is that of design science research (Hevner et al., 2004; March & Smith, 1995; Venable, 2006). While natural sciences try to explain and predict behavioural aspects of the reality by developing and verifying theories, design-oriented research aims to build and evaluate innovative artefacts, in order to extend existing capability limitations. Artefacts represent the actual results of a design process. They can be characterised as “constructs, models, methods, and implementations” (March & Smith, 1995). The model components presented in this contribution can be categorised as constructs since they are used as essential building blocks within process models.

In order to ensure the quality of a new artefact, the design-oriented approaches inherently consist of two iterative steps: build (i.e. construction of the artefact in a transparent and traceable way) and evaluate (i.e. activities to prove innovativeness and ability to solve the addressed problem). In order to demonstrate the functional capability, effectiveness and efficiency of the developed problem solution, analytical (e.g. architecture analysis), descriptive (e.g. scenarios), experimental (e.g. simulation), or observational (e.g. case study) evaluation methods can be applied (Hevner et al., 2004). As it was our aim to test the GAs (which are considered the artefacts of this research) in a ‘real world’ setting and it is difficult to ‘simulate’ a health care environment, we chose the case study method to evaluate our findings (Kitchenham et al., 1995; Smith, 1990). In doing so, a project with five hospitals was started aiming at the depiction of the logistic processes using the identified GAs. An extract of the findings is presented in the subsequent sections. For illustration purpose, the Business Process Modeling Notation (BPMN) is used. However, other modelling notations such as Event-Driven Process Chains, Object Process Methodology, or flow charts can be applied since the proposed findings are notation independent to a large extent.

3 IDENTIFICATION OF GENERIC ACTIVITIES

3.1 Configurative and Compositional Mechanisms of Reference Modelling

For purposes of reducing heterogeneity of process descriptions by means of standardisation and improving syntactic, semantic as well as pragmatic model quality (Lindland et al., 1994), the concept of reference modelling provides generic mechanisms for reuse and adaptation based on predefined models or model components (Thomas, 2005). Mechanisms of adaptation can be categorized into configurative (Gottschalk et al., 2007) and compositional concepts (vom Brocke, 2007). Examples are the configuration of business processes within standard software applications (Dreiling et al., 2005) or the composition of independent software services to complete business workflows (Szyperski et al., 2002). The configurative top-down mechanism requires extensive knowledge about feasible variants potentially occurring within the process and the respective conditions for those variants which have to
be formalised to configuration parameters. Although the adaptation effort is considered low, the construction effort – especially in complex domains – is comparatively high (vom Brocke, 2007). As allowed variants have to be known in the development phase of the reference model, flexibility in creating new (innovative) process solutions during adaptation phase is as limited as the applicability of the predefined models for differing situations which are not supported by the reference model and its configuration parameters. Thus, the configurative mechanism is suitable for highly standardised and well structured processes.

In order to model processes in a more complex, distributed environment, compositional mechanisms of adaptation are considered more suitable (Reichert & Dadam, 1998; Baacke et al., 2007). Especially in information processing domains, process structures are very heterogeneous but basic activities (i.e. model components) recur regularly. Bottom-up composition of modular activities promises moderate effort for adaptation. Although composition supports restricting mechanisms (e.g. by using combination rules) to ensure model consistency and plausibility, the potential for process innovation and flexibility to depict both the individual as-is and the potential to-be situation are high. As a consequence, composition of standardised GAs is considered an appropriate adaptation mechanism for distributed modelling of cooperative processes.

3.2 Applicability of Public Sector Modelling in the Health Care Domain

As the component-based approach used for this contribution originates from the public sector (PICTURE Consortium, 2006), the question arose if it is applicable for business process modelling in the health care domain as well. Although processes in health care organisations are considered rather complex and correct outcome is crucial, there are many similarities in the service production of public and health care services. Example characteristics are

- Division of labour through specialisation and function-oriented organisation
- Cooperative service production involving several specialists and resulting in a number of organisational interfaces
- High autonomy of cooperating units
- Decision-intensive processes (and variable results) cause structural complexity
- Occurrence of similar activities in different processes
- Little experience in process modelling and heterogeneity of existing documentations.

At least for workflows of information exchange and processing as well as for administrative processes the appropriateness of compositional (compared to configurative) process modelling can be derived. Due to the specificity of medical treatment and extensive analogies to administrational processes, this contribution excludes processes of diagnostics and therapy and, instead, focuses on modelling more administrative processes of enterprise management, patient management, care administration, communication, supporting services and business support (Helfert et al., 2005) which predominantly focus on information management as well as procurement and provision of medical commodities for actual treatments. Such surrounding processes (internal and external) in general aim at providing a required quantity of information or products (in the required conditions and in time) for appropriate cost to the right customer (Plowman, 1964).
## 3.3 Decomposition of Modelling Constructs

As already mentioned, the component-oriented modelling approach is based on standardised GAs. Depending on the used notation and the understanding of the modeller, tasks are not only represented by activities or functions but also by organisational units, documents, events, etc. In order to standardise process models and to ensure compatibility to other process models and other model types, a precise differentiation of *Generic Activity* and respective *Processed Object* (PO) is demanded (Baacke et al., 2007). This differentiation is visualised in Figure 1.

![Figure 1. Differentiation of process tasks into GAs and POs.](image)

Although for this contribution medical treatment processes and their specific activities have not been analysed, the conceptual differentiation between GAs and POs supports consistent access and processing of information also for medical purposes (cp. Figure 2).

![Figure 2. Surrounding vs. medical treatment processes.](image)

Depending on the notation used for modelling, further entity types can be connected, e.g. responsible organisational units or supporting information systems (Baacke et al., 2008).
3.4 Procedure for Identification of Generic Activities

The procedure for identification of GAs conforms to the iterative build and evaluate phases of design research (cp. Section 2). The main steps as well as expected results are specified in Table 1.

*Table 1. Design activities and expected results of the methodology.*

Due to the similar characteristics of processes in public administrations and support processes in health care organisations, not all GAs had to be newly identified. Instead, already developed GAs (Baacke et al., 2008) have been reused to some extent. However, the procedure for identification has been applied without modifications (cp. Figure 3).

*Figure 3. Procedure for identification of GAs.*

Analysing existing process models, an activity, function, task, or corresponding element was selected in the first step in order to identify a new GA candidate. In doing so, the core activity had to be extracted (generalisation). As not all selectable components necessarily need to be activities (cp. discussion of heterogeneity of models in Section 3.1), they had to be (re-) phrased as a verb (e.g. “receive” instead of “reception”). This activity then became a potential GA candidate. In the third step, the catalogue of existing GA candidates – which due to the reused GAs was not empty – has been checked whether the new candidate or a synonym was already contained. If a synonym was contained, the new GA candidate has been added as an alternative. Subsequently, the procedure iterated until no new activities were identified respectively the GA catalogue was considered to be complete. As the
GA catalogue was not empty at the beginning, the case of synonym occurrence has frequently been experienced.

3.5 Resulting List of Generic Activities

Result of these design activities is the catalogue of GA candidates (including synonyms) which had to be evaluated. Evaluation was especially important as existing GAs from the public sector domain had been adopted without further reflections. Evaluation should identify those GAs and synonyms which are considered inappropriate or irrelevant for health care processes. In total, the catalogue consists of 19 GAs which are listed and categorised in Table 2. Thereby, 17 GAs from the public sector could have been reused with minor modifications (esp. regarding synonyms). Only two GAs had to be newly added to the catalogue which confirms the theoretically derived similarities of service delivery processes in public administrations and non-medical processes in health care organisation (cp. Section 3.2).

Table 2. Categories and related GAs.

Such categorisation does not only support users in quickly finding and selecting appropriate GAs but also enables implementation of mechanisms to ensure consistency and plausibility of the resulting models by double-checking syntactic and semantic rules (e.g. whether the GA “send” is connected with a corresponding “receive” or not). In addition, each GA is further specified defining its meaning, category, evaluation status, etc.

Although it was not in the focus of this investigation, typical POs have also been identified using the same, slightly modified procedure. Instead of extracting activities and re-phasing as a verb, components have been analysed with regards to contained objects such as documents, information or materials (e.g. medical products). Respective objects have been extracted and added to a PO catalogue. Some examples of the identified POs are drugs, internal requisitions and external purchase orders, invoices, and delivery notes.

4 CASE STUDY

In order to exemplify and evaluate the theoretical results presented above, and to practically prove the applicability of the concept in the health care domain, a case is presented in this section. Thereby, special emphasis is given to the illustration of the expressive power of the identified components. However, to validate our proposal not only the semantic, syntactic and pragmatic aspects are important (Lindland et al., 1994) but also the domain appropriateness since the model components are intended to capture the knowledge of the problem domain for the purpose of communication and understanding among the stakeholders (Siau & Rossi, 1998; Mylopoulos, 1992). Thus, Krogstie et al. (Krogstie et al., 1995) propose to subsume this as explicit evaluation criterion called ‘knowledge quality’.
4.1 What is the Case?

Hospital pharmacy is an interesting arena to bring many functions and relationships together for study. On the one hand, the hospital pharmacy acts as an interface between the many external stakeholders involved in supply of drugs and the particular hospital. The process documentation therefore has to comply with many, sometimes divergent, needs. On the other hand, it serves as a focal point for many internal departments (medical and non-medical). For example, the pharmacy is not only responsible for drugs supply but also offers consultancy services to clinics, prepares medical devices for the laboratory, provides additional information for the patient administration and financial department etc. Having this gatekeeper role, the hospital pharmacy is supposed to be an important opinion leader when logistic processes have to be re-engineered.

For the case study expert interviews represent the essential sources of information, and are the primary means for evaluating the utility of our approach. Semi-structured interviews were conducted with three hospital pharmacists and two purchasing managers who have at least 10 years practical knowledge in medical as well as in administrative needs. Main characteristics of the involved hospitals are provided in Table 3.

Table 3. Characteristics of the surveyed hospitals.

It is important to note that we did not involve explicit control or manipulation of any variables of the subject under study. However, to gain that deeper understanding we acknowledge our own subjectivity as part of research.

4.2 Application of the Components in the Context of a Hospital Pharmacy

Hospital pharmacies have a permanent obligation for service delivery, not only under usual circumstances, but also in case of a crisis. Therefore only a marginal fault tolerance in the procurement processes is admissible. Sophisticated mechanisms to manage the entire supply chain are needed. However, in health care this is more aspiration than reality (Burns, 2002). To understand the current drawbacks it is crucial to have an overview of the present situation. A key process is the general order routine for purchasing regular drugs (cp. Figure 4). We used this process to evaluate our proposal against the ‘knowledge quality’ criterion (cp. introduction of Section 4).
As described in Section 3.3, essential components for modelling processes are GAs and POs. When using BPMN as standard modelling language, the GAs can be used to determine the activity (italic text in rounded-corner rectangle) to be done within a task. The POs (plain text in rounded-corner rectangle) define the object an activity is operating on. However, other BPMN standard elements such as organisational responsibilities (swim lanes), events (circles) and gateways (diamond shapes) can be used as well. For instance, the presented process model starts with an event called ‘demand for drugs’. This event triggers a task within the ward containing the GA ‘search’ and PO ‘drugs’ which on its part causes a decision. The interface to the medical treatment process is represented by a black circle labelled ‘start medical treatment’.

### 4.3 Lessons Learned

Although not accustomed to think ‘in boxes and arrows’, the hospital pharmacists were able to understand and interpret the process descriptions. Furthermore, with a brief training they were able to model even complex processes by their own (simplicity of modelling). After a short period of learning how to model with predefined GAs, the time to depict a process or sub-process was significantly reduced even for inexperienced partners. In addition, comparability of processes has been improved: Same processes were modelled for different hospital pharmacies. Although there were considerable differences in the realisation of the processes, the flow of activities was still comparable since a standardised terminology was used. The terminological standardisation based on predefined GAs not only improves comparability of process models but provides an important foundation:

- to diffuse modelling in health care organisations by addressing also inexperienced users,
- to harmonise decentralised modelling activities,
- to enhance the efficiency of modelling and
- to enable extensive, model-spanning analyses.
Although the case study with hospital pharmacists could not evaluate all of these potentials, as a first step the applicability of the GA-based modelling concept by inexperienced users has been proven successfully. However, the suggested standardisation of modelling terminology still leaves room for misinterpretation. In order to further support the modeller, a system of rules should be incorporated which limit reasonable GA combinations or even suggests frequently used GAs (e.g. based on GA patterns). Such mechanisms will improve model quality by extending consistency and plausibility checks.

5 CONCLUSION AND FURTHER RESEARCH

In this contribution, an approach of component-based modelling developed for public sector organisations was introduced and adopted in the health care domain. Summarising, this adoption is considered quite successful by hospital pharmacists as modelling with GAs considerably improved standardisation and comprehensibility of process models. After brief introductions even inexperienced case study partners were able to conceptualise their process knowledge re-using predefined GAs. In addition, the link-up from GAs to POs supports consistency and model-spanning analyses.

However, some limitations became visible. Although only few GAs had to be newly introduced, the list of GAs is not yet representative as it bases on a limited number of processes used for identification. Thus, further evaluation needs to be conducted in order to complete the specification. Furthermore, the occurrence of specific GA combinations should be analysed in order to identify typical process patterns. Such rules and patterns will significantly improve effectiveness, efficiency and quality of process modelling. In addition, more POs should be identified and categorised in order to further standardise modelling. As competition is not that intensive and externalisation of internal knowledge is not considered that crucial, it is furthermore planned to record and provide process description (best practices) in a common repository.

In order to address divergent processes perceptions of involved people (e.g. medical specialists or administrative staff) and to harmonise their model-based conceptualisation, the composition of GAs should provide alternative terminologies (e.g. synonyms), a set of individual rules to restrict combinations of GAs for plausibility and consistency purposes as well as transformations into user-oriented model views. Those semantic features extend classical syntactical checks significantly. They can be implemented by means of ontologies (Uschold & Jasper, 2001). If GAs and POs are depicted in an ontology they can be re-used (instantiation and composition) by mapping the ontology concepts and properties to the meta model elements of a suitable notation, such as UML Class Diagram or BPMN (Saeki & Kaiya, 2006). The ontology-based standardisation of model content not only improves transparency and model quality but especially provides the foundation for other powerful mechanisms such as semantic analyses, e.g. regarding concrete weakness patterns (Baacke et al., 2008). Weakness patterns are combinations of model components that represent a deficiency, such as a media break or an inefficient communication channel. On that basis, analyses can be automated to some extent. As automated analyses are not limited to single processes, they can easily be applied to the whole process landscape. Hence, further research will aim at the development of standardised analysis patterns specialised on issues of the health care domain.

In order to realise and prove these potentials, the component-oriented and ontology-based modelling approach is currently being implemented in a software tool which will be used for extensive evaluations and further developments (PICTURE Consortium, 2006). As the case study presented in this paper just prove applicability in the context of hospital pharmacies, further – more extensive – evaluations have to address syntactic and semantic interoperability, comparability, processability and quality of resulting models as well as efficiency of process modelling. Last, it has to be investigated if this approach can be adopted to other industries, such as finance or insurance, as well.

Abstract

We show how agent-based simulation is used for analyzing different queuing strategies in the youth health care sector. The simulation model represents an authentic business case and is parameterized with actual market data. We discuss the differences between four queuing strategies which are based on push/pull allocation and centralized/decentralized queuing strategies. The model incorporates, among others, a withdrawal and return mechanism, a non-stationary Poisson arrival process, and a preference algorithm to include a care provider’s case preference. The investigated system accommodates extensive waiting lines which are currently solely judged on their length. We have identified that performance measurement in youth health care should not be focused on queue lengths alone, but should include a case difficulty parameter as well. The simulation results, together with contextual data obtained from stakeholder interviews, indicate that a push strategy with a centralized queue suits the sector best. Most related research in health care focuses on queuing theory which fails to address the complexity of the case. Our simulation approach incorporates additional complexities of the case at hand which turn out to be relevant for the queuing strategy decision. We validate the model and strategies by comparison with real market data and field expert discussions.

Keywords: Agent-based simulation, resource allocation, youth health care, queuing strategies, scenario analysis
1 INTRODUCTION

The Dutch youth health care sector aims to provide care to children on demand. Children can enter the system at the institution for youth health care at their own initiative and obtain an indication for professional help. A formal indication includes a diagnosis and entitles the child to receive care at a care provider of its own preference. The system is publicly funded and enforced by the law on youth health care since 2003. The national system is subdivided in multiple regional systems which cover provinces or urbanized regions. These local systems implement their own structures, including local offices of youth health institutions, care provider agreements, and financial systems (Figure 1).

Over the last few years, the Dutch youth care sector has faced long waiting lists and long waiting times, a problem that has received a lot of media attention. The government has provided funding on several occasions, which did not result in a permanent solution. Hiring interim managers to reorganize internal operations at for instance a local office of the institution for youth health care turned out to be unsuccessful as well. The approach taken in this research starts with the observation that the real problem is not solely the waiting list length or waiting time as such. We claim that it is rather a problem of the current strategy of allocating cases to care providers in general. In our opinion, methods that solely address the symptom of long waiting lists will be ineffective in the long run. We shall consider solution directions that not only focuses on the handling of contemporary waiting lists, but that may require structural changes in the system.

We elaborate on such structural changes by presenting an overview of multiple allocation strategies, based on a combination of push/pull strategies and centralized/decentralized queuing strategies. The push and pull strategies define the party which ultimately makes the actual allocation decision. This could either be the institution for youth health care that pushes specific cases towards care providers, or the care provider that pulls the specific demand for care towards its resources. Centralized and decentralized queuing strategies define the moment at which the actual allocation will take place. A centralized strategy postpones allocation of children until the moment they can instantly get care; in other words, at the moment a care position has become available at a care provider and can be dedicated to the specific case. This strategy results in waiting lines at the institution for youth health care. A decentralized strategy allocates cases immediately as much as possible when they arrive in the system; this will result in waiting lines both at the institution for youth health care and at the care providers. Allocation decision problems, as presented by the youth health care case, suit very well a multi-agent simulation approach, as the allocation decisions depend on communication between the
different parties in the system. Furthermore, institutions and persons have their own objectives and the coordination thereof needs to be addressed explicitly. The actual clientflow through the system is the result of a negotiation process between several parties in the supply chain. Indeed, a case allocation procedure requires input from other parties in the sector on which the final decision can be based. Since a multi-agent simulation is built of individual agents that pursue a specific personal goal, it is fairly easy to configure and study alternative allocation strategies in a simulation environment.

Our objective is to provide insights into the allocation problem and to advice on possible improvements by discussing and evaluating a variety of allocation strategies. The analyses are supported by an agent-based simulation model. The model simulates the allocation process in the youth care sector as well as the directly coupled processes of case indication and the actual treatment. The parameters of the model are loaded with stochastic distributions which are based on actual data taken from one province in the youth care sector. While it is difficult to play around with the actual system itself, the simulation model provides a rich but risk free environment for testing varying resource allocation strategies. A simulated environment has the advantage that multiple decision algorithms and coordination structures can be used for experiments. This approach enables analyses on long term effects of certain strategies while maintaining focus on inter-agent interaction. Such studies would be hard, if not impossible, to perform in the real world system, because one cannot make structural changes in the real world system just to study a certain long term effect. Our approach contributes to the research in information systems and agent-based simulation, since it proves the usability of an agent-based approach in a real world environment by not only matching the current decision making process but also by studying varying alternatives. The model is loaded with an extensive amount of stochastic distributions based on actual market data and successfully matches the performance of the real world system. This research contributes to the research in resource allocation in health care by providing a currently unused approach to counter queuing related issues. Simulation of the resource allocation process helps to understand and test long term effects of varying allocation strategies and coordination decisions. We contribute to research in information systems by improving the human decision-making process. Our study on the different strategies on the youth health care system decreases the information overload which increases the rate of fair child allocations. This will improve socially responsible welfare decision-making.

2 LITERATURE REVIEW

Waiting lines in the health care sector have received little attention in the scientific literature, although hospitals and general health care face similar problems with waiting lines. A common approach taken by governments to tackle these problems is the injection of capital which is used to increase capacity. This provides a short term solution, as available capacity and queue lengths reach a new equilibrium after a short while (Hurst & Siciliani 2003; Postl 2006). Saulnier, Short & Gruenwaldt (2004) identified five popular approaches to decrease waiting times: monitoring of procedures, using priority scoring tools, setting waiting time targets, using an external advisory body, and registering online. However, Rachlis (2005) argues that such methods do not work by themselves; better coordination and flow control should increase performance at the public sector. Waiting lines in health care feature withdrawals when clients have to wait for an extended amount of time. Several studies have shown that the amount of time that a client is willing to wait for care is related to the urgency of the problem (Goodacre & Webster 2003, Goldman et al. 2005). More urgent problems are difficult to treat elsewhere, while they genuinely require attention. These cases will therefore accept longer waiting times. The converse holds for less urgent problems. Most literature on waiting line management in health care are based on the mathematical approach described by queuing theory (Torgerson & Mcnntosh 2006). These studies focus mainly on utilization of resources and calculations of the minimum required amount of treatment positions while maintaining a high service rate (Gorunescu, McClean & Millard 2002a & 2002b; McManus et al. 2004). These studies show how queuing theory struggles with phenomena like seasonal effects and withdrawals. These issues are also identified by
Brown et al. (2003) who argue that traditional queuing theory has a series of shortcomings like, among other things, the absence of customer withdrawal behaviour, time-dependent parameters or customer heterogeneity. These three characteristics are all notably present in a health care system. Mandelbaum & Shimkin (2000) tried to construct a model for withdrawal. They acknowledged that a lot of work needs to be done to achieve practical usability of queuing theory.

Only a limited amount of literature studied the waiting line problem by means of event-based simulation (Ridge et al. 1998, Bagust, Place & Posnett 1999). While these studies include stochastic processes and basic withdrawal schemes, they still solely focus on utilization issues and capacity planning. To the knowledge of the authors, agent-based approaches have not yet been used in this context. Event-based simulation is able to include an extensive level of complexity in the model like withdrawal & return behaviour, seasonal arrivals and client heterogeneity. An agent-based model in addition is also suited to quickly implement and experiment with alternative strategies and coordination flows. These experiments are difficult, if not impossible, to implement with queuing theory. Research on waiting lines and times by means of simulation is rarely used in the health care sector in general. While other sectors with comparable cross organisational networking structures like container ports were studied with agent-based approaches (Moonen et al 2005), an agent based approach in health care is even unique in its kind. This study will therefore provide a first example of the usability of agent-based methods for improving performance in the health care sector. It will contribute to scientific research in studying an agent based simulation approach on a genuine and new business case in practice with a significant amount of market data in the youth health care sector. Unfortunately, research is not able to provide a clear definition of what an agent is. While most researchers agree on certain aspects of an agent, it seems not easy to integrate all views in one grand perspective (Lang et al 2008). The four and most appreciated aspects are autonomy, social ability, reactivity, and pro-activeness, this set has become known as the weak notion of agency (Wooldridge & Jennings 1995). The authors state that an agent is a hardware, or software based computer system, or both, displaying the properties of autonomy, social adeptness, reactivity, and pro-activity.

3 THE SIMULATION MODEL

The agent-based model extends the Distributed Simulation Object Library (DSOL) simulation environment (Jacobs et al 2002) and was run on a conventional desktop computer with settings as shown in Table 1. This environment provides the discrete event simulation engine, the theoretical distributions and a toolkit to design a simulation model as a set of loosely coupled objects. Because of the latter, the suite is ideal for implementing an agent-based model since it enables the design of agent who are physically disconnected from each other. While the simulation environment provides all the elementary building blocks of a simulation, the model itself only concerns the agent specific parts. Other research studied agent-based simulation architectures and the required components for building an agent-based model (Ketter et al 2009, Collins et al 2002).

*Table 1 Technical information of system used for analysis.*

1 The total amount of data used for the study was about 20 GB from 256 replication runs.
2 The model runs on one processor core, therefore the model can be ran on both processor cores simultaneously without drastic influence on the average processing time. The given value is based on the average processing time while running the model twice in parallel on the same machine.
There are several types of information identified in the model. First, there are parameters which define fixed values like agent names, the theoretical distributions and the geographical home location of an agent. These parameters are mined from real world health care data. Second, there are dynamic data stores which hold process information upon which an agent can make decisions. This group of information can be divided in two groups; the transactional data store and the decision data store. The transactional data store holds records of the overall process of an agent. For instance, the agents of the institution for youth health care maintain an internal database of care lines which holds all relevant information of a case. The care provider agent hold a similar database, however holding only information which is relevant and accessible for these agent. The transactional data store in such is factual information which represents historical record keeping. The decision data stores, on the other hand, hold short term information which is relevant in executing the allocation strategy on a certain moment in time. The appraisal of this data decays over time since its trustworthiness decreases as time passes by. For instance, the institution for youth health care who decides on the best location for allocating a case based on known data and estimates of dated data.

The core model is constructed around a strict path which all cases in the system will follow. This flow is used in all four strategies. The white box indicates that the used allocation strategy might differ, while the remaining parts stay the same. Each child or case will be created at the top-left. The model includes mechanisms for the allocation process, the waiting phase and the treatment itself. Further it includes withdrawals during the waiting phase and returns after treatment or withdrawal. A core concept in this model is the use of a case selection process for treatment at the care providers. An overview of this process is shown in Figure 2. When a care provider selects the next case for treatment, he will judge the cases in his queue on certain characteristics for fitting with the available treatment location. This is modelled as an fit with the age of the child which results is a potential list of cases for treatment. While the order of these cases should be on ‘first come, first serve’ basis, this rule is violated by the care providers when possible because they prefer easier cases. More easy cases means more throughput which increases profit for the care providers. The political influenced decision algorithm, which is shown in Figure 2, will order the potential cases by preference of the care provider. The political influenced decisions are responsible for the major part of the differences in performance between the allocation strategies. Without this algorithm all strategies would perform roughly similar because the selection procedure would maintain a strict ‘first come, first serve’ order.

![Figure 2](image-url)  
*Figure 2* Overview of the case selection process for treatment at the care providers. The dashed boxes represent factors which set restrictions on the set of potential cases The single lined boxes represent the set of cases which can potentially be selected while de last (double lined) box represents the final case selected for treatment.

Equation 1 is responsible for the political influenced ordering of the cases which has been developed by use of a balanced scorecard technique (Kaplan & Norton, 2005) based on interviews with field experts and the evaluation of real world data. The matter at hand is intangible, complex and hard to express in words; often these issues live in one’s mind rather than being written down in some kind of procedures, therefore the interviews were of an unstructured kind in order to manoeuvre the discussion into the most fruitful directions during the interview. Among the experts are: a youth health care consultant with a high level of experience in the sector, a case manager at the institution of youth health care with operational experience, a financial director at a care provider with operational experience and some strategic experience, a director at a care provider with strategic experience and some operational experience. The results of these interviews are translated into a set of constraints...
which the equation should obey. These constraints are parameterized into the resulting equation which consists out of two parts; the influence of a case’s waiting time (left) and the influence of the expected treatment time (right). Waiting time is estimated to influence the decision mainly in the first weeks; a case which is waiting just a few days cannot precede a case which is already waiting a long time because the care provider will not be able to justify such a decision to the institution for youth healthcare. This effect is estimated to be decelerating decreasing with the turning point at the threshold value\(^3\). This simulates the effect of a rapid increase in preference in the first weeks of waiting while it flattens out afterwards. The second part represents the expected treatment time by a care provider. Cases with below average treatment times are preferred in any case, however the higher the treatment time, the lesser the preference which is expected to be exponentially increasing. The threshold value is related to the average treatment time in order to set the estimated steepness of the preference line. The graph in Figure 3 shows an example of four potential cases after making a subset for age characteristics of the open treatment position. The cases differ on waiting time and expected treatment time. It can be seen that the waiting time order (when solely looking at the waiting value in decreasing order; B-C-E-G) differs from the preference order (looking at the acceptance value in decreasing order; C-E-B-G). When solely looking at the waiting time, child B should be selected, however the preference function will prefer child C.

\[
\text{acceptance factor} = \frac{\text{threshold\_waiting}}{\text{waiting\_time} + 1} + \frac{\text{treatment\_time}^2}{2 \cdot \text{threshold\_treatment}^2}
\]

\(1\)

![Figure 3](image.jpg)  

**Figure 3** Indifference curves of the political influenced decision algorithm for specific acceptance factors including a example subset of children ready for allocation.

This core model, including the political influenced decision algorithm, is the same for all four strategies. The difference will be in the process which performs the actual allocation. While the current allocation strategy in the youth care sector is based on pushing cases towards the care providers at the moment they receive an indication for care needs, it is considered that a push can be postponed until the moment that a care position becomes available. This centralizes the queue at the institution of youth healthcare which will enable the supply chain to more effectively match cases to care positions. Such an system would reduce the ability of care providers to make preference based selections since the institution of youth healthcare has a much better view and control on final case selection which increases fairness in the system. Care providers are likely better in estimating the actual treatment plan for a child than the institution of youth healthcare since they are the party

\(^3\) Threshold\_waiting is set to 32 days, threshold\_treatment is set to the average treatment time of the care provider in question. These settings are based on interviews with field experts and evaluation of real world data.
providing the actual care to the children. Therefore it would increase the efficiency of the system when the care provider would also decide which child should be treated next. This strategy changes the push system into a pull system in which the care providers select cases from a pool of children requiring treatment. Note that the moment of selection still enables the possibility of maintaining centralized or decentralized queues, therefore we will address the following four types of allocation strategies.

1. **Pushing cases to decentralized queues [Decentralized Pushing].** When a case is indicated at the institution for youth health care, it is immediately pushed to one of the care providers. The push is performed by the institution for youth health care. This strategy is currently implemented in the youth care sector. In this case the care providers maintain and control their own queues while the institution of youth health care only tracks the development of a case. The political influenced decision algorithm can significantly influence the order of treatment because this strategy positions all cases at the care providers. The allocation itself is performed by the institution of youth health care which makes the decision based on a estimated ‘shortest queue’ algorithm. Each institution agent maintains a list of known queue lengths to support this decision. The value of each item in the list however decays when time passes by. The algorithm estimates the current queue length at a care provider by judging the available information while it gets maximal three requests for an updated queue length per case. The agent therefore makes the final decision on partially uncertain information.

2. **Pushing cases from a centralized queue [Centralized Pushing].** When a case is indicated at the institution for youth health care, it is held in a centralized queue until a fitting treatment position becomes available. The institution for youth health care maintains and controls the central queue while the care providers have no queue at all. The care provider announces that treatment positions become available and the institution of youth health care pushes the next case for treatment. The political influenced decision algorithm at the care providers is blocked in this strategy since there are no cases to choose from except for the case pushed by the institution for youth health care.

3. **Pulling cases from a centralized queue [Centralized Pulling].** When a case is indicated at the institution for youth health care, it is held in a centralized queue until it is pulled by a care provider which offers an open treatment position. The institution for youth health care publishes the waiting list on a bulletin board for evaluation by the care providers. The care providers do not maintain their own queues. The institution for youth health care monitors selection behaviour by maintaining ‘first come, first serve’ order on comparable cases. Care providers anticipate on this rule by applying the political influenced decision algorithm to choose between multiple fitting, but incomparable cases on the bulletin board to select the following case.

4. **Pulling cases to decentralized queues [Decentralized Pulling].** When a case is indicated at the institution for youth health care, it is published on the bulletin board until it is selected by a care provider which promises to offer a treatment position in the future when it becomes available. Both the institution for youth health care and the care providers maintain queues in this strategy. A care provider prefers easy cases but must also select the comparable preceding cases if it wants the preferred case. Postponing a preferred selection however increases the chance that another care provider selects the case while it also increases the chance of ending up with an empty queue. An empty queue means that a care provider cannot find a fitting case for a treatment position which is considered worse than treating a unprofitable case. The care provider will evaluate the trade-off between the inclusion of less easy cases in the allocation and the chance on running his own queues empty. This selection behaviour by care providers is simulated by the function from Equation 2. The equation shows the algorithm used to judge cases on the bulletin board. The equation consists out of three parts; influence of current queue length (left), influence of estimated treatment time (middle) and the influence of the interaction between these two factors (right). The equation is based on interviews with field experts\(^4\) which prescribed a set of constraints; When a care provider faces a low queue length for a given treatment type, he is likely more easily willing

\(^4\)Threshold\_queue, threshold\_treatment and threshold\_steep are based on interviews with field experts in order to create the desired effect of decision making for this allocation strategy.
to accept new cases in order to ensure full utilization of resources (i.e. bedrooms). The longer his queue, the less willing he is to accept new cases which will decrease exponentially as the queue increases. The expected treatment time of a case will also influence the decision because the care provider will try to avoid the most difficult and therefore unprofitable cases. Ultimately these two factors interact with each other which weaknesses the willingness to accept cases even further if at least one of the two dimensions scores rather high.

\[
\text{acceptance factor} = \frac{\text{queue length}^2}{\text{threshold queue}} + \frac{\text{treatment time}^2}{(2 \cdot \text{threshold treatment})^2} + \sqrt{\frac{\text{queue length} \cdot \text{treatment time}}{\text{threshold steep}}}
\]  

(2)

## 4 MODEL ANALYSES

The model is parameterized, verified and validated with real world data during three months of full-time analyses. The model is initiated with 7 youth care institutions and 8 care providers which have a capacity and a geographical location in the studied region. These will be unchanged during the entire simulation. The children are generated during the time of the simulation by a non-stationary Poisson distribution to include a seasonal influenced arrival effect. The age of the arriving children is included in the simulation to include the non-uniform division of age over the generated children. The age of a child is important for the age related aspect of the treatment positions. Further a distinction is made on the crises level of a case. Some cases are remarked crises which means that these cases are allocated and get treatment at once. These cases bypass the allocation strategy but do influence the usage of capacity in the model. Note that a ‘crisis’ denotes a case of extreme urgency and that its level of difficulty can be of any kind. Each generated child will be indicated with a varying amount of care needs. These needs can be indicated simultaneously at the first indication or re-indicated after a withdrawal or a successful treatment. This also involves the analyses for withdrawal chances during the waiting phase and return chances when withdrawing or ending care. A return further involves a return interval since the child will not return immediately but after a varying amount of time. Since a child cannot be geographically allocated at random due to practical distance limitation, the analyses include a set of chances for maximal allocation distance from the view of the child’s home location. A case is provided with a identifier which represents an attribute for a case’s difficulty. The difficulty of a case cannot be analysed but is considered to be uniform distributed for the purpose of this research. The treatment time distributions differ among the care providers, the treatment time is therefore coupled to the difficulty identifier and the care provider. Table 2 lists the parameters and types of distributions as they are used in the model.

Table 2 Model parameters with validation and type of distribution remarks. The validity results range from bad to good, respectively: --, -, 0, +, ++.
The model is initiated as a non-terminating system since decisions and performance measures depend on long lasting developments. The model is pre-filled at start in a fully utilized state at the care providers while there are no waiting lists. This procedure will decrease the required warm-up length of the model. Warm-up time has been determined by the method of Welch (1981, 1983) which resulted in a warm-up time of 4 years simulation time. The replication length has been set to 20 years simulation time in total.

The verification of the model is split in two groups; first, the introduction of state-transition control and the implementation of numerous checks during the simulation which ensure a correct flow of cases through the system. Second, in-depth source review by others who didn’t participate in the design of the model verified the correct coding of the model. These two types of verification resulted in the acceptance of the model as technically correct.

The validation process is split in three groups; first, the results for the input parameters of the model are compared to the expected values which are based on the real world data which was used for the input analysis. The comparison of chance variables is performed by matching the average results with the expected value. The theoretical and empirical distributions are visually compared with the results. The results are split into multiple independent sections which enables the comparison with a specific certainty. This procedure is required to avoid biased judgement due to the stochastic nature of the parameters in question. The results of this comparison phase are listed in Table 2; the column ‘valid’ represents the result of the validation process of a particular parameter in the simulation model. Second, two of the most important but less understood parameters of the model are analysed for sensitivity. The determination of a case’s fit by comparing the age of the child to the preferred age of the treatment position depends on a certain range which is considered acceptable. The results showed low sensitivity on this setting. The other value for sensitivity analyses is the political influenced decision algorithm. The results showed moderate sensitivity on these values. The third validation group is the user validation by field experts (1 youth health care consultant with a high level of experience in the sector, 1 case manager at the institution of youth health care with operational experience, 1 financial director at a care provider with operational experience and some strategic experience, 1 director at a care provider with strategic experience and some operational experience). The results show that the model mimics expected behaviour accurately. The field experts recognized much of the real world system in the model’s output. For example, the arrival distribution including seasonal effects and the construction of treatment trajectories including crises, parallel and repeating cases were found realistic representations of reality. The model has been found valid on almost all aspects and is therefore assumed sufficiently accurate for this research.

5 RESULTS AND DISCUSSION

The strategies are judged on a set of 5 Key Performance Indicators (KPIs); 1) Ratio of (difficult) cases that are taken into care, 2) Ratio of (difficult) case withdrawals from the waiting lines, 3) Amount of (difficult) cases on the waiting lines, 4) Aggregated waiting times for the (difficult) cases and 5) Utilization of care positions at the care providers. The KPIs are developed by discussion with field experts, publications from the youth care sector and evaluation of real world data which indicate the importance of these measures. Interviews with field experts indicated that a major shortcoming of the current system is the neglecting of difficult cases. The law on youth care indicates that children in need of care should be able to receive it. However Andriessen and Besseling (2008) argue that there are many cases which receive help via the institution for youth health care are not genuine cases requiring professional help. The authors indicate that these cases shouldn’t enter the system because either the indication of a problem is falsely recognized or the problem is of such a low level that they are able to help themselves. The field experts join this conclusion. The KPIs therefore include a division in average performance and performance for the more difficult cases which are often neglected by the system.
The analyses of the KPIs are based on 10 replications per strategy to avoid biased judgment due to the stochastic nature of the model’s parameters. The replications are joined together in order to construct 95% confidence intervals for each KPI in each allocation strategy. Difficulty has been separated in 5 groups sorted from minimal to maximal difficulty. The two groups of the highest difficulty represent the performance on difficult cases. By means of Pareto analysis we illustrate the trade-off between efficiency and fairness in the system as summarized in Figure 4 which shows the average performance and performance on difficult cases in one overview. The spheres represent the performance scores of an allocation strategy. The horizontal axis illustrates the performance on the service level related KPIs while the vertical axis illustrates waiting line related KPIs. A lower value (towards the lower-left corner) represents better performance. The line in-between the spheres illustrate the continuum on which combined performance will be found depending on the relative importance of the performance types.

The graph shows that the average performance and performance for difficult cases differs significantly among the strategies. None of the strategies score similar performance. It also shows that the choice between a focus on average performance or difficult case performance greatly impacts the order of performance between the strategies as indicated by the rather long lines (except for centralized pulling). It further illustrates a trade-off between waiting line and service level aspects. It appears that decentralized pushing is performing best on waiting line aspects, whether it is on average or difficult case performance. It however loses on the service level aspect from both centralized pushing and pulling. The graph therefore helps to understand the effect of preferring one type of KPI above the other. In this analyses however, the importance of the KPIs is considered equal.

![Figure 4 Trade-off between waiting line and service level aspects.](image)

The relative importance of difficult case performance over average performance is difficult to quantify. There the following assumptions about its ratio explain the effect of a certain choice.

I. Average performance is important, difficult case performance not. This is the set of small spheres, which results in an order of strategies (best strategy first): 1,3,4,2
II. Average performance is equally important as difficult case performance. This is the spot in the middle of the lines. Order of strategies (ampersand means equal): 1,2&3,4.

III. Average performance is not important, difficult case performance is the important measure. This is the set of big spheres. Order of strategies: 2,3,1,4.

IV. Average performance should be respected, however difficult case performance is of a higher importance to avoid the neglecting of these difficult cases. This is the spot on the line which is found between the middle of the line and the bigger spheres. Order: 2,1&3,4.

These assumptions are not randomly chosen but rest on the way the system is judged by different people. Assumption I is related to the traditional way of judging the performance in the youth care system as it is still used currently. Assumption III, on the other hand, is related to the perception of field experts and researchers who claim that the difficult cases should be the primary focus of performance measurement since they are in the greatest need for care. Assumption II is the simplest method to share the importance of both these views and will likely be the result when discussions in the youth care sector don’t bring forward a preference for one or the other. Assumption IV is our point of view since it emphasizes the importance of the difficult case performance while it still respects the average performance. It is considered that a slightly worsened average performance isn’t bad as long as the difficult cases can profit significantly from it. The balance should be towards the point that these difficult cases cannot profit anymore without significantly decreasing the average performance. It is acknowledged that such an strategy would require a change in the financial system because the current system would underpay the care providers who are paid on an average case basis.

6 CONCLUSIONS AND FUTURE WORK

We have presented an approach for analyzing a number of resource allocation strategies in the youth health care sector while including an extensive set of constraints and behaviours from the real world system. The model successfully simulated many of the complex relations between the involved parties in the system. We demonstrated the ability of the model to incorporate different allocation strategies while maintaining an overall structure which deals with the common tasks outside the allocation procedure. We discussed the differences between the scenarios and their impact on system performance. The introduction of a case’s urgency into performance measurement leads us to the advice of the push from a centralized queue strategy for future resource allocation in the youth health care sector. The postponement of the actual allocation in this strategy ensures a higher level of fairness in treatment provision by the care providers because they cannot avoid the difficult cases anymore.

Our approach shows the usefulness of agent-based modelling in complex environments like the youth health care sector where much of the problem is related to coordination and communication between different parties. The research therefore contributes to research in information systems and agent-based simulation by not only showing its usability in such a setting but also showing the ability to study alternative strategies which couldn’t be studied otherwise with this level of complexity. We also contribute to research in information systems by advising a different allocation strategy. This strategy will increase social welfare by increasing the system’s fairness for provision of treatment.

We intend to study further alternative strategies. Within the four strategies there is plenty of room to introduce alternative concepts such as auctioning and case exchange between care providers. We further intend to introduce an implementation of a human preference model into the decision making process as well as human computer interaction. The agent-based architecture of the simulation model is ideally suited to implement such alternatives since it only involves changes in the respective agents. Currently, our evaluation process for the simulation results are based on a balanced scorecard technique. We are planning to define a multi-attribute utility function as a comparison and extension to the current approach. Such a function would allow the floating transition of the trade-offs between different desired properties of patients’ allocation.

RFID-ENABLED PROCESS CAPABILITIES AND ITS IMPACTS ON HEALTHCARE PROCESS PERFORMANCE: A MULTI-LEVEL ANALYSIS

Abstract

In recent years, hospitals have begun to invest in RFID systems to control costs, reduce errors, and improve quality of care. Despite the obvious benefits of RFID in healthcare settings, potential obstacles to effective deployment also exist. The purpose of this study is to systematically understand how hospitals can apply RFID to transform work practices and address cost, safety, and quality of care issues, most notably in inventory management. We leverage an interdisciplinary framework to explore adoption and use of RFID at multiple levels of analysis and adopt a multi-method approach to explore the research questions guiding this study. Our study is expected to contribute to a growing body of research related to the adoption and use of IT in healthcare settings and the enabling role of IT for innovating work practices and improving process performance.

Keywords: RFID, Healthcare IS, Multi-level Analysis, IT-enabled Process Capabilities, IT Adoption
1 INTRODUCTION

The adoption and use of innovative technological solutions for solving business problems have been arguably slow within the healthcare industry (Herzlinger, 2006). However, in recent years, burdened with rising healthcare costs and increased competition, hospitals have begun to invest in advanced IT systems such as RFID-based systems to control costs, reduce errors, and improve quality of care (Datamonitor Report, 2008). In fact, as referenced in Lee and Shin (2007), the global market for RFID systems and tags in hospital settings is expected to increase from $90 million in 2006 to $2.1 billion by 2016 (Harrop and Das, 2006). Nevertheless, despite the obvious benefits of deploying RFID technology, there are some apparent downsides, too. High costs, difficulty integrating with legacy systems and interoperability with life saving medical equipment, incompatible communication standards across major entities in a healthcare network, and entrenched work practices are all potential obstacles to effective adoption and use of RFID in healthcare settings (Smith, 2005).

The focus of this research project, therefore, is to systematically understand how to apply RFID as a transformative technology to address cost, safety, and quality problems in this ever important industry. To narrow our scope, this research focuses on the use of RFID within a bounded set of activities and work processes in the healthcare industry. Namely, we focus on inventory management processes that support the delivery of two types of healthcare services. These services differ on key dimensions related to the variety and value of products used during procedures, the range of procedures performed within the service areas, and the urgency with which services are often performed. We draw from prior research to deepen our understanding of how IT can be leveraged to improve inventory management and purchasing processes (Cohen and Lee, 1998) as well as a broader array of supply chain activities (Rai et al., 2006, Scott and Westbrook, 1991). Although the findings from prior research are relevant and useful, the healthcare context presents some unique challenges for adopting and using IT to improve work practices and the delivery of key services.

First, products and equipment used in medical procedures can be extremely expensive; a basic stent used in a cardiac catheterization can easily exceed three thousand dollars. Second, doctors face high uncertainty in terms of the types and amount of product they will need, due to the diversity in patient characteristics (one size does not fit all when it comes to a stint) and fluctuating volumes. Third, the urgency of medical procedures—where the difference between life and death can be at stake—means that inventory checked out from the holding bins may not be accounted for properly, which makes inventory tracking difficult. Fourth, most hospitals utilize a consignment process for managing inventory, wherein vendors maintain a minimum level of inventory, and hospitals only pay for over-and-above the minimum inventory level. While this lowers the risk for hospitals, it creates issues related to product expiration and tracking due to lack of accountability of the representatives. These contextual characteristics that are specific to healthcare settings lead to our first research question:

1) How do contextual characteristics of healthcare services impact the adoption and use of RFID technologies for inventory management?

In addition to understanding the contextual characteristics that impact RFID adoption and use, it is also important to develop a more sophisticated understanding of the mechanisms through which RFID generates value in specific healthcare settings. Though past studies have moved from a firm-level to a process-level focus for understanding how IT impacts performance (Rai et al., 2006), both types of studies typically remain at a singular unit of analysis. Recent IS research argues that studies adopting a singular unit of analysis have inherent shortcomings, and encourages IS researchers to explore the linkages
between levels of analysis and the processes by which system adoption and use creates value (Burton Jones and Gallivan, 2007). Though the primary focus of this research is on the adoption and use of RFID for improving inventory management processes in healthcare services, we are also interested in the downstream consequences to the work practices that are embedded in the delivery of the specific healthcare services. Thus, inventory management processes fulfill and interface with the delivery of healthcare services, such as the two we have targeted for this study. Therefore, to understand the mechanisms through which RFID generates value (or the obstacles to generating it), it becomes critical to evaluate how the work practices of inventory management change, as well as the corresponding impacts to the work practices of the providers that deliver key healthcare services. Only then can RFID be effectively leveraged and the performance impacts accurately measured. Therefore, the importance of a multi-level analysis in this setting leads to our second research question:

2) How do changes in inventory management work practices (enabled by RFID) correspond to changes in work practices that are embedded in the delivery of key healthcare services?

In the following section, we provide the theoretical background and research model that guide this study, followed by a discussion of the methodology and the plan for completing the project.

2 THEORETICAL BACKGROUND

This article utilizes the IT-enabled process capabilities perspectives (Sambamurthy et al., 2003; Barua et al., 2004; Pavlou et al. 2006, Rai et al., 2006), to study the impact of RFID in healthcare inventory management. According to this perspective, resources refer to the firm's assets such as investments in IT infrastructure, whereas capabilities refer to processes and routines that help a firm to apply and reconfigure resources. The extent to which a firm is able to leverage, reapply and reconfigure its internal resources forms the fundamental basis of its competitive advantage.

Consistent with the IT-enabled process capabilities perspective (Rai et al., 2006), we characterize the investments in RFID technologies as resources, and the corresponding capabilities developed, as RFID-enabled process capabilities. Several technologies have been used for inventory management in the healthcare industry. For instance, bar code technologies combined with inventory management systems have been used in several cases for handling inventory (HealthCareIT News, 2004). However, the characteristics of an RFID-based system (discussed in RFID-enabled process capabilities section) provide unique opportunities for a firm to develop important process capabilities that were previously unavailable to the focal firm (Curtin et al., 2007; Dutta et al., 2007). To develop our arguments further, we draw from extant research on healthcare and supply chain management literature, to build our research model.

3 RESEARCH MODEL

The research model proposed in this article is shown in figure 1. The model postulates that healthcare process performance consists of three dimensions namely economic, structural and clinical performance. Healthcare characteristics, which include inventory uncertainty, patient safety and consignment characteristics are postulated to have a direct impact on healthcare process performance. By eliminating several inventory bottlenecks, RFID-enabled process capabilities are postulated to moderate the relationship between characteristics of healthcare service and process performance. Each of the constructs in figure 1 are described below.

3.1 Healthcare Process Performance
Healthcare process performance refers to the performance benefits realized by the focal hospital for inventory management. It refers to the overall value derived by the focal hospital through its implementation of inventory management strategies and is defined as consisting of three dimensions namely economic performance, structural performance and clinical performance (Solovy and Chaiken, 2003). These three dimensions refer respectively to the financial, work-related processes, and care-related processes in the healthcare context.

Economic performance refers to the return on investment (ROI) from the implementation of inventory management strategies (Solovy and Chaiken, 2003). IT investments are shown to contribute positively to the production of services (Menon et al., 2000) and to financial performance (Menachami et al., 2006) in the healthcare industry. However, several researchers including Bauer (2004) and Vogel (2003) argue that conventional analysis of ROI, as increase in revenues, has led to a misconception among healthcare practitioners that IT investments in healthcare does not yield positive ROI. They argue instead that in healthcare setting ROI should be computed as reduction in costs, and should be based on future cost of health personnel.

Structural performance refers to the process improvements in the functioning of various activities, through the implementation of the inventory management strategies (Solovy and Chaiken, 2003). It includes improvements such as workflow efficiencies in inventory management process, streamlining of inventory management activities, and reduction in processing time, enhanced inventory turns, less inventory shrinkage, increased visibility and provision of secure information.

Clinical performance refers to the process improvements in the various patient-care processes, through the implementation of the inventory management strategies (Solovy and Chaiken, 2003). It includes
improvements in processes such as reductions in inventory errors associated with a patient, reductions in inventory use due to mistakes, and streamlining of inventory ordering for patients.

These performance dimensions refer to the multi-level impacts in healthcare. While economic and structural performance refer to the inventory process performance (therefore at the process-level), clinical performance relates more to the delivery of care, which we consider to be the higher-order impacts. Therefore, to understand the mechanisms through which RFID generates value (or the obstacles to generating it), it becomes critical to evaluate how the work practices of inventory management change, as well as the corresponding impacts to the work practices of the providers that deliver key healthcare services within this context.

3.2 Characteristics of Healthcare Service

Healthcare context presents some unique challenges for realizing inventory management performance benefits. These contextual considerations are documented under the umbrella term healthcare characteristics. We refer specifically to three healthcare characteristics that have an impact on inventory management practices, and subsequently to healthcare process performance, namely: Inventory uncertainty, Task urgency and Consignment accountability.

3.2.1 Inventory Uncertainty

Hospitals typically manage their inventory in a centralized repository, and is transferred to individual departments based on the patient needs and the procedure performed (Ducllos, 1993). Most often, doctors have specific preferences for the type of inventory (such as stents, catheters) to be used in a procedure, than being dictated by hospitals or vendor consultants, and is argued to be a “big source of the inefficiency in healthcare” (McCarthy, 2006, p. 291). Also, predicting the exact product to be used in a procedure is difficult. This uncertainty in inventory requirements means that the number of inventory picked from the central location to the procedure room is usually over-and-above the required set of inventory. Inventory wastage in hospitals happens because such additional inventory is not replaced, accidentally misplaced, or is trashed. Such inventory wastage could contribute to lowering of economic performance in inventory management.

3.2.2 Task Urgency

Task urgency refers to the stress related to the task and the corresponding time pressure faced by the doctors, nurses and hospital staff while performing a particular procedure. Prior research on the work conditions in hospitals, has shown that work-related stress experienced by hospital staff and nurses are consistently high (Caplan, 1994; Stordeur et al., 2001). The stress level in operating rooms and catheter labs are even more pronounced, given the nature of the task performed, such as surgical and emergency procedures. As doctors and nurses face task urgency, the focus is more on the procedure performed, rather than on the handling or management of inventory used in the procedure. This implies that inventory tracking takes lower precedence compared to other important tasks, and could lead to decreased economic performance because of inventory wastage. In other cases, wrong inventory might be chosen in a hurry by the hospital staff and nurses. As the possibility of medical errors due to incorrect inventory exists (McNutt et al., 1997), task urgency could also lead to a decrease in clinical and structural performance.

3.2.3 Consignment Accountability

Consignment system refers to the practice by which vendors own the inventory, until such time it is actually used by the hospital (Ballard, 1991). This practice is a variant of the vendor managed inventory
(VMI) system (Williams, 2000), wherein the vendor assumes inventory risks while stocking, and takes responsibility for replenishing it, and the hospitals pay only after the inventory is used.

Although hospitals stand to benefit from such a system due to decreased inventory risks and costs, consignment system also has important limitations. First, in the consignment system, inventory check is performed by vendor consultants on a scheduled basis (batch activity), instead of on-demand basis (transaction-based) (DiGiacomo, 1991). For hospitals that see fluctuations in demand in inventory (such as accidents increase in certain times of the year), having scheduled inventory replenishment by the vendor could be problematic, due to inventory unavailability. Second, inventory tracking is typically done manually by a vendor consultant. This could lead to errors in inventory tracking, and can subsequently lead to ordering of unnecessary inventory. Both these aspects affect economic performance, as inventory costs increase due to potential last minute ordering of inventory. Clinical performance is affected because inventory expiry could cause problems in providing effective patient care. In addition, due to additional labor involved in constant inventory tracking, structural performance could also be affected.

3.3 RFID-Enabled Process Capabilities

Despite the commonly held belief that digital capabilities are fundamental to an organizations survival and growth, scholars still struggle to specify the underlying mechanisms that link IT investments to improved performance in organizational settings (Bharadwaj 2000). Recent work in this area continues to call on researchers to investigate the causal pathways that connect IT investment and firm performance (Rai et al., 2006; Sambamurthy et al., 2003, Ho et al., 2002). For instance, one area of particular interest in IS research today is the role and potential impact of IT in healthcare organizations (Kohli and Grover, 2008; Fichman et al., 2008).

As noted, the healthcare industry provides a unique context for organizational scholars. For instance, the management and distribution of hospital inventory is often discussed under the broad heading of inventory management (Nicholson et al., 2003). Inventory management is an often researched topic among operations research scholars (Scott and Westbrook, 1991; Turner, 1993) who focus largely on functional problems (Rai et al., 2006). However, inventory management takes on a new light in hospital settings, as one distinct feature relates to the use of periodic review par levels (also termed order-up-to level) for managing inventory (Nicholson et al., 2003). It is not the use of periodic review or par levels that creates the distinction in hospital settings. Rather, these par levels are seldom based on actual usage patterns, and instead reflect the desires of doctors and nurses which are often based on subjective criteria (Prashant, 1991).

In contrast to their storied past, hospitals and other healthcare establishments are expected to increase their investments in advanced technologies—such as RFID—to improve operational efficiencies in areas such as inventory management, and to enhance patient care (Datamonitor Report, 2008). However, to generate value from these IT investments, scholars increasingly argue that organizations must leverage the functionalities of these digital resources to create higher order capabilities, such as innovating business processes, shaping new strategy, and extending the enterprise network (Sambamurthy et al., 2003). This logic extends from the resource-based view of the firm (Barney, 1991), and suggests that digital assets alone are not sufficient for increasing firm performance (Powell and Dent-Micallef, 1997; Zara and Covin, 1993).

RFID enabled process capabilities can improve inventory management in specialty hospital settings by reducing par levels through increased product use visibility. Specialty hospital settings relate to practice areas where high risk procedures are conducted and high value (greater than $2000) products are likely used. By using RFID in these settings, the collection of information across activities—those that are coordinated within a specialty process (such as a cardiac catheterization or interventional radiology...
procedure)—is automated. As a result of the limited human intervention necessary for information collection, materials managers can get a near real time digital representation of material flow within practice areas. This newfound visibility can also be combined with and enable new work practices to develop higher order capabilities for improving cost management, enhancing patient safety, and enabling regulatory compliance in hospital settings.

4 RESEARCH METHOD

We will use a multi-case study method to explore the possible impact of RFID technologies on inventory management practices in healthcare settings, as well as the potential corresponding changes to work practices that are embedded in two distinct service areas: Cardiac Catheterization (CCL) and Interventional Radiology (IR). The case study approach was chosen because it affords the best opportunity to dive deep into the contextual conditions (Yin, 1994) that impact process performance in hospital settings, as well as to explore how RFID is used to improve work practices at diverse contexts. To determine case sites, we are guided by principles of theoretical replication, which lead us to choose sites where the phenomenon under investigation can be explored in its natural setting (Yin, 1989), and so we can test our assumptions that predict divergent results but for predictable reasons (Yin, 2003). Guided by this philosophy, we will conduct a retrospective analysis of four service delivery sites that exist in separate hospitals (two CCL labs and two IR labs). This approach allows us to ensure variance along important contextual characteristics that are assumed to impact process performance over time.

In addition to cross case comparison, we have also identified key roles within each study to explore the impact of RFID technologies at multiple levels of analysis. In doing so, we will interview individuals that have adopted and are now responsible for using RFID to improve inventory management within the healthcare settings (supply coordinators, purchasing managers, and inventory clerks). Additionally, we will interview individuals that participate in the work practices that are directly responsible for the delivery of services rendered in the CCL and IR labs in major US hospitals (doctors, nurses, lab attendants). Miles and Huberman (1994) refer to this as within case sampling, which is an additional way to develop rich insight from case study research (Chu and Robey, 2008). By conducting a multi-level analysis, our interest will not only be on the change that occurs within practice areas, but on the causal linkages that connect changes in inventory management practices with changes in the primary work practices, those that are directly related to the delivery of key healthcare services.

4.1 Data collection

This multi-case study will use three data collection techniques to explore the phenomenon and ensure adequate validity of research findings (Yin, 2003; Miles and Huberman 1994). The primary source of data for this study will be a series of semi-structured interviews. Interviews were first conducted from the perspective of a vendor of RFID solutions in the healthcare industry, and included discussions with C-Level employees such as the Chief Executive Officer, the Vice President of Hospital Services for CCL labs, and the Director of Hospital Services for IR labs. Upon completion of these early exploratory interviews with the vendor, we conducted our initial interviews with members of the first site identified, a CCL lab from a large hospital in the Northeastern part of the United States.

The interview protocol is semi-structured and consists of questions that are both targeted and open-ended to encourage normal conversation related to the peculiarities of the healthcare context and the impact of RFID on work practices and process performance. More specifically, questions ask respondents to assess aspects of the healthcare context that most influence their work, how their perceptions and work practices change at early and late stages of RFID adoption and use, how they use the RFID technology to alter their work practices, and how the overall performance of the unit has changed (in terms of employee
The second source of data will be direct observation, which reflects a data collection method where the researcher acts as a passive observer (Yin 2003). Observational evidence is particularly valuable when acting as a supplement to other data collection strategies (Mason, 2002). Mason (2002) states that the term ‘observation’ “usually refer to methods of generating data which entail the researcher immersing himself in a research ‘setting’ so that they can experience and observe at first hand a range of dimensions in and of that setting” (pg. 84). We leverage this method to observe firsthand the activities that occur in CCL and IR labs, how RFID technology is used to alter inventory management work practices that support these service areas, the procedural linkages that connect inventory management practices with the work practices that enable service delivery, and the contextual characteristics that shape behavior in these work domains.

The third source of data will be archival, which is an important source of data for this study as it provides a means to triangulate findings that emerge from semi-structured interviews and direct observations. In addition to power point slides, meeting notes, and white papers generated from both the vendor and hospital perspectives, we will leverage data generated from use of the RFID system. This data reflects usage patterns and changes to inventory levels of tracked products over time.

### 4.2 Data analysis

We leverage a hybrid analytical technique to analyze the qualitative data, incorporating both inductive and deductive coding and thematic development procedures to generate rich insight (Fereday and Cochrane, 2006; Chiasson et al., 2008). The hybrid approach is particularly useful in novel settings where extant work is limited; it allows us to begin the analytical process by working from the data and move from specific cases to more general conclusions (Schwandt, 2001). Moreover, by alternating inductive and deductive analysis, we are able to leverage the IT-enabled organizational capabilities framework to interpret emerging themes, which will result in richer and more robust findings.

Two of the authors are conducting the interviews for this investigation. After each interview, both authors meet repeatedly in recap sessions to converse on major themes that emerge from the interviews. The third author is then presented with the generated themes and offers critique of the early analysis by reference to prior theory. Additionally, a third party is transcribing all interview files. During the early phases of analysis, the research team will thoroughly listen to, read, code, and discuss the data in an iterative fashion (Eisenhardt, 1989). Themes generated through analysis of individual interviews will be identified by tagging text segments with codes using computer assisted qualitative analysis tools. Saliency as an explanatory factor, rather than its frequency, represents our standard for what constitutes a theme (Glaser & Strauss, 1967; Blatt et al, 2006).

### 4.3 Expected Contributions

The findings from this research study have important potential implications for researchers and practitioners alike. From a research standpoint, the domain of healthcare IT is an emerging field requiring more theoretical and empirical research contributions. Our study attempts to make an important contribution in the healthcare IT context, by examining the contextual factors and impacts of RFID-enabled capabilities on healthcare process performance. Future research can build on our research model by seeking to understand the different dimensions of RFID capabilities in different healthcare scenarios such as patient-tracking, and investigating patterns of use of RFID in different healthcare contexts, and their corresponding impacts on adoption. Practitioners can stand to benefit from this research study, by gaining a better understanding of the various internal factors that inhibit their healthcare process performance. By understanding the impacts of RFID-enabled capabilities, practitioners can effectively utilize these capabilities, for improving their information visibility, tracking, and validity, thereby increasing their healthcare performance.

### 4.4 Project Status

Proceedings ECIS 2009
Our research is being conducted in two phases. The first phase focuses on qualitative interviews from individuals within the vendor firm and four hospitals in the United States. Currently, we have conducted interviews with respondents from the vendor firm and one major hospital. Our next steps will be to complete the interviews with representatives from the other three hospitals. Upon completion of this phase, we will move into the quantitative longitudinal analysis of archival data that are currently being collected by the RFID system within each hospital setting. Through this analysis we will triangulate findings generated from the first phase of our study, as well as search for new insights that may emerge from our longitudinal analysis.

Abstract

Despite the prevalent use of blog for various personal reasons, there is a paucity of research examining the commercialization of blog. Even though it is possible to forge strong buyer-seller relationships among blogger and readers in a blog social network through collective social interaction, a fundamental prerequisite towards blog commercialization is the blogger’s willingness to engage in commercial exchange. Consequently, this paper examines the blogger’s decision making process on using his/her blog for commercial exchange. The decision process involves the appraisal of two novel theoretical notions, namely blog-blogger-reader-product similarity (BBRPS) and perceived reader-negative reaction (PRNR). Drawing on the cognitive-motivational-relational theory, we posit that the blogger’s emotional responses to the two appraisal factors affect how the blogger copes with the exchange situation. The coping strategy adopted by the blogger in turn increases or decreases exchange intention. Results from an experiment we conducted provide support for this model. Specifically, when BBRPS is high and PRNR is low, the blogger would be inclined towards using his/her blog for commercial exchange. Even when PRNR is high, it is plausible for blogger to persist in the use of his/her blog for commercial exchange as long as the negative emotional barrier is not excessively high.

1 INTRODUCTION

In recent years, we have witnessed a growing interest among firms in harnessing blogs to reach out to blog readers as potential customers. These firms could engage the bloggers to post static advertisement banners, product reviews, products endorsement and products for sale on their blogs. Despite the increasing number of blogs engaging in commercial activities, there is still a paucity of related empirical research (e.g. Walsh 2007). This paper addresses the issue of how and why the resources embedded within the social network of blogger and readers can be harnessed for commercial exchange, i.e., the blogger exchanging a product for monetary returns with a blog reader.

To this extent, the collective social interaction, as manifested in the posting of contents by the blogger and the comments made by the readers in response to these contents, can lead to the formation of strong ties within the blog social network of blogger and readers (Lento, Welser, Gu & Smith 2006). That is, strong ties are characterized by close and frequent interactions (Nahapiet & Ghoshal 1998). In turn, these strong ties are useful towards forging strong buyer-seller relationships (Frenzen & Davis 1990; Marsden & Campbell 1984). However, a fundamental prerequisite towards the commercial utilization of the blog social network is the blogger’s willingness to engage in commercial exchange. It is thus important to develop an initial understanding of the blogger’s individual perception in this paper. This provides a basis for future research into the commercial viability of the collective blog social network, which includes the buyers’, i.e., the blog readers’, perspective.

With the above in mind, we propose two theoretical notions of blog-blogger-reader-product similarity and perceived reader-negative reaction that would be relevant to a blogger when he/she is deliberating whether to participate in a commercial exchange. Drawing on the cognitive-motivational-relational theory (Lazarus 1991), we model this deliberation as a decision-making process that generates emotive outcome affecting the blogger’s willingness to use his/her blog for commercial exchange.

2 THEORETICAL BACKGROUND

Personal Blog as a Commercial Exchange: A blog serves as a natural user-alike segmentation whereby the blogger and readers converge towards one or more shared interests, which is reflected through the content of the blog postings and comments. This is best represented by two characteristics explicated in the life cycle model of a personal blog (Gurzick & Lutters 2006). First, as a blog progresses from the first stage of non-directed personal storage, i.e., pure posting of daily events and thoughts, towards the later stage of being an established and interactive blog, i.e., readers could post comments and interact with the blogger, the blogger would have developed contents that are targeted towards interacting with the readers, thereby facilitating the formation of blogger-reader relationships. These contents and relationships could serve as the basis to facilitate commercial exchanges. Second, as more bloggers interlink their blogs with the others, they form a blog community (Kumar, Novak & Tomkins 2004). To the extent that blogs provide a conducive environment for the formation of communities (Nardi, Schiano & Gumbrecht 2004), it is posited that they possess even greater potential to expose individual bloggers to larger pool of like-minded bloggers and readers.

With the formation of a blog community, a blogger could pursue the opportunity of exchanging goods, services and money (Balasubramanian & Mahajan 2001). For instance, a philatelic blog could involve the blogger discussing stamp collection; and with the majority of the blog readers themselves being philatelic enthusiasts. Within this blog, both the blogger and the readers could exchange stamps with one another for monetary returns. Indeed, we could see that an economic leveraging attempt through a personal blog is dependent on two contextual factors: 1) the degree to which a blog, its readers and the products are related (i.e., similarity); and 2) the degree to which readers are against commercial activities in a blog.
Blog-Blogger-Reader-Product Similarity: A recurring theme in the personal and relationship selling literature has been the establishment and maintenance of a fruitful long-term buyer-seller relationship (Dion, Easterling & Miller 1995). The seller plays a central role in this relationship by possessing 1) referent power that is built on the perceived attitudinal similarity between the customer and seller; and 2) the ability to attract buyers based on perceived similarity of interests, beliefs, values and personality (Dion et al. 1995). These two factors have been posited to improve sales performance as well as the trust-building process with customers. In relation to our context, the use of blog for commercial exchange could serve as a personal selling process between the blogger and readers. Specifically, the similarity factor within this commercial exchange relationship could provide sufficient motivation for a blogger to participate in the exchange. This view is in accordance with the similarity attraction theory (Byrne 1971) which posits that people prefer to interact with like-minded others. Empirical evidence supporting this paradigm suggests that personality similarity, specifically attitude similarity, could result in positive interpersonal attraction (Singh & Tan 1992). It is reported that peoples are generally more attracted to similar others than to dissimilar others (Chen & Kenrick 2002).

Leveraging on the above line of reasoning, we present the notion of blog-blogger-reader-product similarity (BBRPS). This notion refers to the similarity of the interest-focused product, or category of product (i.e., product), with the interest-focused blog content (i.e., blog) and interest-focused relationship between the blogger and readers (i.e., blogger and reader). The phase “interest-focused” denotes the shared interest or common topic/theme of the blog. In other words, the blog content and the relationship between the blogger and readers should be closely related to the shared interest of the blog. Moreover, the product to be exchanged on the blog must be congruent with the blog’s shared interest. In the presence of BBRPS, we posit that the blogger should be strongly attracted to the readers and thus more inclined to engage in commercial exchange of the relevant products within the virtual social community revolving around a personal blog.

Perceived Reader-Negative Reaction: Prior research has suggested that as competition in the Internet intensifies, consumers are increasingly being targeted with marketing materials using push-oriented mechanisms (Johnson 1996, pp. 16). Such developments have lead to calls to address the issue of commercialism (for instances, see Johnson & Ambrose 2006). An interesting comment is raised by Donnelly (1996) who believes that the Internet should be divided into different areas where advertising and commercial traffic is acceptable and those where they are not. Just how negative could a perception on commercialism be? Some studies have advocated that a consumer’s attitude to commercialization could affect buying behavior (Mortelmans & Damen 2001). For instance, we could encounter a cultural critic which denounces the gift-giving practice during Christmas as “nothing more than materialism and unlimited consumption which are promoted under the veil of traditional values and habits” (Mortelmans & Damen 2001, pp. 157). In relation to our context, we believe that the negative perception of Internet commercialism could impede the use of personal blogs for commercial exchanges by dissuading readers from continuing to read these blogs.

Leading on from this line of reasoning, we posit a second theoretical notion of perceived reader-negative reaction (PRNR) which is defined as the blogger’s perception regarding the negative reaction of the blog readers in response to the use of the blog for commercial exchange. It is unlikely that a blogger would perceive reader-negative reaction as positive. Instead, we are more interested in the strength of the negative perception. Specifically, reader-negative reaction could manifest in the form of negative comments left on the blog suggesting non-purchase intention and a boycott of the blog. If the blogger perceives these comments as sufficient threats to the blog readership, i.e., the virtual social community that his/her blog is painstakingly building, it is conceivable that the blogger would sacrifice any thought of commercialism to retain the community.

Cognitive-Motivational-Relational Theory: Our present study adopts a decisional process model to trace the decision steps taken by the blogger when evaluating whether to continue to exchange. A decision scenario-based experimental approach (commonly used in the decision making literature such as Payne, Bettman & Johnson 1993) was also adopted in which the participants were told that they were currently using their personal blogs for commercial exchange. Moreover, the initial usage of the
blog for commercial exchange may not derive as much benefit for the blogger compared to its continued, sustained usage (Agarwal & Prasad 1997). Thus, to the extent that intention can usefully predict future usage (Davis, Bagozzi & Warshaw 1989), we focus on how the current usage of personal blog for commercial exchange can affect its continued usage intention.

Our process model builds on the cognitive-motivational-relational theory (CMRT) (Lazarus 1991). The CMRT postulates that a factor affecting a decision-maker’s stake in the outcome of a goal, i.e., his/her well-being, will trigger an emotional response (Lazarus 2000; Luce, Bettman & Payne 2001). If the factor facilitates the goal of the decision-maker, i.e., bringing him/her closer to the desired outcome, a positive emotion could be generated. On the contrary, if the factor impedes the decision-maker from achieving the goal, the resultant emotion becomes negative. Finally, the exact emotion elicited is dependent on the type of personal commitment involved. This entire process is collectively known as primary cognitive appraisal (Lazarus 1991). The CMRT further posits that a decision-maker could cope with the emotional encounter in two ways: with a problem-focused or emotion-focused reaction (Lazarus 1991; 2000). Problem-focused coping is associated with a planned action to alter the environment such that the overall emotional situation is improved. Emotion-focused coping attempts to alter the meaning of the events or regulate the expression of the emotion through avoidance or denial behaviors (Yi and Baumgartner 2004). In summary, the appraisal of BBRPS and PRNR as either facilitating or impeding the goal of using a personal blog for commercial exchange incites positive or negative emotion, respectively. The blogger adopts the appropriate coping strategy based on this emotional response, which in turn affect his/her choice of whether to continue exchanging or not (Luce et al. 2001).

**Conceptual Overview:** The theoretical concepts that we have discussed thus far is summarized in Figure 1. In gist, the blogger’s decision making process focuses on the appraisal of BBRPS and PRNR to determine his/her continued exchange intention in accordance with the CMRT. We believe that this is a necessary first step towards establishing the viability of commercializing the blog social network.

![Conceptual Overview Diagram](image)

**Figure 1 Summary of theoretical concepts.**

### 3 HYPOTHESES

**Blog-Blogger-Reader-Product-Similarity:** As emphasized earlier in the similarity attraction paradigm, shared interests, relationship building and transaction are three common motivations for consumers to join an online community (Hagel & Armstrong 1997). Considering these three motivations, an online community, such as a blog, could be perceived as a niche with a very narrow interest relationship that could be used to harvest commercial benefits (Pitta & Fowler 2005). The extant literature in the area of personal and relationship selling suggests that sellers are generally more likely to develop exchange relationships with consumers with similar interests (Wilson & Ghiold 1981). More specifically, similarity in a seller’s attributes such as appearance, lifestyle and socioeconomic status has been found to improve the effectiveness of relational selling (Crosby, Evans & Cowles 1990) and that a seller would sell primarily to prospects who share similar characteristics such as gender and age (Dwyer, Richard & Shepherd 1998). Leading from this, we reason that a high BBRPS should facilitate the commercial exchange goal of the blogger (Smith 1998). In conformity with the CMRT (Lazarus...
1991), we predict that a blogger could develop a positive emotion if the product that the blogger intends to sell is congruent with the interest-focused blog content that he has posted as well as the interest-focused relationship developed with the readers. On the contrary, low BBRPS would impede exchange and lead to negative emotion.

**H1a:** Blog-blogger-reader-product similarity is positively related with positive emotion.

**H1b:** Blog-blogger-reader-product similarity is negatively related with negative emotion.

**Perceived Reader-Negative Reaction:** Intuitively, if the readers react negatively to the commercial exchange activities to the extent that they would stop visiting the blog, it would be impossible for a blogger to achieve the goal of selling his/her products. In addition, extant literature on Internet commercialism suggests that a reader-negative reaction is likely to impede the blogger’s exchange goal. For instance, Internet users, in general, have been found to possess a strong negative attitude towards advertising and its societal effects (Previte & Forrest 1998). Specifically, Internet users develop a negative attitude towards Internet advertising that increases with their years of Internet usage experience. Moreover, the credibility of information on Internet sites has been found to be negatively affected by the presence of commercial advertisements (Burbules & Callister 1998). This indicates, in relation to our context, the possibility that blog readers could form a poor perception of the blog if it is to be used for commercial exchange (Gumbrecht 2004). Consequently, the blogger’s perception of this potential fallout with the readers is likely to deter him/her from selling products. In the light of this, we reason that a high PRNR should impede the commercial exchange goal of the blogger. In conformity with the CMRT (Lazarus 1991), we believe that a blogger could develop negative emotions in view of the perception of negative reader-reaction resulting from readers expressing non-purchase intention or threatening to boycott the blog. On the flip side, low PRNR would facilitate exchange and thus lead to positive emotion.

**H2a:** Perceived reader-negative reaction is positively related to negative emotion.

**H2b:** Perceived reader-negative reaction is negatively related to positive emotion.

**Coping Strategy:** Decision-making often entails the objective of minimizing negative emotions (see Bettman, Luce & Payne 1998). For instance, Yi and Baumgartner (2004) observed that worry, fear and anxiety resulting from undesirable and uncertain events could lead a buyer to adopt emotion-focused coping strategies such as mental disengagement. On the contrary, a buyer who could proactively deal with the situation would adopt problem-focused coping strategies such as planned problem-solving and seeking social support for instrumental reasons. This observation is consistent with the general propositions of Luce et al. (2001) on the effects of negative emotion on decision-making. Specifically, negative emotion may degrade cognitive performance or attention control as well as motivate the decision-maker to avoid making a choice (i.e., adopting the emotion-focused coping strategy). However, negative emotion could also motivate the decision-maker to approach the choice through an increased processing effort, thus suggesting the use of the problem-focused coping (i.e., adopting the problem-focused coping strategy). On the contrary, it has been shown that positive affects can provide support for continued coping efforts, broaden an individual’s attentional focus and increase the available behavioral response, i.e., the adoption of the problem-focused coping strategy (Folkman & Moskowitz 2000). Consequently, a positive affect provides the capability to induce creativity and flexibility in thinking and problem-solving, as well as to process important information (Folkman & Moskowitz 2000). The broaden-and-build theory proposed by Fredrickson (2001) adds that positive emotions such as joy and pride can increase an individual’s physical, intellectual, social and psychological resources.

**H3:** Positive emotion is positively-related to problem-focused coping.

**H4a:** Negative emotion is positively-related to problem-focused coping.

**H4b:** Negative emotion is positively-related to emotion-focused coping.
**Continued Exchange Intention:** Prior research has suggested that problem-focused coping could motivate the decision-maker to exert increased decision effort while emotion-focused coping could induce avoidance behavior (Luce et al. 2001). Furthermore, an individual will attempt to manage the source of a stressful emotional experience with problem-focused coping. From a negative perspective, an individual who opts for emotion-focused coping will alter the meaning of the event or regulate the expression of the emotions (Yi and Baumgartner 2004). Consequently, we believe that problem-focused coping strategies should enable a blogger to explore the potential monetary benefits associated with commercial exchange brought about by BBRPS while simultaneously resolving the threats posed by a PRNR that is caused by Internet commercialism. On the contrary, emotion-focused coping strategies should result in avoidant behavior in which the blogger avoids the perception of threat caused by reader-negative reaction by boycotting the blog.

**H5:** Problem-focused coping is positively related to continued exchange intention.

**H6:** Emotion-focused coping is negatively related to continued exchange intention.

4 **RESEARCH METHODOLOGY**

A 2 (low vs. high BBRPS) × 2 (low vs. high PRNR) full factorial between-subject design was employed. The target population of this study comprises Internet users who are existing bloggers. For each blogger who had responded to our survey, we requested his/her blog address and we painstakingly validated each blog for authenticity. The reason for not including the non-bloggers is that they would reduce the internal validity of the study since they suffered from a lack of the required contextual knowledge and experience. The two independent variables, i.e. BBRPS and PRNR, were operationalized in the form of a treatment blog in the experiment to stimulate the decision-making process (see Figure 2 for a sample blog used in the experiment). In addition, there was a control blog, which was a typical personal blog used as an online diary for a typical undergraduate. It contains 4 postings about the daily life of the undergraduate. The sole objective of the control blog was to orientate the participants to the blog structure used in the experiment. The treatment blog extends the control blog to sell a product, i.e. a shopblog selling Apple iPod Nano MP3 players. Both blogs are structurally similar but with three exceptions in the treatment blog: 1) Posting 1 and the area below the blogger profile are used to advertise the product being sold; 2) Posting 3 is used to discuss the undergraduate’s interest; and 3) Only the treatment blog contains readers’ comments to the postings. However, the participants were not expected to make any recall comparisons that could bias the results since they cannot return to read the control blog and the control blog did not involve product selling.

The low BBRPS was manipulated by portraying the blogger as an avid stamp collector (i.e. blogger similarity) who shared his interest in stamp collecting on the blog (i.e. blog similarity), and which attracted many stamp collectors (i.e. reader similarity). All three aspects are reflected in the blogger profile.
profile with the last one also being reflected in the comments made by the readers. Additionally, Posting 3 was mainly about how to start a stamp collection (i.e. blog similarity). The high BBRPS was manipulated by portraying the blogger as an MP3 player enthusiast who shared his own MP3 purchase and usage experiences with the readers on the blog, and which attracted many MP3 player enthusiasts. Posting 3 mainly contained information on how an MP3 player works. Essentially, the low and high BBRPS was manipulated with a philatelic blog and MP3 player blog respectively (see Figure 3). The low PRNR was manipulated by means of readers’ comments reflecting positive perceptions towards the selling of MP3 players and positive purchase intentions; while the high PRNR was manipulated using readers’ comments reflecting negative perceptions towards the selling of MP3 players (i.e. threats to boycott the blog) and negative purchase intentions.

Figure 3  Manipulation of BBRPS.

MP3 player was chosen as the product since it is a common community product that is gender-neutral and can be considered a search good. It is thus feasible for the readers to purchase MP3 players from the blogger based on what they had read in the blog. While MP3 players can be purchased from other electronic commerce shopping websites, comparing the sales channels is not the objective of this paper. Moreover, there is no convincing reason to believe that the participants had considered sales channels when indicating their response since the controlled experiment made no reference to them other than the blog. Nonetheless, it is necessary to control for the participants’ familiarity with the product, i.e. the MP3 player, and brand, i.e. Apple iPod Nano. This is because, to the extent that consumers generally have a better impression of new product information associated with familiar brands (Kent & Allen 1994), bloggers could be more inclined towards exchanging familiar products or brands versus unfamiliar ones. Finally, we also controlled for the participants’ demographics, Internet usage experience and blogging experience through random assignment of participants to the treatment conditions. As much as possible, the constructs in our research model were operationalized and measured using existing scales that have been validated in prior studies (see Table 1). The remaining scales were developed based on the recommendations of Moore and Benbasat (1991). All scales are 7-point Likert (1-Strongly Disagree to 7-Strongly Agree) scales except for product and brand familiarity.
Problem-focused Coping (PFC) (Yi & Baumgartner 2004)
With respect to the problems that I might encounter in the selling of products in my personal blog; I will:
1. think about how I may best handle the problem.
2. try to come up with a strategy on what I should do.
3. think about what steps to take to resolve the problem.

Emotion-focused Coping (EFC) (Yi & Baumgartner 2004)
With respect to the problems that I might encounter in the selling of products in my personal blog; I will:
1. try to keep my feelings to myself.
2. try not to show other people how I do really feel.
3. try to hold back my feelings.

Continued Exchange Intention (CEI) (Terry, Hogg & White 1999; Agarwal & Prasad 1997)
If I have additional Apple iPod Nano MP3 players available for sale within the next 12 months; I intend to continue to use my personal blog to:
1. sell them.
2. put them on the market.
3. use my personal blog to advertise them.
4. use my personal blog to put them up for sale.

Product Familiarity (PF) (Johnson & Russo 1984)
1. I am not familiar at all – very familiar with MP3 players.
2. I am not knowledgeable at all – very knowledgeable about MP3 players.

Brand Familiarity (BF) (Allen & Kent 1994)
1. I am not familiar at all – very familiar with Apple iPod Nano.
2. I am not knowledgeable at all – very knowledgeable about Apple iPod Nano.

Table 1 Instrument scales used to measure constructs.

The experiment was conducted in April 2008 through the Internet. Invitation messages were posted on local major Internet blogging forums. All respondents were checked to ensure that they had an existing personal blog that had been actively maintained for at least the past 12 months leading up to the experiment. The experiment began with the participants reading the opening narrative, which asks them to assume the role of an undergraduate who maintains a personal blog as an online diary, i.e. the control blog. The participants next proceeded to read the control blog for 5 minutes and answered a series of questions on the blog’s content. The participants could not proceed until all the questions were correctly answered. The participants next read the scenario narrative which tells them that they also blog about their personal interest. More importantly, the participants were told that they would be selling Apple iPod Nano MP3 players on their personal blogs. The participants then read the respective treatment blogs assigned to them for 7 minutes and answered another series of questions on the blog’s content. Thereafter, the participants were told that they were to make a decision on whether to continue to use their personal blog, i.e. the treatment blog shown to them, to sell the MP3 players.

In summary, the adoption of a scenario-based approach for the experiment is appropriate since not all the subjects might have experience on commercial blog (Sheng, Nah & Siau 2006). It also allows us to isolate which treatments have a differential impact on the subjects’ emotional response.

5 RESULTS

A total of 238 participants responded to our invitations. There were 13 incomplete entries (5.46%) and 1 participant (0.42%) who reported a blog address that was ascertained to be doubtful. These were excluded from the data analysis leaving us with 224 participants. Although the number of male participants was lower than the female participants (27.23% versus 72.77%), the univariate analysis of variance (ANOVA) tests indicated that there was no significant difference in the participants’ mean ratings of BBRPS (Mean = 3.99, δ = 1.523, F (1, 222) = 0.108, p = .743) and PRNR (Mean = 3.87, δ = 1.689, F (1, 222) = 1.498, p = .222) across gender. There was also no significant difference in the participants’ Internet usage and blogging experiences across treatment conditions. Interestingly, a sizeable percentage of the participants engaged in some forms of commercial activities using their blogs. Altogether, 46.90% of the participants had previously engaged in at least one form of commercial activity. However, the univariate ANOVA tests indicated that there was no significant difference in the participants’ mean ratings of BBRPS (Mean = 3.99, δ = 1.523, F (1, 222) = 3.146, p = .077) and PRNR (Mean = 3.87, δ = 1.689, F (1, 222) = 0.017, p = .897) across experience in commercial activities.
Manipulation checks were performed to ensure that our manipulation of the treatment blogs reflecting low and high levels of BBRPS and PRNR were successful. Independent samples t-tests using the mean of the respective sets of instrument items indicated that our manipulations were successful: 1) The mean score of BBRPS for the low treatment group (Mean = 3.04, δ = 1.288) was significantly lower than the high treatment group (Mean = 4.94, δ = 1.088), t = -11.924, p < .001; 2) The mean score of the PRNR for the low treatment group (Mean = 4.78, δ = 1.556), t = -9.567, p < .001. In addition, the univariate ANOVA tests on the product and brand familiarity indicated that there was no significant difference in the mean value of these two control variables across treatments: 1) for product familiarity, Mean = 5.39, δ = 1.132 [F (3, 220) = 0.642, p = .589]; and 2) for brand familiarity, Mean = 4.53, δ = 1.591 [F (3, 220) = 0.376, p = .770]. In general, participants across treatments had a consistently high level of product and brand familiarity. Coupled with the consistent Internet usage and blogging experiences of the participants across treatments, it appeared that the random assignment was successful in controlling for differences in participants’ characteristics across treatments.

**Figure 4 The structural model.**

Data analysis was performed with structural equation modeling in LISREL 8.54. The measurement model was first tested using a confirmatory factor analysis. Most of the model fit indices were greater than their respective thresholds (e.g. RMSEA = 0.064; SRMR = 0.053; GFI = 0.85; NFI = 0.92; NNFI = 0.96; CFI = 0.96). Thus the measurement model had a good fit with the data. In addition, the convergent validity, internal consistency, discriminant validity and reliability of the measurement items were assessed to be above their respective thresholds. The correlations among latent constructs did not indicate any multicollinearity problem. Figure 4 depicts the results of the structural model. We observed BBRPS to be positively-related to positive emotion and negatively-related to negative emotion, thus supporting H1a and H1b. The PRNR was found to be positively-related to negative emotion and negatively-related with positive emotion, thus supporting H2a and H2b. Positive emotion was positively-related to problem-focused coping thus providing support for H3. Though negative emotion was positively-related to problem-focused coping; this result is not considered significant. We observed that negative emotion was positively-related to emotion-focused coping. Thus, H4a is not supported while H4b is supported. Problem-focused coping was positively-related to continued exchange intention thus supporting H5. Finally, emotion-focused was observed to be negatively-related to continued exchange intention but this is not deemed significant. Thus, H6 is not supported.

6 DISCUSSION

The integrative decisional process model shows that there are three distinct emotion-coping paths that can lead to either higher or lower continued exchange intention: 1) positive emotion to problem-focused coping; 2) negative emotion to problem-focused coping; and 3) negative emotion to emotion-focused coping. This suggests that consumers may use different coping strategies depending on their emotional responses to online blogs. Understanding these mechanisms can help in designing effective marketing strategies that cater to the emotional needs of consumers.
focused coping. The exact path that the blogger would traverse is contingent on the cognitive appraisal of the two decision factors (Luce et al. 2001). Specifically, high BBRPS facilitates the blogger’s goal of exchanging and positive emotions should be elicited from the blogger (Lazarus 1991). The blogger should then acquire additional coping effort (Folkman and Moskowitz 2000) leading to the adoption of problem-focused coping, i.e. the first path. This enables the blogger to explore options in utilizing the blog for commercial exchange, which can be translated into higher continued exchange intention. For instances, the blogger could create more useful postings on topics relevant to the products or use the blog for after sales communication with the readers.

In contrast, high PRNR impedes the exchange goal and induces negative emotion (Lazarus 1991). On the one hand, if the blogger opts for problem-focused coping, i.e. the second path, he/she could attempt to pacify the readers by making posts designed to project the blog as a one stop location for readers to acquire product knowledge before making purchase. The blogger could also attempt to reply to each negative comment cordially to appease the readers or seek advices from other peers facing similar problem. On the other hand, if the blogger opts for emotion-focused coping, i.e. the third path, he/she is likely to suppress the negative affection associated with the dual threats of non-purchase intention and boycott actions (Yi and Baumgartner 2004) thus increasing the avoidance tendency. For instance, the blogger might refuse to seek advice from other bloggers facing similar situation.

We may therefore surmise that when BBRPS is high and PRNR is low, the blogger would be inclined towards using his/her blog for commercial exchange. Even when PRNR is high, it is plausible for blogger to persist in the use of his/her blog for commercial exchange as long as the negative emotional barrier is not excessively high. This is consistent with the notion that blog is a personal “protected space” (Gumbrecht 2004) and thus the blogger might be more inclined towards retaining the readers at the expense of commercial exchange. In fact, H4a only approaches but did not reach statistical significance. Moreover, the non-significance of H6 could be attributable to the fact that the blogger activated social support seeking, which is one type of emotion-focused coping strategy (Yi & Baumgartner 2004). When the blogger approaches friends for advice or emotional support, it may be perceived by the blogger as self-justification (Bettman, et al. 1998) to minimize the negative emotion caused by high PRNR. Consequently, the blogger could feel vindicated in exchanging commercial products despite unfavorable readers’ comments. In gist, the results of the experiment demonstrate that bloggers could be willing to engage in commercial exchange when contextual factors are favorable. It is thus feasible to leverage blog social network for commercial purposes (see Figure 1).

However, future research must still investigate the decision making process from the blog readers’ perspective (see Figure 1). To this extent, the present process model may be adapted to study the exchange intentions of blog readers. More specifically, the present sellers’ appraisal factors of BBRPS and PRNR may be complemented with other appropriate theoretical constructs to create a set of buyers’ appraisal factors. For instance, the perceived tie strength (Nahapiet & Ghoshal 1998) among other readers with the blogger and perceived trust towards the blogger could be critical factors determining whether a particular reader would exchange with the blogger (Kim & Srivastava 2007).

7 CONCLUSION

This paper has several limitations that readers should be cautioned. First, given that H4a is not supported, future research should examine how and why high PRNR could simultaneously lead to problem-focused and emotion-focused coping. In this regard, whether the blogger perceives a loss of control over the given commercial exchange situation could differentiate the coping behavior (Yi and Baumgartner 2004). Second, this study examines a single product type, i.e. MP3 players, which may not be a suitable one for all the subjects. Finally our model suffers from low $R^2$, i.e. low predictive power. A likely cause could be that the product used might have incited neutral response. Nonetheless, the ability of our model in establishing significant causal relationships between key constructs, i.e. descriptive and explanatory purposes of theory, is a significant one.
Despite these limitations, this study has made numerous contributions. Theoretically, we conceive BBPPS and PRNR in conjunction with the development of a novel decisional process model. These could be extended or generalized to study the impact of commercialism on other social computing tools. Practically, we explicate how personal blogs could be carefully utilized for commercial activities, i.e. capitalizing on the similarity between the blog, blogger, readers and the products. Additionally, the identification of PRNR as a plausible impediment factor implies that individual bloggers should exercise caution when turning their personal blogs into commercial tools.

Abstract

This study focuses on consumers’ perception of control over personal information disclosure on the Internet. Specifically, we examine how consumers perceive controlling their personal data that online companies collect for marketing and customer relationship management purposes. We aim to answer this research problem by clarifying 1) how do consumers express the perception of control over their personal information, and 2) how do consumers perceive controlling their personal information disclosure. Our empirical data is based on four computer-mediated focus group interviews. Our findings show that the perception of control is combined with all stages of personal data utilization: collection, storage and usage. Thus, consumers keep these stages in mind when thinking about their attitudes towards the collection and offering of their personal information. The interviewees also spontaneously mentioned various means with which they control personal data. Perceived trust towards companies, own initiative and permission-based marketing were also combined to the control speech. In summary, the interviewees mostly perceived that they were not controlling their personal data on the Internet. Only when they were talking about control methods of the information disclosure stage, they expressed the perception of control.

Keywords: Privacy, Online self-disclosure, Perception of control, Focus groups.
INTRODUCTION

The development and adoption of information and communication technologies (ICT) among consumers have enabled large-scale utilization of personal data for marketing purposes (Moon 2000). With personal data we mean information that can be connected to an identifiable individual (Culnan & Milberg 1998). This information can be grouped to identifier information (such as an e-mail address), sensitive personal data (information concerning e.g. health), and preference information (e.g. hobbies) (Andrare, Kaltcheva & Weitz 2002). Especially in the Internet, consumers increasingly face situations in which they have to provide personal data for some purpose (Heikkinen et al. 2004). Ordering and buying products, experimenting and adopting e-services, and registering into various loyalty customer programs are typical examples of situations in which submission of personal data is required. The data collection is often well justifiable from the consumer’s point of view; for example an e-commerce site needs customers’ contact information in order to deliver purchases, or to inform customers about possible delivery problems. However, companies collect personal data also for other purposes, for example to be able to advertise their products, or to utilize data in some other way in the future. This is usually acceptable, sometimes even good customer service. However, the customer should be aware 1) that her personal data is utilized, and 2) of the rights granted to her by legislation (e.g. the rights of inspecting, correcting, and prohibiting the usage of personal data). Customers should be able to execute these rights also in practice (Personal Data Act 1999, Velasquez 2006: 290-291).

According to several studies (e.g. Sayre & Horne 2000, Dommeyer & Gross 2003, Chellapa & Sin 2005), most consumers accept the collection and utilization of their personal data for marketing and customer relationship management (CRM) purposes in return for proper benefits. However, privacy questions have received much attention during the last few years (Milne 2000). According to several studies (e.g. Phelps et al. 2000, Eurobarometer 2008, Privacy & American Business 2004) consumers are concerned about their privacy, especially in the Internet. To some extent, the Internet is experienced as an unreliable and unsecure environment (e.g. Knights et al. 2001, Suh & Han 2003, Jensen et al. 2005).

Privacy itself is a multidimensional and ambiguous concept, the definition of which is often based on sociologist Alan Westin (1967, p. 7): Privacy is both control over 1) information disclosure and 2) the environment in which transactions occur. The first dimension is concerned with control over own information, while the latter with the control over one’s own state and of protection from different external intrusions, such as spam. In this study, we concentrate on the first dimension, on control over providing personal data, which, according to Goodwin (1991), can be seen to include also other control aspects than just disclosure regarding personal data utilization. Posner (1981), for example, refers to privacy violation when observing an individual without disturbing her concretely.

Research over personal information control has traditionally emphasized control over the consumers’ environment, for instance the intruding nature of direct marketing (e.g. O’Malley et al. 1997, Evans et al. 2001, Morimoto & Chang 2006). This area has been regulated, e.g., by establishing prohibition registers for marketing measures. Nevertheless, ICT-enabled interactive marketing actions pose more serious threats to consumers’ personal data control. Goodwin (1991) includes the risk of potentially harmful usage to the control over personal data – it is for instance possible to combine separate pieces of personal data and registers together. In that case, the decision whether to disclose or not a single piece of data will be of minor significance with respect to data protection.

The control over disclosing personal data has been examined in connection with several studies (e.g. in Phelps et al. 2000, Sheehan & Hoy 2000, Evans et al. 2001), where it has been found an important factor affecting the provision of data. However, the control over disclosure has seldom been the main focus in privacy studies, apart from a few exceptions. For example, Goodwin (1991) has examined privacy conceptually as the control over personal data and own environment, whereas Olivero and Lunt (2004) have studied whether the consciousness data collection influences the control and trust of consumers. On the other hand, the methods consumers are using to control their personal data have
been widely studied (e.g. Foxman & Kilcoyne 1993, Cranor et al. 1999, Dommeyer & Gross 2003).
The objective of our research is to increase the understanding of consumers’ perceived control over
their personal data that companies operating on the Internet collect for marketing and CRM purposes
(see e.g. Milne 2000, Romano & Fjermestad 2003). Consequently, we restrict our study to this
business-to-consumer context as distinct, for example, from authority transactions or criminal
operations. We aim to answer our research problem by investigating 1) how do consumers express the
perception of control over their personal data, and 2) how do consumers perceive controlling their
personal information disclosure. Next, we will present the research methodology and data, after which
we discuss our results in Section 3. The study finishes with discussion and conclusions.

2 RESEARCH METHODOLOGY AND DATA

A number of research techniques have been developed in order to better understand consumers, and to
assess their desires and preferences. These techniques include surveys, focus groups, statistical
modeling, and video ethnography (Prahalad & Ramaswamy 2004). As control over information
disclosure has been previously studied mostly in connection with privacy surveys (see review in
Kobsa 2007), we felt that an in-depth qualitative study is warranted in order to get a more
comprehensive view on the topic. Thus, we chose focus groups as our research method.

The research data was collected in Finland in September 2006 through focus group interviews that
were conducted electronically via computers in the same-time – same-place mode (Kontio et al. 2007).
That is, the participants were invited to a computerized meeting room to answer structured questions
presented by the researchers, and also to comment on each others’ thoughts. This mode represents
focus group interviews instead of focus group discussions (see Boddy 2005), as we wanted to receive
answers from every participant, and also to prevent the derailing from the issue that easily happens in
more free-form discussions. We utilized a group support system (GSS) called GroupSystems®
MeetingRoom, which has originally been designed to support teamwork and group decision making
(Nunamaker et al. 1991), but which can equally well be used for carrying out of focus group
interviews or discussions (Clapper & Massey 1996, Kontio et al. 2007, Tellefsen et al. 2005). A
typical GSS meeting consists of 10-30 networked computers in the same room, which gives the
facilitator and the interviewees the opportunity to communicate also verbally with each other. It is also
possible to conduct fully virtual meetings via the Internet (Klein et al. 2005, Kontio et al. 2007), but
these require usually audio or web conferencing support in addition. The utilization of different
computer-mediated systems in marketing and consumer research has been steadily increasing (see e.g.

Our study comprised of four group sessions, each lasting 2.5 hours, with 11-14 interviewees in each
group. The sessions were administered by the same main facilitator and two other adjunct facilitators.
The interviewees were posed a small set of related questions at a time, and they were allowed to
answer them in the order they wished, before the facilitator let them proceed to the next bundle of
questions. The interviewees saw each others’ answers, and they were allowed to comment on them or
to further deliberate on their own answers. We opted to carry out the sessions fully anonymously so
that all the comments remained individual. After each session ended, all the interview answers were
immediately available in writing using the automated reporting function of the GSS tool. This was one
important reason for selecting computer-mediated instead of traditional focus groups as the research
method, as our research partner (retail bank) needed to have the preliminary results as soon as possible
in order to plan a subsequent field experiment at its online bank (see Bragge et al. 2007 for details).

The computer-mediated focus group interviews can be seen as an intermediate form between
traditional face-to-face and fully virtual focus groups (Kontio et al. 2007). Some of the strengths of the
method compared to traditional oral interviews are, for example, their efficiency (enabling bigger
group sizes, simultaneous communication, and automated reporting), digital group memory during and
after the sessions, as well as anonymity. The advantages compared to a fully virtual implementation
are the possibilities to detail questions further, to interact verbally, as well as to present confidential or
physical support material (such as product prototypes) during the sessions. The weaknesses of the method compared to traditional groups are certain deficiencies in expression (the lack of gestures and facial expressions in communication), the need for special premises and technical expertise, and the possibility for technical problems. Compared to fully virtual discussions the computer-mediated same-place settings place restrictions on the participants’ geographical recruiting and are more expensive with respect to travelling expenses and venue costs (Klein et al. 2005, Kontio et al. 2007). As the topic of online information disclosure and the control thereof is fairly abstract, we did not consider fully virtual focus groups. In face-to-face settings possible ambiguities can be easier clarified.

Altogether 53 persons participated in our interviews in four groups, which is considered as a good amount for focus groups (Morgan 1996). The pilot group consisted of 14 business university students using online banking services. The other interviewees were randomly selected from among the online customers of a Finnish retail bank. Thus, the interviewees had at least basic computer skills to be able to participate in the electronically mediated interviews, in addition to which they were able to draw from their own experience when asked opinions about online information disclosure. Furthermore, the previous online bank usage made it possible for the interviewees to refer to a concrete context regarding the questions that might otherwise have felt too abstract for them. Thirty of the participants were female and 23 were male, all between the ages of 21 and 49. Occupationally, the interviewees were mainly higher or lower level officials (26), students (20) or workers (11). The majority of the interviewees used Internet daily (46); either at home (33), at work (28) and/or at their study place (11).

The underlying setting was a situation in which a reliable company (for example a bank) collects information online in order to utilize it for marketing and CRM purposes (e.g. for personalized advertising or services). This way we wanted to guarantee that the context experienced by all interviewees would be similar, and that no extreme context or experience (e.g. a foreign e-auction) would affect the answers too much. Furthermore, we were able to inquire their attitude also for the collection of sensitive personal data (concerning e.g. financial situation). Our questioning frame covered the following themes: 1) attitudes towards the collection of personal data on the Internet; 2) the recognition and control over collection and utilization of personal data online; 3) the understanding of the privacy protection concept. Thus, we were able to examine the control and disclosure of personal data both with direct questions and indirectly, without prompting the interviewees too much.

We asked the interviewees’ attitudes also towards the personalization of online services and to the utilization of personal data especially in the banking sector (see Sunikka et al. 2007). These questions are here dealt with only in so far as they are related to the control over information disclosure.

The content analysis of our data started from the question that was presented to the interviewees: “Do you perceive that you are in control over the collection and utilization of your personal information on the Internet?” Utilization, which consumers often understand as usage was brought up in addition to collection, because one can see that the purpose of usage affects the disclosure of personal data (cf. Andrare et al. 2002). First, we developed conceptual labels attached to the interviewees’ verbatim descriptions. Second, based on these conceptual labels, categories were formed at a more abstract level of classification. At the same time, the labels were constantly revised by merging categories expressing similar concepts, or by splitting a category representing different concepts (cf. Olivero & Lunt 2004). The categories thus formed were 1) disclosing, 2) storing, 3) usage, and 4) control methods of personal data. Finally, these main categories were studied thoroughly using the whole data that was collected. This was done by coding the data according to the formed categorization.

3 RESULTS

We will next present the analysis of the empirical findings of this study. Firstly, we will examine what kind of expressions the interviewees used when talking about the control over personal information on the Internet. Secondly, we will examine how the control over personal information in the Internet context is perceived by the interviewees.
3.1 The conception of control over personal data

The control over personal data proved to be an important theme. The interviewees brought it up when asked directly; in 39 of 56 comments the interviewees stated that they do not perceive that they are in control over the collection and utilization of their personal data online. Furthermore, the interviewees spontaneously expressed their concerns about the storage of personal data indicating a fear that third parties could get a hold on the information. This fear was mentioned in 31 (out of 55) comments for the question that inquired the interviewees’ own definition of data privacy protection. Furthermore, 14 comments were connected to the protection from undesirable usage. From the viewpoint of companies, the collection, storing and usage of personal data forms a process of personal data utilization, about which the interviewees thus talked with a negative tone because of their perceived lack of control.

The interviewees talked positively mainly about the methods of control, such as restricting the disclosure of their personal data. Thus, when talking about the control methods, the interviewees expressed the control perception of their data. The methods of control were connected mainly to the offering stage, and the main method was the decision not to disclose personal data. In most answers, the methods of control were blended with expressions of the control perception. In a couple of cases the interviewees, however, expressed both the lack of control and the deployment of control methods somewhat conflictingly at the same time: “I do not perceive well enough [that I am in control over the collection and utilization of my personal information on the Internet]. On the other hand, a huge amount of issues can be found out, but one must be critical herself and choose whom to believe”.

The interviewees also talked about own initiative and permission-based marketing, which can be seen as one type of control manifestations (see Milne & Gordon 1993, Evans et al. 2001). With own initiative the interviewees referred mainly to the desire to make the first move themselves in instigating a customer relationship (pull approach), and not just being a passive target for advertising. If customers perceive themselves as objects of push marketing, personal data is not willingly disclosed: “…one must still always be careful, where to provide personal information. It is always better if you have created the contact yourself, than if it would be an impulsive answer to some advertisement.” The motives behind taking own initiative were the control over own environment (e.g. restricting targeted advertising), and control over own information: when consumers take the initiative themselves, it is easier for them to act deliberately. This view is compatible with the contemporary conception of an active consumer (Pavlou et al. 2002).

Regarding permission-based marketing the interviewees expressed their desire to make a conscious decision of whether to accept the utilization of personal data, and to control their own information this way. The benefits gained from providing personal data were emphasized. “It is rather understandable [that companies collect information from and about you], but the protection of privacy is, of course, put to the test. To become a victim of, for example, advertising or spamming, is slowing down the computer and thus really strenuous. If the information I receive is related to my own interests, and approved by me, then it is quite OK”. A few interviewees (8/55 comments) associated the permission-based marketing system with their perception on privacy protection. In general, the fact that permission is asked before collecting and utilizing data for marketing purposes was appreciated.

Finally, the trustworthiness of a company (also its familiarity, or an existing customer relationship) added the willingness to disclose personal data. In addition to personal experiences, the interviewees’ trust was increased if the company is known or domestic, in which case the reputation of a company and the legislative environment (domesticity) increased the feeling of safety. A similar typology of trust was presented also by Milne & Boza (1998) regarding consumers’ views on utilizing personal data in marketing. In their study, the trust was manifested in earlier experiences of the company, in the reputation of the company, and in the confidence which is based on regulation or agreement.

Trust in a company was often mentioned as a prerequisite for the disclosure of personal data. We could interpret from the interviewees' comments that trust increases the perception of control, in other
words trust itself is a control method, which is also a prevailing view in the literature (see for example Cranor et al. 1999): “The disclosure of data to small, unknown companies nearly always raises doubts about where the information is used. If a piece of information seems irrelevant to the issue at hand, I will not usually disclose it.” On the other hand, trust compensates the need for control on the pursuit of privacy protection, especially on the Internet (e.g. Milne & Boza 1998, Olivero & Lunt 2004).

The different manifestations of the control speech are presented in Figure 1. The interviewees expressed the control perception of their personal information mainly through control methods, such as restricting the disclosure of personal data. The control perception was manifested also by the interviewees’ own initiative, by permission-based marketing, and by the trust in the company. The methods of control were applied especially to the disclosure of data, which was otherwise experienced to be poorly in control. Merely with the decision whether or not to disclose data the interviewees control their own data and their privacy. On the other hand, the interviewees did not perceive that they were in control over the storage or usage of personal data, not even when utilizing control methods.

![Figure 1. The manifestations of the control speech among the interviewees.](image)

In the following four sections we will deliberate on the four main classes we found when analyzing our interviews: (1) disclosure, (2) storage, (3) usage and (4) control methods of personal data.

### 3.2 Avoidance of disclosure of personal data to companies on the Internet is difficult

The interviewees experienced that it is difficult to avoid the disclosure of personal data on the Internet since personal data is collected everywhere, even when the consumers do not notice it. In the interviewees’ opinion, companies can too easily access the personal data of consumers. Additionally, there are more and more situations in which information must be disclosed, even though one would not want to. According to several interviewees, the companies in general collect too many personal data. Similar results were obtained also in a study by Statistics Finland (Muttilainen 2007), in which 28 per cent of the respondents experienced having given too much information of themselves. Alike thoughts were presented already in the 1970's in opinion polls (see e.g. Katz & Tassone 1990). Thus, the attitudes seem to have remained comparable in spite of the increase in the digital data collection.

The interviewees often experienced that the data collection is not always necessary. “I understand the objectives of companies to get the best possible picture and profile from the customers, but there should be sensible limits to it. One could think that the information on what are my hobbies or which country I have last visited would hardly be useful to anyone.” The interviewees' views are supported by numerous studies (e.g. Sayre & Horne 2000, Dommeyer & Gross 2003, Chellapa & Sin 2005, White et al. 2008), according to which consumers want to gain more in exchange for the disclosure of their personal information. Furthermore, unnecessary inquiries are regarded as time-consuming and
irritating. In our study, the perceived purposelessness of the data collection was the most common reason for not disclosing personal information.

The data registers were regarded as problematic: a few interviewees felt that the storing of personal data in registers is uncomfortable. Furthermore, some felt it difficult to remember afterwards what information they had given and to whom. The interviewees commented that they did not know any more what the companies knew about them, or whether this information was up-to-date. They hoped for the possibility to access their own data and also to edit or delete it, when wanted. Thus, the interviewees were not particularly aware of their own rights (e.g. to inspect personal data in registers), or the exercise of the rights was regarded as difficult in practice. On the other hand, the online data collection was regarded as a more reliable method of acquiring data than other means, as the data did not disappear or change when processed (e.g. when using traditional forms). In the opinion of a few interviewees, the privacy protection requires also the consumers’ own activity and carefulness: “Firms get a lot of data easily; it is given without thinking about it too much.” On the other hand, they admitted that they are sometimes careless themselves and disclose data without consideration.

Several interviewees experienced that a lot of personal data is collected without telling it to the consumers, of which they disapproved: “In a way I perceive that I am in control over the collection of information. However, the information can be gathered in a way that one does not notice it, one does not even always understand how the collection of information on something might be significant ...”. In this comment, the possibility of disclosing information accidentally emerged; consumers do not always understand the consequences of information collection. Also the risk of information acquisition by combining data from several registers was mentioned. Furthermore, the interviewees were worried about data collection that is enabled by recording and analysing click-stream data, or using other methods. In general, the interviewees felt uncomfortable being observed.

The majority of the interviewees (46 of 57 comments) were not sufficiently aware of the collection of personal data online or the usage of the information when asked directly. Especially the purpose of use of personal information puzzled most interviewees. It was also challenging to stay ahead of the technological development; for example cookies were experienced as threatening. The reasons for the unawareness were both consumer-driven (e.g. lack of interest and passiveness) and company-driven (e.g. the difficulty of getting information when one needs it).

Finally, several interviewees commented that one is occasionally compelled to give information to service providers. Companies might request information that is essential for the functionality of the service (e.g. alert services), and then the data collection was regarded as justified. Often the interviewees, however, experienced that they had to give information of lesser importance or of sensitive nature to be able to conduct transactions, even if they would not have wanted that: “If I took the initiative myself, then I would react neutrally to the fact that a company needs information e.g. for granting a loan decision. If, on the other hand, the company has phished my contact information, or if I am otherwise unable to proceed on a company’s website without answering all required questions, that is really irritating. I don’t like it either if a really long form with many compulsory fields must be filled in (especially when asking home address, social security number, children’s names etc.) in order to be able to register as a user to some service.” In this example the usability of the answer form (e.g. the plenitude of compulsory questions) has an effect, too. However, the interviewees said that they are disclosing their personal data to companies even when compelled, but still with certain terms only.

3.3 Controlling third party access to stored own data is challenging

With regard to the control over personal information the interviewees were worried over the collection of data and what happened to the data after it. The majority of these instances were related to a third party’s access to own data when it already was in the possession of the company. The worries included the forwarding of data to external parties without permission, the uncontrolled spreading of personal data online, and to whom one’s personal information eventually ends up on the Internet. Some of the observations made were connected to data security issues. Firstly, the interviewees were uncertain
about where their data eventually ends up after its disclosure, and whether some third party can have access to this data: “I do not [perceive that I am in control over the collection and utilization of my personal information on the Internet]. Every now and then I fill in for example various surveys, but I always have to think where my information eventually goes.”

The interviewees were especially worried that their information might end up ‘in the wrong hands’, for example to conmen. They hoped that the companies informed them better of who has access to their data; they wished more openness and honesty. On the other hand, the interviewees did not necessarily trust the information provided by companies even though the mere existence of data protection statements already aroused the confidence in a few interviewees (see discussion also in Kobsa 2007). The data protection statement is a report given by the registrar about how it acts with the personal data it has acquired in its possession, what are the data protection rights of the person being registered, and how the rights are implemented in practice (Data Protection Ombudsman 2008).

Several interviewees also experienced that personal data spreads easily on the Internet. When own information is disclosed online, it is perceived to spread everywhere without any means of controlling it: “Frighteningly poorly [I perceive that I am in control over the collection and utilization of my information on the Internet]. One can only be amazed by the ways with which information travels online, and suddenly, for example, your e-mail is flooding with spam.”. Whereas the uncontrolled spreading of information was connected especially to the Internet, the disclosure of personal data or selling that systematically to third parties, usually for advertising purposes, was seen as a problem also outside the Internet realm: “Yes, most of the time [I perceive that I am in control over the collection and utilization of my personal information on the Internet]. I always consider carefully where I disclose my information. The problem is naturally the fact that companies can pass on or sell the information, if, e.g., the forwarding of information for marketing purposes has not been forbidden.”

The deliberate forwarding of personal data was strongly disapproved, especially in the financial sector. In general, the interviewees trusted the banking sector actors with regard to the use of personal data. This is in line with the latest Eurobarometer (2008), according to which 90% of the Finns trust banks and financial institutions in this respect, which is 24% more than the EU-27 average. However, the recent value network developments (e.g. increased co-operation between banks, insurance companies and real estate agencies) caused some hesitation. Finally, what comes to third parties’ possibilities to get a hold on personal data, several interviewees expressed their concern about data security: “In e-commerce it is handy to use your credit card. However, the problem is the risk that the credit card number can be stolen at the data transmit stage. The site must be reliable.” The interviewees were willing to disclose sensitive personal data only in secured connections. In spite of the cautious attitudes many interviewees said that they had given their credit card number on the Internet also in unsecured connections, e.g. when booking a hotel reservation. However, the events had troubled them afterwards. Regarding information security the media appears to have an effect on the consumers; a few interviewees mentioned cases that had been reported recently by the media, for example fake websites with which information is phished for criminal purposes.

3.4 Control over the usage of personal information is difficult

The interviewees discussed in several occasions the usage of their personal data. When making a decision whether to disclose information or not, they felt uncertainty about the purposes of their personal data usage, and considered it difficult to control the usage. The interviewees did not perceive being sufficiently aware of how and to which purposes personal information is utilized: “I do not [perceive that I am in control over the collection and utilization of my personal information on the Internet]. I disclose information very randomly, depending on which sites I happen to end up. I can of course decide where and what kind of data to provide, but later on I am not able to remember or identify what I have given. Especially the usage of information can remain totally murky.” In these uncertain situations, a few interviewees were unwilling to disclose their personal data to companies. They wanted to know clearly how their information would be used. On the other hand, a few admitted
that they were too unconcerned regarding the usage of their personal data. However, several interviewees thought that personal data is utilized without informing the consumers properly, and even though companies would give information about how they use consumers’ personal data, most consumers would not believe that the companies would do as they say.

Secondly, the interviewees felt that it is difficult to control the usage of personal data; when information is disclosed, the control over it is easily lost. In any case alertness is required from the consumer with the control over personal information. Thus, in practice, the possibility to control personal information is connected only to the disclosure of data: “It is quite impossible to control fully [the collection and utilization of my personal information on the Internet] except for the information you provide. On the other hand the information is obscured into the data mass so it will not necessarily hurt you personally.” Once again, the control perception of the consumers’ personal information and their actual rights do not seem to meet each other. Thus, the consumers should be more informed of their own data protection rights.

3.5 Methods of control regarding personal data

The control methods of personal data utilized by consumers can be divided into active (invoking options) and passive (avoiding practices) means (see e.g. Givens 1997). The active means require deliberate actions from consumers, e.g. signing up to a prohibition register of direct mail advertising. Conversely, the passive means denote that something is not done, that is, restricting the disclosure of personal data in different ways, for example, by avoiding shopping on the Internet altogether.

The methods of control mentioned by the interviewees were limited mainly to the passive means, which, according to previous studies (e.g. Dommeyer & Gross 2003) are also best known by the customers. A critical attitude towards information disclosure was mentioned as the main passive means. In addition, awareness of companies’ actions was emphasized. Based on the consumers’ ability to distinguish reliable marketers from suspicious ones, consumers can decide to whom personal information is disclosed and what services are used. Many interviewees actually restricted the disclosure of their information in some way. A part of the interviewees avoided the disclosure of certain information (e.g. own name), whereas a few provided as few information as possible: “The less information you disclose, the better you are able to control that. But the information that I already have disclosed, I am not able to control that, but I trust that the firms use it confidentially.” Some of the interviewees conditionally disclosed their information in some ways, for example by forbidding the forwarding of their personal data to other parties. The majority of the interviewees disclosed information only to companies that they considered reliable.

Regarding the active means, only lying and making up false details were mentioned: “With surveys to some extent [I perceive that I am in control over the collection and utilization of my personal data]. Sometimes a service which I want or must use is asking to fill in compulsory information that I would not like to give. Within certain limits you may give something else than your truthful information.” This was expected to some extent as most control methods that require actions are in fact connected to the control over own environment rather than that of own information. For example, the marketing prohibition registers protect the consumer from direct mail advertising, not from the processing of personal data. On the other hand, not a single interviewee mentioned using a commercial e-mail account (Hotmail etc.) for the control over own information even though their usage is quite common.

4 DISCUSSION AND CONCLUSIONS

This study contributes to the area of privacy protection by offering a comprehensive view on how consumers perceive controlling their personal information disclosure on the Internet regarding marketing and CRM contexts. This topic has not been previously studied separately, but rather in connection with related research questions; thus our study produces valuable knowledge to the discussion of consumers’ control perceptions in the online context. Our categorization of the control
perceptions experienced by online consumers to four separate themes - or problem situations and control methods - supplements especially the work of Goodwin (1991) regarding the control over personal information disclosure.

The findings of our study show that the consumers perceive the control over their information relating to data collection as a part of a wider whole; when considering whether to disclose information, most consumers think about its sensible and safe storage and purpose of use. On the other hand, it is clearly difficult to control, or even grasp, the utilization of personal information in its entirety. Consumers look at the utilization of personal information from different viewpoints: one emphasizes data and channel security, and the other ponders on the reliability of the company that utilizes the personal information. Even though the interviewees said that they were not in control over their personal information, they, however, demonstrated the perception of control by utilizing control methods suitable for themselves. The lack of control, however, did not necessarily disturb all the interviewees. In future research, control should thus be examined more thoroughly paying attention to the different approaches employed by consumers.

One of the central themes of the interviewees’ control speech was trust, which can also be considered on the basis of our data as one method of control, or as a factor that increases the perception of control. Alternatively, trust can be regarded as a compensating factor for the need of control, as preliminarily presented by Olivero and Lunt (2004). According to our qualitative data, both assumptions are supported. On one hand, several interviewees mentioned trust as a prerequisite for disclosing personal information, especially sensitive one, thus referring to a method of control. On the other hand, the interviewees who did not generally trust the Internet, however, disclosed their information using other methods of control, e.g. restricting the disclosure of information with certain conditions. The significance of trust in the control over the consumers’ personal information is definitely an important topic for further research.

As for the limitations of this research, we should note that there might be differences between the stated and actual behaviour regarding online information disclosure (see discussion in Kobsa 2007 and Jensen et al. 2005). However, we believe that a survey would be more prone to this distortion than anonymous focus group discussions, as many of our interviewees admitted that they had disclosed information in situations where they in principle would not state to do that. Furthermore, the focus group interviews were carried out only in Finland, and with relatively homogenous sample of participants (online banking customers of age 21-49) which might lower the generalizability of our results. In Finland, online banking is the third most popular application on the Internet, thus almost three out of four Internet users are online banking customers (Statistics Finland 2008). According to the latest Eurobarometer (2008) survey, Finns (as well as other Nordic citizens in general) have higher confidence than the 27 EU countries on average to all market actors and public authorities regarding the usage of their personal information in an appropriate way. Only the market and opinion research companies are trusted equally little in Finland as in the other EU countries on average (33%). Thus, future research might examine the perception of control over online information disclosure in some other parts of the Europe or in the USA, and compare the results to the present study. Moreover, additional research is warranted that studies control in relation to personal information that is provided in consumer-to-consumer relationships (e.g. in social networks or via google mail), as companies exploit increasingly also this information in their marketing efforts.

Abstract

File-sharing has become synonym with the “digital economy” where large music conglomerates as well as certain artist voice strong concern over the impact on their bottom line. This research analyzes the music industry, which has been heavily impacted by a major technological shift i.e. the invention, and rollout, of the Internet. We look to the technological shift that has enabled the downloading phenomenon, as well as analyze the uniqueness of the music industries situation. By comparing the book publishing industry as well as the software industry, which are arguably also influenced by intellectual property rights and plagiarism, we try to find similarities as well as dissimilarities with the music industry. We find that the music industry has used alliances as well as Mergers and Acquisitions in order to consolidate their positions in an attempt to slow down change. There is no consensus on the exact extent of ill effects of filesharing. We point to an unwillingness to achieve convergence of purpose between the IT-community and the much of the music industry. Finally we point to the historical fact that consumers always get what they want in the end, which should indicate a need to find a viable e-commerce solution.

Keywords: Music Industry, piracy, Intellectual property rights, alliances, Internet
1 INTRODUCTION

A lot of public attention has been focused at the economic impact on the music and film industry by filesharing. If we have not tried it out ourselves, most of us know of someone that has tried downloading. What has enabled this change is the more profound technological change that the spread of the Internet has brought about.

Drucker (1994) discusses how a company’s business is based on a number of assumptions. These assumptions relate to market, customer, technology and strengths and weaknesses in them. The assumptions that companies have on the three topics must correlate with reality as well as with what the companies’ core business is. Drucker (ibid.) argues that the changing external environment forces the company to always question its business assumptions and this is something that we argue that the music industry has failed to do.

One way of understanding what Drucker refers to as the external environment (macro-environment) is what in market analysis terms are called ‘PEST’-factors; referring to Political, Economic, Social and Technological (cf. Armstrong, 2006), the Internet is an example of such a technological change.

The rise of the ‘digital economy’ or ‘new economy’ came about during the 1990’s. Scholars like Tapscott (1996), Brynjolfsson & Kahin (2000) have used the term to denote an era where IT is assumed to have revolutionary impact on society. Rayport & Sivokla (1995) suggested that IT is an enabler to endless replication of transactions. Tapscott (1996) suggest that in the digital economy old rules, norms, and customs will no longer apply and this will cause both relationships as well as economic activity to change and in some cases be even inappropriate.

These are all ‘voices’ from the past decade; today we know differently. The dot-com era, in most cases, did not deliver the share-holder value promised, several companies went bankrupt, the much often referred ‘easiness’ of the Internet actually gave rise to challenges not projected in the past. But at the same time, there has been an ever-increasing spread of Internet nodes, which in turn gives rise to an exponential increase in interconnectivity across the world.

According to the Internet World Stats (2007) there were 1,244 Billion users of the Internet per September 30, 2007; which results in a world penetration of nearly 20%. The Internet penetration displays the highest numbers in North America (70%), Australia (55%) and Europe (42%). Hence, downloading is by and large a phenomenon represented by the demand of the Western-oriented societies, due to its relatively large penetration.

The possibility for connectivity to a great number of people as a consequence of the compression of geographical distances due to the Internet, the speed of change as well as the need for change has also increased because of the flexible nature of the new system.

Returning now to the music industry we are interested in how this industry is changing compared to other, but similar, industries. Can it be the case that other industries are experiencing the same kind of claimed sales drop as the music industry, or put more as a general question: what is unique with the music industry?

1.1 Purpose

The purpose of the paper is as follows:

*To describe and analyze an industry affected by modern piracy mediated by a major technological shift in form of Internet technology.*

The industry at hand is the music industry. And in order to reach this purpose, we are interested in answering the following questions:
• What is the technological shift that has enabled the piracy phenomenon?
• What is unique with what is happening in the music industry?
• Are similar industries experiencing the same kind of transformation?
• Analyze the differences by contrasting the music industry with these references industries.
• And finally, what are the future implications for the music industry?

1.2 Structure of the paper

The approach to the topic is critical realism and a mix of qualitative and quantitative methods. In section 2 the mediating technology change and related phenomena is described. In section 3 the analysis of the music industry presented. Followed by section 4 where possible future directions for the music industry are elaborated upon. Finally, section 5 presents our concluding remarks.

2 TECHNOLOGY CHANGE: INTERNET

The Internet as we know it is a worldwide network, that is built on, or by, a multitude of interconnected computer networks that are for the most part publicly accessible. All the computers on this network share the same common language of communication, namely Internet Protocol (IP). The different networks are built up from businesses, academia, government and other players, who together move information such as mail, chat, music, documents, file transfers and interconnected web pages, which all together form the World Wide Web (www). The Internet Protocol can be said to be the backbone, or rulebook, of the WWW. The authors of this article are especially interested in if, and how, file-transfers or more accurately file sharing has affected the music industry.

The company most often “accused” of starting the file-sharing craze is Napster. This was a Peer-to-Peer (P2P)\(^1\) service, that in reality paved the way for other similar programs such as Kazaa, Morpheus, DC++, BitTorrent and many more that are still operating today even though the original Napster was closed down as early as July of 2001.

2.1 The music industry

The music industry as such is a $35 billion industry world wide (IFPI 2004a). Music plays, and has played, an important part in our everyday life. As a reference, the software industry was worth $380 billion according to Software Magazine (2006). Yet, music matters greatly in our everyday life. Music is available in your phone, in most stores, as background when you see a movie, in the car, as a leisure activity and so forth.

Currently there are four big players – in the music industry, representing between 70-75 % of the total market. Sony BMG is the result from a merger between the music division of Sony and BMG in 2005\(^2\). Sony owns 50% of the shares and Bertelsmann Group the other 50%. The three other players are Universal Music Group (owned by French Vivendi), Warner and EMI.

In an attempt to get a more detailed and exact understanding of the music industry sales, the annual reports from the five companies were examined. The purpose of the comparison (table 1) is to see how

---

\(^1\) P2P file sharing is distinct from file trading in that downloading files from a P2P network does not require uploading, although some networks either provide incentives for uploading such as credits or forcing the sharing of files being currently downloaded.

\(^2\) References to the big five, refers to the pre-SONY BMG period.
sales have been affected in each of the individual cases. Therefore, the sales numbers have not been adjusted to a common currency.

In four out of five cases the sales have dropped. Comments from senior management from these companies suggest that some of the lost sales of physical music have been replaced by digital sales, but not to the extent that it makes up for the lost sales on the physical side. Consequently, a more general remark about the industry is that the market as such is shrinking.

The prime reason for dropped sales are new distribution forms using the Internet and mobile phones. The Internet functions as an enabler as well as a threat simultaneously. Digital pirates constitute a threat, but also industrial piracy, e.g. counterfeiting where illegal physical copies of CDs are made; often in smaller industrial ‘labs’. This problem is not very widespread in the Western Countries, but more often reported from Latin America and Asia.

Looking then into more detail to some of the remarks from top management of the largest companies:

*Piracy, both organized and casual, continues to take a large proportion of potential earnings from the pockets of our shareholders and artists. Protecting our intellectual property remains a top priority for EMI.* (Annual Report 2006, EMI, p. 3)

*The industry and UMG are increasing their anti-piracy activities with a multipronged approach focusing on legal action, including participation in industry legislative efforts, public relations and education, and technical countermeasures while offering consumers new products and services.* (Annual Report 2006, Universal Music Group, p. 46)

*SMEI is also continuing its work with the Recording Industry Association of America (RIAA) and the International Federation of the Phonographic Industry (IFPI) on the industry’s anti-piracy efforts, and has led the industry in the development of an innovative initiative known as the Campus Action Network (CAN). CAN is designed to help colleges and universities across the country launch legal online music services and combat illegal filesharing on campus.* (Annual Report 2004, Sony, p. 50)

Judging from the comments in the annual reports, file-sharing is a top-management concern. It is also a kind of battle that needs to be fought on several arenas, e.g. through education as well as by lobbying through the different national legal systems.

However, looking purely at the music industry it can be concluded that piracy has affected their business to a significant extent, which confirms the conclusions by Peitz and Waelbrock (2006), Liebowitz (2004) and the music industry as well. Consequently, it makes sense to say that the music
industry reacts to lost sales by pursuing both the offenders and also changes the way they make their money, i.e. re-configuring their business model.

2.2 Drivers for alliance building

The software industry is potentially threatened by the risk of piracy related to use of software that is not licensed to the user. Being a digital kind of product it lends itself to be easily distributed through the Internet. The interesting case of the book publishing industry is that it reassembles the music industry in certain important aspects. One of the important features of the book publishing industry is the ownership, i.e. TimeWarner and Bertelsmann Group both stand behind two of the world’s largest publishing houses; DC Comics and Random House.

2.2.1 The book publishing industry

According to Hunt (2007) one of the first recorded uses of piracy on intellectual property rights was in 1701 when Daniel Dafoe published the poem “The true born Englishman” which was promptly copied and sold in the streets of London without Dafoe’s permission. Although the first copyright act appears first in 1709 this could be regarded as a copyright infringement.

The interesting thing about this was that Dafoe himself was not very upset by the plagiarism, since the wide circulation of his work had made him famous and enabled him to sell more of his coming works. In this case there were definitive gains from the circulation of the material.

Another example where the gains have not been so evident is the Harry Potter books. According to March (2007) legitimate book sales in India where down an estimated 50% due to pirate prints. In China there where “new” sequels being released in 2002 where the content was made up from other books where the character names had been swapped to match with Harry Potter characters. J.K. Rowlings lawyers have pursued all known cases of copyright infringements. The interesting aspect here is that the publishing industry probably has tried to stem the flow of piracy longer than any other business, where new technology has continually threatened the industry of more than 300 years and yet they are still here even though there are still pirate prints around.

Having gone through the annual reports dating back to 2002 for the book publishing industry for the 4 biggest book publishers of English-speaking books, i.e. HarperCollins, Penguin, Random House and Simon & Schuster, we can conclude that the none of these annual reports comments upon being effected by illegal downloading through the Internet; nor are there any reports on dropped sales as a consequence of file-sharing.

2.2.2 The software industry

In 2004 the director of research at IDC John Gantz claimed (in Locklear, 2004) that the piracy loss figures that are reported by the software industry are highly misleading. According to their study, done on the behest of the “Business Software Alliance” (BSA), only one out of ten unauthorized copies of software is really a lost sale. The correct term to be used when discussing loss figures should be “retail value of pirate software” according to John Gantz, since many of the copies out there are in developing nations where the users just can not afford to buy it.

According to Davis (2007) this is something that was backed by Romania’s president Traian Basescu, who claimed that “piracy rocks” no later than in February of 2007. He went on to thank Bill Gates for opening a new global technology support centre in Bucharest, which ironically was possible due in large measure to the widespread piracy in the country, which has enabled the employees to be familiar with the wares they need to give support on. According to the president “Piracy helped the young generation discover computers. It set off the development of the IT industry in Romania.”
Hunt (2007) points out that Jeff Raikes, president of Microsoft’s business group has admitted to the fact that pirated Windows is easily the best marketing tool they have ever had and was quoted to saying: “If they’re going to pirate somebody, we want it to be us rather than somebody else.”

Similarly for the software industry, the annual reports of Microsoft and Adobe were examined back to 2002. Microsoft’s operating system and its Office suite are common products subject to illegal downloading. Adobe is the software house that develops some of the most important tools for the graphic- and image industry and the suite of applications offered by Adobe are often subject to downloading and copyright breaches.

We may not be able to protect our intellectual property rights against piracy, infringement of our patents by third parties, or declining legal protection for intellectual property. We defend our intellectual property rights and combat unlicensed copying and use of software and intellectual property rights through a variety of techniques. (Microsoft, Annual Report 2006, p. 15)

Although we defend our intellectual property rights and combat unlicensed copying and use of software and intellectual property rights through a variety of techniques, preventing unauthorized use or infringement of our rights is inherently difficult. (Adobe, Annual Report 2006, p. 34)

Piracy is seen, both by Microsoft and Adobe, as just one type of threat among many others, and also a threat that they acknowledge being difficult to fight. That is a different view than the one conveyed by the music industry. On the other hand and as indicated by table 2, neither Microsoft nor Adobe has suffered any drops in their sales since 2002.

2.3 Intermediary conclusion

The music industry has experienced a considerable drop in sales

Addressing the piracy and illegal downloading as the main threat has been a central issue to the top management of the music industry when communicating with the shareholders.

The book publishing industry does not actively recognize downloading as a strategic threat to their operations and sales.

The software industry is affected by piracy of different kinds. However, a more complex pattern of more general business threats exist in that industry.

3 ANALYSIS OF THE MUSIC INDUSTRY

As indicated above, it can be stated that the music industry informs their share-holders about the effects of illegal downloading. Neither the book publishing industry nor the software industry makes such a strong case about piracy to their shareholders. How are we to make sense out of the differences observed between the different industries?
Departing from the five forces-model suggested by Porter (1980) a division is made about several competing forces that needs to be taken into consideration when analyzing an industry; the supplier’s bargaining power, bargaining power of the customers, internal competition, threat of substitute products and, finally, the threat of new entrants.

Looking into more details to the category of threat from substitute products where switching costs become a central theme; the possible migration from one product to another in this case is relatively low when it comes to music due to the ‘low-cognitive’ nature of the product. Music and films are ‘consumed’ in a less complex manner than for example books and software, which creates a situation of low switching costs as regards substitute products. However, music works complementary to movies, mobile phones, MP3-players etc. and that is where the future revenue streams exist in the future. The quotation from the EMI Annual Report of 2006 confirms this view:

*We continued to broaden our digital distribution channels globally by entering into agreements with partners who will make our music available on their platforms. During the year, we entered into partnerships including: a multi-territory deal with Apple; regional partnerships with MTV, Yahoo, Last.fm and Sony; and national agreements with Amazon in the US, Baidu in China, Napster in Germany and Playlouder and BT Vision in the UK.* (EMI, Annual Report 2006, pp. 18-19)

Although piracy holds a threat to the software industry as well as the book publishing industry the nature of the products is somewhat different, e.g. a piece of software or book has an overall longer ‘consumption durability’ that makes them less vulnerable to the effects of piracy. There are exceptions of course but a large amount of today’s music have short ‘consumption durability’. This is has worked against the music industry in the sense that, for instance, music is consumed once or many times over the radio, where the music is free to the consumer and on top of this it is legal to record the radio music and listen to again i.e. there is already a low threshold towards using the music freely.

3.1 Bargaining power of suppliers

Assuming that artists are as numerous and fragmented in the music industry as in the book publishing industry; the software industry is somewhat different in the sense that in what is referred to as the ‘industry’ the companies are not only intermediaries between the artist and the consumers, but rather both the artist and the intermediary at the same time. Hence, the upstream threat visible in the music industry, where artist may take over responsibilities that the music industry served in the past, is not present in the same way in the software industry. Although a reservation here should be made about conflicts with patent holders to base technology used in assembled end-user software or technology. The typical large software house controls more of the value-creating process.

The music industry has lived strongly on the asymmetrical power relationship that exists between the industry and the music creators. One could even claim that it has a strong institutional character where bands artists long to be ‘signed’ to a large record company or label. Having been the cash cow for decades, the relationship is being questioned by the music creators to a larger extent.

3.2 Bargaining power of customers

In the case of the industry software, end-users are often corporations and consumers. The existence of a clear corporate customer works to the software industry’s benefit. Copyright protection can be more easily upheld in the case of a corporate counterpart. A more detailed documentation of the customer together with legal accounting principles works to the software industry’s benefit. The wide demand from both consumers and corporations also makes the end-user fragmented in many instances, which favors the industry.

The fact that there is a limited amount of available alternatives of operating systems and the bundling with the office suite of MS Office has rendered Microsoft a very strong bargaining position vis-à-vis its customers.
The music industry and the book publishing industry on the other hand have potentially much less loyal customer base than the software industry. Customers can easily change their consumption patterns by putting their next potential spending on a different kind of entertainment media than music, e.g. movies, Internet, TV or even illegal downloading.

3.3 Internal competition

All industries studied are subject to internal competition. But what is more interesting to see is the internal cooperation in the music industry, where forces are joined in order to limit illegal downloading.

Both the music publishing industry and the book publishing are somewhat similar; ‘Imprints’ is the corresponding term to the music industry’s ‘record labels’ and many of the larger publishing houses maintain a large number of imprints.

3.4 Threat of new entrants

Of the three industries studied the software industry is probably the one that has the lowest barriers of entry. One example of this is the open source-movement driven by Linux as a kind of prime example on an operating systems that threatens the market position of Microsoft Windows. Getting access to established sales channels of books and music is a difficult task compared to how easily software can be distributed through the Internet.

3.5 Summary of findings

Concluding the industry analysis, the following points can be made:

In the past, the music industry has thrived on the relationship between the music industry and the suppliers of music, i.e. the artists, but also on controlling the distribution forms to their customers.

New technology-enabled distribution forms have loosened the music industry’s control of the distribution and also enabled illegal downloading.

Artists see possibilities of by-passing the music distributors.

Music and songs per se, are easily consumed and subject to low switching costs to complementary means of entertainment in comparison to the publishing industry and the software industry.

4 FUTURE DIRECTIONS FOR THE MUSIC INDUSTRY

As discussed earlier, the use of Music is something that affects all of us whether or not we listen to this music of our iPod, a CD or sitting in the outback listening to a Didgeridoo. Because of this widespread use of music the industry as such is well adapted at alliance building as well as M&As, which have been used to form partnerships and alliances worldwide. Lorange and Roos et al. (1992) describe how alliances can be used offensively, by creating or accessing markets in order to define and/or set industry standards, or defensively in order to protect current market positions, gaining economies of scale or sharing financial risks.

It would seem as if the music industry to date has used alliances and M&A to consolidate their position on the market, being unwilling to change and adapt. Considering that it is very hard to research the total number of music sales today, since we have music in phones, computers, and shopping malls as well as on CDs and in Movies, it is hard to pay heed to talks about the industry being on the verge of collapse. Rather there is an issue of an unwillingness to change and adapt to the new rules of engagement that the Internet and electronic sales have brought to the negotiating table.
4.1 Other values from file-sharing?

Oberholtzer-Gee et al. (2007) debate the promotional value power of file-sharing, but other authors such as Hunt (2007), Locklear (2004), SIIA (2007), and Wilen (2007) also carry discussions in and around this area. The music industry’s point of view has been that all forms of file-sharing hurt their sales, but there has been proof of other views, most recently Radiohead released its new album only online and let their audience decide the price they are willing to pay. This is interesting since Radiohead was also one of the first bands to take a different view of file-sharing. In 2000 their album Kid A came into circulation on the internet before it was actually released as a CD, but contrary to regular beliefs and opinions of file-sharing the result for Radiohead was to hit the #1 spot on the billboard 200 sales chart its very first week in real circulation.

4.2 A changing landscape

It seems as if many artists as well as musicians of today actually embrace the Internet as a tool and platform they can use both to create and sell their work, and more importantly it is a very powerful channel for promotion. According to Madden (2004) the big issue is the actual impact of the free file-sharing and the effect this has on copyright issues.

There is no doubt that illegal downloading of files has become more common as the Internet diffusion has grown. The ongoing debate seems to be centered on copyright issues in the music industry and whether or not file-sharing has helped or hindered sales of CDs. Most studies – including ours – and academic articles show that file sharing affects CD sales in a negative way. Peitz & Waelbroeck (2006) argue that the possibility to download songs and text at any time from anywhere over the Internet on the one hand increases the value of the product, but on the other hand that rights management tools, e.g. DRM-protection, can restrict and even lock the use of the digital media.

This unwillingness to achieve convergence of purpose between much of the music industry and the IT community is maybe what lies at the heart of the problem. There are 4 conglomerates, who control and own much of the music labels. EMI, Sony BMG, Time Warner and Vivendi Universal controlled 84% of the US market and 79% of the European music market in 2002. The fact that some of them also have a diversified product portfolio seen from a corporate view, i.e. they control many other parts of the different verticals of the industry, such as hardware for playing different media, e.g. CD, DVD, projectors etc. creates a situation of almost total control. The typical scenario when you have an oligopoly is to have an unwillingness and resistance to change, or even to participate in any form of partnerships outside of the small group (INFO, 2006).

According to Dr Jo Bryce, University of Central Lancashire “The purchase of counterfeit goods or illegal downloading are seen as normal leisure practices” In the same article by Hermedia (2005) “Teenagers are being tactical spenders,” said Dr Bryce. “The money saved lets them spend more on mobile phones, going to the cinema or eating out.” This is an interesting observation, since it would insinuate that the money that is not taken in on selling an actual record is taken in from movies or by downloading ring-tones to the mobile phone both of which are markets that are heavily controlled by many of the same players that control the music scene.

5 CONCLUDING REMARKS

It would seem as if the “pirates” are here to stay and the best way to handle this is to embrace the change. History has shown that the consumers always get what they want in the end. Consider the upheaval the film industry had towards VCRs when they first came to market or the music industries cry when cassette tapes where introduced. Over the years we have seen a number of new technologies being introduced in the music industry as well as the movie industry and most of the time there have been problems and downturn in sales of the current predominant media channel. It would be
interesting to do a study of the dips in sales after external events affect the sales of an industry, i.e. how were sales affected after the Disco era was over? How were LP sales affected by CDs, how were CDs affected by DVDs and maybe mp3s? How was cinema attendance affected by Cable TV? The list goes on and on.

We arrive back to the statement of complexity. The new market is extremely complex where the big musical giants are also the big movie giants, but also giants in producing hardware for both markets. When you are both vertically and horizontally integrated it is had to know where one market ends and another begins and the real overall loss or gain of the full market is something probably only the big four themselves can truthfully answer.

Abstract

Data warehouse projects bring together different communities of practice, with the primary objective of producing one body of information which is capable of comparative advantages in business analysis. Due to the number of involved communities and the complexity of their collaboration, data warehouse projects are costly. In this paper we give a closer look at communication problems on boundaries between participating data warehouse projects’ communities. Our analysis enlightens the potential relation between the early creation of language communities of the involved communities and lowering data warehouse project development costs. As today, there is hardly any methodology available for analyzing and aligning mutual understanding between data warehouse project participants. In this paper, we propose a data warehouse development scheme for project improvement based on our discussion as a first step in a design science project.

Keywords: Data warehouse, Boundary Objects, Community of Practice, Design Science.
1 INTRODUCTION

Since business environments and information technology (IT) are now changing at an extremely fast pace, management information systems (MIS) become a crucial prerequisite for the long-term efficiency of any organization. Well-informed actions (i.e., those based on true beliefs) are more likely to achieve desired ends, and information is valuable insofar as it helps individuals form true beliefs which, in turn, promote effective, goal achieving action (March and Smith 1995, p. 251). The central purpose of MIS is to provide information for the management activities carried out within an organization (Curtis and Cobham 2005, p. 27 f.). Thus MIS are systems that assist management in decision making and in forming true beliefs. This includes both, executive information systems (EIS) and decision support systems (DSS) that allow ad hoc queries, and analytical reporting systems. Those IS are among one of the most prominent subjects in IS research (Claver, Gonzalez and Llopis 2000, p. 183).

It is general consensus that state-of-the-art MIS are based on data warehouses (DWH) and online analytical processing (OLAP) (Codd, Codd and Salley 1993; Devlin 1997; Inmon 2005). DWHs support the management perspective on business processes technically, but their implementation is extremely complex and costly (Vassiliadis 2000). The complexity manifests itself in the high failure rate of projects and increasing development costs (BCS 2004; Kimball and Caserta 2004; SGI 2001). Therefore, a clean design and specification of the system is of great importance. Consequently, the involvement of the management users and management’s support are deemed key factors for MIS quality and system success (Wixom and Watson 2001, p. 35 f.). One of the major issues in the conceptual specification of management views relates to the bridging of the so-called “communication gap” that originates from differences in semantic understanding (e.g., homonyms and synonyms) (McDavid 1996). This gap exists between business units using a MIS and computer departments designing and implementing the MIS within an enterprise (Alter 2001; Peppard 2001). As Alter (2001) puts it: “Of course most IT professionals know more about computer hardware and software, but the communication gap is about the difficulty business and IT professionals have in establishing mutual understanding that helps them communicate in both directions about their views and concerns” (p. 46).

In DWH projects, IT professionals developing DWHs (DWH professionals) are confronted with communication gaps on boundaries towards two communities of practice (Wenger 1998): business experts in decision-making fields (BEDF), who define business requirements, and operative system professionals (OSP) in charge of data required for fulfilling those requirements. According to several authors (Brown and Duguid 2001, p. 209; Star and Griesemer 1989, p. 393; Wenger 1998, p. 105), there are two forms of boundary connections: (1) boundary objects and (2) brokering. Therefore, DWH professionals in these circumstances have brokering roles in closing the communication gap on both boundaries. Moreover, we argue that boundary objects mediate the creation of language communities (Kamlah and Lorenzen 1984, p. 57) that afterwards enable the transfer of knowledge across boundaries between communities of practice. We argue that the creation of a language community between DWH professionals and both BEDFs and OSPs in early stages of DWH development plays an important role for the success of the final product. We suggest that early creation of language communities lowers DWH development costs by helping DWH professionals to construct extraction, transform and load (ETL) processes faster and more correctly, and by synchronizing decision-makers’ requests with sources of data. Consequently, we propose that the development of IT artifacts should not start sooner than a language community is created. The fundamental question that arises from this argument is how we are able to determine whether the creation of a language community was successful or not.

The structure of the remainder of the paper is as follows. In the next section, we discuss the motivation for our research. Afterwards, we present our research objectives. Following this, we review related work and possible theoretical foundations. We present an overview on our research-in-progress project and summarize the findings and limitations so far, giving an outlook on further research.
2 MOTIVATION FOR RESEARCH

Because DWH projects often fail or significantly exceed budgets, existing research has concentrated on quantitative or qualitative analyses of success factors as well as contemporary best practices for building DWH (e.g., Herrmann and Melchert 2004; Hwang, Ku, Yen and Cheng 2004; Hwang and Xu 2007; Watson, Fuller and Ariyachandra 2004; Weir, Peng and Kerridge 2003). March’s and Hevner’s (2007) thorough literature research warns how links between data warehousing, strategic decision-making and evaluation are under-researched. They present four overarching objectives for DWH support of management decision-making processes and influences of those objectives on the successful use of decision support in business organizations: integration, implementation, intelligence and innovation.

Integration, the first objective, is concerned with the consolidation of data from disparate sources into one consistent body of data. Integration lies at the heart of decision-making tools, with content management as one of the biggest challenges of DWH designers (March and Hevner 2007, p. 1036). March and Hevner (2007) warn that effective integration decisions can only be reached by experts having intimate acquaintance with knowledge domains pertaining to business internally and to the context in which the business that the MIS was built for is immersed (March and Hevner 2007, p. 1041). Therefore a pre-sequence that prefigures an integration process should be DWH professionals’ affiliation with the community of individuals (BEDFs) that are familiar with the business logic and the business environment (internal and external business ontologies) and the community of individuals (OSPs) familiar with operational source data (internal technical ontologies).

The next objective, implementation, addresses DWH development alignment with existing business processes in the organization, overcoming the current role of DWH as a repository of historical data which addresses passed organizational transactions (March and Hevner 2007, p. 1038). This is only possible when DWH professionals understand the business logic and can introduce learned business logic into the DWH.

The third objective, intelligence, refers to a right fit between DWH users and different type s of tools (March and Hevner 2007, p. 1041). Once the fit is found users receive appropriate training and support from DWH professionals. Analytical and data mining tools provide interfaces between decision-makers and data in the DWH. The users as decision-makers use the data to generate meaningful information on which they act. The last objective, innovation, deals with change management, specifically how changes in DWHs propagate to MIS. The DWH professionals’ job is to design the DWH to be ready for change so that every change is transparent to decision-makers (March and Hevner 2007, p. 1041).

We argue that only when the first two objectives (integration and implementation) have been successfully realized, decision-making can use the DWH to engage into the objectives of intelligence and innovation. Therefore we suggest that research should focus on concepts and theories that help DWH professionals to successfully accomplish both objectives of integration and implementation. In this context, the concepts of convergence and divergences between communities of practice and information artifacts offer a useful starting point for further research.

Star et al. (2003) introduced the concept of convergence to describe processes of mutual constitution between communities of practice and information artifacts they use: “information artifacts undergird communities of practice, and communities of practice generate and depend on the same information resources” (p. 244). Basically, DWHs are shared information artifacts between OSPs and BEDFs. Given the term convergence, the alignment of practice with information artifact increases when use and practice fit design and access (Star et al. 2003, p. 224). Therefore, DWH professionals’ main concern should be to build a DWH that will satisfy both the BEDFs’ needs for information and OSPs’ needs for easy integration. The complex processes at the boundaries between the two communities of practice include the discussion of differences between community insiders and outsiders. Members of
one community are called insiders of that community, whereas all others are outsiders. The thin line between insiders and outsiders is not easy to draw (Star et al. 2003, p. 262).

What follows from this discussion is that shared IS such as DWHs are a kind of boundary object, and DWH professionals are brokers between multiple communities of practice (Pawlowski, Robey and Raven 2000, p. 332). Apart from IS as such, entities pertaining to IS (e.g., system documentation, user training materials, standards, policies) are also considered boundary objects that are shared by the set of communities (Pawlowski et al. 2000, p. 334). Pawlowski et al. (2000) pointed out a major problem IT professionals (such as DWH professionals) face while supporting IS shared by several communities of practice: they have to learn the practice of each community and have to become insiders of both communities (not only learning about these practices, but also entrée to practice-enough legality) (Pawlowski et al. 2000, p. 335). In this context, the process of brokering means to get members of the one community (insiders) to understand and accept changes in their work necessitated by changes in the shared system that are needed by the other community (outsiders).

Based on these suggestions, we propose a solution for lowering the development costs of DWH projects and for creating business value. Creating mutual understanding between DWH professionals and communities of practice involved in data warehousing (i.e., OSPs and BEDFs) is a precondition for building successful and cost-efficient DWH-based MIS that add business value. We describe “evolution of a shared IS” (the DWH-based MIS) as developing a boundary object between OSPs and BEDFs based on various artifacts. Moreover, these artifacts also exist as boundary objects between DWH professionals and OSPs, and between DWH professionals and BEDFs. We propose that investigating how these artifacts influence the creation of language communities between the involved communities of practice should yield interesting and useful new insights for research. We are especially interested in exploring which phenomena contribute to the coherence of this language community, and how a language community, once created, enables DWH professionals to overcome the previously mentioned problems during the development of decision-making systems.

3 RESEARCH OBJECTIVES AND QUESTIONS

To summarize, the importance of communication in DWH projects has been widely recognized and studied (e.g., Wixom and Watson 2001). Research on impact of communication on DWH project success is limited, but is growing (e.g., Behrmann and Räkers 2008; Gallivan and Keil 2003; Joshi, Sarker and Sarker 2007; Ko, Kirsch and King 2005). As yet, little is known about how communication in DWH projects is influenced by boundary objects. While previous studies on boundary objects have, for instance, dealt with their influence in traditional ISD projects (e.g., Sapsed and Salter 2004), there is a lack of valid, reliable measures for assessing the boundary objects used in communication in DWH projects. This research-in-progress paper focuses on the role of boundary objects for communication in DWH projects with the aim of understanding how boundary objects influence the success of such projects. There are four objectives to this research:

- Which boundary objects are used in DWH projects to connect different communities of practice?
- How do the boundary objects (both formal and informal) evolve during a DWH project?
- How does selection or availability of adequate boundary objects or/and brokers in early phase of requirements analysis affect DWH project success, and how do these boundary objects affect DWH project success from the perspective of the different communities of practice involved?
- Can the development of boundary objects and the process of brokering be regulated or influenced in order to achieve better project results?

This research hopes to contribute to previous work on boundary objects in IS development projects by investigating the evolution and use of boundary objects in DWH projects and by developing and validating artifacts for leveraging such boundary objects. We also hope to provide a practical contribution by developing a framework that project managers and project teams can use to measure and assess the effectiveness of specific boundary objects at various stages throughout a DWH project.
4 THEORETICAL FOUNDATIONS

Communities of practice are characterized as shared histories of learning (Wenger 1998, p. 86; Wenger, McDermott and Snyder 2002). Such histories are known to create discontinuities between the ones who participate in the community work and the ones who do not (Wenger 1998, p. 103). These discontinuities are also revealed in development of DWHs. We distinguish two major communities of practice which confront each other in DWH projects: (1) OSPs with knowledge of the legacy and source systems, and (2) BEDFs. OSPs are in charge of maintenance and further development of operational systems; whereas BEDF influence the course of actions the company needs to take in order to stay competitive in the environment. Connection between these two practices is made by introducing a third practice, DWH professionals who are responsible for the development of the DWH.

Wenger (1998) uses the term negotiation of meaning as “the process by which we experience the world and our engagement in it as meaningful” (p. 53). Thus, our personal meaning of the world around us is located in the process of “negotiation of meaning” which involves an interaction of two constituent processes, namely reification and participation (Wenger 1998, p. 52). Participation involves all kinds of relations. In social communities participation shapes our experience, and also shapes those communities. Trough the process of reification, aspects of human experience and practice are congealed into fixed forms and given the status of objects. Participation and reification form a duality that is inherent to human perception of meaning and hence reflected to the nature of human practice (Wenger 1998, p. 52).

The two constituent processes of participation and reification have to be in balance (Wenger 1998, p. 56). When one of the processes predominates, negotiation of meaning is negatively affected or disturbed. If the process of participation prevails, negotiation of meaning lacks real, physical arguments that could help participants coordinate their argumentation lines and solve the differences. If on the other hand, the process of reification predominates, very little interaction and experience exchange remains. In these conditions, reconstruction of meaning buried in the products of reification (reified objects), could be very difficult (Wenger 1998, p. 56). Participation and reification can both contribute to the discontinuity of boundaries (e.g., a specific jargon is understood only by participants of a community where it is used), but can also create continuities across boundaries. Thus, the process of reification produces objects that can move across boundaries (Wenger 1998, p. 105). Likewise, members of one community of practice can participate in multiple communities of practice at once and help to introduce those reified objects from one community of practice to the others, when such translation is needed. Therefore two forms of boundary connections exist, as introduced before: boundary objects and brokering (Brown and Duguid 2001, p. 209; Wenger 1998, p. 105).

Star and Griesemer (1989) define boundary objects as “both plastic enough to adapt to local needs and constraints of the several parties employing them, yet robust enough to maintain a common identity across sites” (p. 393). Boundary objects may be abstract or concrete, are weakly structured in common use, and become strongly structured in individual-site use. In different social contexts (i.e., communities of practice), they can have different meanings; however, their structure is common enough across contexts to make them recognizable by means of translation. Consequently, the creation and management of boundary objects is especially important in developing and maintaining coherence across intersecting social contexts (Star and Griesemer 1989, p. 393). In the context of DWH projects, the artifacts (e.g., shared documents, tools, business processes, objectives, schedules) exchanged between communities of practice (Brown and Duguid 2001, p. 209) can potentially become boundary objects if they should belong to (at least) two different practices. These artifacts then form a nexus of different perspectives (Figure 1), which then needs to be coordinated (Wenger 1998, pp. 107-108).
Pawlowski et al. (2000, p. 331) emphasize the role of legitimacy in the jobs of IT professionals such as DWH professionals that helps them to influence the development of practice, to mobilize attention and to address conflicting interests. DWH professionals have a coordinative role as brokers in DWH projects. They create participative connections between the two practices of OSPs and BEDFs:

- On the one hand, gathering requirements in DWH projects means not only gathering reports and documents created, for example, by the BEDF community (boundary objects), but also meeting with community’s representatives. Reports do represent and are related to some of the more tactical decision-making requirements (Kimball and Ross 1996, p. 15), but they are purely reifications of them. Only through interaction with members of the BEDF community, where those objects were reified, can a full understanding of the requirements be reached. These objects then form the nexus where different perspectives of BEDFs and DWH professionals through processes of participation align and hence form DWH professionals’ understanding of the objects. This suggests that communication between both practices is of paramount importance for successful DWH projects.

- On the other hand, in interaction with members of the OSP community, DWH professionals concentrate on the main process of DWH development: implementation of extraction, transformation and loading (ETL) of operational data with the goal of creating more appropriate data-sets matching the BEDFs’ requirements. Compared to the overall costs of DWH projects, the costs resulting from the ETL process have a major share (Kimball and Caserta 2004). Extraction of operational data implies knowledge of what operational data exactly needs to be extracted to meet the requirements and business demands, and from which operative system this data needs to be extracted. In this context, we suggest that communication between OSPs and DWH professionals is a profound prerequisite for aligning different perspectives of exchanged boundary objects (e.g., database schema, database tables, excel tables, text files etc.) between those two communities. Only in close cooperation with OSPs, DWH professionals can extract and interpret operational data so that it matches the requirements of the BEDFs.

We propose that DWH professionals generate a mutual understanding of artifacts on the nexus of perspectives (i.e., boundary objects) through communication with members of both OSPs’ and BEDFs’ communities. In accordance with Ågerfalk and Eriksson (2004), we argue that traditional research on requirements analysis has focused too much on the syntactic and semantic aspects of conceptual modeling languages, and too little on the pragmatics of the requirements process. But where Ågerfalk and Eriksson (2004) use speech act theory as a theoretical foundation, we suggest to employ a different theoretical foundation from philosophy of language. Language critique (Kamlah and Lorenzen 1967; Kamlah and Lorenzen 1984), a branch of constructivist philosophy known as the “Erlangen School”, provides useful insights and backup for our understanding of DWH projects, and has been successfully applied to IS research before (e.g., Becker, Niehaves and Pfeiffer 2008; Holten 2007; Holten, Dreiling and Becker 2005; Holten and Rosenkranz 2008; Rosenkranz and Holten 2007; Rosenkranz, Laumann and Holten 2009).

Kamlah and Lorenzen (1984, p. 47) argue that language as a system of signs promotes mutual understanding as a “know-how” held in common, the possession of a “language community”. A new term is introduced by explicit agreement between language users with respect to its usage (first agreement) and meaning (second agreement) (Kamlah and Lorenzen 1984, p. 57). This agreement leads to a relation of concept and term, and is shared by a language community as the knowledge of using this term. Accordingly, if members of a group of people communicate, and each has an aligned semantic and pragmatic dimension of a symbol (or term) in mind, then this group of people forms a
language community. All members have the same concept in mind if they are confronted with a symbol of the language and vice versa.

According to our understanding, boundary objects play a significant role in making language communities explicit: if members of communities of practice have a same concept in mind when confronted with a same artifact (boundary object), they belong to the same language community (Figure 2). It is difficult for non-members of a language community to understand the local artifacts in a proper way. An individual has to revise his or her understanding of the given language signs with respect to the ones of the language community in order to become its member, and thus gain the possibility of using the same terminology in discourse with the other community members (Holten 2007, p. 3). One can readily say that an alignment of a community’s terminology is essential for its viability.

We argue that DWH professionals have a unique and moderating role: since they simultaneously belong to both communities of practice, and hence to both language communities, they are aware of the different perspectives that OSPs and BEDFs have. Their job is to moderate and manage the mediating process of translation, coordination and alignment between the two perspectives. Therefore it is essential that DWH professionals have a free hand to influence the development of practice and to mobilize their attention to address conflicting interests (Pawlowski et al. 2000, p. 331). In order to achieve a successful implementation of the developed DWH, both involved communities of practice need to fully participate in the development process. Therefore, we suggest that the job of DWH professionals is to make the developed DWH to be accepted and actively used in both practices (brokering). This implies that OSPs know why they prepare source data for the DWH, and BEDFs to comprehend the benefit of the reports generated by the DWH solution. As a result of DWH projects, a DWH is constructed, which represents a new boundary object between OSPs and BEDFs as a new nexus where community’s perspectives meet and align trough the process of negotiation of meaning (Figure 3).

We argue that the brokering role of DWH professionals remains a significant success factor even when a DWH is finally implemented. Up until now, maintenance of DWHs often relies entirely on the
knowledge base these high-skilled professionals prepare in form of exhaustive documentation or as consultancy service they offer (Rükers and Rosenkranz 2008, p. 10).

5 RESEARCH METHODOLOGY

5.1 Design Science Research

We propose to adopt design science as a research framework, which is recommended for scientific studying in the field of IS when artificial, human-made phenomena, such as DWHs, are examined (March and Smith 1995, p. 253). Developed and evaluated IT artifacts that are useful and capable of solving research problems in the IS realm constitute the cornerstone of this approach (Gregor 2006, p. 62; Hevner, March, Park and Ram 2004, p. 78). That is, rather than producing general theoretical knowledge, we aim to create efficient IT artifacts by design science research. In contrast to behavioral science, design science research aims to provide four general outputs: (1) constructs, (2) models, (3) methods, and (4) instantiations (March and Smith 1995). Therefore we aim to develop and provide useful methods and instantiations of IT artifacts that DWH professionals can utilize for their role as boundary spanners and brokers. We argue that research has to support this role explicitly in order to support the integration objective. We plan to follow the design science research methodology as suggested by Vaishnavi and Kuechler (2008, pp. 19-22). In order for DWH professionals to acquire the necessary understanding of the involved communities of practice (OPS and BEDF), and thereby to develop cost-efficient DWHs which add business value, we propose the following DWH development scheme for DWH project improvement as a first step in our design science project (Figure 4).

![DWH Project Improvement Scheme](image)

Figure 4. DWH Project Improvement Scheme

Furthermore, the improvement scheme acts as a framework for our research. We envisage that project managers and project teams can use a more elaborate version of the scheme for identifying potential problem areas and for planning and coordinating their requirement analysis processes (see Figure 5 for a first tentative proposal). Initially, it is necessary to discover community’s representatives (BEDFs and OSPs). During the process called negotiation of meaning, BEDFs and OSPs together with DWH professionals discuss the meaning of BEDFs’ set of business requirements and OSPs’ operational data sources. We suggest that this process should be supported by a kind of Analysis Panel. Artifacts such as business documents, source system documentation, source system data or interview notes will be gathered and stored in an Input Data Storage. The Analysis Panel is by no means an ETL tool. Whereas ETL tools try to map source systems and DWHs unequivocally, we consider ambiguities in both requirements and sources as opportunities for negotiation and creation of new understanding. The Analysis Panel then serves as a foundation for engaging into negotiation of meanings between DWH professionals and the other stakeholders. As a result of this process, DWH professionals produce, vary and store a set of terms in the so-called Term Storage. Terms in the Term Storage represent the
explicit definition and meaning of the domain language that DWH professionals have developed while negotiating the meaning of the information artifacts with the help of the Analysis Panel (and stored in the Input Data Storage). The sketched feedback loops suggest how the process of negotiation affects all participants and changes their preliminary understanding of the discussed artifacts. Each time participants meet, the process of negotiation influences the DWH professionals’ set of terms. Consequently, the Term Storage should support versioning of each single term. When no novel versions are produced, the meaning of a term is stable and ready for usage (i.e., a language community is created when all necessary terms are stable). In later phases of a DWH project, these terms should enforce further business requirements and operational data source collection as well as the development of the final DWH.

Figure 5. **DWH Project Improvement Scheme – Detailed Version**

For example, consider the following scenario: company X is in charge of DWH development for an insurance company, in our case called company A. During the first phase of requirements gathering, companies’ representatives, DWH professionals from company X, BEDFs and OSPs from company A, meet on regular basis. Most of the meeting sessions include discussions over company A’s legacy systems specifications as well as company X’s DWH solution proposition. Those documents represent the foundation for negotiations of the meaning for concepts and terms involved (e.g., differences in the meaning of the terms “hospital” and “clinic”, that DWH professionals are unaware of, is clarified and both terms are afterwards stored in the Term Storage). Our proposed DWH improvement scheme could act as a framework that facilitates systematic investigation of hidden, weak and unexpected relationships between language terms from the perspective of visual exploration and analysis of discussed documents.

5.2 **Proposed Data Collection & Further Course of Project**

The goal of design science is utility. For evaluating a proposed artifact, its utility for solving specific problems must be assessed. In presenting the development of methods and instantiations used to support the presented improvement scheme, we will firstly explore and introduce theoretical constructs and express the relationships among constructs to propose “how things are” in DWH projects. By building a logical chain of arguments for our reasoning, we will discuss why artifacts that we propose and build during our project will provide a suitable basis for addressing those problems.

First, in extending our already thorough literature review, we will conduct a second review in the hope of finding existing and related approaches in other areas in order to detail and refine our improvement scheme. Second, we plan to conduct expert interviews with DWH professionals in DWH departments of software development companies. The interviews should revile a set of communication problems and their probable causes in DWH projects. We will then match the results (in form of cause-problem pairs) with our scheme for DWH project improvement and the suggestion that the early creation of language communities between involved communities of practice, using boundary objects as nexus of different perspectives, will lead to alignment between participants. Furthermore we will conduct an
additional round of interviews with a second group of experts in other software development companies to test if they experience the same set of problems as the first group. This should show if the perceived practical problems can be linked to the theoretical foundation and the suggested improvement scheme. Then we plan to generalize our project improvement scheme and test it against other shared IT projects in the companies, conducting surveys. Third, we plan to explore how specific IT artifacts (i.e., both methods and instantiations) can be used (1) to support the creation of boundary objects and the process of brokering in general, and (2) implement the proposed improvement scheme. This will include several proposals for IT artifacts, which will be based on a more detailed improvement scheme and aim to solve issues arising from this scheme.

By conducting field studies to evaluate the usefulness of our improvement scheme and the to-be developed IT artifacts, we hopefully will show significant improvements in language community creation, reduction of DWH development costs, and added business value. Since design science is characterized by an iterative search process, during these “micro evaluations”, minor redesigns will probably occur on several occasions, which is a common occurrence in design science research (Vaishnavi and Kuechler 2008, p. 25). Despite the problems inherent in the subjectivity of these approaches, we strongly believe that there is a need for field studies to examine the usability and actual usage of proposed IT artifacts.

5.3 Current Status of the Project

The project to date has reviewed the literature on boundary objects in many different domains. Literature relating to DWH projects has also been reviewed. At this point the motivation for the research is clear, the overall research objective has been identified and the research questions are defined. Currently, various possible artifacts that relate to the improvement scheme are being identified and critiqued for their suitability and applicability to this study. It is hoped that at least some of the constructs already detailed in the literature can be adopted, but the expectation is that some new constructs will need to be developed that relate specifically to boundary objects in DWH projects. Once the improvement scheme is defined and pilot tested, IT artifact construction will proceed.

6 CONCLUSION

In this paper we argue that the creation of a language community between DWH professionals and both BEDFs and OSPs in early stages of DWH development lowers DWH development costs by helping DWH professionals to construct ETL processes faster and more correctly, and by synchronizing decision-makers’ requests with sources of data, thus allowing for effective and efficient integration. By using boundary objects as means to create mutual understanding between participating communities, we proposed an initial scheme for DWH project improvement as a first step in our design science project. According to Kimball and Ross (1996), the combination of understanding the business requirements and the available data is necessary as a first step toward the design of a DWH (Kimball and Ross 1996, p. 33). From our perspective, only DWH professionals belonging to both BEDFs’ and OPSs’ language communities can live up to these design expectations.

7 ACKNOWLEDGMENTS

We would like to thank our reviewers for their recommendations on our work. Furthermore, we would like to thank the German Federal Ministry of Education and Research (Bundesministerium für Bildung und Forschung), which funded this work under record no. 01FD0611.

Abstract

Data warehouses play important roles in the IT landscape of the financial industry. Banks have to deal with complex communication issues in financial data warehouse projects. Especially the creation of extraction, transformation and loading (ETL) processes depends on the project team’s communication ability and given communication barriers. We briefly present a theoretical efficiency model based on philosophy of language and the conceptualization of information systems development projects as language communities. We test the model against three case studies to derive evidence for and confirm three propositions leading to suggestions for project management of financial data warehouse projects.

1 INTRODUCTION

In order to cope with proliferating complexity (Courtney, Merali, Paradice and Wynn 2008), information systems (IS) are often developed in the form of structured approaches (Hirschheim, Klein and Lyytinen 1995, p. 33). IT projects are a structured set of activities concerned with delivering a defined IT capability to an organization based on agreed schedule and budget (Ribbers and Schoo 2002, p. 45). Complex IS development projects are large-scale IT projects with a significant and complex software component (Xia and Lee 2005). IS development projects are inherently complex because they must deal with both the technological issues and the organizational factors that, by and large, are outside of the project team’s control (Xia et al. 2005, p. 46). Consequently, the complexity of IS development manifests itself in the high failure rate of IT projects (SGI 2001, BCS 2004). This is especially true for large financial data warehouse (FDWH) projects (Behrmann and Räkers 2008, pp. 7-9);

1. FDWH projects have to deal with several business domains and fields of knowledge. To build up a centralized and integrated system a common understanding between all involved departments and subsidiaries has to be reached.
2. FDWH projects are characterized by high semantic complexity. Due to the different fields of knowledge a high number of context-dependent homonyms (e.g., limit, facility, book value, and market price) and synonyms (e.g., debt security, bond, and obligation) can be observed.
3. Specification-based approaches are not sufficient in FDWH projects. Beside the specification, additional methods are required, for instance, face-to-face communication.
4. FDWH projects require knowledge transfer methods and strong interaction. For a successful implementation a common understanding between all involved project members has to be ensured.

Therefore, the imperative of this paper is to develop and test an understanding of how communication influences decisions of (FDWH) project managers. The following research questions are of special interest to us: (1) How do managers deal with the efficiency and effectiveness of a (FDWH) project? (2) How do identified communication barriers influence management decisions?

The structure of the paper is as follows. In the second section, we discuss related work and the theoretical basis for the later sections. Then, in section 3, we introduce three case studies we extended to find evidence for our propositions. Afterwards, we discuss and generalize our findings in section 4. Finally, section 5 summarizes this paper and draws conclusions for further research.

2 RELATED WORK AND THEORY

2.1 Communication in IT Projects

It has been known for complex IT projects that coordination between the various stakeholders involved becomes a necessity (e.g., Gallivan and Keil 2003, Ko, Kirsch and King 2005, Joshi, Sarker and Sarker 2007). Communication is considered to be a prerequisite for organizational coordination (e.g., Malone and Crowston 1994, Nahapie and Ghoshal 1998, Pondy 2005, Quinn and Dutton 2005), and successful communication between involved stakeholders is deemed to be one of the main drivers for project success (e.g., Ribbers et al. 2002, Gallivan et al. 2003, Vlaar, Fenema and Tiwari 2008). Moreover, as organizations grow, they differentiate and specialize – a single company has several departments, a project has several specialized sub-projects. Each of the specialized units generate its own values, terms and coding schemes for information processing, which leads to a mismatch and a communication boundary hindering the information flow (Tushman 1977). From an information processing view, organizations information flows to function, and strive to create efficient information flows to be effective (Tushman and Nadler 1978, Jin and Levitt 1996). This perspective implies that project managers should first consider the tasks, composition and structure of subunits, and then
consider appropriate mechanisms for linking those units together, using a range of communication tools (e.g., electronic mail, fax, phone, management IS, etc.) (Levitt, Thomson, Christiansen, Kuntz, Jin and Nass 1999). Therefore, an important task of project management is to design the communication within the project organization in an effective way (Boland and Tenkasi 1995). Consequently, the structured sharing and communication of relevant information is crucial for the overall success of any project.

2.2 A Theoretical Efficiency Model

Looking at the challenges of FDWH projects (Behrmann et al. 2008), effective and efficient team communication plays an important role for project success. In this part of the paper we briefly sum up a theoretical model for explaining and predicting project efficiency in FDWH projects that is described in detail in Räkers (2009). This paper aims to test this model. The following brief description is needed to explain our further proceedings. One of the major roles of project managers is to ensure that a project reaches its goals (effectiveness). Additionally, from an economic perspective, s/he should try to reach the predefined goal with as few resources as possible (efficiency). As s/he decides how work should be done (types of action), s/he is the leading part in an ongoing process of decision-making. As different types of actions consume different resources in different amounts, the project manager has to decide – based on her or his assessment of the current situation – what type of action is perceived as the most appropriate for reaching a desired goal.

As a FDWH project’s success depends greatly on successful integration of source systems and consequently on the ETL processes (March and Hevner 2007), they especially have to deal with challenges regarding communication problems and common understanding of involved parties. While team members’ time efforts are the driving cost component of a FDWH project, communication issues become crucial for project success. Therefore, we argue that the efficiency of communication inside the project team has to be managed well to be successful. A conceptualization of IS building on philosophy of language adds thoughts of communication costs in differently developed, domain-specific language communities (Holten 2007, Holten and Rosenkranz 2008). By investing differently in terminology progress, language communities reach different levels of shared understanding and communication efficiency. This principle is shown in Nikolopoulos and Holten (2007) and was used in Räkers (2009) to develop a theoretical efficiency model. From this perspective, each project team is a more or less developed language community that progresses in the project with a subjectively observable efficiency. Only if project team members use and understand the same domain-specific terminology as a know-how held in common, ambiguity and uncertainty are both lowered, and misunderstandings resulting from different interpretations should occur less frequently. Another problem the project manager has to care about is the estimation and measurement of the project’s complexity (e.g., Xia et al. 2005). During the course of the project, as the project manager continuously engages into sense-making of the situation, complexity can be assessed more accurately.

To summarize the proposed model, using the cost function derived from the application of the conceptualization of IS as language communities, goals of higher complexity (increased variety) can only be reached by current members of the project team by investing more resources (i.e., person-days) into the development of domain-specific terminologies and creating a mutual understanding of a situation. The efficiency decreases while complexity that can be handled grows in the cost curve belonging to a project team, having its specific terminology T in place to attack problems of different complexity levels C (see Figure 1, left side).

In general, we argue that in a continuous process of decision-making, a project manager has to check the current project status and make forecasts for the project outcome (goal and complexity). The less unambiguous and uncertain a project environment is the better the forecast will be. Building on this, we propose that there are points D in time where project managers of FDWH projects take actions to shift the project team’s cost curve to a different efficiency level by investing into additional terminology. Doing this initially might raise costs in the short-term, but lowers overall costs of
communication in the project in a long-term view. The project-specific curve of efficiency is the path determined by costs curves and decision-triggered terminology-building steps between them (see Figure 1, right side).

![Diagram](image)

**Figure 1. Proposed Efficiency Model for ETL projects in FDWH**

This directly leads to the central propositions to be addressed in this paper:

P1: The curve of efficiency really exists in real project situations and can be observed.

P2: Projects go through phases with different levels of efficiency by creating additional terminology (terminology-building steps which shift the curve).

P3: Projects which explicitly address communication problems are more successful than others that do not.

We believe that project managers inherently observe projects and their team communication to detect points of efficiency change and that FDW projects should become more successful if project managers explicitly keep this possible shift in mind and react accordingly.

### 3 MULTIPLE CASE STUDY

3.1 Method & Case Selection

We decided to conduct a multiple, embedded case study in order to examine the central proposition made in section 2. Case studies are ideally suited when the investigator has limited control over events and boundaries of a phenomenon and when the phenomenon and the context in which it is investigated are unclear or closely related (Yin 2003). Challenges of communication and requirements specification in FDW projects certainly satisfy these criteria (Miles and Huberman 1994, p. 15). Since we wanted to test the propositions previously made, we followed a deductive pathway (Lee 1989).

Two case selection criteria were applied. First, the research decided to focus on FDW projects in the financial services industry. The selected cases are typical for recent projects in this sector. Second, one of the authors worked for more than six years at a major German consultancy which focuses on IT in the financial services industry. He therefore had broad experience with working in FDW projects, first as a consultant and later as a project manager, enabling him to establish contacts and to get in touch with the key informants. Moreover, he participated for some time in two of the projects (source of potential bias). The trigger for all the projects was the supervisory requirements known as Basel II. These regulations have an impact on the whole structure of a financial service provider and especially affect ETL due to the needed integration of various source systems.
Three FDWH projects of various banks in Europe were selected, which offered access to members of all stakeholders involved, that is, internal project members from IT and business units, external IT and business consultants, and project managers. Table 1 gives an overview of the selected cases.

3.2 Data Collection & Data Analysis

The risk that participants displayed retrospective bias was minimized because at the time of the interviews, all selected projects or directly related successor projects were still ongoing. Data was collected from various data sources and with the help of different data collection methods, enabling triangulation (Eisenhardt 1989, p. 539). The interviews were undertaken in 2008, two years after the involved researcher had dropped out of the projects in order to counter his potential bias. Unstructured and semi-structured interviews, project documentation, and self-estimation surveys of project members activities were used to generate the data for a case study diary (Yin 2003, p. 105). The interviews were guided by an interview outline which was not shared with the interviewees and was only used by the researchers as a checklist and guideline. The interviewees were encouraged to provide a narrative of their experiences as freely as possible. The interviews were all recorded and fully transcribed. Follow-up e-mails and draft reports were sent to request clarifications and to offer informants the possibility to provide feedback and comments. Natural controls and treatments that were already in place were utilized in testing (Lee 1989, p. 39). For instance, the control was already in place by virtue of focusing on persons which were participants in more than one of the three projects, interviewing the same person for different projects.

3.3 Case Descriptions

Bank A is an international banking group having 18 major subsidiaries. The project at Bank A has been started in 2001 and was planned to end in December 2007. To fulfil the requirements of Basel II and to enable a group-wide calculation one of the main tasks of the project was to implement a central data warehouse. Primarily, data of transactions, collaterals, customers and rating information of both head office and subsidiaries had to be delivered into the central data warehouse. To achieve this, each subsidiary had to deliver specification-conform flat files to be imported into the central data warehouse. At the beginning, the core project team at headquarters, which consisted of consultants and Bank A experts from business and IT had designed a detailed data model for Basel II, and specifications for data loading interfaces in XML Schema Definition (XSD) format, which were send out to the project members in the subsidiaries (i.e., network banks). At the beginning of the project, an initial training workshop was conducted to explain the XSD format to the subsidiaries.

Bank B is a large European banking group with foreign subsidiaries. In order to deal with Basel II demands, Bank B put up a FDWH project in order to fulfil the requirements of Basel II. The project started in 2005 and officially ended in 2007. In addition, Bank B was in a post-merger situation and was the target of an acquisition during the project, so the ongoing consolidation process in the banking industry is considered as well. In addition, beside the Basel II-related data warehouse project, another large project was established in Bank B at the same time. A new core banking system was developed and switched productive during the second half of 2006. So nearly every department was involved in
two large and important projects at the same time while doing the normal daily work as well. From core banking systems over the group-wide data warehouse to the reporting and supervisory systems, nearly every application and business process was affected. All in all, Bank B was undergoing enormous organizational changes, and the changing environment heavily influenced the project.

Bank C is mid-sized European bank with mainly national activities. While implementing a new core banking system the bank’s management decided to take the opportunity to renew the technical landscape regarding regulatory systems and the underlying data warehouse as well. The project started in 2005 and was finished by the end of 2007. One of the major goals was the implementation of the Basel II requirements, which makes this case comparable to the cases of Bank A and B. Like in the other cases, this project was supported a consultancy and all departments of the bank were involved in the project. Looking at Bank C, this case gives us a different view on a smaller and mostly national bank to compare and analyze whether size and geographical diversity have impact on the projects and the theorized curve of efficiency.

3.4 Case Findings

3.4.1 Bank A

The complexity at Bank A was perceived as high (1) due to new regulatory demands and (2) the existence of various important subsidiaries with different environmental situations. However, since the specification was assumed to be unambiguous by the project managers due to the use of XSD, it was sent to each subsidiary via e-mail without further descriptions. Furthermore, the project managers believed that employees in the subsidiaries would share the same knowledge about the banking domain as employees at head office, that is, that the meaning of each of the used terms and descriptions would be understood without any problems. Since after the distribution of the specification all support requests of the subsidiaries could be satisfied by a contact person at headquarters, the head office team assumed that each subsidiary had understood the specification in the intended way. But first completeness checks of the flat files that were delivered by the subsidiaries showed several problems resulting from a different understanding of the meaning of the terms. It seemed as if employees from head office and subsidiaries spoke different languages, since the interpretations of the published specification varied to a considerable degree, although the required data and data structures were perceived to be unambiguous due to the use of XSD and additional extensive textual descriptions.

“A classical example is that the central business data base table was named ‘counterparty’ due to a translation error […]. This caused a lot of confusion because therefore this term appears relatively often in the data warehouse. […] In fact, there are really 13 data warehouses that have to be loaded identically, but which weren’t loaded identically […]. This was the case in the first implementation phase, that one just gave the documents to everybody and everybody did interpret them. And the result was 13 interpretations. […]” (Mr. JS, project worker)

“At the moment of the rollout, specific concepts were not clear for the people on site, what turned out only afterwards, and specific types of business naturally only existed locally or, again, used other terms, so that it was not clear to them how to convert that adequately into the warehouse.” (Mr. WB, project manager)

After this problem surfaced (following the first release of the data warehouse that had already been implemented), a change in the course of action was observable at Bank A. Additional workshops were conducted once the project management team realized that the sent XSD specifications were not enough for coping with proliferating complexity of the situation. During the workshops, changes to the data model in subsequent releases were introduced and the meaning of terms and concepts was discussed in detail with all involved stakeholders of business units and subsidiaries. After the workshops, once it was realized that the delivered data quality was still not satisfactory, the project
managers decided to engage into local visits of head office project members at problematic subsidiaries. Patterns of terminological discourse are traceable once the existence of separate sub-terminologies and jargons had been understood and accepted, and those sub-terminologies began to be consolidated into a terminology by the project team (generation of language community). The project managers explicitly decided to switch from written specifications to direct face-to-face communication. The joint discussion, clarification and learning of terms (i.e., the creation of a language community) were time-consuming, but perceived as necessary for reducing ambiguity and to be able to deal with the complexity at hand.

“At one point in the project [...] it was recognized that the specification must be improved and refined [...] then one realized that this XSDs are not enough, and then one created the data delivery concept, and drove out to the subsidiaries to explain this. This were points where one noticed that they needed a little more support, but the real turning point, where this issue had full management attention, came actually in April 2007, where one said the data delivery does not work at all [...] and then did decide that we need so-called task forces, [...] very different persons now became involved, who really were on-site [at the subsidiaries] and went through the data with them weekly, looked at the data fields and discussed every single thing. This actually was one of the greatest turning points for me. There, the upper management realized ‘Now we have to do something, and we have to spend money [...].’” (Mr. BK, project worker)

The on-site visits and the discussions with all project members and subsidiary employees finally succeeded in establishing a shared, mutual understanding of terms. Ambiguity was mostly lowered by the subsequent face-to-face discussions between all project members. Afterwards more complex topics were discussable.

“Absolutely, it became apparent that the number of questions which one brought back from the countries and the on-site visits, that by looking at these one saw, that many open questions existed and once we had those, we could clarify those. [...] There are still questions, but these questions are much more difficult to answer because most of these require much more detailed knowledge. Also it didn’t run like it’s on rails afterwards directly, but I think, the amount of questions which had been clarified in this did certainly justify this [the on-site visits].” (Mr. JS, project worker)

Thus, the project went through phases of different communication policies due to project management decisions. Each of these decisions changed the style of communication. For example, based on assessments of the self-estimation survey, these changes doubled the time spent on communication and also doubled efforts for on-site meetings. By conducting expensive on-site meetings, a shared terminology and a common understanding regarding project issues was built. After those changes in policy, project members state a perceived increase of efficiency in the project in later phases compared to earlier phases.

3.4.2 Bank B

In general, the complexity of the project was perceived to be very high, since (1) Bank B was faced with new regulatory demands, (2) Bank B was target of an acquisition, and (3) a new core banking system was implemented in parallel to the Basel II project. Ambiguity and uncertainty were perceived as being high due to the existence of several jargons and terminologies in the project and its surrounding environment. As in Bank A, particularly the creation of a shared understanding between head office and subsidiaries proved to be difficult. On the one hand, the interfaces to the subsidiaries and the core banking system were very complex. On the other hand, the types of businesses in foreign countries were fundamentally different from businesses at head office, leading to an even greater complexity and much more ambiguity for the project, which was not perceived as a problem at the beginning. Similar to Bank A, the project managers at first did not address that different understandings and meanings for the same words existed in Bank B.
“[...] There was this nice module, which was called [offer processing application] [...]. Under this term, one can imagine quite a lot, and there we had a lot of discrepancies between both projects, even concerning the question where this is positioned with regard to IT, technically. And then we had different coordination meetings where one said ‘OK, what really is the content of this system?’ so that later you really could clarify the business activities and could limit responsibilities and interfaces relatively well.” (Mr. TA, project manager)

But as different understandings proved to be the case, the procedure for dealing with those problems explicitly changed as the project progressed (change in the course of action). According to our findings, the project at Bank B was characterized by two distinct procedure models, where the shift from procedure 1 to procedure 2 was consciously made by the project management team. The first phase was specification-driven whereas the second phase was communication-driven. For example, the project manager’s self-estimation efforts for on-site meetings were three times higher during the use of procedure 2 than before using procedure 1. For some of the subsidiaries which showed immense problems, so-called task forces were established. The technical face-to-face coaching on-site was very important to make members at the subsidiaries understand the requirements. Therefore the creation of a language community by intensive face-to-face communication was one of the central factors for project success and the handling of the high complexity.

“This then changed from the initial procedure of ‘We send you a concept, look what you got and send us back the results’ to a much more workshop-oriented procedure. So one did say ‘We have to support you much more, we come over to you and look everything through in workshops together with you’ and in a second step one conscripted the colleagues respectively and said ‘We let our project member sit with you and he will support you for the next days and weeks.’” (Mr. TA, project manager,)

Due to the fact that one key informant was a team member of both projects in Bank A and Bank B, we could directly address the difference between both projects. The initial external complexity and uncertainty due to Basel II are comparable. Bank A has more subsidiaries than Bank B, but Bank B was the target of an acquisition during the project and also implemented a new core banking system.

“Uncertainty in both projects was rather almost equal. At Bank A, it simply lasted five years [...] and had a multiple of effort [of Bank B]. [...] they certainly started in 2003 in earnest, and practically, they now have reported for the first time [...]. They had a much longer project runtime. Fair enough, it is a slightly larger bank with much more subsidiaries, so they have 18 subsidiaries in different countries [...], this is really much bigger in dimension. But they also had to make some real turnarounds and extra loops within the project, concerning the subject of classification: what is market risk, what is credit risk? Where do I represent the credit risk, in which data warehouse, where do I represent the market risk, and so on. They certainly got closer to the target more serpentine [...].” (Mrs. SK, project worker).

So while external complexity, ambiguity and uncertainty that both projects faced due to new regulatory requirements and other external circumstances were comparable, Bank B reached the same goal faster (two years compared to six years), and the quality of the processes and product were also perceived as being clearly superior. Basically, Bank B changed its course of action (investing in language community creation and shifting the curve of efficiency) earlier and faster.

“[Bank B’s project] also had a much shorter duration, thus we have now in 2008 reported with the standardized approach, and the project has started in 2006, that is, we have implemented the basic functionality for Basel II in two years [...] the duration compared to the number of resources that have been burnt, is certainly much lower than at Bank A [...].” (Mrs. SK, project worker)

3.4.3 Bank C

The FDWH project at Bank C had to integrate the topics “regulatory reporting” (Basel II, loss database) and “controlling” (operational and business control). The to-be-developed data warehouse was intended to be an integrated database for both project topics. Consequently, changes in one area
had significant impact on the other area, which had to be taken into account. During the project, three different consultant teams were active at Bank C and had to work closely together to implement the new core banking system, the regulatory reporting system and the central data warehouse. Since the data warehouse team had to build interfaces and integrate data from both other systems, this was deemed one of the most important tasks for project success. External and internal complexity were both perceived to be very high by the project management team (1) due to environmental factors (e.g., new regulatory requirements) and (2) the organizational situation (e.g., implementation of a new core banking system). However, in contrast to the previous projects, no subsidiaries did exist. At the beginning, the presence of three teams was hindering the project due to the existence of several different terminologies in the teams. The teams had quite separate IT-related jargons and also different understandings of banking-related technical terms that were important for the project. Between those sub-language communities, misunderstandings occurred quite frequently during the project. This was caused by the perceived ambiguity concerning the different meanings of terms in the different teams.

“The example ‘validierter Saldo’ [German: validated balance] strikes me on this level. […] this wasn’t a problem at the beginning of the project, […] but something that happened at some time during the project […] for us it was clear, this is an established term and means the actual capital disbursed […] but in the core banking system team, they understood it differently, or in the core banking system the data field with this description yields something different respectively, namely the original capital disbursed […] this led to many bad coordination loops and to costs on our side because we had to adapt the data history.” (Mr. VC, project worker)

As in the previous projects, the general procedure was consciously changed by the project managers in order to create a shared language understanding and to reach the project goal on time. For example, the efforts for communication became three times as high as before.

“[…] In the first phase, one had the attitude, we really don’t want to understand the core banking system, instead, we want to have interfaces filled, delivered data requests catalogues respectively and one hoped that this will match somehow. Then the second phase […] ‘OK, that isn’t really working out, now we sit together and try to understand their basic problem.’ And in the last phase, I had the feeling that one had a look at the core banking system oneself a little bit, did discuss this with some bank employees and the interface developer […].” (Mr. JD, project worker)

This consolidation and the intensive discussions of all involved stakeholders reduced ambiguity and finally led to better data quality. The project was perceived as running more smoothly once ambiguity had been reduced or when it was noticed that a different understanding of a term was existing.

“When you […] talked this through together, then you had no discrepancies. In certain circumstance, it wasn’t clear for single data field, because our software has its requirements and if you don’t name them explicitly, they are hard to infer from the field names or field descriptions. […] you have to address such things explicitly if this was somehow lost in the torrent of data requests. […] Such things are very important, meaning the precise description of data requests or technical contents. In my judgment, this accounts for more than half of project success in such an IT or data warehouse project.” (Mr. VC, project worker)

4 DISCUSSION

To link our findings to our propositions we sum up our findings from the cases.

- In each case the project management team got to a point where a change of the general procedure and original project plan (type of action) was undertaken in order to increase efficiency or at least being effective. The types of action became more communicative and sense-making-related and succeeded in creating a more shared and joint terminology. So within all cases, the existence of a curve of efficiency as theorized before can be observed (proposition P1).
• Project members of all projects state that fundamental problems in communication and understanding existed which led to a change in the project procedure. We recognize these approaches as an increase of terminology creation and as a shift to a different level of efficiency (proposition P2).

• By changing the efficiency, all three projects assured project success. Projects which addressed those communication issues earlier (i.e., Bank B compared to Bank A) were perceived to be more successful than others (proposition P3).

Two important consequences for research and practice arise from our findings. First, the extension of the cost curve to a cost curve with multiple efficiency levels (curve of efficiency) allows the explanation of communication behavior and possible types of action for project managers in complex project situations. Therefore we are very confident that the derived efficiency model, which was applied to FDWH projects in this paper, is stable for other types of complex IT projects as well. This leads us to suggest that replicating our study in other settings and using a diversity of different research methods (e.g., case studies, surveys, experiments, action research) will lead to similar results. Second, project managers in practice should explicitly address communication efficiency in their project management approaches and project plans for integration and ETL processes in complex (FDWH) projects. Variety and ambiguity are major problems in complex IT projects. It has been over 60 years since Ashby (1956) proposed that only variety destroys variety, and over 25 years since Daft and Macintosh (1981) argued that ambiguity and uncertainty are important organizational design factors. But still IT project managers make the mistake of misjudging the impact of those factors and try to implement IT before the variety of a problem situation has been matched and ambiguity has been reduced by creating a language community. Usually, issues and problems of communication, understanding and sense-making are not a part of the “accepted” or “rationalized” costs. But as our findings suggest, those costs should be explicitly addressed and incorporated in the management process of complex IT projects.

Case studies can confirm, challenge, or extend a theory because they can be used to reject propositions (Lee 1989). The theoretical efficiency model itself has been previously derived from literature and exploratory field studies, and has been challenged by us with case study data. Qualitative methods were employed to generate an interpretive understanding of the problem situations and to test the propositions (e.g. interview-based evaluation techniques). Nevertheless, further studies are needed to confirm the efficiency model for complex IT projects beside current FDWH projects and to generalize our findings. The chosen cases deal with comparable project topics, but the findings are not derived from a ceteris paribus (“all other things equal”) configuration; instead, we rely on “natural” situations, where influences of other factors cannot be excluded. Furthermore, we greatly rely on subjective impressions from case study participants and our own interpretation. In order to counter those problems, rigorous case studies that want to test theories must address four requirements (Lee 1989, p. 42), which we explicitly tried to address. As a check for falsifiability, we verbally formulated propositions based on the model of the curve of efficiency, which have subsequently been tested against the data. As a check for logical consistency, the propositions follow from the logic of this model. The cases have been selected in order to provide generalizability and to allow checking for consistency. As a check for empirical validity, the theorized curve of efficiency has been confirmed and corroborated. Since this study was interested in providing first empirical evidence for the curve of efficiency and not in refuting any rival theory, a check for relative predictive power has not been addressed yet.

Since we wanted to provide first evidence for our propositions, this research is mostly dealing with construct validity. According to Yin (2003), construct validity is critical in qualitative research and can be improved by three tactics. The first is the use of multiple sources of evidence, which provides multiple measures for the same phenomenon. We explicitly addressed this issue and examined three projects with a multitude of informants in a multiple, embedded case study. The second tactic is that key informants review the case study, which we have addressed as well: the research project was introduced and discussed with the key informants; draft reports were sent to the key informants for
Finally, Yin (2003) recommends maintaining a chain of evidence, which we did by formulating propositions based on the efficiency model, collecting case study data, discussing it with our informants, and creating a case study diary that allows us to trace back from findings to initial propositions. However, further tests are necessary to corroborate our findings, e.g., in laboratory experiments.

5 CONCLUSION & OUTLOOK

The variety of complex IT projects is often underestimated and therefore has to be managed. We used a theoretical model based on efficiency considerations to explain the general behaviour of integration and ETL processes in FDWH and derived three major propositions. Three projects were evaluated in a multiple, embedded case study. Our findings provide evidence for corroborating our propositions. Project managers dealing with integration and ETL processes in FDWH can benefit from explicitly addressing communication issues in their project plans and general project procedures. By finding ways to remove existing communication barriers and misunderstandings, the efficiency of a project team can be improved. The project manager has to decide how much efforts need to be invested into this improvement to be most efficient for reaching the desired project goal.

From a theoretical perspective, the efficiency model is a building block for knowledge on communication in FDWH projects. We contributed to project management by providing concepts for this efficiency model. If “sound” FDWH project management is among the desired goals, researchers and practitioners may benefit from our insights on how to measure the relationship between communication, complexity and ambiguity, and FDWH project success. Of course, several instances are needed to support a theory. At present, the projects are the only setting for which our findings are valid. Our study needs a replication of the findings in additional cases. To strengthen our findings, we will conduct additional case studies to deal with more special topics of other projects and action research settings for explicitly addressing communication barriers in early phases of projects.

A COMMUNICATION EFFICIENCY MODEL FOR ETL PROJECTS IN FINANCIAL DATA WAREHOUSING

Räkers, Marc, zeb/information.technology, Schlossstr. 22, 48455 Bad Bentheim, Germany, marc@raekers.com

Abstract

The financial industry relies greatly on information technology (IT) because of its work with immaterial goods. Nowadays, most information collected by a financial institution is usually stored in a central data warehouse system. This central financial data warehouse (FDWH) is permanently under construction. Requirements from all over the bank have to be met by FDWH projects in an ongoing process. These requirements need to be communicated to the FDWH project team to do implementations properly throughout the system landscape. Especially the creation of extraction, transformation and loading (ETL) processes depends on the project team’s communication ability and given communication barriers. Enhancing recent research in FDWH a theoretical efficiency model based on philosophy of language and project management fundamentals is built in this paper. The conceptualization of information systems development projects as language communities is an important presumption for this theoretical model. Suggestions derived from this model lead project managers of FDWH projects to more appropriate decisions keeping efficiency drivers in communication in mind.

Keywords: financial data warehousing, theoretical efficiency model, project management, communication efficiency.
1 INTRODUCTION

Financial data warehouses (FDWH) are an important and relevant issue for most financial services providers today. Especially large banking groups with foreign subsidiaries have to deal with new regulatory demands, e.g., Basel II, IFRS or Sarbanes-Oxley Act (Behrmann and Räkers 2008). Moreover, financial service providers try to employ DWH for controlling their risk management approaches. It is general consensus that DWH support the management perspective on business processes technically, but their implementation is extremely costly (Vassiliadis 2000). Therefore, a clean design and specification of the system is of great importance. Consequently, the involvement of the management users and management’s support are deemed key factors for DWH quality and system success (Wixom and Watson 2001, p. 35 f.). Since DWH projects often fail or significantly exceed budgets, existing research has concentrated on quantitative or qualitative analyses of success factors as well as contemporary best practices for building DWH (Weir, Peng and Kerridge 2003, e.g., Herrmann and Melchert 2004, Hwang, Ku, Yen and Cheng 2004, Watson, Fuller and Ariyachandra 2004, Hwang and Xu 2007).

March’s and Hevner’s (2007) thorough literature research warns how links between data warehousing, strategic decision-making and evaluation are under-researched. For March et al. (2007), integration (i.e., the consolidation of data from disparate sources into one consistent body of data) lies at the heart of decision-making tools and is one of the biggest challenges for DWH designers (March et al. 2007, p. 1036). Effective integration can only be achieved by experts who have access to knowledge about internal and external business contexts (i.e., “what questions are momentarily important?”) and access to knowledge pertaining operational systems that have to be integrated (i.e., “which operational systems provide data for answering those questions?”) (March et al. 2007, p. 1041).

This theoretical argument is consistent with statements which suggest that FDWH projects show specific integration characteristics (Behrmann et al. 2008):

- **Financial data warehouse projects have to deal with several business domains and fields of knowledge.** This leads to different domain knowledge in different departments and subsidiaries and specific fields of knowledge arise. To build up a centralized and integrated system a common understanding between all involved department and subsidiaries has to be reached.

- **Financial data warehouse projects are characterized by a high semantic complexity.** Several business domains can occur within a single financial institution. Due to the different fields of knowledge a high number of context-dependent homonyms (e.g., limit, facility, book value, market price) and synonyms (e.g., debt security, bond, obligation) can be observed. Due to this variety, the definition of terms (e.g., dimensions and measures) is challenging.

- **Specification-based approaches are not sufficient in financial data warehouse projects.** Beside the specification additional methods are required, for instance, face-to-face communication.

- **Financial data warehouse projects require knowledge transfer methods and strong interaction.** For a successful implementation a common understanding between all involved project members has to be ensured. This cannot be reached by merely interchanging a written specification.

In this paper a theoretical model is developed to explain and predict interconnections in FDWH projects that lead to project management decisions which change general procedures within these projects over time. During phases of terminology creation, a foundation for more efficient communication (i.e., better aligned to the current project environment) is built by the project team. This changes the ability of the project team to solve problems either by using formal specifications or using face-to-face communication. We argue that the beginning of a phase of terminology creation is decided by the responsible project manager based on efficiency considerations and the perception of project status and future project progress.

The underlying research approach is in line with Lee’s (1991), approach of integrating positivist and interpretive approaches in organizational research. After having created a subjective understanding of
everyday meanings and common sense within observed organizations, which provides the basis for the interpretive understanding, the researcher creates a positivist understanding in order to explain the empirical reality – the explanation being a scientific theory which can be tested against the subjective meaning as recorded in the interpretive understanding (Lee 1991, pp. 351-354). Therefore, as a first step, the subjective understanding of involved persons in FDWH projects was analyzed by creating an interpretive understanding of the specifics of FDWH projects (Behrmann et al. 2008). In order to create a positivist view on FDWH projects, this paper introduces an efficiency model which explains theoretically why observed behavior and procedures in FDWH projects operate as they do. Further research will test this model in additional FDWH project situations and try to apply the model in a broader scope than financial data warehousing.

The remainder of this paper is structured as follows. In section 2, related work concerning research approach, software project management and language theory is presented. Section 3 contains the communication efficiency model for FDWH projects. Finally, section 4 summarizes the findings and gives an outlook to further research.

2 RELATED WORK

ETL projects take about 70 percent of the efforts of a data warehouse project (Kimball and Caserta 2004, p. 391) and therefore need professional project management. Accordingly, Kimball et al. (2004) suggest specific project structures and organizational rules to manage the inherent complexity of ETL projects. To complete a project successfully, the objectives (goals) have to be reached within time, cost and performance as the most critical project dimensions (Jurison 1999). Projects are usually conducted in four generic phases (e.g., Jin and Levitt 1996, Kunz, Christiansen, Cohen, Jin and Levitt 1998):

1. Conceptual phase: the project scope is determined by the project sponsor and the project manager. Software designers work together with the project manager on possible arrangements of the future software.

2. Planning phase: the project manager builds a project plan containing project tasks. Each task has allocated resources, duration and a defined result. This information is generated by conducting estimations with different techniques as summarized by Boehm (1981, p. 203).

3. Execution phase: in the execution phase the software development and testing of the built software product takes place.

4. Termination phase: During the termination phase the project is documented, closed and delivered to the operations department of the company. The project sponsor approves the results to the project manager.

Furthermore, complexity is identified as one of the major problem-driving factors in information system development (ISD) projects (Jurison 1999, Xia and Lee 2005). With the advent of the fourth generation of ISD methodologies in the 1980ies it became clear that intensive user involvement is needed for coping with proliferating complexity, and ISD has an important social component as well (Hirschheim, Klein and Lyytinen 1995, p. 36). The social system resulting from an ISD project is closely interconnected to the project team itself. Therefore, purely mechanistic and formalized system development methodologies need to be treated more critically (Fitzgerald 1996). For example, to be able to handle complex ISD projects successfully, different kinds of communication between project members need to be combined efficiently. Effective communication has already been researched concerning requirements (Coughlan and Macredie 2002). Although requirements play an important role for FDWH projects and especially ETL processes, this paper focuses on explaining operational project management and not on building an additional methodology for requirements specification.

Adding to this, a conceptualization of IS building on philosophy of language adds thoughts of communication costs in differently developed, domain-specific language communities (Holten 2007, Holten and Rosenkranz 2008). By investing differently in terminology progress, language communities reach different levels of communication efficiency. This principle is shown in
Nikolopoulos and Holten (2007). This and other findings form organizational research (e.g., Boisot and Li 2006) suggest that the building of a shared terminology and language community is beneficial for coordination and communication.

3 A THEORY EXPLAINING MANAGEMENT IMPACT OF COMMUNICATION EFFICIENCY IN FDWH PROJECTS

3.1 Basic Components of an Efficiency Model for FDWH Projects

Further development of the efficiency model proposed by Nikolopoulos and Holten (2007) is based on project management basics, for example, as summarized by Jurison (1999). The relevant management dimensions can be derived directly from Jurison (1999) and have been observed to be of relevance in empirical studies of FDWH projects (Behrmann et al. 2008, Räkers and Rosenkranz 2008):

- **Time**: the time needed to reach a project’s goal. Time is a constraint in projects as there usually is a specified deadline in a project plan. Furthermore, time is an effort-driving component of a project. As overall tasks like project management need resources every day during the running time of the project, a longer project needs more resources for these tasks.

- **Cost**: the amount of efforts needed to reach a project’s goal. The main driver for costs is the assigned project team members. Personnel expenses are the relevant cost driver in FDWH projects, because the hardware and technological components are usually needed anyway, are becoming more and more a reliable and well-tried commodity nowadays (Avison and Fitzgerald 1995, p. 6), and do not influence the organizational view on project management this paper tries to address. The working hours of a team member can be split into travel time, meetings, telecommunication etc.

- **Performance**: the created results of a project. The performance of a project is tracked by project managers throughout the whole project. Performance corresponds directly to the benefit a project has for its sponsor. For the project sponsor, the benefit is the primary goal of the project. From an economic point of view, the (rationalized) goal of a project can be summarized as creating a benefit with least possible costs under the constraint of time.

In ISD projects, complexity has been often identified as one of the main reasons for problems. Complexity is often underestimated when starting a project. As complexity is one of the problem-driving factors mentioned by Jurison (1999, p. 4), it becomes an important part of the efficiency model as well. However, complexity is difficult to pin down. Generally, the term has a multiplicity of meanings (Flood and Carson 1993) and is a fundamentally subjective concept (Backlund 2002). In this paper, we build on Ribbers and Schoo (2002) and argue that the complexity of a (FDWH) project evolves from the variety of a project environment. Complexity arises from the inherent *variety of elements and interconnections* of an ISD project (Rosenkranz and Holten 2007). The project organization (i.e., the project team and its organizational setup) needs to be able to handle this variety. According to the law of requisite variety only “variety destroys variety” (Ashby 1956), the project team essentially needs to build up this variety itself. To be able to handle a certain degree of complexity, the variety of this situation needs to be addressed by a project team with at least the same variety at hand (Bar-Yam 2004).

In the beginning of a project, the project manager usually estimates the complexity of the project environment and builds up a project plan to address time, costs and the expected result (benefit for the project sponsor). After the project has started, the project manager has to track the status of the project. This is done by measuring time, cost and results while at the same time estimating whether the rest of the plan fits to the actual situation. As ambiguity and uncertainty in new situations usually are comparably higher at the beginning of the project, the more the project progresses, the less ambiguous and certain it becomes – maybe by risk elimination techniques (Boehm 2003, p. 9). The estimations become more realistic and more precise. While the desired project goal does not change, the variety...
(i. e., complexity) of both the environment and the required tasks to cope with this variety become clearer with every step that is done towards the project goal.

A project plan consists of project tasks that are linked to each other as a network of activities. The most popular illustration of a project plan is a Gantt chart to visualize interdependencies of project tasks. All of these project tasks also have a desired benefit, a timeframe and costs. The project manager arranges different types of actions to reach his or her major project goal. Each type of action has its own profile regarding benefit, time and costs. During the project, the project manager comes to decisions about changing the project plan by reassembling the actions and changing types of actions to come to a different structure of benefits, time and costs. A constraint coming from the project sponsor is to deliver the expected project results, which means to be effective in the project. The project manager is usually trying to achieve this by also having economic efficiency in mind. Efficiency is defined here as the benefit reached per cost. Efficiency is important to the project manager for two reasons. Being efficient during the first part of the project increases freedom in later parts of the project. Furthermore, higher efficiency might be rewarded by the project sponsor. However efficiency becomes most important for the project manager when s/he realizes that the project goal cannot be reached with the current project plan, because the variety (i. e., complexity) of the project was underestimated earlier. As the expected benefit is fixed by the project sponsor, the efficiency can be increased by decreasing the project costs. It was mentioned above that the costs of a FDWH project are driven by personnel expenses for ETL process creation. Furthermore communication drives personnel expenses, what makes communication costs a very important influence factor for FDWH projects.

3.2 Matching FDWH Project Management with Communication Costs

One way of bringing theories about communication costs and project management together is having a look at the project costs. Assuming that the costs of communication have a major impact on project costs and assuming that communication has a major impact on project efficiency as well, the total costs of communication are chosen as an important measure for the suggested efficiency model. As benefit and time are constraints given by the project sponsor, the remaining influence factor is complexity. A visualization of this context is shown in Figure 1.

![Figure 1. Cost Curves: Total Costs of Communication given Degrees of Complexity (adapted from Nikolopoulos & Holten (2007))]
for a language community to deal with it, the variety of the problem becomes greater than the variety of the language community (i.e., project team). To cope with this increasing variety, the terminology of the language community has to be increased as well. In a project environment, for example, this can be done by decisions about activities (D) of the project management, that is, explicit decisions to engage into language community creation and sense-making. On the one hand, these decisions increase the total costs of communication. On the other hand, they subsequently create a more effective terminology for the language community and shift the project to a different cost curve.

In Figure 1, the upper cost curve is less efficient for project degrees of complexity below C1, but is more efficient for degrees of complexity above C1. We propose that if a project manager adapts the estimations for the degree of complexity in his or her project from a level below C1 to a level above C1, and his or her project team uses terminology T1 right now, s/he will decide (D1) to engage into terminology creation and to switch to terminology T2 by investing in this terminology training (special type of action).

3.3 Enhancing the Cost Curves to an Efficiency Model

To enhance and detail this model findings from FDWH project research (Behrmann et al. 2008) are applied. Proceeding from a terminology T1 to another terminology T2 in FDWH projects means to change the style of communication from a specification-based way to a more personal face-to-face communication. By doing this, a higher degree of complexity can be handled by the project team. This is consistent with usual theories about media richness and information processing (e.g., Daft, Lengel and Trevino 1987) Therefore, the shift (D1) from the cost curve of terminology T1 does not proceed in a straight line, but is more diagonal as shown in Figure 2.

![Figure 2. Efficiency Model for ETL Projects in FDWH](image)

During large and long-running projects, multiple of these decisions are observable. This leads to a step-wise increase of total communication costs concerning the degree of complexity of a project. While the project team deals with more and more complexity over time, this step-wise increase should be observable in real projects. Consequently, as multiple cost curves are relevant for a project manager’s decision (i.e., a set or continuum of cost curves), there are a lot possibilities to be taken into account. Depending on his or her estimation of how a single cost curve appears, s/he (intuitively or deliberately) identifies thresholds (such as C1 or C2 in Figure 2).

The next step in our construction is to fit the project manager’s estimation of project complexity into this model. In case the estimated project complexity is below C1, the project stays with terminology
T1. Having an estimated project complexity between C1 and C2, the project manager should decide to invest into terminology T2. If the estimated project complexity is above C2, the project manager should think about additional terminology building or enhancements, and at last decide to switch to terminology T3. The example in Figure 2 shows a project where the project manager decided (D1) to switch from terminology T1 to T2 in a first step. After more complexity was encountered within the project, new estimations showed additional need for communication and terminology investments which led to decision D2 and terminology T3.

![Figure 3. Curve of Efficiency for a Specific Project](image)

Figure 3 shows the resulting curve of efficiency based on decisions of the project manager for this theoretical and exemplary project. As the project passes a complexity threshold, the project manager gets evidence whether his or her decision was right or wrong. Anyway, s/he does not know for sure at all, because s/he had no chance to observe the real cost curve s/he used before s/he made his or her decision (based on estimation). Obviously, taking into account the previous remarks, there is a lot of subjective appreciation and perception of the project manager in the model. However, this is precisely the reason why this model should be able to explain and predict project observations in real situations (which, in contrast to laboratory situations, are characterized by high variety, ambiguity, and uncertainty) very well. It should become clear why project managers act and decide as they do with regard to communication efficiency.

3.4 Explicit Consideration of Constraints

Adding to this basic efficiency model the constraints for the project manager are addressed in this section to completely incorporate all influences identified in section 2. The basic constraints for this model are the fixed benefit and the time limit to finish the project successfully.

The fixed benefit as a background factor for the project’s complexity might change over time while the scope of the project is adjusted. This is normally done by bringing change requests into a project. Changes of scope (e.g., due to external perturbations) can have a direct impact on the resulting curve of efficiency by changing the available or (subjectively perceived from the project manager’s point of view) possible cost curves. The fixed time limit (deadline) is a more important constraint for a FDWH project. As financial companies today rely on IT to a very high degree (Guo, Tang, Tong and Yang 2006) and the data warehouse is a central system with a lot of interdependencies to core banking systems and distributive systems, a precise timing is needed for the release cycle of a FDWH. Postponing of FDWH releases has high impact on the whole IT infrastructure of a bank since release cycles are highly interrelated.
Figure 4 adds this time constraint to the efficiency model. As there is no time dimension included in the model yet, the time has to be aligned to each possible way a project manager can chose to go. A fixed duration for a time period is defined and every time a period ends a dot is put on a curve of efficiency. By changing from one curve to another ways are split and each way has its own remaining distance until the end of the next time period is reached. As projects have to deal with a general time constraint, only a predefined number of spots should be passed by the project to be successful. The following paragraph contains a short example of how the time constraint can have impact on management decisions.

Given a time limit of three time periods, every end of a time period is represented by a black dot. After taking decision D1, the project manager has to decide whether s/he stays on the cost curve associated with terminology T2 or makes a decision D2 to change to the cost curve of terminology T3. Given an (subjectively) estimated degree of complexity for the project of a little more than C2, the project would reach the fixed time limit in period three before the estimated degree of complexity for the project is reached. That is, the project would be overdue. Although switching to T3 would be more efficient regarding total cost of communication, the time constraint limits possible decisions for staying with the cost curve of terminology T2. To state it more simply, the shift from one cost curve to another does not only come with the price of investing resources such as project workers, but also consumes time in itself.

![Figure 4. Curves of Efficiency and Time Constraint](image)

In addition to the constraints discussed above, projects can have a cost constraint as well. The project sponsor usually might announce a cost limit or the project is done for a fixed price, so the project manager has to meet a cost limit. This cost constraint is added in Figure 5. Enhancing the previous example of Figure 4, the project manager now has to decide whether s/he wants to violate the time or the cost constraint. S/he can keep the cost constraint by switching to the cost curve of terminology T3 and choosing curve of efficiency E1.

3.5 Explaining Special Cases

There might be situations where the predefined complexity cannot be reached by the current cost curve. Looking at the example of Figure 4 in Figure 6, this would be the case if the estimated project degree of complexity becomes too high to be handled by the cost curve of terminology T2. There would be no other way than switching to the cost curve of terminology T3 to be able to reach the project goal defined by the project sponsor. In that case, the time constraint would need to be violated. The curve of efficiency E1 would be the result of the project manager’s decisions.
Another phenomenon having impact on curves of efficiency is reusability. If the investment in terminology building phases does not only help the current project but also other activities of a company, this reusability effect can influence the curve of efficiency. Therefore the project manager has to estimate to which extend the costs can be split up between costs that can be directly allocated to his or her project and costs that can be allocated to other projects or general company cost centers. This might decrease the total cost of communication for the terminology building phases (i.e., directly after decision D1 and D2). The cost curves of terminology T2 and T3 would have to be shifted down in that case.

3.6 Limitations

The efficiency model with its different cost curves is only meaningful and applicable if one of the following situations occurs:
- The actual estimated project degree of complexity is higher than the project degree of complexity estimated before.
The scope of the project was changed and new estimations for the curve of efficiency are needed to adapt the project plan. The curve of efficiency has to be adapted due to possible time constraint violations becoming clear by actual estimations. The curve of efficiency has to be adapted due to possible cost constraint violations becoming clear by actual estimations.

Therefore the efficiency model is only suitable for complex projects like FDWH projects. Simpler projects without change of scope or with limited complexity will not need to be reviewed and adapted as often. So the efficiency model is only suitable to explain and predict management decisions in complex projects depending on communication efficiency. Another limitation is that the whole approach is based on subjective understandings of the involved project members and project managers. As project managers rely on information coming from the project team, the project team evaluates itself. Furthermore the approach is based on the precondition that project managers work in line with the goals of the project sponsor and no other interfering goals exist.

Although the model shows only a few possible cost curves in the examples, there is an infinite number of cost curves due to the huge set of possible terminologies. Each term added to a terminology produces a new terminology. So possible terminologies and their corresponding cost curves for a specific project lead to a floating intersection of cost curves for this project. However, the project manager cannot have all of these possibilities in mind. It depends on his or her subjective awareness of different terminologies or approaches to gain them. Most times the project manager will not be able to define concretely how a new terminology should look like, but makes some kind of best guess what terminology and corresponding cost curve might be reachable. That brings project managers to just define how much costs are invested and to hope that a suitable cost curve is reached. This once again makes clear that project management has to do with experience and a feeling for efficiency. As far as the model is developed, it is only applied to the financial data warehouse context. Further research should focus on generalizing the model to other complex ISD projects and implications for less complex projects.

4 CONCLUSION & OUTLOOK

A theoretical model for communication efficiency in FDWH projects was derived based on a theory of communication costs and project management fundamentals. The model is based on exploratory research of the last years and should be able to explain and predict identified specifics of FDWH projects.

The model suits the conditions for theoretical models given by Lee (1989) based on Popper (1965):

- **Falsifiability**: the theoretical model is presented in a way that allows testing against the theoretical approach by conducting empirical studies focusing on it.
- **Logical consistency**: the inherent mechanisms of the model are explained in a step-by-step way to assure logical consistency. Additionally, special cases and common project situations were stressed.
- **Relative explanatory power**: the theoretical model explains FDWH project observations in a more sophisticated and detailed way than the introduced general communication cost model or the introduced general software project management classification.
- **Survival**: since the first idea for a cost-based approach to FDWH in the beginning of 2007, no better applicable model could be found by our research group.

As all criteria are met for the moment, further research steps can be taken to corroborate the theoretical model for FDWH projects in real settings. Currently, additional research focuses on testing the theory in different FDWH project situations in multiple case studies (Räkers and Rosenkranz 2009) and future research will try to apply the theoretical approach to ISD projects beside financial data warehousing as well.
To sum up the findings and formulate theoretical suggestions coming from the efficiency model for FDWH projects, there are already practical implications for the behavior of project managers. They should keep in mind that communication costs are one of the most relevant drivers for project efficiency, and that the complexity of the project has to be judged and estimated throughout the project to stay on the most efficient curve. Due to the characteristics of communication cost functions, investments in terminology should be done as soon as a need for a higher estimated degree of complexity for a project is identified. Practically, this means to engage team members more into face-to-face communication when new variety enters the project environment or becomes visible.

CONTINUANCE USAGE INTENTION IN MICROBLOGGING SERVICES: THE CASE OF TWITTER

Abstract

The emergence of Web 2.0 has brought with it a plethora of social networking technologies. Among these, microblogging has emerged as a new and popular tool for short, frequent communication via Web postings. The most popular microblogging service, Twitter, has established a large user base, in spite of numerous criticisms. This study aims to examine why this is the case. In particular, the study develops a model of microblogging use continuance based on theories of continuance, habit and critical mass. The model is then tested by means of a Web survey of Twitter users (n=131) and structural equation modelling using the partial least squares technique. The results suggest that continued use intention is strongly determined by perceived usefulness, satisfaction and habit ($R^2=0.454$) which together provide a strong explanation for Twitter user behaviour. Further, critical mass and frequency of prior behaviour, both influenced by social network size, are strong determinants of the habit construct. The paper rounds off with conclusions and implications for future research and practice in this very new area of inquiry.

Keywords: microblogging; microblogs; continuance; critical mass; habit; Twitter.
1 INTRODUCTION

Dramatic changes are afoot in how users interact using the World Wide Web. The concept of ‘Web 2.0’ or ‘social software’ has become used to describe revolution-like developments associated with Internet applications like wikis, weblogs and social networking software. Although the term ‘Web 2.0’ was first introduced around 2004, the development process has been a continual one, spawning ever new types of software. One of the newest developments in this area is that of ‘microblogging’. As the technology is so new there are even several opinions about its name. In addition to ‘microblogging’ terms like ‘microsharing’ and ‘activity streaming’ are also typically used.

Notwithstanding the strong adoption of microblogging by private users and enterprises there is, as yet, very little academic research on the topic. Microblogging in general and the currently most popular microblogging service Twitter (www.twitter.com) in particular are presently among the most discussed Web 2.0 tools in the ‘blogosphere’ and in spite of substantial positive arguments many users complain about a lack of functionality or reliability issues. Considering the fact that Twitter use is nevertheless not declining but sharply rising there must be strong reasons why users continue using the service. Discovering an explanation for this finding could help us to understand the processes in microblogging platforms as well as to provide implications for the successful future implementation of microblogs in enterprise contexts.

The rising adoption of Twitter is a perfect setting for research in IS continuance theory. The purpose of our work is to understand the continued use of the microblogging service by its general users. The research question to be answered is “Why do users of the Twitter microblogging service continue to use the platform?” For this purpose we developed a research model using continuance theory (Bhattacherjee 2001) and related theories of habit (Limayem et al. 2007) and critical mass (Van Slyke et al. 2007). Data was collected via a Web survey of Twitter users. The data was then analysed using structural equation modelling via the partial least squares technique (Chin 1998).

The structure of the paper is as follows. In the next section we provide some background on the nature and growth of microblogs. In the following section we discuss the theoretical development of a research model of continuance in microblogging services. In the third section we describe the study’s methodology before presenting the results of the analysis in section four. Finally we discuss the findings and their implications for research and practice in the conclusions.

2 BACKGROUND

Microblogs are a smaller version of weblogs combined with features for social networking and mobility. Users post short updates without a headline or additional information in their microblog. Other members can add them to their social network (i.e. ‘follow’ them). The messages from a member’s social network appear in a chronologically ordered and combined view on their starting page. Most microblogging services limit the number of characters used in a posting to 140 or similar. The goal is to animate users to post short messages often in their microblogs. Access to microblogging services is also possible using mobile text messages, desktop clients or several third party applications.

The first and currently the most popular microblogging service is Twitter. Having earned an estimated US$20 million of venture capital (Crunchbase 2008) the service has seen an exponential growth in its user base since launching in July 2006 to an estimated 3 million users in September 2008 (Twitter Facts 2008). Twitter shapes the understanding of microblogging by asking the user “what are you doing”. Around Twitter a whole ecosystem of third party applications have been developed and much of the microblogging vocabulary has its origins in this particular service, e.g. the verb “tweet” for the action of posting into a microblog. In the U.S. Twitter appears to have reached critical mass and is becoming common sense. For instance, President Barack Obama used Twitter massively in his
election campaign. As Twitter has become perceived as a standard many so-called Twitter-clones have emerged, in part due to the relative ease in imitating the software. Serious competitors such as Pownce, Plurk and Jaiku tried to differentiate from Twitter by offering wider functionality or slightly different approaches. Google’s acquisition of Jaiku (in 2007) and Facebook’s offer for Twitter worth US$500 million in shares (in 2008) demonstrated the strategic importance of microblogs. Eventually, a first rationalisation of the market led to the closure of Pownce in December 2008. Notwithstanding, new competitors entered the market in 2008 with open source microblogging software like laconi.ca; different installations of this program communicate with each other and contribute towards building a big peer-to-peer microblogging network.

Gartner (2008) added microblogging to its hype cycle in 2008 and predicts that the technology will garner a sharp rise in popularity. This was also a consequence of the fast growing debate on using Twitter-like tools in professional contexts. While Twitter itself can be an interesting channel for companies to develop their brands and improve their customer service, many argue that due to privacy regulations there should be such a tool behind the company firewall. Major companies such as IBM, Oracle and SAP experimented with so-called enterprise microblogs and in the second half of 2008 special enterprise microblogging products like Communote, Presently and Yammer were launched.

3 THEORY AND RESEARCH MODEL

In this section we present prior research and concepts that have informed the development of the research model tested in the study. Three main strands of theory have contributed to theoretical development: continuance theory as the basic theory of our investigation complemented with concepts of habit and critical mass. Let us briefly discuss each of these areas in turn.

3.1 Continuance theory

Continuance theory within the discipline of information systems stems from initial research in marketing. Expectation-confirmation theory (ECT) emerged from the consumer behaviour and services marketing literature and has proven broadly robust in a number of service contexts (Dabholkar et al. 2000, Oliver 1993). The general thrust of ECT is the assessment of post-purchase intentions, as influenced by initial expectations about a product or service, subsequent adoption and use (consumption) and the formation of perceptions about performance as influenced by the confirmation or not of initial expectations, the latter determining the level of satisfaction with a purchase and subsequent repurchase or use discontinuance. Bhattacharjee (2001) was the first to fully formalize the theory into an ex-post framework that could be applied to the domain of information systems, adapting the theory to be applied post-acceptance and to encapsulate perceived usefulness (Davis et al. 1989, Davis 1993) as a replacement construct for expectations. Perceived usefulness has consistently proven to be an important construct in longitudinal adoption to post-adoption behaviour (Davis et al. 1989, Karahanna et al. 1999). Thus Bhattacharjee’s (2001) model relates the constructs of perceived usefulness and satisfaction to the extent of confirmation of a user’s expectations about an IS, whereby expectations that are fulfilled drive greater satisfaction and perceived usefulness. High levels of perceived usefulness are also posited to lead to greater satisfaction with a system. In turn, the outcome variable of continuance intention is determined by the level of satisfaction with an IS and the perceived usefulness of the system.

Bhattacharjee’s model has been successfully applied to individual user contexts involving the Web, such as online banking, and the Internet more broadly (Bhattacharjee 2001, Limayem et al. 2007). Microblogging services are also distributed systems reliant on Internet technology, and the focus of this study is on individual users; Bhattacharjee’s theory (which appears to have broader application and generalization in any case) is adopted as a suitable core for a model examining continuance behaviour in this context.
3.2 Habit

Habit refers to the extent to which behaviour has become automatic as a result of prior learning (Limayem et al. 2007). Previous research has found a strong relationship between habit and continuance behaviour. However, the use of habit in research models is more complex. Research has variously examined habit as a moderator between intention and actual behaviour, as a direct effect on actual behaviour, and as an indirect effect on behaviour that primarily determines intentions. Our focus in this research is on use intentions rather than actual behaviour, and so naturally we focus on the latter of these formulations. Our focus on intentions is in line with a core body of previous IS literature (Legris et al. 2003), whilst the focus on indirect habit effects is a view that is held in a number of previous studies that have examined the effects of habit (and the much used proxy construct of experience) on behavioural intentions (Bagozzi & Warshaw 1990, Legris et al. 2003).

In addition to the effect of habit on intention to continue using an IS, we also posit that habit is significantly influenced by satisfaction. Limayem et al. (2007) in their comprehensive definition, application and analysis of the habit construct in continuance theory find very strong support for the linkage between satisfaction and habit. Further, they find that frequency of prior usage and comprehensiveness of usage both have a positive associations with habit, both assertions that we also make for the purposes of model development.

The creation of habit requires a stable context conducive to its formation through repetition or practice (Orbell et al. 2001); we would hold that such a context exists when focusing on individuals’ behaviour with respect to a single system such as a microblogging service. This position is in line with that of Limayem et al. (2007) in their study of habitual use of the Internet.

3.3 Critical Mass and Perceived Critical Mass

Critical mass in technology adoption has been discussed in the literature for many years (e.g. see Markus 1994; Rogers 1995). Some of the seminal work in this area was that of Rogers (1995) as part of his diffusion of innovation theory. Rogers (1995) defined critical mass in terms of a ‘tipping point’ whereby a certain minimum number of users have adopted an innovation which then feeds into rapid continued adoption of the new technology, at which juncture further adoption is self-sustaining.

Further research into the application of critical mass theory to electronic communication media has demonstrated that universal access to a communication medium is major driver for critical mass; the decision to use a particular interactive media for routine communication relies on others in a communication network having adopted it and an overall social consensus (Markus 1994). Social context thus envelops individuals’ choices and “As more and more individuals in a system adopt an interactive communication innovation, the innovation is perceived as increasingly beneficial to both previous and potential adopters” (Van Slyke et al. 2007, p 274). As a result, positive network externalities ensue as a result of technology use (Lou et al. 2000, Van Slyke et al. 2007).

Van Slyke et al. (2007) examined perceived critical mass within the context of instant messaging, which has similarities to microblogging. They applied diffusion of innovation theory and found direct effects on numerous variables, including social norms, perceived relative advantage, perceived compatibility, ease of use and behavioural intention. As part of continuance theory we focus on continuance intention; however, in our habit model we posit that the effects of critical mass will manifest themselves indirectly through automatic behaviour. Thus, based on Markus (1994), an individual will exhibit greater habitual behaviour and choose a technology for interactive communication if there is a greater perception of critical mass. Such a perception will be driven, at least in part, by the size of an individual’s network – the extent of their personal communication network on the microblogging service. Further, the size of a network is posited to play a role in determining the frequency and comprehensiveness of an individual’s behaviour: the greater the extent of the network, the greater possibilities there are for communication, coordination and cooperation, and the more activity that will take place.
3.4 Research Model and Hypotheses

A combination of all of the above theorisations into a single model results in Figure 1. Here we use Bhattacherjee’s (2001) continuance theory as basic core of our research model (marked white in Figure 1). This leads to our first basic hypothesis:

**H1: Bhattacherjee’s continuance theory can be applied to explain Twitter usage.**

Further, we extend the model with the construct of habit and the relationship from satisfaction (Limayem et al. 2007). In contrast to Limayem et al. (2007) however, we model it as a direct effect on continuance intention:

**H2: Satisfaction has a direct effect on habit.**

**H3: Habit has a direct effect on continuance intention.**

We accept the habit indicators of frequency of past behaviour and comprehensiveness of usage introduced by Limayem et al. (2007) and extend these constructs with perceived critical mass due to the property of Twitter as a communication tool.

**H4: Habit in microblogging usage is driven by: (a) perceived critical mass; (b) frequency of past behaviour; and, (c) comprehensiveness of usage.**

As a basic determinant for these three constructs we introduce social network size:

**H5: The construct of social network size is a driver of: (a) perceived critical mass; (b) frequency of past behaviour; and, (c) comprehensiveness of usage.**

**Figure 1. Research Model.**

4 STUDY DESIGN AND METHOD

In this section we briefly outline the process of data collection, scale development and data analysis. Let us examine each of these in turn.
4.1 Data Collection

Twitter is clearly the best known microblogging service on the Web. This is one reason why we chose this platform as the basis for our investigation. Another point is that Twitter has had several downtime and reliability issues during 2008 and most recently additional, smaller competitors have emerged with broader functionality. Even in the face of this, Twitter’s user base experienced exponential growth. It can be supposed that there are strong reasons why existing users continue to use Twitter and new users choose this service over the various alternatives. Finally, there was a practical reason for selecting Twitter. Twitter has an accessible Web API (application programming interface) which enabled us to retrieve data about users and thus gave us the opportunity to measure real behaviour for some constructs. For this reason survey participants were asked to give a valid Twitter user name.

Data was collected via the survey Web site, QuestionPro. Data collection was promoted mainly in Twitter with a few blog postings outside the platform. Promotion was initiated only from one of the author’s Twitter accounts using this network as a starting point for viral marketing and ‘hashtags’ to reach completely different communities of users. Hashtags are usually short terms describing several topics, such as an event (i.e. #smclondon08 for Social Media Camp London 2008). People attending such an event and writing about it on Twitter use this tag in their postings. In searching for this term one is able to get related messages even from people who are not in one’s network. These streams from Web-related events were used to post advertising for the survey. Overall, we received a total of 131 usable survey responses during the 13 days the survey was open (of the 138 originally collected, 7 were excluded due to incorrect user names or closed accounts which prevented us collecting usage data from the Twitter service). Based on the logfiles of QuestionPro, some 26.0% of the participants were from Germany, 18.3% from the US, 16.8% from the UK, 10.2% from the rest of Europe and 6.1% from the rest of the world (with 22.9% unknown). This shows a wide distribution of the survey. In addition, based on the API data, some 45% of the participants registered their specific username on Twitter in the year of the survey (2008) and 47% in the year before (2007). Only 6% were initial adopters in Twitter’s first year of operation (2006).

4.2 Measurement

Scale development was largely based on a strong foundation of scale items from existing literature. The survey items selected and their provenance is demonstrated in Table 1. All but three constructs were measured using traditional 7-point Likert scales. Our constructs were extended with the new construct of social network size and two other constructs were measured in different ways to the existing literature. First, using Twitter’s API it was possible to get data for both the frequency of past behaviour and social network size using a custom software programme developed by one of the authors. Frequency of past behaviour was defined as the two weeks prior to survey completion. Based on the date the survey was completed by each respondent we were able to measure this accurately based on the number of Twitter updates posted on the service. We used two weeks rather than the four weeks of Limayem et al. (2007) because we considered it more appropriate for the nature of this interactive medium. Social network size was based on the complete network of ‘followers’ and ‘following’ connections. Comprehensiveness of usage relied on a new conceptualisation of the variety of usages of Twitter based on a simple three-part categorisation into communication, coordination and cooperation, with each being activated as one-way and/or two-way (six uses in total).

4.3 Data Analysis

Data analysis was performed using a variance maximization approach to structural equation modelling (SEM) and associated statistics for validity and reliability. More specifically, we used the partial least squares (PLS) technique with reflective indicators in Smart-PLS 2.0 (Ringle et al. 2005). The PLS technique has become increasingly popular in information systems research, marketing and in
management research more generally in the last decade or so, influenced by its flexibility; indeed, PLS does not have the same distributional assumptions of normality for data and is able to handle small- to medium-sized samples (Chin 1998, Compeau & Higgins 1995).

5 RESULTS

In this section we discuss the results of model testing, including scale validity and reliability and the results of our partial least squares path modelling analysis.

5.1 Tests for Validity and Reliability of the Measures

Table 2 demonstrates that the scale items exhibit high levels of convergent validity – the extent to which theoretical scale items are empirically related. The loadings of the measures on their respective constructs in the model range from 0.727 to 0.955, with all being significant at the 0.1% level.

Table 2 also demonstrates that all of the constructs fulfil the recommended levels with reference to composite reliability (CR) and average variance extracted (AVE). All items were higher than the cut-off of 0.50 recommended by Fornell and Larcker (1981), ranging from 0.695 to 0.891. Similarly, the values for composite reliability are very good, ranging from 0.842 to 0.942, well above the reliability values of 0.70 and 0.80 that are typically advised for building strong measurement constructs (Nunnally 1978, Straub & Carlson 1989).

Table 3 examines the extent to which question items measure the construct intended or other related constructs, otherwise known as discriminant validity. Fornell and Larcker’s (1981) standard test for discriminant validity was used, whereby the square root of average variance extracted for each construct is compared with the correlations between it and other constructs; discriminant validity is demonstrated if the square root is higher than the correlations. Table 3 clearly indicates that each construct shares greater variance with its own measurement items that with other constructs with different measurement items, with a good margin of difference.

Table 4 provides an additional test for discriminant validity. Here we utilized the cross-loading method of Chin (1998). The method prescribes a requirement for measurement items to load higher on a construct than the scale items for other constructs and for no cross-loading to occur. Item loadings in the relevant construct columns were all higher than the loadings of items designed to measure other constructs; similarly, when glancing across the rows the item loadings are considerably higher for their corresponding constructs than for other constructs.
Overall, the results of testing for validity and reliability are very positive and provide us with a high
degree of confidence in the scale items used in the study.

5.2 Test of the Research Model

The results of PLS path modelling are shown in Figure 2. For this analysis we utilised the software package, Smart-PLS (Ringle et al. 2005). The shaded items are those that have been added to Bhattacherjee’s (2001) basic continuance model. A power analysis in G*Power 3.0 (Faul et al. 2007) shows that the sample size (n=131) has good power for explaining medium population effects ($f^2=0.15$; $\alpha=0.05$; $1-\beta=0.88$), and is thus suitable for the testing of the model under these conditions.

All relationships in Bhattacherjee’s (2001) original model are strongly supported by the data (H1), with links from confirmation to perceived usefulness ($R^2=0.445$) and satisfaction at the 0.1% and 1% levels of significance respectively. Similarly, perceived usefulness is strong driver of satisfaction ($R^2=0.397$; $p<0.001$). Both perceived usefulness and satisfaction are strong drivers of Twitter users’ continuance intentions at the 1% levels of significance. Together with habit, which provides a smaller but nevertheless significance influence (H3; $p<0.05$), some 45.4% of variance in Twitter use continuance intentions is explained by the model.

In line with the findings of Limayem et al. (2007), we find that satisfaction is a major determinant of the manifestation of automatic behaviour (H2; $p<0.001$). Along with strong linkages from the frequency of past behaviour (H4b; $p<0.05$) and perceived critical mass (H4a; $p<0.001$), these variables account for a considerable 47.4% of the variance of habit. We consider this to be a very strong explanation in statistical terms. The linkage between comprehensiveness of usage and habit is not supported. This finding corresponds with additional comments given by the survey participants suggesting that there is a wide range of possible usages but that one particular use can be enough to create value for a user. The comments included: “I use twitter as a learning tool”, “We use Twitter to feed in blog posts from our blog network” and “I use Twitter mainly for entertainment purposes & social networking.” Together these give an impression of different usage possibilities and a possible
explanation why comprehensiveness of usage may not be important in creating habit in the microblogging context.

Further, we find that social network size exerts a strong influence over perceptions of critical mass for Twitter (H5a; p<0.001), the frequency of previous usage of the service based on the last 14 days (H5b; p<0.01), as well as comprehensiveness of usage in our model (H5c; p<0.01), although the latter does not link further to habit.

6 DISCUSSION AND CONCLUSIONS

This paper has tested an extended research model of continuance behaviour in the context of the most popular microblogging service, Twitter. To our knowledge this is the first academic research paper that has examined use continuance behaviour with respect to this very new social networking tool. The results suggest that the continuance behaviour of Twitter users is strongly determined by their perceptions of value of using the service, satisfaction manifested in their usage of the tool and prior development of automatic behaviour or habit surrounding the use of the service (H1 and H3). Further, we find that social network size influences the development of past use behaviour and of perceptions of critical mass, as users see the value of interacting with a significant group of nodes in their network (H5). In turn, habit is driven by satisfaction (H2), past usage behaviour and the aforesaid perceptions of the significant size of the network via perceived critical mass (H4). However, one link is not supported – between comprehensiveness of usage and habit – which leads to the partial falsification of hypothesis 4 (H4c).

Although the findings are both original and significant, there are a number of limitations of note in the research. In using the Twitter API for retrieving data about the participants there is a clear advantage in collecting direct measurements. However, the obverse is that there could be the possibility of ‘missing’ use data. We used each user’s number of Twitter postings during the 14 days before survey participation as a measurement for past behaviour. Notwithstanding, there are Twitter usages such as
plain reading of other’s postings or building a social network which are hidden from the API. Although posting updates on Twitter is seen as the primary usage it would be interesting to see further studies comparing individual perceived frequency of past behaviour with measured posting behaviour. In this way the importance of passive usage could be discovered.

Linked with this limitation is an issue that emerged during the study. We used six categories (communication, coordination and cooperation, each one-way and/or two-way) with real-world examples to capture comprehensiveness of Twitter usage. Nevertheless, a number of comments from respondents suggested introducing additional usage classifications such as work/personal, seminars/events or mobile/desktop. Clearly the development of a comprehensive, valid and reliable typology of Twitter usage is a matter for future research.

Another limitation of the study is the sample size. Although the sample has good explanatory power for medium-sized effects ($f^2=0.15; \alpha=0.05; 1-\beta=0.88$), a larger sample could help to reveal smaller population effects, which may for example uncover missing relationships. A further limitation of our research model is the absence of demographic and other factors, such as age, gender, experience with Twitter, use intensity and so on. Since we may have a heterogeneous sample of a global nature; capturing and analyzing information on the sample may help to understand the behaviour of different groups of global consumers.

From a practical perspective, our research provides useful guidelines not only in terms of understanding public microblogging users, but in terms of other nascent applications of microblogging. Enterprise microblogging or “Twitter for the enterprise” is currently a very hot topic of discussion among Web 2.0 developers. Our research model provides practitioners with some advice regarding not only how to launch a microblogging service successfully but also how to make sure that users continue to use it. In addition to the core influences of perceived usefulness and satisfaction the strong relationship between habit and continuance intention could be an important starting point. Practitioners need to design high quality microblogging services that provide clear benefit and that provide a satisfying experience, but that also become permeated within users’ daily routine activity to such an extent that usage becomes habitual. Incentives to build a core of users may be valuable in creating a self-sustaining body of users and in building perceptions of universal access. Clearly organisations will need to expend considerable effort in trying to create habit. It is not only important to find good initial use cases and incentives to create past behaviour but also to provide perceived critical mass. The corollary of this is interesting; this implies that there is actually no need to start a microblogging service within a whole organisation as long as there is perceived critical mass among the current set of users. A good starting point might be a single department or a single subsidiary. In our research, no relationship was detected between comprehensiveness of usage and habit, implying that there is no need for a wide range of uses of microblogging to build use continuance. One or two strong valuable use cases could be enough to create habit among users.

In conclusion, we perceive that microblogging is clearly becoming an established and much used interactive social medium. This study has shed light on a number of explanations for this phenomenon. We hope that this research paves the way for others to begin investigating aspects of user behaviour surrounding this very new and interesting social networking tool.

Abstract

The advance in User Created Contents (UCCs) web sites like YouTube changed the role of Internet users from contents receivers to contents creators; a role which requires more pro-active user behaviour. However, the literature on user behaviour in information technology lacks theories that explain the pro-active user behaviour of producing and sharing UCCs with others on the Internet. This paper aims to reveal the major attributes of Internet users that have a positive impact on the intention to produce UCCs on the Internet. Extant related theories are reviewed to extract major factors of Internet users that lead to the production of UCCs. A questionnaire survey is administrated to 400 sampled respondents in South Korea to test the relationships among the identified factors. The results show that playfulness, self-expressiveness/sharing intention, innovativeness, computing skills and reward have a positive impact on the intention to produce UCCs. In particular, innovativeness turned out to have the biggest impact, while social participation is not a significant factor. Mediator variables such as age, gender and types of UCC also turned out to be playing a role in the causal relationships among the factors and the intention to produce UCCs. A model pertaining to the intention to produce UCCs online is developed and tested. The academic and practical implications of the study are also discussed in details.

Keywords: virtual community, social networking, user participation, technology acceptance.
1 INTRODUCTION

The American weekly newspapers ‘Times’ selected YouTube as the invention of the year in 2006 (Time, 2006). Furthermore, the weekly newspapers ‘The Economist’ envisaged that Web 2.0 and user created contents (UCCs) was the mega-trend of year 2007. There is no widely accepted definition of User Created Contents (UCC). According to Wunsch-Vincent and Vickery (2006) UCCs are “content made publicly available over the Internet reflecting a certain amount of creative effort and which is created outside of professional routines and practices”. A more simplified definition is provided by Chin (2006) who defined UCC as content created by users themselves. Internet users are in the centre of this new trend by creating original and creative text, audio, image and video contents which require much more efforts than traditional Internet activities such as simply posting a reply to a web page. They create and upload their own images, audios, and videos using their mobile phone onto Internet web sites such as YouTube, FaceBook, and Phandora TV. One of the enablers of this trend is the evolution of web 2.0 that aims to facilitate bi-directional interactions between web sites and their users overcoming the one-sided information provision by web sites to their users in web 1.0. As a result, the role of users in web pages development is becoming more important (or proactive) than before as they are the major source of web contents.

Despite the new trend on the behaviour of Internet users, there is no study that aimed to investigate and explore the reasons behind such online user behaviour. Existing research on user behaviour towards Information Technology (IT) adoption have been concentrating on user acceptance (Fishbein and Ajzen 1975; Davis, 1989; Mathieson, 1991; Thompson et al., 1991; Davis et al., 1992; Taylor and Todd 1995; Moor and Benbasat 1996; Venkatesh et al., 2003). For example, Venkatesh et al., (2003) summarise the major factors for user acceptance proposed by previous studies to be: “perceived ease of use”, “perceived usefulness”, “attitude”, “subjective norm”, “extrinsic & intrinsic motivation”, “perceived behavioural control”, “job-fit”, “complexity”, “social factors”, “visibility”, “compatibility”, and “voluntariness of use”. However, user acceptance is passive user behaviour and those identified factors fall short in explaining the proactive behaviour of producing, uploading and sharing digital contents with others on the Internet; a behavior that goes well beyond technology acceptance. Most of the UCC web sites have two different types of users: content creators and content viewers. While extant factors can be employed to explain the behaviour of content viewers, it is necessary to identify the factors which explain the behaviour of content creators. Furthermore, most existing studies focused on IT in both the organizational and academic contexts in which new IT (excel, word processor, task supporting systems) are necessary or very helpful to execute users’ given tasks. As a result, the acceptance of the ITs is mandatory or implicitly mandatory rather than voluntary to users. However, UCC web sites are purely voluntary and the difference in perception is under researched which strove the authors to attempt to fill this gap in the literature.

This paper aims to identify major factors that make Internet users create and share contents on the Internet in a process that requires investing intensive efforts in terms of time and resources. The study undertaken in this paper identifies seven major factors that would explain the behaviour of content creators via a thorough literature review and proposes a conceptual research model. The proposed conceptual model is tested on 400 sampled respondents in South Korea. The results show that playfulness, self-expressiveness/sharing intention, innovativeness, computing skills and reward have positive impact on the intention to produce UCCs. In particular, innovativeness turned out to have the biggest impact in comparison to social participation which does not have a significant impact on UCCs production. The academic and practical implications of the study are also discussed.

The organisation of the paper is as follows. Section 2 proposes the research model of the paper. Section 3 explains the methodology used to test the research model and section 4 presents the results. Lastly, section 5 discusses the implications of the findings and concludes the paper.
2 RESEARCH MODEL

2.1 Factors affecting the intention to produce UCC

Even though existing studies did not differentiate between the intention to use and the intention to produce, it is possible to identify the factors that initiate and affect the proactive behaviour of online content production and dissemination.

Since the 1990s, researchers such as Ahn et al., (2007), Moon and Kim, (2001), and Webster and Martocchio, (1992) focused on playfulness as a factor that explains why people adopt information systems. Barnet (1990) defines playfulness using five generic attributes namely; perceived volunteerism, social volunteerism, physical volunteerism, explicit pleasure and humorous sense. He also found that differences in individuals’ playfulness positively affect the use of computers. The content creators may find it playful during the process of creating exciting contents and this leads to the repetition of the contents’ creating behaviour. As a result, the first hypothesis is derived as follows:

H1: Playfulness has a positive effect on the intention to produce UCCs.

Artists express their ideas, ideology and feeling by producing artistic materials. Similarly, the purpose of producing UCCs can be compared with that of artists. Boneva et al., (2001) differentiates expression based communication from instrumental communication in computer mediated communication research. While instrumental communication is used in general behavioural communication, expressiveness is used in communications to improve mental familiarity and sharing. In this paper, expressiveness is defined as individual consciousness of how much s/he considers UCC as a tool to express himself/herself. Pederson et al., (2003) revealed that expressiveness is one of the major factors for the acceptance of multimedia messaging services (MMS). Otherwise stated, users of MMS use the services as a tool to express themselves to others in order to share their emotions. Using the same rationale, it can be inferred that the producers use UCCs as the tool to express themselves to others in public via the Internet medium. Consequently, the second hypothesis is derived below:

H2: Expressiveness has a positive impact on the intention to produce UCCs.

Most of UCCs are shared within online communities. The users produce UCCs and upload them on the Internet to share with others rather than keeping them locally on their PCs in the form of private diary entries. Butler (2001) and Hare (1976) define the Internet community as a process in which information and knowledge are shared among the community members. Butler (2001) insists that the sharing activities are an important factor to explain the dynamics of the Internet community. From this perspective, one of the reasons of producing UCCs on the Internet can be considered to be motivated by the intention to share UCCs with other community members. The intention to share is defined in this paper as “the intention to provide others with their knowledge or accept others’ knowledge through UCCs on the Internet community”. Based on the preceding the third hypothesis is deduced:

H3: Intention to share has a positive impact on the intention to produce UCCs.

The innovation diffusion theory provides a useful analysis framework to explain how and why new technologies are accepted and used by users (Atkin and LaRose, 1994; Leung and Wei, 1998; Lin and Jeffres, 1998; Li and Yang, 2000; Reagan, 1987). According to innovation diffusion theory (Rogers, 1995), early adopters or pioneers tend to be proactive in accepting new technology or ideology and in taking risks. Hence, innovative people tend to have stronger interests in new ideas or information and consequently have a high probability to buy new products before others (Lin and Jeffres, 1998; Ha 2005; Ban 2007). The adoption of technological innovation is determined by individuals’ innovativeness or volunteerism to try new products or technologies. Innovative people have skills to understand complex technical knowledge, and tend to adopt innovation when it is not widely adopted by other social members. This segment represents those who are young, adventurous, active in...
external activities and pro-active to adopt new ideas in societies (Rogers, 1995). As a result, it is natural to derive the following hypothesis.

**H4:** Innovativeness has a positive impact on the intention to produce UCCs.

Rogers (1995) also relates innovativeness with social participation by noting that people who adopt innovative ideas more than others tend to have a stronger desire to participate in social affairs. In this paper, social participation is defined as the level of interests or actual participation of an individual in social affairs. Human beings naturally tend to be part of society and have a basic desire to be involved in social affairs that may affect their lives. Within the online community literature, social participation (sometimes referred to as ‘social enhancement’ or ‘affection social presence’) is one of the major motivators that triggers people to participate in and contribute to online communities (Dholakia et al., 2004; Shen and Khalifa, 2007). As the number of users of UCC web sites increases, many of the UCCs contain politic or environmental messages. For example, edited video clips of the President of United States were one of the most popular contents of YouTube after the Iraq War in 2003. As a result, it can be deducted that people create and upload digital contents on web sites as a way to participate in social affairs. Therefore, the fifth hypothesis is derived as follows:

**H5:** Social participation has a positive impact on the intention to produce UCCs.

On the other hand, producing UCCs requires users to possess a certain level of computing skills. A computing skill is defined as a competence that enables people to achieve given tasks using computer based information systems or related technologies (Lee et al., 1995). Nelson (1990) asserts that the acceptance of information technology is affected by the level of individual knowledge or skills as well as the technology itself. In the literature, it is reported that computing skills affect perceived usefulness and playfulness (Igbaria et al., 1996; Webster and Martocchio, 1992; Kouparis, 2002). UCCs require certain level of computing skills to edit or create digital contents. It can be inferred that the higher the level of computing skills a user has, the stronger s/he is attracted to create the digital contents. Based on the above, the sixth hypothesis is derived as follows:

**H6:** Computing skills have a positive impact on the intention to produce UCCs.

Finally, Park et al., (2006) report that people share UCCs in order to be famous or make money though this has been investigated only in South Korea. The result is in line with existing studies that identify monetary reward as one of the major motivator of online communications. Kang et al., (2006) measures the economic incentives of UCCs through qualitative metrics. In their study, the interviewees confirmed their satisfaction with the economic reward from the UCCs they produced. This leads to the final hypothesis of this paper:

**H7:** Reward has a positive impact on the intention to produce UCCs.

Figure 1 summarises the proposed conceptual research model based on the derived hypotheses:

![The Conceptual research model on Users' intention to produce online UCCs](image)
2.2 Control Variables

According to the global leader in internet media and market research Nielsen//NetRatings by Wunsch-Vincent and Vickery (2006), men are 20% more likely to visit YouTube than women. Furthermore, of those who actively produce UCCs 86% are males. In the meantime, while Blogging is very popular in countries such as China, India, and Iran, a recent Microsoft survey shows that of all Asian Internet users, women are very active bloggers accounting for 55% of bloggers in Asia with men mostly overwhelming blogging in India (Stern, 2006). There is a clear indication that there are differences in the level of involvement of males and females in UCCs. This level of involvement differs depending on the geographical location as per the aforementioned statistics. As such, in this study gender was introduced as a control variable to measure its effect on Internet users’ intention to produce UCCs in South Korea.

The social drivers of UCCs production such as willingness to share, contribute and to create online communities are altering the media consumption habits of internet users particular within the younger age group of 12 to 17 years old. According to the Nielsen//NetRatings’ (2006) report, UCC has already begun to have an impact on traditional media industries. The statistics show that users aged between
15-24 years of age reduced their consumption of offline media in the UK. This reduction is driven by Internet use (Ofcom, 2006). This implies that out of the various possible age groups to view or produce UCCs 15-24 years old are probably the most potentially effective segment. This claim is also supported by findings in the report that state that that YouTube visitors aged between 12-17 years of age (those who mainly view but might not necessarily have produced UCC before) are the highest among all the various age groups. For those internet users who publish UCCs namely amateur video contents, 75% are under the age of 25. In the light of the above, it is clear that the age group to target falls around the 12-15 years old, hence the authors defined a control variable that would accommodate such a segment namely; 10s and 20s years of age to test the effect of the two age groups on the intention to produce UCCs.

Reflecting on the previous subsection 2.1.2, it is apparent that within such an age segment lay two user categories namely; those who have previously created UCCs and those who are mainly viewers of UCCs with possibly no previous experience in UCCs production. The research distinguishes between these two categories of internet users and introduces a control variable (self / non-self produced UCC) to test the effect of the level of involvement in UCCs on the intention to produce UCCs.

3 METHODOLOGY

In order to test the conceptual research model presented in section 2, a survey questionnaire method was applied. The operationalisation of the variables was conducted via a literature review and are summarised in Table 1. A pilot survey had been performed to test the validity of the questionnaires before they were administrated to the respondents. The sample for data collection was targeted at teenagers and people in their twenties in South Korea as they are the most active users of UCCs (Yim, 2007). Four hundred respondents who had an experience of producing or plan to produce UCC in the Seoul and Kyong-gi province have been sampled randomly for a questionnaire survey. Out of a total of 400 completed questionnaires 389 were used for the analysis after filtering out 11 non-sensible questionnaire responses. Male respondents represent 45.2% of the respondents while 54.8% of respondents were females... The respondents’ ages were distributed as follows: 49.6% teenagers, 46.3% in their twenties, 3.1% in their thirties, and finally 1% in their forties. Most of the respondents had more than five years of Internet experience and about 60% of the respondents were visiting UCC related web sites at least 3 times a week. As a result, most of the respondents had enough knowledge to respond to the questions.

4 DATA ANALYSIS AND RESULT

4.1 Validity and reliability test

To test the reliability of the survey constructs, Cronbach’s alpha value was used. As for the validity test, firstly, the exploratory factor analysis was used to judge unidimensionality of sub variables. Secondly, the principal component analysis using varimax rotation has been employed to extract factors to reduce the number of factors with minimum loss of data. First, the factors whose eigen value is bigger than 1 from principal component analysis were extracted. Then, varimax rotation was performed on the extracted factors. The analysis of variables resulted in 6 factors which were used as measurements of users’ intention to produce UCCs. Among the 7 variables, self-expressiveness and sharing intention have been represented and grouped into one factor based on the fact that users want to show off themselves by sharing their contents to provide others with a pleasure. The detailed data of the factor analysis is not shown here for the conciseness of the paper but the variables were well tied to each other according to each factor and the factor loading values were bigger than 0.6.
A reliability test using Cronbach’s alpha was performed after excluding the invalid variables from the factor analysis. As shown in Table 2, the most of the alpha values are higher than 0.8, hence the collected data can be considered as reliable for the variables.

</tbody>
</table>

4.2 The research model test

Multiple regression analysis and ANOVA were employed to test the hypotheses in the conceptual research model presented in Figure 1. Six among seven factors were used as independent variables after merging ‘self-expressiveness’ with ‘sharing intention’ while the intention to produce UCCs was defined as the dependent variable. The result of the regression analysis and the ANOVA results are summarised in Table 3 and 4 respectively.

*Table 4  ANOVA results*

From the above tables, the $R^2$ value of the regression equation is 0.467 and the significance level of the ANOVA is 0.05. As a result, the regression equation can be considered valid to explain the dependent variable namely; the ‘intention to produce UCCs’.

(a) According to Table 5 and (b)

Figure 2 (a), five factors apart from social participation turned out to be significant in explaining the intention to produce UCCs without a multi-collinearity issue.

</tbody>
</table>

*Table 5  Estimated regression equation*
Further analysis was made to investigate the effect of control variables such as gender, age and UCC type on the intention to produce UCCs with the results shown in Figure 2 (b) and Figure 3. According to the results, innovativeness turned out to be the most important factor that affects the intention to produce UCCs regardless the type of contents, gender or age. On the other hand, social participation does not affect the intention to produce UCCs. Figure 2 (b) shows the relationships between the six factors and the intention to produce UCC according to the type of contents. Playfulness, self-expressiveness, computing skills and reward turned out to be significant factors for producing self-produced UCCs, while they do not have significant impacts for non-self produced UCCs. In particular, computing skills and reward were the most significant factors for self produced UCCs which can be explained by the fact that a high level of computing skills is required for self produced UCCs. In addition, the desire to be compensated for their idea and creativeness on the UCCs is one of the major motivator of the self producers. Figure 3 (a) shows that males and females are affected by different factors in producing UCCs. Males are affected by playfulness and reward, while females by self-expressiveness / sharing intention and computing skills. On the other hand, according to Figure 3 (b), the major motivation to produce UCCs for teenagers is playfulness and computing skills while the motivation for twenties are self-expressiveness / sharing intention and reward. Finally, Table 6 summarises the hypotheses test results as discussed above.
It is worth to note that the proposed research model does not include some factors used to explain the intention to accept new ITs in previous studies like social influence, perceived ease of use, perceived usefulness as those factors are strongly related to the passive behavioural intention. Hence they are not appropriate to explain the pro-active behavioural intention to produce UCCs without any external pressure. Lu et al., (2005) report a positive impact of social influence on the acceptance of new IT like mobile services which were provided to users in non-working environments. They argue that users feel that the use of new IT can improve their (social) image which demonstrates an example of how social influence can affect user acceptance. However, the behaviour of producing UCCs is performed in virtual society with anonymity, and the impact of the social image does not play a significant role in the context. As a result, the role of social influences which represents the influences of other people who belong to a user’s social network was excluded from the research model.

Table 6  The conceptual research model hypotheses test results.

As shown in Table 6, all hypotheses apart from H4 were accepted. In particular, innovativeness turned out to be the most significant factor for producing UCCs. Even though there are studies that highlight the important effect of personal innovativeness on user acceptance (Lu et al., 2005; Agarwal and Prasad, 1998a; Agarwal and Prasad, 1998b), the result in this paper revealed that the innovativeness has the strongest impact among others on the acceptance of purely voluntary and computing skill demanding IT processes such as UCCs. In their studies, innovativeness was found to be a moderator rather than a direct determinant of the intention to use new ITs. Such a difference can attribute to the fact that the role of users in ITs in general is still passive compared to being pro-active as demonstrated in UCC web sites.

The acceptance of H5 needs to be interpreted in relation to existing studies that report the irrelevance of computing skills to IT acceptance. Computing skills have not been considered as one of the major factors in the acceptance of IT in the literature. The main reason being the high level of user knowledge of IT as a result of the widespread of computers and Internet technology. As a result Igbaria and Nachman (1990)’s proposition that Information Systems (IS) satisfaction is affected by computer use was considered not longer valid in modern society. However, the results in this study showed that computing skills significantly affect the intention to produce UCCs. This is because UCCs production is a more complex task than using other back office systems as such production requires more advanced computing skills to create and edit videos and pictures using digital devices and software.

On the other hand, the motivation for social participation turned out to be an insignificant factor for the production of UCCs. This is due to the nature of the respondents who are mostly teenagers or in their twenties who normally do not have strong interests in politics and social affairs (Kimberlee, 2002).

The role of mediation variables such as age, gender and UCC type turned out to be significant in explaining the relationships between the factors and the intention to produce UCCs. In particular, the identified factors can explain the intention to produce purely self-produced UCCs, but not non-self
produced UCCs. This implies that the identified factors have more to do with proactive user behaviour because self-produced as opposed to non-self-produced UCCs require more effort. With regards to gender differences, the results are in line with existing studies that reported gender differences in user acceptance of new IT (Venkatesh et al., 2003). In this study, females are more sensitive towards computing skills to produce UCCs; which again is in line with existing studies that report that in general, females have less computer experience and have a negative attitude towards accepting new IT (Schumacher and Morahan-Martin, 2001). Furthermore, playfulness turned out to have a significant impact only on males’ intention to produce UCCs. In other words, males produce UCCs as a tool to play, while females do not perceive it in this perspective. This result concurs with existing studies by Phillis et al., (2002) that report gender difference on electronic games. With regards to age, it was found that teenagers tend to be more sensitive to computing skills than those who are in their twenties as teenagers are usually not well trained on IT as much as twenties. Also, those who are in their twenties consider compensation is a more important factor than playfulness, which is not the case for teenagers. Finally, innovativeness turned out to be significant while social participation is insignificant. Both facts are regardless of differences in age, gender or UCCs’ type.

The paper delivers a number of contributions to both theory and practice. Firstly, to the authors’ knowledge, this is the first effort to identify the major factors that affect Internet users’ intention to produce UCCs. A process that requires more proactive user behaviour than that of just accepting new information technology. In particular, innovativeness turned out to be the most significant factor to explain this proactive user behaviour. Secondly, this paper joins existing studies that highlighted the role of mediator variables namely: age and gender in user acceptance literature from proactive user behaviour’s perspective. Thirdly, from a practical perspective, managers of UCC web sites would benefit from the research model when setting up their strategies as to focus on innovativeness and playfulness to enable a sustainable production of UCCs by their users.

The goal of the paper was to identify major factors that affect the intention to produce UCCs and as a result it lacked the scope to focus on the components that explain the internal users’ process in producing UCCs on the Internet. As an example and a potential future research, structural equation modelling (Kline, 2005) would be a good approach to reveal the procedural structure among the factors identified in this paper, along with any potential external factors in future studies. The implications of the study are self-evident. Firstly, the contextual variable that determines how a new IT is introduced in a society or an organisation affects the acceptance of the technology. As shown in this study, the UCCs are typical example of voluntarism, and the innovativeness plays the most significant role in the user acceptance in this context.

Abstract

Massively Multiplayer Online Game (MMOG) is a unique categorization of electronic game which allows thousands of players to play simultaneously through the Internet in the same virtual environment. A number of researchers have started to introduce the use of MMOG as a new generation of educational platform, allowing players to interact and to learn together through collaborative game-play. However, the answers for the occurrence of collaborative learning behaviour and the motivational drivers for learning collaboratively in a MMOG are still under-researched.

Motivated by such concerns, this study tests a theoretical model to explain individual’s intention to learn by peer motivations. The model employs motivational theories to propose two external motivational factors, namely peer intrinsic motivation and peer extrinsic motivation, and investigates effects of the two new constructs on MMOG players’ intention to learn individually and intention to learn collaboratively by building on the cognitive learning theory.

Based on a study with 94 valid current MMOG player responses, PLS analysis shows that peer intrinsic motivation to play has a significant positive influence on the intention to learn collaboratively, while peer extrinsic motivation to play has a significant positive influence on the intention to learn individually. The results of our findings indicate potential implications to researchers, educators and game developers.

Keywords: Collaboration, Learning, Virtual world, Technology Acceptance Model (TAM)
1 INTRODUCTION

This study aims to bring together Massively Multiplayer Online Game (MMOG) and technology-based collaborative learning streams of research to examine peer motivational factors influencing intention to learn that is under-researched so far. As a hedonic information system, MMOG is a unique categorization of electronic game. By definition, “MMOGs are highly graphical 2- or 3-D videogames played online, allowing individuals, through their self-created digital characters or ‘avatars,’ to interact not only with the gaming software (the designed environment of the game and the computer-controlled characters within it) but with other players’ avatars as well. These virtual worlds are persistent social and material worlds, loosely structured by open-ended (fantasy) narratives, where players are largely free to do as they please – slay ogres, siege castles, barter goods in town, or shake the fruit out of trees” (Steinkuehler 2004). A growing number of researchers have started to introduce the use of MMOG as a new generation of educational platform (e.g. Gee 2004, Childress and Braswell 2006, Mikropoulos 2006), allowing players to interact with each other, and so as to learn together through collaborative game-play. However, the answers for the occurrence of collaborative learning behaviour in MMOG, and the motivational drivers for learning collaboratively in a MMOG environment are still under-researched.

To address this under-researched area, the objectives of this study are to examine the occurrence of collaborative learning behaviour and motivational drivers in MMOG by extending motivation to play to the peer level, bridging the characteristics of MMOG with peer motivations, and investigating the effect of peer motivations towards players’ behavioural intention to learn in the context of MMOG.

In the next section, we present the literature review. Then we discuss the research model, hypotheses and methodology, followed by the discussion of the results, implications, limitations and future research directions. The conclusion of this study is presented in the final section.

2 REVIEW OF LITERATURE

The first stream of reviewed research is on MMOG game-based learning which believes MMOG is a new type of computer-mediated communication application and the unique characteristics of MMOG may trigger learning behaviours of game players in the gaming context. The second stream of reviewed research is on the explanation of relationships between motivational factors and intentions to play/use/learn in a gaming context by Technology Adoption Model (TAM).

2.1 MMOG game-based learning

MMOG is a new type of Computer-Mediated Communication (CMC) application, with recreational and playful context that are designed to support dynamic social structures (Pena and Hancock 2006). MMOG consists of several unique characteristics that may trigger learning behaviour in the gaming context:

- **Avatar / Virtual Identity**: The existence of an avatar is the player’s representation which enhances the player’s sense of identity and presence, and helps the player to successfully perform the learning tasks (Mikropoulos 2006). The use of avatar in MMOG aligns with Gee’s (2004) example of virtual identity in gaming environment that the self created avatar is necessary for players to commit and take on a new identity they value and in which they become heavily invested in deep learning.
- **Co-presence**: Co-presence is the sense of being there in other places and being together with other people (Biocca et al. 2001). It is the fundamental prerequisite of collaborative learning and it is claimed to be one of the crucial social components of computer-mediated communication (Spears and Lea 1992).
• **Collective Identity:** Players can join *guilds* (named teams) to socialize and play together. Collaborative-competition is introduced in MMOG and encourages collaboration among in-team players to compete with out-team players. According to the social identity theory (Tajfel and Turner 1979), when individual is faced with such situation, collective identity would be introduced and individuals tend to act in the benefit of the team and discriminate the out-teams.

• **Transparency:** Transparency in MMOG is to allow players to retrieve values of attributes of avatars in the environment. Such characteristic allows informational influence to happen between players’ actions in the virtual environment, which in return generate an internalization process when a player perceives information as a means to enhance his/her knowledge above that of reference groups (Kelman 1961).

2.2 Technology Acceptance Model (TAM): Motivation to Use/Play and Intention to Use/Learn

A game is not necessary to be designed for educational purpose in order to make learning happen from the player’s point of view. Squire (2005) argues that commercial computer and video games have mostly been overlooked by educational technologists. Such argument aligns with the constructivist belief of learning, which views knowledge not as information transmitted from a teacher to a learner, but rather as the result of the active engagement of the learner in the comprehension and conception of the information (Bradsford 1979). Looking at the constructivist belief of learning from the Information Systems (IS) perspective, computer games and their subset MMOG fall into the category of hedonic information system (Van der Heijden 2004), in which learning in a MMOG can be a process through motivating a player with an intention to learn and play the game individually and collaboratively.

According to motivational theories (Deci and Ryan 1985), motivation to play can be determined by two fundamental types of motivation, namely intrinsic motivation and extrinsic motivation. From the IS perspective, the area of research on users’ acceptance of information systems is mainly rooted in the Technology Acceptance Model (TAM) (Davis 1989), which explains user’s intention to use an information systems is affected by perceived usefulness, perceived ease of use, and perceived enjoyment. Based on motivational theories, Davis et al. (1992) further clarifies perceived usefulness as an example of extrinsic motivation, whereas perceived enjoyment is an example of intrinsic motivation.

Moreover, MMOG is more than single player participation due to its “massively multiplayer” nature, in which players’ participation can be motivated by his/her peers in the same team. According to cognitive learning theory, learning consists of two components — personal and social (Entwistle and Entwistle 1992). Player-to-player interactions in MMOG allow learning to occur not only individually but also collaboratively. In addition to individual engagement in the learning process, computer-mediated learning can be initiated and motivated at peer level through collaborative learning interaction (Alavi 1994).

With the recognition of the importance of peer motivations, learning intentions, collaborative interaction in game-based learning reported in the TAM and cognitive learning research, this study proposes two new constructs, *peer intrinsic motivation* and *peer extrinsic motivation*, and studies their effects on intention to learn individually and intention to learn collaboratively in the context of MMOG game-based virtual environment.

3 METHODOLOGY

3.1 Research Model

This study proposes two new constructs, *peer intrinsic motivation* and *peer extrinsic motivation*, and studies their effects on intention to learn individually and intention to learn collaboratively (See
Figure 1 for the research model, and Table 1 for the definitions of constructs). This study is set in the context of a MMOG game-based virtual environment, World of Warcraft (WoW). The reason for us to pick WoW because it is currently the best selling MMOG in the world with over 11.5 million subscribers worldwide (on 23rd December 2008, Blizzard Press Release: http://www.blizzard.com/us/press/081121.html).

</tbody>
</table>

Table 1. Definitions of Constructs

The concepts of peer intrinsic and peer extrinsic motivations for a team are new and form the core of this study. A thorough Google Scholar and online article database search did not show any prior work on these constructs.

In distinguishing intrinsic and extrinsic motivations for an individual, it is very important to note that motivation that comes from peers is counted as external factors, not on the game itself (that is being mainly studied in the current game research), but on knowing about team members’ enjoyment of the game in general (peer intrinsic motivation), and on knowing that team members achieving certain game rewards (peer extrinsic motivation).

3.1.1 Social Comparison and Intention to Learn Individually

This hypothesis is formulated based on Tesser and Campbell’s (1990) argument that the closer the relationship an individual is to someone, the more likely that envious comparison processes will occur. In the context of MMOG, players can be from the same team or belong to the same guild, fighting for the same goal in the same quest (a collective task). Transparency characteristic of MMOG allows players to read his/her peers’ values of attributes and observe their performance. Applying the concept of envy into the virtual environment of MMOG, feeling of envy will arise when one player perceives another player possesses more superior ability than his/her own.
Envy was seen to be helpful in motivating people to increase their performance in battle or civil competitions such as athletic contents. The effect of upward social comparisons on negative psychological reactions could be explained by the relevance of the superior target person as a role model (Lockwood and Kunda 1997). Consistent with this reason, the social learning literature has found that individuals tend to imitate others whom they perceived as being more successful and/or more highly rewarded (Bandura 1986).

In the MMOG environment, the feeling like “I wish I had what you have” is a result of social comparison between the player and his/her peers. Besides the negative feeling of envy, players may also appreciate the successful players of their team because their external rewards will be shared by the peers including the ones who envy others. In other words, in addition to envy that players focus on competition, players may also focus on helping behaviour and target for sharing of collaborative victory. To our knowledge, the amount of research is limited for this kind of peer extrinsic motivation, generated with the feeling of envy from upward social comparison process and collaborative victory, will motivate a player’s intention to learn on his/her own in order to differentiate him/her from his/her peers in a MMOG context. Therefore in this study, we stipulate that a MMOG player, who focuses on peer extrinsic motivation in the game-play process, will have a high tendency to learn on his/her own in the MMOG environment. Therefore, we have the following hypothesis:

Hypothesis 1: Peer extrinsic motivation to play will have a significant positive influence on intention to learn individually in a MMOG context

3.1.2 Knowledge Sharing and Intention to Learn Collaboratively

Kalling and Styhre (2003) comment on the relative lack of attention paid to the role of motivational factors that influence knowledge sharing behaviours. As reviewed by Bock et al. (2005) on the benefit of knowledge sharing, knowledge sharing can benefit individual, group and organization. As MMOG is a kind of hedonic information systems, some MMOG players may focus on the fun-aspect rather than productive-aspect of the game. In general, we may consider the benefits of knowledge sharing at three levels: individual fun, group fun and organizational fun, where group and organizational fun may belongs to our definition of peer intrinsic motivation. Individual fun is possibly an interesting area for investigation, however, this study focuses mainly on peer motivations and suggests further research on this construct.

According to studies of social capital and knowledge sharing, individuals will be motivated to contribute their knowledge in the community. Wasko and Faraj (2005) proposed two constructs that would affect individual motivation for knowledge contribution: (1) reputation and (2) enjoy helping. In order to share knowledge, individuals must think that their contribution to others will be worth the effort and that some new value will be created, with expectations of receiving some of the value for themselves (Nahapiet and Ghoshal 1998). These personal benefits or “private rewards” are more likely to accrue to individuals who actively participate and help others (Von Hippel and Von Krogh 2003).

In addition to enhancing their reputations, individuals may also receive intrinsic benefits from contributing knowledge. Self-evaluation based on competence and social acceptance is an important source of intrinsic motivation that drives engagement in activities for the sake of the activity itself, rather than for external rewards (Bandura 1986). Players may perceive that helping others with challenging problems is interesting, and because it feels good to help other people by solving their problems (Kollock 1999). Prior research in electronic networks suggest that individuals are motivated intrinsically to contribute knowledge to others because engaging in intellectual pursuits and solving problems is challenging or fun, and because they enjoy helping others (Wasko and Faraj 2000). Therefore, instead of focusing on comparing the extrinsic rewards of peers, a MMOG player who focuses on peer intrinsic motivation is likely to share knowledge and learn collaboratively through helping each other to learn in the MMOG environment, and therefore we have the following hypothesis 2:
Hypothesis 2: Peer intrinsic motivation to play will have a significant positive influence on intention to learn collaboratively in a MMOG context

3.2 Development of the Questionnaire

A survey design was used to investigate the aforementioned hypotheses. The literatures on behavioural intention and motivation are reviewed. Survey questions were constructed with reference to prior empirical work and modified to fit the context of this research. All questions were phrased from the perspective of current WoW players, and anchored on a seven-point scale from Strongly Disagree (1) to Strongly Agree (7).

Questions on peer intrinsic motivation and peer extrinsic motivation were drafted based on Work Preference Inventory (Amabile et al. 1994). These questions assessed intrinsic and extrinsic motivation in terms of work preference. Eight questions (four for peer intrinsic motivation; four for peer extrinsic motivation) were selected from the inventory and modified according to the definition of peer intrinsic motivation and peer extrinsic motivation from the perspective of current WoW players.

Questions on intention to learn individually and intention to learn collaboratively were created with reference to construct “behavioural intention” from Venkatesh et al. (2003). With reference to their original source, these questions are modified to assess one’s behavioural intention to learn within the next month. Eight questions (four for intention to learn individually; four for intention to collaborate) were created based on the definition of intention to learn individually and intention to learn collaboratively.

A total number of 16 items were generated for the validation process of the constructs. Conceptual construct validation was carried out following Moore and Benbasat’s (1991) card sorting procedure. Table 2 presents the measurement of items for the questionnaire.

Table 2. Measurement of Items in the Self-Reported Survey
3.3 Data Collection

This study utilizes an online survey website to collect data from current players of WoW. Players of WoW are invited to fill in the survey through online WoW communities, like game forums and corresponding network on Facebook. To guarantee the quality of respondents, raw data are filtered based on the following criterions:

3.3.1 World of Warcraft Experience

One “yes-or-no” question at the beginning of the questionnaire required the respondent to answer “Have you ever played World of Warcraft?” All respondents who indicated without experience in WoW will be filtered.

According to the design of WoW, players create their avatar by selecting race and class. Limited by the design, several classes are exclusive to certain races. Based on these rules of combinations, two questions are included in the questionnaire, which ask the respondent to select the race and the class of their strongest avatar. The combination of race and class will then be checked with the above rules. Those who fail this check, or indicate “others” in the selection, will be dropped for analysis.

3.3.2 Definition of Current Participants

Dependent variables of this research are intention to learn individually and intention to learn collaboratively (see Table 1 for their definitions). One question is added in the questionnaire and the subject is required to disclose “When was the last time you played the game World of Warcraft?”. Only those responses which indicate “within one day” and “longer than one day and within one week” will be used for analysis.

The survey received a total number of 94 valid responses from current active players of the WoW after corresponding data filtering procedure. Table 3 summarizes the demographic information of respondents:

Table 3. Demographic Information of Respondents
3.4 Data Analysis

The research model and hypotheses were estimated using 200 iterations of the bootstrapping technique in PLS Graph 3.00.

3.4.1 Measurement Model

The Average Variance Extracted (AVE) of PLS analysis attempts to measure the amount of variance that a latent variable component captures from its indicators relative to the amount due to measurement error, and so as to assess the convergent validity of the constructs. AVE values should be greater than the generally recognized .50 cut-off. The Internal Composite Reliability (ICR) of PLS analysis attempts to assess inter-item reliability, and so as to ensure internal consistency of indicators. Acceptable values of an ICR for perceptual measures should exceed .70 and should be interpreted like a Cronbach’s Coefficient Alpha. Table 4 summarizes the measurement model results with all ICR and AVE values satisfied the recommended values:

<table>
<thead>

Table 4 – Result of Confirmatory Factor Analysis

Discriminant validity indicates the extent to which a given construct is different from other constructs. To evaluate discriminant validity in PLS analysis, the square root of AVE for each construct should be higher than the levels of correlations involving the construct (Chin 1998). One criterion for adequate discriminant validity is that the construct should share more variance with its measures than with other constructs in the model (Barclay et al. 1995). Table 5 demonstrates discriminant validity with the square root of AVE for each construct is greater than the levels of correlations involving the construct.

Table 5 – Correlation between Constructs

The explanatory power of the structural model is evaluated by looking at the $R^2$ value of the two dependent constructs. Model testing is divided into two separated PLS analysis: (1) test of hypotheses, and (2) test of the full model. The first analysis tests the proposed hypotheses of this study, while the second analysis tries to validate the proposed research model by considering the other possible paths as full model.
3.4.2 Test of Hypotheses

**Hypothesis 1:** Peer Extrinsic Motivation to Play will have a significant positive influence on Intention to Learn Individually in a MMOG context

As shown in Figure 2, the $R^2$ value for Intention to Learn Individually is 12%. The proposed path between Peer Extrinsic Motivation to Play and Intention to Learn Individually is significant ($\beta = 0.34$, $p < 0.01$). Statistically, this result showed that Peer Extrinsic Motivation to Play had a significant positive influence on Intention to Learn Individually in a MMOG context.

**Hypothesis 2:** Peer Intrinsic Motivation to Play will have a significant positive influence on Intention to Learn Collaboratively in a MMOG context

As shown in Figure 2, the $R^2$ value for Intention to Learn Collaboratively is 22%. The proposed path between Peer Intrinsic Motivation to Play and Intention to Learn Collaboratively is significant ($\beta = 0.47$, $p < 0.01$). Statistically, this result showed that Peer Intrinsic Motivation to Play had a significant positive influence on Intention to Learn Collaboratively in a MMOG context.

3.4.3 Test of the Full Model

**Paths to Intention to Learn Individually**

The $R^2$ value for Intention to Learn Individually is 13%. As shown in Figure 3, for the links to Intention to Learn Individually, only the path between Peer Extrinsic Motivation to Play and Intention to Learn Individually is significant ($\beta = 0.24$, $p < 0.1$). The path between Peer Intrinsic Motivation to Play and Intention to Learn Individually is not significant. With the consideration of the full model, this analysis result shows that by including the path between Peer Intrinsic Motivation to Play and Intention to Learn Individually into the PLS analysis, it will not affect the existing significant path discovered in the first analysis.

**Paths to Intention to Learn Collaboratively**

The $R^2$ value for Intention to Learn Collaboratively is 23%. As shown in Figure 3, for the links to Intention to Learn Collaboratively, only the path between Peer Intrinsic Motivation to Play and
Intention to Learn Collaboratively is significant ($\beta = 0.38$, $p < 0.01$). The path between Peer Extrinsic Motivation to Play and Intention to Learn Collaboratively is not significant. With the consideration of the full model, this analysis result shows by including the path between Peer Extrinsic Motivation to Play and Intention to Learn Collaboratively into the PLS analysis, it will not affect the existing significant path as discovered in the first analysis.

Table 6. Comparison of Analysis Results

4 DISCUSSION AND IMPLICATIONS

4.1.1 Academic

For academic researchers, the study contributes to a better understanding of the motivation to play in a MMOG context. Hedonic information systems (i.e. MMOG) differ from utilitarian information systems in terms of reasons for use, and this study is one of the very few that has attempted to investigate the motivational drivers of user acceptance in a hedonic information system context. More specifically, this study introduces two new constructs, namely peer intrinsic motivation and peer extrinsic motivation to explain players’ behavioural intention to learn individually and collaboratively in the MMOG environment. Using the card sorting method and various validations in the data analysis, this study introduces items which are possible to assess the degree of peer motivations and intention to learn under the MMOG context.

Furthermore, unique characteristics of MMOG were put into the explanations of hypotheses in this study, and the results showed that a player’s perception on peer intrinsic motivations is associated with his/her intention to learn collaboratively, while the perception on peer extrinsic motivations is associated with his/her intention to learn individually. This study is one of the early attempts to associate characteristics of MMOG with peer motivational factors and learning intentions in a MMOG context, which may help to act as a theoretical foundation for further studies.

4.1.2 Educators

For education practitioners, the results from this study suggest that in a MMOG environment, players’ peer intrinsic motivation is associated with their intention to learn collaboratively while players’ peer extrinsic motivation is associated with their intention to learn individually. Although the scope of this piece of research does not take into consideration of the context of learning material that MMOG will deliver to the player, the result from this paper is suggesting that educators who want to adopt MMOG
as a platform will need to pay special attention on how they want to manipulate the peer motivational factors and learning intentions of the players from a psychological perspective.

4.1.3  Game Developers

Finally, according to cognitive learning theory, knowledge acquisition consists of two components — personal and social (Entwistle and Entwistle 1992). In the MMOG environment, a player’s intention to learn can also be categorized into intention to learn individually and intention to learn collaboratively. From the player’s point of view, the design of MMOG forces them to collaborate, and the struggle between the feelings of “envy” and “collaborative victory” may apply to the player from the psychological point of view. The design of the game interfaces should give reasonable expectation to each player on the number of experience points needed for promoting towards the next level, and what kind of spell that his/her avatar can cast (with preview demonstration on the effect).

4.2  Limitation of Study and Future Research Directions

The data of the presented study was collected using a survey method from MMOG players of WoW only. We suggest future research may conduct a broader survey and compare players of different MMOG. Also, in addition to a snap-shot of self-reflected data collection, a longitudinal study of individual online gaming behaviours is required for in-depth understanding of team dynamics in MMOG environment.

5  CONCLUSION

This study examines players’ intention to learn in a hedonic information system - MMOG. More specifically, this study investigates the roles of players’ Peer Intrinsic Motivation and Peer Extrinsic Motivation on both Intention to Learn Individually and Intention to Learn Collaboratively in MMOG environment. The results indicate that Peer Intrinsic Motivation to Play has a significant positive influence on the Intention to Learn Collaboratively, while Peer Extrinsic Motivation to Play has a significant positive influence on the Intention to Learn Individually. The results from this exploratory study also expand our understanding of the use of MMOG for collaborative learning purposes as well as its potential causes of threats like addictiveness rooted by players’ continuous “play-to-learn” and “learn-to-play” modes of engagement in MMOG.

CONSULTANTS’ EXPERIENCE OF REQUIREMENTS ELICITATION CONVERSATIONS – AN EMPIRICAL MODEL

Davey, Bill, RMIT University, 239 Bourke St Melbourne, 3001 Australia, Bill.Davey@rmit.edu.au

Cope, Chris, Latrobe University PO Box 199 Bendigo 3552 Australia, c.cope@latrobe.edu.au

Abstract

Research continues to show that poor requirements elicitation leads to costly information systems failure. We also know that the most information can be obtained by a consultant conducting conversations with clients. Research was conducted into consultants’ experience of these conversations. Twenty professionals involved in these conversations were interviewed and Phenomenographic analysis of all of the quotes within transcripts from these interviews was undertaken. The analysis resulted in a list of five distinctly different ways in which these conversations can be experienced by consultants. These are given the labels: domination, manipulation, problem resolution, negotiation and partnership. The labels are attached to a range of attributes where differences were found in the data. These well defined categories of description allow us to structure professional development and to clarify future research efforts.
1 INTRODUCTION

In this paper we report research into the conversations between information systems (IS) consultants and clients that are part of requirements elicitation (RE). The research investigated the consultants’ experiences of the conversations. We intend the term “consultant” to be synonymous with “business analyst”, “analyst programmer” or “senior analyst”, among others. We use the term “conversation” where others might use “interview” to avoid confusion between the discussions between consultants and clients as part of RE, and the research interviews.

An early stage of developing an information system is requirements elicitation (RE). There is evidence to suggest that accurate requirements elicitation is difficult and that failure to elicit accurate requirements can cause considerable problems. Davis, Fuller, Tremblay, & Berndt (2006) found “accurately capturing system requirements is the major factor in the failure of 90% of large software projects” echoing earlier work by Lindquist (2005) who concluded ”poor requirements management can be attributed to 71 percent of software projects that fail; greater than bad technology, missed deadlines, and change management issues.” The cost of this failure is enormous. One study found that failed or abandoned systems cost $100 Billion in the USA alone in 2000. (Browne & Rogich, 2001) Not only does a failed system cost money, but fixing mistakes made at the requirements elicitation stage accounts for 75% of all error removal costs (Urquhart, 1999).

What is the nature of the communication between humans that occurs during requirements elicitation? We are indebted to Davis, Dieste, Hickey, Juristo, & Moreno (2006) for a fairly comprehensive review of the research into requirements elicitation techniques. Some findings were:

- Interviewing is cited as the most popular requirements elicitation method
- Structured interviews gather more information than unstructured interviews
- Unstructured interviews gather more information than sorting and ranking techniques

As structured interviewing appears to be the most common RE technique, an important step in avoiding IS development failure would seem to be conducting effective, structured conversations between consultants and clients.

Significant research has been put into improving RE conversation performance. One area of research starts with theories of cognition. Cognitive science tells us that communication between people is hampered by the limitations of human cognition and by problems that arise when communication needs to be conducted by language (Bolloju, 2004, Kim & Peterson, 2001, Siau & Tan, 2005, Gaines, 2003, Hudlicka, 1996)

Several researchers have taken these theories and tried to find techniques for overcoming the cognitive difficulties. The most recent of these was research (Pitts & Browne 2007, Browne & Rogich 2001) which found that using procedural prompting strategies designed to overcome cognitive difficulties produced more meaningful requirements than other prompting techniques. Cognitive science has been used to investigate stopping behaviour. That is, the elicitation of requirements must eventually be called to a halt. Some work has been done by Pitts & Browne (2004) in determining what factors lead to a best choice of when to stop.

The process of requirements elicitation is often seen as a process of mutual education of consultant and client. Some researchers have taken current educational theory and applied it to improving elicitation. Efforts include applying collaborative elaboration – from education theory (Majchrzak, Beath, Lim, & Chin, 2005), mental imagery (Zmud, Anthony, & Stair, 1993), collaborative requirements negotiation (EasyWinWin) and group communication theory (Grünbacher & Briggs, 2001).

Despite this knowledge of possible improvements in RE conversations, they continue to fail. If we accept that the consultants are those who must perform better then we must conduct studies of the way consultants relate to RE conversations. An understanding of this relationship will enable us to
influence these conversations. One powerful way of approaching variation in experience is the method of phenomenography. This method has been used to examine the way in which students experience computing concepts (Bruce et al., 2004; C. Cope, 2002; C. Cope, 2006; Stoodley, Christie, & Bruce, 2004), the way in which teachers experience teaching computing, (C. Cope & Ward, 2001; Kinnunen, McCartney, Murphy, & Thomas, 2007; Levy & Ben-Ari, 2007; Lund & Baker, 1999) in experience of professional management skills (Chen & Partington, 2006) in experience of nursing (Falk, Wahn, & Lidell, 2007; Frank, Asp, & Dahlberg, 2009; Johansson, Swahn, & Strömberg, 2007; Jormfeldt, Svedberg, Fridlund, & Arvidsson, 2007) physiotherapy (Larsson & Gard, 2006) patients families (Schröder, Larsson, & Ahlström, 2007; Widang, Fridlund, & Martensson, 2007) and doctors and sick listing (Swartling, Peterson, & Wahlström, 2007). A consistent finding of phenomenographic research is that a phenomenon can be experienced in a limited number of qualitatively distinct ways. These distinctly different ways of experiencing a phenomenon are described as an outcome space of a number of categories of description. These categories give us a viewpoint of the relationship between a person and a phenomenon that has been shown to be useful in making decisions about affecting that relationship.

2 RESEARCH APPROACH

The aim of this research is to uncover the relationship between consultants and RE conversations. To do this we ask the question “What variation exists in the way that consultants experience RE conversations?” An understanding of this variation will help us understand how to influence conversations.

2.1 Participants

In qualitative research based on interviews sample populations are normally drawn until no more variation exists in data being obtained. In phenomenography this is often taken to be about 20 to 25 interviews. Twenty consultants with professional experience in RE conversations were interviewed. All the initial interviewees were involved in dealing with clients in various stages of implementing systems after the signing of a contract between the consultancy company and a client company. To broaden the scope further targeted people were approached. This included analysts offering information system services within a company, those involved in a range of industries including manufacturing, financial services, government services and retail services. The stages of interaction between consultant and client addressed specifically avoided sales conversations and those situations where a product was being implemented with no concern for the specific requirements of the client. Äkerlind (2005 p103) advises demographic variation so as to maximise the chances of variation of experience of the phenomenon as possible. The selected population showed variation in the attributes: place educated, country of residence, age, years of experience (0 to 30 years), current job, scope of projects (company internal to consultancy), company type, industry (NGO, government, retail, banking, manufacturing, insurance) and gender. It must be emphasized that the method does not cross match outcomes from interviews with these demographic variables.

2.2 Interviews

The phenomenographic approach seeks to control the extent to which the interviewer imposes a view on the interview (Bowden & Green, 2005). Interviews were semi structured and started with an introduction that was consistent and defined RE conversations. A closed question “describe your last RE conversation” was asked and followed by open questions. Analysis of these interviews examines transcripts for meaning rather than textual content, so open questions are designed to explicitly reveal the meaning within initial statements of the interviewees, using only words they had introduced. Interviews ran for between 45 and 90 minutes. Each interview was then transcribed.
2.3 Data Analysis

The data gathering and analysis was conducted using a phenomenographic approach as described by Marton (Marton, F. 1981, Marton, F., & Booth, S. 1997) and detailed in Bowden & Green (2005). The result of this analysis should be a description of the variation of experience of the phenomenon expressed as a set of related categories of description of the phenomenon. Each transcript was entered into a specially written database program. The transcripts were examined for every statement that contained some meaning and these quotes were separated from the transcript with a link maintained to the original text. The links allowed quick checks of each quote in context to ensure that meaning was not mistaken due to fragmenting the transcript. Quotes were organised according to any aspects of the phenomenon they addressed. Variations in meaning and structure were allowed to emerge from the quotes through an iterative process comparing quotes, possible dimensions of the phenomenon showing variation and the original transcripts. Multiple iterations of this process were conducted as recommended by Bowden and Green (2005). In each iteration candidate categories are postulated and then checked against the data to see if each candidate category sensibly reflects meaning found in the data. A sensible set of categories is also one where some structure exists that is supported by quotes. A useful category would describe a range of aspects where the quotes indicate that a view of one aspect is related to a view of another aspect, or where there is a simple logical connection between aspects. It is important when constructing categories to ensure that they come from meaning within the data rather than the researcher finding quotes to support a previously determined structure. Candidate categories were compared with the data as a whole to ensure that significant ideas in the transcripts were represented in the categories. Categories were continually checked against whole transcripts to make sure no important sections were not represented in the outcome and that the categories truly reflect things said by the participants without leading from the researcher. When this check was done it was found that each respondent had several views of the phenomenon. The categories reflect variations in views rather than variation between respondents.

Links between the categories were analysed and presented in the results. An indication that a candidate category be preferred was the existence of several quotes directly supporting the category and quotes explicitly relating dimensions within a category.

3 RESULTS

As a result of analysis of the data five distinct categories of description of experience of RE conversations emerged. These categories are a way in which the researcher seeks to create a logical structure from the variation found in the data. Many concepts were described in the transcripts, each exemplified by multiple statements showing a range of meanings. For convenience of reporting these have been summarised through three dimensions:

- **aspects of the requirements** – what is their nature, how are they seen in terms of the aim of the conversation, where they come from.

- **aspects of the people** - how the consultant sees themselves, how the clients are seen and the relationships between them such as power and personal relationship.

- **aspects of the dynamics** of the conversation are experienced in a range of ways. Concepts such as behaviours that are noticed, strategies that are employed and how progress is experienced. This aspect has been called ‘The act of the conversation’

Each category reported here includes a single transcript quote, chosen from several available, that helps show the distinction between the name of a category and the meaning within the data. The categories are reported in order. The categories range from a collection of many of the simple ideas to a collection of the complex. There is no intention to imply any other order. It should be noted that
categories arise from all the quotes, not from particular people. A phenomenon can be experienced by the same person in different ways at different times. This was clear in the data.

3.1 Category 1: Domination

In this category a requirements elicitation conversation is experienced as a conflict in which the consultant understands the client's requirements, predetermines a set of requirements, and the conversation is needed to have the client sign off on those requirements. Increasing power is a significant aim of the conversation. The consultant has an understanding, possibly from previous projects, of the business and what an envisaged information system could do for the business. The conversation is required since the client is required to sign off the requirements, even though they probably will not understand them or their significance.

- 'Because [person in the consulting company] had come to a certain conclusion about the ‘right’ way forwards with this, which was effectively one based around conflict. It was based around ‘let’s set up an us against them trial, and see who wins’

The requirements are seen as an absolute, determined by the logic and experience of the consultant. Quote 104 “So we’ll tend to chair it, which does give us the power to direct the conversation in ways we want” is typical of data showing that the consultant goes into a requirements conversation with a clearly defined idea of what the outcome should be.

The people are seen as clients, who are a potential nuisance that need to supply a sign off on a document so that the project can proceed, and consultants with a clear idea of the whole project and a need to get started. Examples that illustrate this include the quote “this person [the client] had very, very limited knowledge on information technology, how it works, what sort of benefit it can bring to an organization” This typical quote shows that the consultant sees the client as not being capable of expressing any opinion of the requirements of the system. This is indicative of the external horizon where the consultant sees their company as having exclusive knowledge of what is ‘good for the client.’

The dynamics are seen as presenting to or teaching the client what it is that the client needs. Data often showed that the consultant had a metaphor with other professions where the knowledge of the professional was the source of progress in the conversation. For example Quote 61 “you know, your doctor can prescribe you a medicine, and you’re comfortable to take it without knowing exactly how it works. And so, ah, yeah it’s usually around getting, getting the client comfortable that they’ve, that you’ve got a solution that they’re happy with.”

3.2 Category 2: Manipulation

In this category a requirements elicitation conversation is experienced as a manipulation of the client so that the client agrees to the requirements that the consultant wants to fulfil. A conversation is experienced as convincing the client that our requirements are what they need. The client need not understand the requirements, but must be convinced that they are desirable.

- So that they [the clients] can get a feel of, they [the clients] obviously don’t understand but the fact that they are asking a question like that, they don’t understand what our [processes of the consulting company] processes are, and so we explain a bit about our processes so that hopefully they [the clients] both, get the answer to their questions and feel happy, but also have a better understanding of what we [the consulting company] do

The requirements are seen as an absolute, determined by the consultant, that the client must be taught enough about to make them happy to sign off. Quote 112 “I [the consultant] think another important
way of explaining something like that is trying to distinguish between the important technical bits that someone is trying to understand and the technical bits that if you don’t understand you still get enough out of it. I guess that relates back to breaking things down into pieces and treating the bits that aren’t that important as a black box” shows that the outcome of a conversation can be experienced as a client that understands the requirements to some extent. The object is to make the client feel happy and considered, rather than bullied into signing off.

**The people** are clients, seen as having power but no worth and consultants with technological expertise who are responsible for getting client “buy in” on the requirements. Quote 14 “what I’ll [the consultant] normally do is I’ll prepare presentations, and what I’ll generally do is I’ll target, um, I’ll try and target it at their [the clients] level.” This type of data shows that consultants can see the elicitation conversation as one way. It also demonstrates a view of the conversation as a “presentation” of the predefined requirements. Clients are seen as students of the requirements, needing to be talked to at a level that enables them to understand.

**The dynamics** are seen as using feedback from the questions asked by the client to both create an understanding of the requirements and convince them that they are valuable. Quote 6 “The problem that we had was that he kept trying to sort of ah, cut us off” indicates that the consultant sees it frustrating if the client attempts to make input into the conversation. The conversation actions are seen as directed by the consultant driving towards an acceptance of the requirements.

**How does this differ from domination**

This category sees the conversations as two way exchange. The client expresses lack of knowledge and the consultant gives that knowledge of the requirements in a teaching like situation. Much of the data talks about how the consultant learned from their own teachers as how to explain and react when people demonstrate lack of understanding. Although, as in Domination, the requirements are brought to the conversation, in this category it is seen as important that the client understand them rather than take on faith that they are good for the business.

### 3.3 Category 3: Problem Resolution

In this category a requirements elicitation conversation is experienced as the exchange of information. The conversation is aimed at both finding the things the client needs to implement their part of requirements and the things the consultant needs to know about the business that make this implementation different from previous examples. Conversations are needed to provide each party with the information needed to put known solutions into a new situation

- “since everybody in the meeting have, know each other really well, so we shoot straight into the problems that we were facing last couple of weeks. And pretty we are pretty much just brainstorming ways of solving those problems”

**The requirements** are seen as a problem that must be solved. Requirements are mutable but easily satisfied by finding an answer. The main problem is understanding what the client really means. This is often done by starting with a solution (consultant provides a set of requirements) and finding ways in which the client is confused by or is happy with that solution. Quote 72 “There are some audiences that are, don’t like taking your suggestion or solution. Ah, and so for those audiences you might just state your understanding of the problem and not state the suggested solution. You still should think about what that suggested solution is so that it still makes sense as you discuss the problem, and perhaps where you lead the discussion.” Much of the data actually uses the word “problem” when describing why a RE conversation was initiated. In early interviews the subject was asked ‘are you sure this was a requirements interview?’ which they affirmed. It seems common, especially where agile methods are being used, that requirements are seen to arise from inspecting initial models. While agile methods do not presume this approach to requirements, some views of the process see no distinction between a problem resolution session and requirements gathering.
The people are seen as having power through their understanding of how the business operates but an ignorance of technology. The client often has a confused idea of what they want. This is often expressed as a problem with a prototype, or a problem with the expression of the requirements.

The dynamics are seen as determining the problem and ensuring that the solution presented solves the problem. Quote 305 “What the purpose of it is, how they imagine using it and I don’t know, what data or whatever they imagine supplying to it and sometimes they don’t understand all the pieces so we need to talk about what those pieces actually are and trying to join that up to something we can actually develop on the software side if it’s a software issue” Data of this type indicates that requirements arise when the client starts to try to answer questions such as ‘can you give me the data that the system needs for input?’ or ‘what should the report look like?’ Again a clear picture of what the system should be has been brought by the consultant, but the RE interviews are seen as allowing the client to make changes based on things they find wrong with the initially proposed solution.

How does this differ from Manipulation: If Manipulation involves a set of requirements that must be communicated then Problem Resolution sees RE as a process of refining requirements as clients encounter problems.

3.4 Category 4: Negotiation

In this category a requirements elicitation conversation is experienced as a type of negotiation. Outcomes are seen as dynamic and power is used but not created. The data shows sets that can be described as “Negotiation.” This category is defined as “a negotiation where the client attempts to specify as much as possible for the needs of the company and the consultant tries to narrow this to things that can be done with the skill set available and within the price for the project.” The consultant is focussing on finding a way of dealing with each request of the client in a way that fits within the needs of the consultant. The conversation consists of finding requirements in the context of “some things we can effectively charge the client for, and some things we can’t effectively charge the client for.”

- “they know that most of the things that I [the consultant] suggest to them [the client] are to the best of their interest, as long as they are not conflicting with [the consulting companies’] interest.”

The requirements are seen as an outcome to be negotiated within the general conditions of a contract or memorandum of understanding. This shows in data that clearly indicates a view of the conversation as a bargaining based on expressed wants against cost. For example Quote 101 “trying to detail where we’ve put on some limitations or where we think something is not realistically possible or and in some cases and this is something we have been dealing with recently actually um giving some different options and different if its something we are going to charge for separately then you know different options and different levels of cost for each option”

The people are seen as clients with business needs and consultants with a set amount of resources allocated to the project. Quote 330 indicates the existence of a distinct category of experience “they know that most of the things that I suggest to them are to the best of their interest, as long as they are not conflicting with [the consultant’s company] interest.” This quote shows that the consultant sees, within a conversation, two ‘sides’ with separate interests. The conversation, then, includes finding things for the project that will have a good business outcome for the client without compromising the interests of the consultant.

The dynamics are seen as conducting a give and take type of negotiation until a “fair” outcome is reached. Quote 269 paints this starkly “just because the client asks for it doesn’t mean a) they should want it and, b) that we want to do it. Um, because the, the starting point of most people in the industry is ‘I should please the client’. And I guess, one level of thought of what that means - if the client asks for something I should say ‘we can do it, and we will do it’. Um, and so that’s the largest most common mistake, that staff make. Um, some of that’s completely selfish, there is nothing about um providing the, what the client actually needs. It’s about some things, some things we can effectively
charge the client for, and some things we can’t effectively charge the client for. Our staff aren’t doing us a good service if they’re doing a lot of things for clients that we can’t charge the clients for.”

This piece of data contains a host of rich detail:

“just because the client asks for it” indicates that the client is seen to have expectations and requirements that the consultant is not aware of in advance. “just because the client asks for it” also indicates that the consultant see the conversation as a two way communication where the client can and will ask for requirements. “doesn’t mean a) they should want it” shows a view of the conversation as a place where the client can ask for things and the consultant use their expertise to comment on the business sense of the proposal. “doesn’t mean a) they should want it and, b) that we want to do it” shows that the consultant is aware of a ‘position’ that he/she is to hold during the conversation that ‘represents’ the interests of the consulting company (or group), as opposed to purely technical considerations.

In explaining this in detail with “some of that’s completely selfish, there is nothing about um providing the, what the client actually needs. It’s about some things, some things we can effectively charge the client for, and some things we can’t effectively charge the client for. Our staff aren’t doing us a good service if they’re doing a lot of things for clients that we can’t charge the clients for.” The consultant is suggesting that the principal focus of the conversation is negotiating a set of requirements within the commercial boundaries of the contract. This is very distinct from a view where the needs of the business system are central. This can be seen as an example of the difference between a logical and physical design problem.

How does this differ from Problem Resolution: In problem Resolution the consultant is still the originator of the requirements. In Negotiation the two parties are committed to a project through a contract, memorandum of understanding or other instrument, but the project is not tightly defined except in business terms. The requirements are specified through the RE process. The consultant knows what they are capable of and the client knows what the business needs. The conversation then becomes a negotiation where the client attempts to specify as much as possible for the needs of the company and the consultant tries to narrow this to things that can be done with the skill set available and within the price for the project.

3.5 Category 5: Partnership

In this category a requirements elicitation conversation is experienced as partnership. Mutually respected parties attempt to determine requirements that will create a greater whole. A conversation is experienced as a step towards finding the real needs of the business and the possible ways in which the consultant can help the business meet those needs. For example the technology and previous implementations are not seen as a constraint. Many of the quotes supporting this category talk about the project as being a small step in an ongoing relationship between the parties.

• “that means they [the client] understand it so deeply, that they can understand where to apply it in a way that you haven’t told them.”
• “what the purpose of meeting them [the client] right now is and um what we are going to be looking to do with them in the future and so what sort of things we should be talking to about when we are meeting them”

The requirements are seen as a short term goal of several discussions. The project is seen as the next step in a developing an ongoing relationship to benefit both parties. Quote 85 “Um try to learn a bit of background about the clients business and um what their specialties are, what their ah focus is and um what their objectives in business”

The people are seen as equals with developing relationship and knowledge of each others needs and abilities. Quote 270 “if something seems a bit crazy, don’t say, don’t just silently say ‘yeah sure, we’ll do that’, say ‘I’m having trouble understanding why you want X, can you give me some more
information about what’s motivating X’. Or if can, if you think you understand what’s motivating it, suggest an alternative solution that achieves what they want and isn’t crazy. Um, and repeat that process until either you understand why they want the thing that didn’t make any sense to you, or, they, together you’re asking for something different that does seem to make sense.”

The dynamics are seen as developing and deepening the relationship between the individuals and their organizations. Quote 167 “Well, if we tell them what they need, um, so in other words, if we thought something was a stupid thing for them to need, we don’t do that, we do the thing we thought they should do. If they’re right that they did need that, they don’t get ‘it’. Um, if we’re right, and they did need it, um, then at the very least someone’s ego has been dented at the client, that we said ‘no, that’s not what you need, this is what you need’. Whereas if we ask them questions until they ask us for something different, they asked us for ‘something’. And so it’s still, you know it, you know that, I mean they’re not dumb. They don’t, they don’t think oh yeah that way was my idea, this way it was still my idea.”

How does this differ from negotiation: Negotiation sees requirements in the context of a single concrete project. Partnership envisages a continuing relationship between the two companies or groups. Conversations seen as partnership do not drive towards an outcome, nor are they seen as failures if a set of requirements does not arise as a clear document. RE is seen as a genuine attempt to find business solutions rather than software specifications. It was found that partnership is an experience of RE across all the types of companies involved in the data collection.

4 DISCUSSION

The aim of this research was to understand variation in the way a consultant can experience an RE conversation. The researcher found that five categories of description of ways of experiencing RE conversations could be constructed. These have been given the labels domination, manipulation, problem resolution, negotiation and partnership. The labels have meaning only to the extent that they reflect a general meaning from the variation in attributes. The categories can be given an ‘order’ based on complexity of meaning in the many quotes that relate to each category. Let us consider each category and look at what correspondence there might be between the category, commercial reality and the literature.

Domination, in terms of the variation in description is the simplest of the categories. That is, the view of the client, the view of the requirements and the impact that the conversation might have on them, is very limited. In a commercial context, however, it could be seen as the quickest way of concluding the RE phase of a project. If clients are seen as having no possibility of contributing to the project, then wasting time on interviewing them is silly. Requirements must be signed off at the start of a project so that project completion can be proven later. Urquhart (2001) found evidence of similar domination in one case where the client saw the consultant as “hiding behind a veil of expertise.”

Manipulation also sees requirements as something simple that are a product of the experienced and professional consultant and hence the process of carrying on a conversation is only complicated by the problem of convincing someone of what seems an obvious given. Again, in a commercial context, it could be motivated by the belief that people not committed to a project can make trouble later if they feel no involvement.

Problem Resolution may seem a different type of approach, but still starts with a consultant supplied project specification. It recognises that new clients can have different ways of doing things that we did not anticipate, that circumstances can change and that the requirements of a perfect solution may need to adapt to circumstances.

Negotiation is a label that should not be confused with the generally accepted meaning. Negotiation has been defined as “an interpersonal decision-making process by which two or more people agree how to allocate scarce resources” (Thompson, 2000). Adair & Brett (2005) found empirical evidence
of a four stage model of negotiation relational positioning, problem identification, solution generation and finding agreement. Our data does not reflect this process oriented view of negotiation, but does reflect the responses one would expect when two people are concentrating on the issue of allocating scarce resources.

Our negotiations are about two parties coming to the table with a set of wants on one side and a set of skills on the other. The conversation tries to find ways of meeting as much of the wants as possible within a set price. It seems to arise from the commercial imperative. The client has signed off to pay for a generally described service, which has been identified in enough detail to form the basis of a contract. The consultant comes to the requirements phase with a general project brief including a contract price and a general description that must be fulfilled. The consultant knows that the system to be specified in the requirements must be built within the price agreed. The consultant also knows that the client must be satisfied with the final system in order for there to be continued business. These constraints on the conversation are consistent with a focus on the conversation as a bargaining or negotiation where these two positions must be traded off in a result5ant requirements document.

Partnership does not recognise the boundaries of a project as being impermeable. RE conversations are seen as being in a much larger picture where new projects arising may be as important as finishing the current project.

5 IMPLICATIONS FOR THE PROFESSIONAL DEVELOPMENT AND FURTHER RESEARCH.

As indicated in the literature section above, much of the research into conducting RE conversations has been directed at the conversations, that is directly focussed on the phenomenon. An examination of the ways that a consultant can experience conversations allows us to gain insight into how consultants can be influenced to improve conversations. This has great implications for the IS development profession as consultants may be experiencing conversations in a way not likely to lead to accurate requirements. Future research will be needed to describe different approaches to conducting interviews. It should now be possible to relate different approaches to different quality of RE outcomes and to relate different approaches to different experiences of RE conversations. If we can analyse the experiences that are likely to lead to higher quality outcomes this would inform our professional development efforts.

6 CONCLUSION

The data showed five distinct ways in which consultants can experience RE conversations: As Domination, Manipulation, Problem Resolution, Negotiation or Partnership. Each of these categories is a label standing for a complex set of variations in the way RE conversations are experienced.

On one level we have a hierarchy of categories of description. Ranging from Domination where the consultant is not even interested in the client understanding the requirements through to Partnership where the requirements are seen as part if an evolving relationship between the consultant and the client. In this case the hierarchy might be useful to a consultant, but different commercial environments make a particular view more relevant than others. Many of the participants in the research mentioned the problem of scope creep. In this phenomenon a price is decided for a project, but in what is supposed to be a process of refining requirements, new requests are introduced that gradually move the project well beyond what was originally quoted. Things a client can see as minor changes and improvements can eventually grow to be far more costly than the whole original project. Hence a Domination view of what requirements elicitation could be the most effective way of avoiding scope creep and could be seen as the most valuable and mature way of looking at requirements elicitation. Each category has its own value. The outcome space describes five different ways of seeing an RE conversation.

SERVICE SCENARIOS - A SOCIO-TECHNICAL APPROACH TO BUSINESS SERVICE MODELING

Lars Bækgaard, Aarhus School of Business, Aarhus University, Haslegårdsvej 10, DK-8210 Aarhus V, Denmark, lab@asb.dk

Abstract

The paper presents and discusses the notion of service scenarios. A service is work done by a service executor in interaction with a service consumer. A service scenario is a model of a service system and the roles that are played by the actors that participate and interact during the execution of a service. The model represents the roles and the interactions between the participants. Service scenarios can be used to model specific services and the roles played by human beings and IT systems in the execution of services. The use of service scenarios is demonstrated by means of a case study in a public library. The case study indicates that service systems should be understood as socio-technical systems in which service executors and service consumers co-create value in mutual interaction with each other and with a set of shared resources.

1 INTRODUCTION

The notion of a service is a business concept. Service-orientation represents an organizing principle in which everything that is offered by a business is thought of as a service. The inherent perspective of service-orientation is that a process is viewed as a set of services that is offered to consumers that interact with the services. Each service may itself be the consumer of other services. Thus, a process is viewed as a network of interacting services and consumers. Businesses engage in such networks of services.

Services have been studied in areas like, say, financial services (Dandapani 2004; Homann, Rill et al. 2004; Kumar and van Hilegersberg 2004; Mallat, Rossi et al. 2004; Pan and Vina 2004; Tas and Sunder 2004), health care services (Tan, Wen et al. 2005), and public services (Goldkuhl 2006; Janssen, Gottmaker et al. 2008). Across such diverse areas the service concepts share the common characteristic that a service is work done by one party for another party. Shared services are support processes from which many parties can benefit (Ulbrich 2006).

The purpose of the paper is to present the notion of service scenarios that can be used to model services as socio-technical systems in which service executors and service consumers co-create value. It is necessary to model services in order to design and deliver them in an effective, efficient, and flexible manner. As pointed out by Quartel et al. (2007) the service concept “[…] has so far not been used to its full potential due to the lack of a comprehensive conceptual framework.

Service scenarios support conceptual modeling of existing and envisioned business services and they facilitate analysis of and creative discussions about business services. They can be used to represent the internal structure of a service provider, a service executor, a service consumer, and their shared resources. And they can be used to represent the potential relations (including interactions) between provider, executor, consumer, and shared resources. A service scenario can be viewed as a model that represents a service as a socio-technical work system. The executor of a service can be composed of a combination of human beings and IT systems.

The use of service scenarios is illustrated by means of a case study at a library in which they have been used to model information search services. The case study indicates that service scenarios can be useful tools that can create insights into services and their strengths and weaknesses. Consequently,
service scenarios can support service design. Furthermore, the case study indicates that service scenarios highlight important aspects of services. For example, service scenarios can be used to highlight service systems as socio-technical systems in which service consumers and service executors collaborate to co-create value.

The paper’s contribution is a modeling approach that can be used to model the architecture of services and their execution. Existing service modeling approaches like COSMO (Quartel, Steen et al. 2007) and process modeling approaches like role-activity diagrams (Aburub, Odeh et al. 2007) and BPMN (White 2004) can be used to model service processes. Service scenarios can be used to supplement such approaches in terms of models of structural and architectural aspects of services that highlight the human and material operants that participates in service executions.

Section 2 contains a discussion of business services and their characteristics. Section 3 presents and discusses the notion of service scenarios. Section 4 reports from a case study in which service scenarios are used to model information search services in a public library. Section 5 discusses our findings and some of their implications. Section 6 concludes the paper and suggests directions for future research.

2 BUSINESS SERVICES

The value propositions of businesses and their information systems can be viewed as services that offer support to consumers’ creation of value (Cherbakov, Galambos et al. 2005; Maglio and Spohrer 2008). Such services can be viewed as systems in which actors act upon resources in interaction with service customers (Maglio, Srinivasan et al. 2006). In general, it is too simplistic to claim that a service creates value for its customer. Value cannot be created without active participation of the consumer. Service-orientation is inherently a consumer-oriented approach (Rust and Miu 2006) in which value is co-created (Maglio and Spohrer 2008; Payne, Storbacka et al. 2008; Vargo and Lusch 2008a; Vargo and Lusch 2008b). Services are about doing something together rather than merely producing output (Vargo and Lusch 2008a). Service science is the study of service systems, which are dynamic value co-creation configurations of resources, i.e., people, technology, organizations, and shared information. This implies that the client does much more than receive the result of a service in a passive manner. The client’s actions contribute to the value-creation in a significant and active manner (Maglio and Spohrer 2008).

Service execution implies many types of interaction between service consumers, service executors and shared resources. Service execution is carried out in networks of interacting services in which actors dynamically switch roles and act as executors in some situations and consumers in other situations (Quartel, Steen et al. 2007). Every service system is both a provider and client of service that is connected to other services in value chains, value networks, or value-creating systems (Maglio and Spohrer 2008). A business can be viewed as a network of federated service—a network of interacting components (Cherbakov, Galambos et al. 2005).

Maglio et al. (2006) characterize a service in terms its provider, client, and target. The provider is comprised of an individual or organization and technology operated by or owned thereby. The client is an individual or organization. The target is a part of reality that must be transformed or operated on by the provider for the sake of the client. The target may be comprised of a combination of people, businesses, products, and information. This implies that the effect of a service should be explicitly understood in terms of the changes made to a target that is shared by the provider and the client.

Vargo and Lusch (2008a) focus on the competences of the involved operants, i.e., the actors that participate when a service is executed. This implies that the human and technological actors that act as operants must possess the knowledge and skills that are necessary for the execution of a service.

Mathiassen and Sørensen (2008) characterize services as socio-technical systems in which “… configurations of people and IT artefacts interact to support work, communication, and decision-
making. A service is executed by a combination of human beings and IT systems (Sheth, Verna et al. 2006; Vidgen and Wang 2006).

OASIS’ reference model for service-oriented architecture defines a service as the performance of work by a service provider for a service customer (OASIS 2006). A service provider may be the consumer of other services. A service enables access to capabilities using a prescribed interface that comprises the specifics of how to access the underlying capabilities. There are no constraints on what constitutes the underlying capability or how the service provider implements the access mechanism. Thus, the service could carry out its described functionality through one or more automated and/or manual processes that could invoke other available services.

The implementation of a service is typically hidden from the service consumer except for information and behaviour that are visible through the service interface and information that is required by service consumers to decide whether a given service is relevant. This is known as service information hiding (Barros and ter Hofstede 1998). The effect of executing a service is a realization of one or more effects in terms of delivered information and/or changes to a shared state.

COSMO is a modeling framework that views a service as common interactions, the results of these, and their mutual dependencies (Quartel, Steen et al. 2007). Services are seen as units of composition and decomposition. This implies that services are executed in interaction with other services in networks in which the interactions are constrained by mutual dependencies. A service has a structure, a potential behaviour, and available information that influence its potential interaction.

Kaner and Karni (2007) characterize service systems in terms of the following nine aspects. (1) The customers that benefit from or are affected by the system. (2) The goals and meaning of the system. (3) Inputs to the system; (4) Outputs from and effects of the system. (5) Processes that are performed by the system. (6) Human enablers, i.e., human resources that own and/or operate the system. (7) Enablers, i.e., physical and technological resources which aid in operating the system. (8) Information and knowledge resources that support the system. (9) The system’s environment.

3 SERVICE SCENARIOS

The following service characteristics can be derived from the preceding discussion of service concepts. (1) Service is delivered by means of provider-client interaction. (2) Humans and technology may act as operants. (3) Value is co-created when provider and client interacts. (4) Services are executed in networks of interacting services. (5) The provider and the client interacts with a shared service target. (6) Service execution is constrained and supported by the interaction structures of the involved services. (7) Service execution is constrained and supported by the operants skills, potential behaviour, and available information. (8) Service implementations are hidden for clients by means of service information hiding.

A service scenario is a model of a service system and the roles that are played by the actors that participate when a service is executed. Service scenarios can be used to model specific services and the roles played by human beings and IT systems in the execution of services. Service scenarios are based on characteristics (1)-(6) with the following modifications. The provider-client relation has been extended to a provider-executor-client relation. And the label “target” has been changed to “shared resources”. Service scenarios do not focus on characteristics (7) and (8). Figure 1 illustrates the elements and their potential relations (including interactions) in our conceptual service scenario model.
Figure 1. Conceptual service scenario model

Service scenarios distinguishes between service providers that offers services and service executors that executes services in order to emphasize that a given service can be executed in several different ways by different executors.

A provider possesses the right to offer the service and make it available to potential consumers. A provider and a consumer may negotiate conditions for access to services. This may include service-level agreements about price, payment, availability etc. The provider hires, rents, builds, buys and organizes executors. If the executor is a person the provider may hire him or her. If the executor is an IT system it may be bought, rented or constructed by the provider.

An executor may be a set of persons and/or IT systems that performs the work necessary to execute a service in interaction with a consumer that may be a set of persons and/or IT systems that uses the service.

Providers, executors and consumers may share and interact with a set of resources. The executor and the consumer perform a series of actions when a service is executed. The executor may interact with executors of other services relative to which it acts as a consumer. The effect of executing a service is a realization of a set of effects in terms of delivered resources and/or a change to a set of shared resources.

Example. A bank (provider) may offer a service like “withdraw money from account” to bank customers (consumers) that have accounts in the bank. The execution of the service may include actions like “check pin code” and “dispose money” and it may be performed in different ways with different executors. (1) The service may be executed by software (executor) that interacts with the customer through a web interface. (2) The service may be executed by a bank employee (executor) that interacts directly with customers (consumers) in one of the bank’s departments. (3) The service may be executed by a combination of software (executor) and an ATM machine (executor) that interacts with bank customers through an interface through which the customers can insert bank cards and enter, say, pin codes and amounts. Bank customers share access to accounts (shared resources) with the bank and with the executors of withdrawal services. When a “withdrawal” service is executed the executor changes the balance of the involved account.

4 CASE STUDY

We have performed a case study at a Danish public library in which an information search service offered to library users was changed (Bækgaard, Jørgensen et al. 2007). The case study was carried out as a part of a change project at the library. The purpose of the change project was to identify and implement possible improvements of the library’s mediation of library user’s search for relevant information.

During the project a number of analysis and design activities were carried out. User simulations were used to establish understandings of the current activities. Models of current activities were used to capture aspects of these understandings. Formulation of future stories and brainstorms were used to create visions about changed activities and new ways of using IT systems. Modeling of future situations were used to capture aspects of the visions.

During the modeling process a variety of modeling approaches were used. Service scenarios were found useful because they highlight the socio-technical aspects of services and because they highlight the types of interactions that occur when services are executed. Service scenarios were used in the case
study to model interaction between consumer, executor and shared resources. The provider was not modeled in the case study.

4.1 Current service

The purpose of the service is to satisfy a library user’s information needs. The service is based on communicative interaction between a library user and a librarian that engage in a dialogue about the library user’s information needs, potential search terms, and the relevance of search results. The library user expresses needs for information and the librarian uses his understanding of these needs to search for information resources via library databases and Internet-based search engines.

The diagram in Figure 2 represents the current information search service in terms of a service scenario. The rectangles represent the roles that can be played by human actors, IT systems, and other resources that participate when the service is executed. Elements can be decomposed. For example, the executor is decomposed into a librarian and a set of search systems (database, Internet search engine, etc.). A star means that an element can occur as multiple instances simultaneously. For example, more than one search result can occur at a given point in time. The arrows represent potential interactions between the elements.

![Service Diagram](image)

**Figure 2. Service 1 – Current service**

The current service is executed by a combination of a librarian and a set of search systems. A library user formulates information needs and the librarian asks questions in order to improve and verify his understanding of the information needs. There is an important element of cognitive activities in which the user and the librarian tries to understand the problem at hand and in which they consider possibilities and reflect upon formulations and search results.

The librarian uses his understanding to formulate parameters and queries to one or more search systems. The search results are available for both the librarian and the library user as shared resources. The library user and the librarian analyze and evaluate the search results. The librarian uses “cut & paste” to copy relevant resources from an answer to the resource collection—a text document in which the selected resources from search answers are stored. Near the end of service execution the librarian formats the resource object and enhances it with clarifying comments.

The effects of the service can be characterized as follows. The librarian adds information resources (URLs etc.) that are relevant for the library user to a resource object that contains the selected resources. For example, if an Internet search engine returns one or more relevant URLs these are added to a digital text document using cut-and-paste, they are written on a piece of paper or the screen shots on which they appear are printed. This implies that a resource object is comprised of unrelated digital text documents and pieces of paper.

4.2 Future service

The current execution of the current service has a number of disadvantages. The librarian creates the resource object by means of cut-and-paste, handwriting, and printing operations. Consequently, the librarian creates the semantic integration of the search systems and the resource object. The IT systems
do not support the integration in any way. Also, the resource object itself is heterogeneous and it is not internally integrated because it is composed of hand-written notes, printed screen-shots, and digital text documents. Finally, it is very difficult to reuse past search results and share the information represented by these among librarians and library users.

The diagram in Figure 3 represents the future service in terms of a service scenario. The future service is based on the same interaction between library user and a librarian as the current service (Figure 2). However, the execution of the future service differs from the current service in the following ways.

![Diagram](image.png)

**Figure 3. Service 2 – Future service**

First, a piece of software called resource manager is added to the executor. The librarian uses the resource manager to select and modify resources from search results. This resource object is a structured and integrated digital document that contains structured resource items. When the librarian and the library user identify a relevant information resource (for example a URL) the librarian can use the resource manager to add selected resources to the resource object. Rather than using cut-and-paste or paper-and-pencil to maintain the resource object the librarian marks the relevant part of a search result and tells the resource manager to add the selection to the resource object that is now structured and fully digitalized.

Second, the resource manager stores the final version of the resource object in a resource database that can itself be used as a search system. Consequently, the librarian can use the resource database as a memory of past service executions that may be searched and reused in future executions of the service.

Apart from simplifying the recording of relevant resources the resource manager integrates the otherwise non-integrated search systems. The service has two effects. It produces a resource object with information resources and it records this object in a resource database that can itself be accessed as a search system.

From the librarian’s point of view the service is improved because of the better integration of search systems and the resource object. From the library user’s point of view the service is improved because of the integrated, digital resource object that is delivered as the effect of the service.

### 4.3 Future service without librarian

It is possible to give library users remote access to the resource manager and thereby to offer a version of the service that is executed solely by IT systems. This implies that a library user interacts directly with search systems and with the resource manager. Consequently, the library users must perform the cognitive activities that are performed by a librarian in the previously discussed versions of the service.

The diagram in Figure 4 represents the future service without librarian in terms of a service scenario. The service scenario in Figure 4 differs from the service scenario in Figure 3 in one important way.

---

**Proceedings ECIS 2009**
The library user interacts directly with search systems and with resource manager without the mediating help of a librarian.

![Diagram](image)

Figure 4. Service 3 – Future service without librarian

From the librarian’s point of view the service frees him or her from serving all library users. This may give the librarian more time to other work activities. However, a potential disadvantage is that the resource database may be “polluted” by resource objects of low quality. From the library user’s point of view the service can be executed any time without the library user having to be present at the library. However, a potential disadvantage is that the library user cannot benefit from the knowledge and experience of librarians.

5 DISCUSSION

We have used the library case study to demonstrate how service scenarios can support modeling of important socio-technical aspects of business services. In this section we discuss some of the implications of the case study.

5.1 Implication #1 – Co-creation

*Service scenarios can be viewed as media for experiments, reflections, and decisions about different levels of co-creation.*

The future library service (Figure 3) cannot be understood solely in terms of value created by the librarian for the library user. The library user plays several active roles and participates in and contributes to the value-creating process. The library user interacts with the librarian by means of oral communication in which the user expresses information needs and the librarian suggests interpretations of the needs and asks clarifying questions. An isolated librarian cannot fully determine the value of an information search service. Only the library user can determine this value. And the librarian’s ability to use search systems in relevant manners is fully dependent on input, guidance, and evaluation from the library user.

The librarian uses a software system called a resource manager to create and maintain a shared resource called resource object that is visible to the library user. The resource object contains the (partial) result of the librarian’s search for information. During this search the librarian uses search systems like databases and Internet search engines. The results of these searches are visible to both the librarian and the user in terms of a shared resource called search result. The library user participates actively in the evaluation of search results and the resource object.

The level of co-creation is different in the two services that involve librarians in comparison to the service without the librarian. In the latter service the library user has to do all the cognitive work without any help from librarians.
5.2 Implication #2 – Interaction

*Service scenarios can be viewed as media for experiments, reflections, and decisions about external and internal interactions in service executions.*

The essence of a service is work performed in socio-technical networks in which human beings, technology, and other material objects interact.

COSMO is a framework that supports modeling of executors (COSMO uses the term provider) and consumers (COSMO uses the term user) in a manner that highlights interactions between the two parties (Quartel, Steen et al. 2007). Service scenarios and COSMO actor models are similar in the sense that they represent interactions between consumers and executors.

Service scenarios highlight the three interacting parts of a service system (executors, consumers, shared resources) as a socio-technical work system. Furthermore, service scenarios support modeling of internal interaction in executors. In the library case this corresponds to the internal interaction between librarians and search systems.

COSMO do not support modeling of interaction with shared resources and it does not support modeling of internal interaction in executors. Without the structural picture offered by service scenarios it is hard to use a COSMO model to communicate an overview of the totality of elements and interactions in a service system. In particular, it hard to identify the shared resources and their roles in interactions from a COSMO model.

5.3 Implication #3 – Shared resources

*Service scenarios can be viewed as media for experiments, reflections, and decisions about the roles and use of shared resources during service execution.*

All the three studied library services share the characteristic that the library user and the service share two important resources, i.e., the resource objects and the search results. A search result is an intermediate resource that is used by the librarian and the library user to evaluate potential information resources and their relevance for the library user. The resource objects contain the information resources that the library user finds relevant with respect to his information needs.

COSMO supports modeling of interaction between executor and consumer but it does not support modeling of shared resources. Use cases share this characteristic. Use cases are somewhat service-oriented in the sense that a use case is a part of a system that is supposed to create value for its user (Jacobson, Booch et al. 1999; Kruchten 2000). However, use cases are based on insufficient assumptions that does not support rich modeling of a consumer’s interaction with resources, human actors, and technology.

5.4 Implication #4 – Mediated interaction

*Service scenarios can be viewed as media for experiments, reflections, and decisions about the use of IT systems to mediate interaction.*

Interaction can be mediated by IT tools. In the library case the new services are based on a software component called a resource manager that mediates interaction between human beings and the resource objects that contains the information resources that are created during service execution. In the future service (Figure 3) the librarian interacts with the resource object via the resource manager. In the future service without librarian (Figure 4) the library user uses the resource manager.

Service scenarios support modeling of different levels of direct or mediated interaction and hence they support decisions about how the elements of a service system should interact. For example, they can be used to answer questions like the following. Should communication between librarian and library
user be face-to-face as implied by the scenarios in Figure 3 and Figure 4? Should it be possible for librarians and library users to interact via an IT system?

**Implication #5 – Human beings versus IT systems**

Service scenarios can be viewed as media for experiments, reflections, and decisions about the roles played by human beings and technology in service execution.

The library case study represents two types of services that are commonly used by businesses. The service without librarian (Figure 4) is executed solely by IT systems whereas the other service versions are executed by a combination of human beings and IT systems.

Service scenarios can be used to evaluate advantages and disadvantages of including human beings in service execution. The service scenario in Figure 3 indicates that the communication between librarian and library user has a value-creating potential in the sense that librarians can use their experience and broad access to search databases to improve the quality of the information search. The service that is modeled in Figure 4 does not have this potential but it offers a more flexible service access to library users that can operate without depending on the availability of librarians.

The future service without librarian can be called a self-service in the sense that no human beings participate in the execution. The library user is the only human being that participates when the service is executed. This does not imply that the library user does all the work. The involved IT systems perform work as well and there is a significant amount of co-creation occurring during the interaction between the library user and the IT systems.

**Implication #6 – Service networks**

Service scenarios can be viewed as media for experiments, reflections, and decisions about the roles of services in broader service networks.

The future service (Figure 3) and the future service without librarian (Figure 4) contain two interacting service executors. In both cases the resource database acts as a service for the storing of information resources. Also, the search systems in all three services can be viewed as services even though they have not been modeled as such. In the future service from the library case (Figure 3) the librarian acts as an executor intending to serve the library user in some situations. And the librarian acts as a consumer that uses a service executed by a resource database.

**Implication #7 – Processes and information**

Service scenarios should be supplemented by tools for modeling of information structures and processes.

Service scenarios do not support modeling of information structures and processes. COSMO uses information models to represent the information that is used during service execution. A process model represents the dependencies and temporal organization of the actions. COSMO process models may be used to model the processes executors and consumers. COSMO use information models to express preconditions for the actions of consumers and executors.

6 **CONCLUSION**

We have presented and discussed the notion of service scenarios. A service scenario represents a business service and the participating actors and their shared resources as a socio-technical activity system. Three types of actors participate. A provider offers a service to a set of consumers. An executor performs the work that constitutes a service. A consumer benefits from a service and co-creates its value. When a service is executed a consumer interacts with an executor in the sense that they communicate and exchange resources. The consumer provides input that is necessary for the executor in order to perform the service. The effect of a service can be characterized by the delivered resources and changes made to shared resources.
The use of service scenarios have been demonstrated by means of a case study in which information search services have been modeled by means of service scenarios. The case study demonstrates that service scenarios highlights some of the essential characteristics of business services as socio-technical systems characterized by co-creation, interaction, shared resources, mediation, human participation, and networks.

Future work includes more case studies in which the notion of service scenarios is evaluated and improved. In particular, studies of more complex services than the studied library services are needed in order to evaluate the advantages and disadvantages of service scenarios. We are currently studying medical e-consultations in which patients can communicate with and seek advice from doctors through dedicated web sites. And we are planning a study of consultancy services in farming.

Also, future work includes analysis of process modeling languages and approaches and evaluation of their relevance for modeling the processes of consumers and executors. This includes analysis and evaluation of languages like BPMN (White 2004), EPC (Dehnert 2002; Lübke, Lüecke et al. 2006), action-oriented modeling (Ågerfalk and Eriksson 2004), action diagrams (Goldkuhl 1996), event-activity diagrams (Bækgaard 2004; Bækgaard 2007), action-oriented development (Rittgen 2006), role-activity diagrams (Ödeh and Kamm 2003), resources-events-agents diagrams (Poels, Maes et al. 2007).

7 ACKNOWLEDGEMENTS

We would like to thank the anonymous referees for their valuable and constructive comments and we would like to thank The Danish Strategic Research Council (NABIIT) for support to the eGov+ project.

Abstract

In this paper we report on an empirical study on requirements engineering of hybrid products. Hybrid products (often also referred to as product service systems) – a combination of product, software and service elements – are an emerging trend on the market. Companies intend to offer holistic solutions for customer problems and not single products. The development of hybrid products differs from the development of “classic” products because of the high-level of technological integration of the elements that hybrid products consist of, the interdisciplinarity and the different lifecycles of their single components. We have conducted fifteen expert interviews to explore current practices in requirements engineering in three industries developing hybrid products: automotive, IT-consulting and system integrators, and medical technology. Our results show that most components of hybrid products are developed independently from each other. Based on our empirical insights we have identified requirements and challenges for the design of an integrated requirements engineering process for hybrid products.

Keywords: requirements engineering, hybrid product, software, hardware, service, empirical study, product-service systems.

1 INTRODUCTION

The success of a manufacturing company is directly related to the success of its products on the market. And the success of a product on the market depends on its capability to meet the needs and wishes of customers and environment (Beiter et al. 2006, Lindemann 2006, Nuseibeh and Easterbrook 2000). These points are essential for the development process. The development process is also affected by factors such as shortened development and production time, as well as cost pressure (Lindemann 2006, Spath et al. 2001). Further, the quality pressure – to produce better products than competitors – is growing. Thus, products are becoming more and more complex, and customer requirements are becoming more specific and leading to the development of individualized products and services built to individual customer needs (Abramovic and Schulte 2007). Customers have no interest in products or services per se, but they want their problems to be solved. The companies offer not a product, but a solution that is “a customized, integrated combination of products, services and information that solves a customer’s problem” (Sawhney et al. 2006). The distinction between products and services is disappearing and a so called hybrid product emerging (Berkovich et al. 2009, Knackstedt et al. 2008, Leimeister et al. 2009). In contrast to classical hybrid products consisting of a physical product and a service part, we also consider a combination of software and service, and software as a hybrid product (Böhmann and Krcmar 2007). Only by coordinating the development process of each element of hybrid products is it possible to achieve a customer’s benefit that is greater than if the product and service were to be bought separately (Schmitz 2008).
The development of hybrid products differs from the development of “classic” products because of the high number of sub-elements, the high level of technological integration and the degree of customer-integration (Leimeister and Glauner 2008, Pahl et al. 2006, Zellner 2008). The literature discusses products – physical products or software – and services separately. In practice, the development of products and services is also reported to take place separately (Leimeister and Glauner 2008, Müller and Blessing 2007).

One of the most important aspects in a development process is the successful handling of the requirements (Brooks 1987, Pohl 2007). Defining and handling the requirements is a very complex and difficult process. Deficiencies in this process often lead to costly project failures (Boehm et al. 2001). Keil (1998) finds that two of the three major risk factors in software development have to do with requirements engineering (RE). RE is especially important for hybrid products which consist of elements with different life-cycles; for example, hardware and software are developed by different disciplines, namely product, software and service engineering. Another aspect is hybrid products aiming at solving specific customer problems. Thus, the RE of hybrid products have to show and consider the different views of the involved disciplines on the RE, and also provide the customer-orientation and coordinated development. For the successful development of hybrid products, well-founded knowledge about the interdependencies of different characteristics of these products, their value-enhancement and the resulting output quality are necessary (Leimeister and Glauner 2008). Thus, it is a very gainful step to develop integrated RE for hybrid products.

This paper presents and discusses practice requirements for the RE process for hybrid products. In the study we first analyzed the literature on product, software and service engineering. Then we conducted a series of expert interviews on RE for hybrid products in practice. We collected empirical data from fifteen interviews in three industries – automotive, consulting and systems integrators, and medical technology. These interviews were the basis for our definition of the requirements and challenges for the design of the RE process for hybrid products from practice.

2 RELATED WORK

To understand the RE for hybrid products, it is important to comprehend what hybrid products are. It is necessary to understand the RE in general and to know how the RE is performed in the three disciplines of product engineering, software engineering and service engineering.

2.1 Hybrid Products and Software

Hybrid products consist either of physical products or software or a combination of these elements and service-components (Becker and Krčmar 2008, Beverungen et al. 2008). There are two main reasons why software is an essential component of hybrid products: First, implementation and consulting activities are very often combined into service bundles (Bonnemeier et al. 2007). Second, the importance of software is growing in general. For example, in the field of embedded systems, producers find that software development often takes more than 50% of the total development costs (Baskerville 1999). In the automotive domain it accounts for 20% to 40% of the production costs (Bender 2005). Today, software is not only a part of the product, but an indispensable part of it: Functionality realized by software cannot be replaced by hardware. Also, the value creation of modern systems relies on software (Liggesmeyer and Rombach 2005). On that account, the strengthened integration of the software development in the overall development process is necessary.

2.2 Requirements Engineering in general

RE is a discipline for handling the requirements, and is an essential part of the development process. Software engineering has already defined a profound understanding of RE as consisting of requirements elicitation, analysis, negotiation and validation. Change management and traceability of requirements are also parts of RE. Several studies illustrate that faulty implementations of the RE
process have an impact on the overall development process (Finkelstein and Dowell 1996, Hall et al. 2002). Failures arising during the RE process resulting in substantial costs for their elimination, especially in the latest phases of the development process (Boehm and Basili 2001, Pohl 2007). The process of RE is one of the most difficult phases of a development process (Damian and Chisan 2006). RE has to involve different stakeholders – users, customers, managers, domain experts, standards, laws, etc. – in order to get the requirements (Cheng and Atlee 2007).

The following two sections discuss each of the following phases of RE: requirements elicitation, requirements analysis, requirements documentation, requirements validation, and change management and traceability.

2.3 RE in Product Engineering

This section describes some aspects of the RE in the domain of product development. Our primary source of information was the top-10 textbooks, according to the amazon.de/amazon.com sales ranking (accessed on 09/17/2008). With the focus on the RE process, we selected only the books describing process models for product development (Ehrlenspiel 2002, Lindemann 2006, Pahl et al. 2006). These books contained useful references to other sources, which we then analyzed (Ahrens 2000, Jung 2006, Kruse 1996, Ulrich and Eppinger 2003, VDI-Richtlinien2221). To cover the latest developments in this area, we analyzed the journal articles of the years 1997 to 2008 and conference proceedings from 2002 to 2007. The Chair of Product Development of the TU München (http://www.pe.mw.tum.de) provided us with a list of relevant journals and conferences. The results of the analysis are presented below.

Requirements elicitation: The main source of requirements is the customer; other sources are legal documents, standards, existing systems, etc. In product engineering (PE), checklists are a widely used technique to elicit requirements (Ehrlenspiel 2002, Pahl et al. 2006). Most analyzed conference-papers and journal articles present minor improvements of existing methods for elicitation. The importance of the customer for a successful product development is emphasized by nearly all approaches, but is restricted to the first phases of the RE process (Jung 2006).

The main task of the requirements analysis is to derive technical requirements from customer requirements. The technical requirements have to be detailed, solution-independent and in a quantified form (Ahrens 2000). Most analyzed conference-papers and journal articles present variations of the QFD method or put their focus on the management of functional requirements.

Requirements analysis. This has the task of resolving conflicts between requirements. Lindemann (2006) and Kruse (1996) purport that it is important to prioritize requirements to resolve conflicts and to define the focus of the development.

Requirements documentation. This requirement is very important for the development process, as misunderstandings and misinterpretations are often caused by inadequately documented requirements. Most approaches agree on the basic rules on how requirements are to be formulated: solution-independent, unambiguous, positive formulation, etc. (Lindemann 2006, Ulrich and Eppinger 2003).

Requirements validation. The main goal of requirements validation is to ensure that the requirements express the product as the customer needs it. The analyzed approaches describe only the subtasks of checking the requirements for completeness and consistency.

The importance of RE for successful development processes has been recognized in product engineering, but it is often seen as merely the initial step of the development process where the customer places the order. Due to the nature of hybrid products, this view of RE is not sufficient. Hybrid products need an even stronger customer orientation, often leading to customer integration (Leimeister and Glauner 2008, Zellner 2008). Services and software are parts of a hybrid product, but the RE in product development mentions neither the integration of services, nor the parallel development of them. Interdisciplinary products and the integration of software development into the product development are handled only marginally.
2.4 RE in Software Engineering

RE is a discipline within software engineering “about defining precisely the problem that the software is to solve” (Cheng and Atlee 2007). We have selected the approach of Sommerville and Kotonya to show the main aspects of RE. This approach defines the phases of RE and takes into consideration the parallel and iterative execution of individual RE phases (see Figure 1).

![RE process according to Sommerville/Kotonya (1998)](image)

The activities of traceability of requirements and change management are also parts of RE. The following sections discuss the phases of RE and the role of the stakeholders in the RE process.

Requirements elicitation. Requirements elicitation is the first phase in the RE process. This activity is defined as “understanding of the goals, objectives, and motives for building a proposed software system” (Cheng and Atlee 2007). It aims at identifying the problem that needs to be solved (Nuseibeh and Easterbrook 2000). For a successful elicitation, it is necessary to consider all different stakeholders (Sommerville and Kotonya 1998). The most popular techniques are: interviews that can be defined as a discussion about the system in the development with different stakeholders, workshops based on a group discussion, scenarios showing interactions in the developing system, and observations and brainstorming (Aurum and Wohlin 2005, Pohl 2007, Somerville and Kotonya 1998). Prototyping can also be used to elicit requirements (Arnold et al. 2003).

Requirements analysis and requirements negotiation. In this phase the requirements are to be concretized. Afterwards the stakeholders negotiate on these requirements. The goal of the negotiation is to solve the conflicts between the requirements, to specify a set of consistent and complete requirements, and thereby to satisfy all stakeholders (Aurum and Wohlin 2005, Somerville and Kotonya 1998).

Requirements documentation. Documenting the requirements is a basis for other RE activities (Pohl 2007). The requirements and the changes of the requirements are to be documented carefully. The common art of documentation is the natural language documentation. Pohl (2007) suggests model based forms of requirements documentation, for example with UML.

Requirements validation. The process of validation means to ensure that “models and documentation accurately express the stakeholders’ needs” (Cheng and Atlee 2007). Boehm (1984) purports that validation should answer the question, “Am I building the right product?” The techniques applied for validation are reviews based on reading and analyzing the requirements, checklists, prototyping and walkthroughs (Pohl 2007, Somerville and Kotonya 1998).

Change management and traceability. Change management has to verify and evaluate changes of requirements and then to examine its impact for the system in development (Somerville and Kotonya 1998). Thus, change management has to guarantee that the proposed change is documented and analyzed, the costs for the implementation are checked, and the change can be realized. Another aspect
is traceability of requirements describing “the life of a requirement, in both a forwards and backwards direction” (Gotel and Finkelstein 1994).

We conclude that RE of software engineering is well elaborated, but not directly applicable to hybrid products. For example, hardware is seen as system context and therefore as unchangeable. The integration of services into the product is not considered.

2.5 RE in Service Engineering

Gill (2004) and Burr and Stephan (2006) define service engineering as follows: service engineering is the systematic development and organization of services by deploying engineering methods, practices and by using tools of the engineering design field. The focus of this paper lies in the use of appropriate methods and instruments.

In the literature there are some different views on service engineering:

- Burr and Stephan (2006) basically see service engineering as the process of developing services. The first step is to collect the ideas in a systematic and effective way. Afterwards the ideas are evaluated and the most auspicious ones selected and documented. Thereafter the requirements are elicited for which the needs and wants of all potential users have to be regarded. The last step is to design the service by defining the following information: technical goals, market goals, etc.

- Schmitz (2000) suggests that service engineering is handled in large parts by marketing divisions. According to him, RE for service engineering is a task that is carried out by qualitative marketing research. To elicit the requirements, the customer should imagine the service and should then express a hypothetical evaluation.

- Ramaswamy (1996) defines services as transaction processes. He separates the quality of a service into quality of service design and quality of service delivery. The service design consists of various steps. The step “Defining Design Attributes” realizes the RE in which the key-customers are identified and their expectations and requirements elicited and prioritized. It appears that RE for services is intended, but no precise methods are provided.

- A process model eliciting customer requirements during a “concept phase” is suggested by Schneider et al. (2006), but no methods are proposed for this activity.

Even though there are several process models for service engineering, they contain no applicable methods. Most approaches agree that it is necessary to elicit the requirements for the services and that the customer is the main source of these requirements. All in all, the role of RE in service engineering remains vague.

3 RESEARCH METHOD

In the literature review described above, we found that in the context of RE, hybrid products were not treated as a single unit. We identified several problems regarding the RE of hybrid products in different disciplines. To solve these problems, we conducted a series of semi-standardized expert interviews. The goal of these interviews was to capture current practices in RE in industry and to collect the requirements of an integrated RE for hybrid products. In the course of the study we interviewed fifteen experts in companies within the trade automobile, medical technology, consulting and system-integrators industry, who were involved in the design of hybrid products. These companies produced products consisting of parts that were typical for hybrid products. We perceived experts to be those employed in the field of RE or those who handled the requirements because of their position, such as project managers or business managers.

We selected three premium manufacturers from the automotive industry and six companies from the top-25 IT-consulting and system-integrators in Germany (http://www.luenendonk.de/it_beratung.php) of the consulting and system-integrator industry. From the medical technology industry, we selected four companies in which we had contacts. Table 1 shows the characterization scheme according to (IfM 2002).
The interview partner selection relied on theoretical sampling, which is suitable for studying problems that are not understood or not fully understood (Glaser and Strauss 1967).

The interviews were carried out between June 2008 and October 2008. Three interviews were carried out by telephone, and twelve were face-to-face. Table 2 gives a summary of the positions held by the interviewees.

Table 2  Companies

The interview guideline was structured according to the phases of RE as defined in software engineering (Aurum and Wohlin 2005, Somerville and Kotonya 1998). In our analysis we paid attention to the activities of each phase and to the methods applied there. Further, we were interested in the cooperation and interdisciplinary work of the involved disciplines and the role of the customer for the RE process. Another aspect which furthers staying in connection with the RE and with the communication with the customer is prototyping. Davis (1992) posits that using a prototype for the understanding of a problem or a solution helps to improve communication between the customer and the developer. The companies were also asked about the role of the RE in the service development and the integration of services in the development process.
The developed interview guideline was split into the following subject areas: general information about the company and the role of the interviewee, general information about the companies’ RE, all phases of RE (elicitation, documentation, analysis, negotiation, validation and verification), change management, prototyping, and integration of services (with a special focus on the composition of service- and product development).

The interviews were recorded when it was technically possible and only if the interview partners were in agreement. The records were then transcribed and analysed using Mayring’s (2007) techniques.

4 FINDINGS

This section summarizes the main results of the interviews. We take a look at each phase of RE as defined in the previous sections. The RE process in general, prototyping and the integration of services are described in greater detail.

Requirements Engineering process: Thirteen (out of 15) of the interviewed partners have an iterative process for RE that relies basically on models suggested in the literature. Only 2 of the interviewed partners do not have an iterative RE process since they deal with maintenance projects and use a change-request process. A minority of companies have a continuous requirements management: they not only keep records of the change requests, but also keep the requirements documentation up-to-date.

In software engineering, the development is usually done in multiple releases. The first release realizes the basic functions. In the development of the second, learning-effects take place and additional functions are realized. By developing in incremental release, the risk of the overall project is minimized.

All companies see the customer as the main source of requirements. A customer can be an external client or an internal department of the same company. Most companies distinguish between internal requirements and laws/standards. In the field of medical technology, the companies rely heavily on market analysis to elicit requirements, a field in which laws and regulations are particularly important.

Two interviewees reported that existing systems were an important source of requirements and needed to be analyzed thoroughly. All companies distinguished between functional and non-functional requirements. Nine (out of 15) of the interviewees reported that in the majority of cases the changes concerned functional requirements. In contrast, only 4 (out of 15) considered the majority of changes to be in the non-functional area. Two (out of 15) were unable to give detailed statements about changes.

Requirements elicitation: All interviewees reported using workshops and interviews to elicit the requirements. Only one interviewee reported observing the users to elicit requirements. Two (out of 15) of the interview partners did not have an explicit elicitation phase because they received the prepared requirements from their customers. The prevalent problems during the elicitation were that the stakeholders did not express their requirements clearly and the different stakeholders had different goals regarding the system in development. A further problem was the different understanding of the requirements by the stakeholders and the developers. In many cases the customer has unrealistic visions regarding the time and costs of the development.

Requirements analysis: With respect to requirements analysis, 14 (out of 15) of the interview partners had a process model. Only one company had no analysis phase since they received sufficiently detailed requirements from their customers. Two interviewees used tools to support the analysis. Three interview partners prioritized the requirements according to a “must-have/should-have/nice-to-have” scheme. The priorities were assigned according to law restrictions, financial aspects and the importance of the requirement for the customer. According to the iterative development described earlier, it is also possible to postpone the requirements until a later release. Only one company did not prioritize the requirements.
Requirements documentation: All interview partners used office tools to document the requirements, and thus the requirements were documented in natural language. Most interview partners used templates that precisely defined the structure of the requirements. One interview partner used EPKs (Scheer 1997) to document the business processes. For documentations, special tools were also used: five (out of 15) of the interviewees used Doors, two (out of 15) used CaliberRM. Two (out of 15) had other tools supporting the RE, especially the documentation. Twelve (out of 15) interviewees reported using Office-tools, among others, for the documentation of requirements. Office-tools have the big-disadvantage of not supporting multi-user operations and not supporting version-control. These tools were thus not adequate for the requirements management in large interdisciplinary projects.

Requirements negotiation: All interview partners reported conflicts between requirements, the reason for the conflicts being that customers and contractors held different views on the developed product. The common methods of resolving the conflicts were negotiating and holding workshops. The following aspects needed to be considered when resolving conflicts: dates, costs, and performance if the requirements were to be realized. Only one interviewee stated that conflicts were impossible because he had a consistent set of requirements from his customer.

Requirements validation has the task of asserting that the developed solution conforms to the requirements. The decision that requirements needed to be realized was taken mostly by customers. The realizing company only gave recommendations. If the company saw that it was impossible to realize a requirement, the customer was consulted. In the area of medical technology, the validation is mandatory by law.

Change management: Most interview partners used the change-request process to manage changes of requirements. This process was used when new requirements were added and when existing requirements were changed. Customers often dictated how the change management process was to be done. The expenditures for new requirements and changes were fixed in advance. When deciding whether a change-request should be realized, costs factors and time factors needed to be considered.

Prototyping: Prototypes are predominantly used to communicate with customers. The main audience for prototypes was therefore the customer and other stakeholders. The most common form of prototypes were Mock-ups created on paper or with office-tools. Two interviewees also used software-prototypes. The decision as to whether prototypes were to be used depended on the cost-benefit ratio due to the high cost of the development of a prototype.

Integration of services: Most companies of our study offered services offered in combination with software or the implementation of the software as part of the service. Typical services were management consulting and IT consulting. Management consulting included process- and organisation consulting, project management, business process analyses. IT consulting can include conception and implementation of software, security assessments, rollout tests, architecture definition, infrastructure and network consulting. An important aspect is the quality assurance of the services that is done according to standards.

5 DISCUSSION

On the basis of the interviews, we identified the following demands on the RE for hybrid products.

Coordinated RE process for the components of a hybrid product: The RE of the different components of a hybrid product has to be coordinated. Only by doing this can the requirements for the solution as a whole be found, and only in this way can the product fulfil the customer requirements for the entire solution. Today, the RE and development of single components, both in literature and practice, is done separately (Leimeister and Glauner 2008). This empirical study revealed that the RE for products and services was done in parallel but without coordination. The development processes do not consider the changes of single parts. Only at the end of the development the single components are brought together.
Support incremental development in releases: In software engineering, incremental development in multiple releases is applied successfully. For hybrid products, a support of incremental development is necessary. Incremental development has the advantage that the fully integrated product is tested not only at the end of the development, but also during different stages of the development process so errors can be found early and the risk of the product is minimized.

Improvement of the interdisciplinary work between the disciplines: The single disciplines often have only the overview over their own area and have a distinctive technical mindset with specific terms. These differences in terms and notions lead to interdisciplinary communication difficulties. It is very important to come to a common understanding of the problem to be solved. Only in this way is it possible to realize a harmonized communication between the disciplines. Therefore, already during the RE a common set of terms have to be defined in a glossary. That glossary is a central repository which will be used by all disciplines. In this way, misunderstandings are excluded a priori.

Stronger integration of the customer into the RE process: The interviews revealed that the customer was not sufficiently integrated into the development process. The companies did not entirely realize that the customer and his wishes were pivotal for the success of a product. The analysis of the requirements was done without customer-involvement. Thus, the requirements negotiation confronts the customer with concepts and terms of the realization domain which are unknown to him. On account of this, we requested the customer to be integrated into further RE processes, such as analysis and negotiation. The communication with the customer during these phases needs to be done in a way that it bears the context and domain of the customer in mind. Prototypes have good potential for this by visualizing the main concepts of the system in development.

Careful selection of stakeholders: The requirements on the developing system have multiple sources, such as customers, users, standards and laws. These sources of requirements are called stakeholders. “A stakeholder is a person or organization who influences the system’s requirements or who is impacted by that system” (Glinz and Wieringa 2007). The importance of selecting the right stakeholders is recognized by many authors (Pouloudi and Whitley 1997, Sharp et al. 1999). These authors agree that the selection of the right stakeholders remains a difficult area. A wrong selection of stakeholders or the selection of stakeholders which are not relevant for the system can influence the development negatively. At worst, phases such as requirements elicitation or negotiation have to be repeated. The selection of stakeholders is particularly important in the interdisciplinary context of hybrid products.

Better tool-support of the requirements management: Even though there are many tools for documenting and managing requirements, they are rarely used in practice. Instead, office tools (Excel, Word, etc.) are used.

Better traceability and a version control: In the context of interdisciplinary work, it is very important to have traceability and a version control system that offers the possibility of tracing which person changed a requirement and restoring old versions of the requirements documentation. The simultaneous work of different people on the requirements specification has to be supported. This so called multi-user capability is not realized by office tools. It therefore becomes necessary to introduce tools that are capable of coping with these demands. What is required is an analysis of whether tools on the market are sufficient or whether individual tools need to be developed.

Improving requirements negotiation: In highly interdisciplinary projects, the requirements negotiation phase is especially important because many different stakeholders with different backgrounds have to agree on a common set of requirements. This empirical study has shown that in practice, this phase is not supported by advanced methods. New approaches for the requirements negotiation using win-win methods and tool support by groupware (Boehm et al. 2001) could support this activity more effectively. What is required is an analysis of how these approaches could be adapted for hybrid products and introduced successfully.
Consideration of changes when the development is complete: Services should be provided after the development of the hybrid product is complete. The change of the product-lifecycle providing support has an impact on other aspects of hybrid products. The RE for hybrid products must be able to handle the requirements that emerge during the use of the product. Therefore, special methods and processes have to be developed in order to support further development of hybrid products.

Thorough documentation of the source of the requirements: The requirements on components of hybrid products are treated differently according to the discipline for which they are intended, and thus need to be documented for relevant disciplines.

6 OUTLOOK AND FUTURE STEPS

This study reports on 15 interviews carried out in industry in order to ascertain the state of practice of RE for hybrid products. This empirical study shows that RE for hybrid products is very important, but in practice the single components of hybrid products are developed independently, which is also true for the requirements. From these results, the requirements for the RE of hybrid products were derived. These requirements represent the main fields that have to be addressed in order to establish a comprehensive RE for hybrid products.

As a next step in research, we propose taking a closer look at the RE and development process of one single company. Based on our findings and this analysis, an integrated process for the RE of hybrid products should be developed. The single methods of the RE process also need to be adapted.

ACKNOWLEDGMENT

We thank the German Research Foundation (Deutsche Forschungsgemeinschaft – DFG) for funding this project as part of the collaborative research centre ‘Sonderforschungsbereich 768 – Managing cycles in innovation processes – Integrated development of product-service-systems based on technical products’. Abstract

Interorganizational systems (IOS) are a relatively common technology in mid-to-large organizations, and much research has been conducted into why firms adopt these systems, and the types of benefits obtained. However, IOS development projects, which is where the adoption becomes crystallized, and where specific ways to use an IOS are made possible, has been largely ignored and so are poorly understood. In this paper, we describe the IOS Motivation Model that explains how motivation determines project activities within the limits imposed by environmental affordances. We argue that motivation — the reason an IOS project is initiated — is a key determinant of the activities performed in a project and, through these activities, the types of business capabilities obtained. Two motivation types, activity control and market position, are explained in detail. Two case studies are then presented to exemplify IOS implementation projects that correspond to these two motivation types, and illustrate more clearly how motivation influences the pattern of activities performed in an IOS project. This is important for firms planning IOS implementation projects and for researchers in understanding the importance of IOS project-level motivation and its interaction with organizational strategy.

Keywords: Inter-organizational system, strategy, motivation.
1 INTRODUCTION

Interorganizational systems (IOS) are increasingly a standard component of the IT infrastructure for mid-to-large organizations. These systems automate information flows between organizations, typically to streamline the operations of a supply chain management system, but they may also be used to coordinate other boundary-spanning activities, such as product design. The large body of research into these systems has particularly looked at adoption influences and post-adoption impacts. Adoption studies explain the importance of selected environmental and organisational factors, such as partner pressure or IT readiness, on the intention to implement an IOS (Markus & Tanis 2000). Post-adoption impact studies, on the other hand, examine the relationship between system attributes (e.g. integration) and business outcomes (Subramani 2004). Few studies, however, have examined the intermediate step, the implementation process, which is where intentions, designs, and capabilities become actualized.

Understanding this intermediate stage helps explain IOS impacts, but involves more than just looking for general relationships between IOS characteristics and outcomes (e.g. integration and cost). As Subramani (2004) observes, to explain why particular outcomes are achieved, one must first know what the system was intended to achieve. A conceptualization of IOS projects that incorporates intentionality is therefore required. The idea that technologies are appropriated, proposed by DeSanctis and Poole (1994), is useful in this context because it helps to explain why diverse outcomes may be observed, even when the technology and the context of use are held constant.

We develop the concept of intentionality in IOS projects by proposing that project motivation determines project activities, and through them, business outcomes. Our theory builds considerably on descriptive exploratory work by Peffers et al. (1998), Rahim et al. (2006, 2007) and Smith et al. (2007) to provide detailed theory about the types of motivation that are possible, as well as specific project activities likely to be observed for these motivation types. In this paper, we focus on exchange (transactional) systems, a common type of IOS application. Collaborative IOS projects are described briefly, but an in-depth analysis is beyond the scope of this work.

This paper is organized as follows. We first theorize how motivation affects the implementation process for an IOS and describe in detail a typology of IOS project types, with that theory constituting the primary contribution of this paper. We then present two exemplar systems, in the form of case studies, to explicate these concepts. In other words, like Hirchheim and Klein (1989), cases are a used as a rhetorical tool rather than as a formal test of the theory. Finally, we describe the implications of this work for theory and practice, and directions for future research. The article provides a new vehicle for theorizing about the nature, purpose, and practice of information systems development.

2 THEORY AND PROPOSITIONS

Organisational motivation, the central concept in this theory, refers to the type of issue or deficiency that an organisation is trying to address when initiating an action. Motivation is related to technology capabilities in that a technology will usually be implemented to help solve a specific problem. IT solutions often provide capabilities beyond those specifically required, but one should not confuse project intent with technical potential. Project intent refers to the specific goals of a project, whereas potential refers to all capabilities regardless of whether they are actualised through the project.

Diverse reasons have been cited for using IOS technology, including enhancing cooperation, increasing bargaining power, improving process efficiency, and even survival (Johnston & Vitale 1988). These reasons are not surprising given the capabilities of IOS as a technology. Many reasons are “transactional” (in the broad sense of the term) in that they are concerned with improving the efficiency of organisational systems, particularly sales or purchase process; others are strategic in nature and aimed at changing or maintaining relationships with external bodies, particularly the relative amount of bargaining power held by partners. Dividing motivations in this way is common in the lit-
erature, with influential studies including Johnston and Vitale (1988) and Subramani (2004) modelling IOS impact as a function of whether the application is relational and transactional or just transactional. IOS technology, however, is useful for more than just transacting and managing supply chains. Some systems support cooperation between groups without any exchange of planning information, and the relational focus of these systems can also vary. We now explicate these issues.

2.1 Relational Investment

Because IOS technology is a communication tool that requires cooperation between organisations just to be implemented, an IOS project can be thought of as an investment in a relationship-based resource. This relational investment can be low (i.e. arms-length relationship), or could be high, meaning that the relationship is very close with significant integration, perhaps even to the extent that partners see each other as an extension of their own firm (Sahay & Mohan 2006). For a low relational investment, some idiosyncratic technology will be present (e.g. EDI template), but the primary focus of projects is on developing internal systems and processes to achieve an operational benefit such as cost reductions. These projects do not aim to expand business opportunities, only to improve internal operations. By contrast, when investment is high, the focus is on supporting more externally focused goals such as creating business opportunities or preventing the loss of existing business (Madhok & Tallman 1998). The motivation focus is therefore on developing resources that are embedded in (specific to) the relationship and non-salvageable should the relationship end. This type of electronic integration between organizations using inter-organizational systems has even been discussed as an alternative to actual financial ownership of adjacent value-added stages of the supply chain (Zaheer & Venkatraman 1995).

2.2 IOS Purpose

The inherent relational nature IOS technology (to communicate with a business partner) also means that any classification of motivations must take into account the cooperative intent of the system. Computer-based collaboration research commonly classifies cooperation on the basis of whether it is more transactional (market exchange) or collaborative (Markus & Christiaanse 2003). An exchange-oriented IOS enables arms-length trading and supply-chain management (e.g. EDI), whereas a collaboration system supports cross-organizational work-flow, particularly development or design work, and so will involve some type of cooperative work system. Web 2.0 tools are particularly suited to this application (Lee & Lan 2007). IOS use for transacting and IOS use for collaborating are therefore conceptualized as distinct patterns of appropriation for interorganizational technologies.

2.3 IOS Motivation Types

We combine relational investment and IOS purpose in Figure 1 to form four motivation types, which we label activity control, market position, long-term partnership, and short-term project. The activity control motivation type is internally oriented, primarily concerned with transactional efficiency via automation. For the market position motivation type, the project is concerned with securing business opportunities and developing a relationship, although project work is directed at facilitating exchange rather than supporting cooperative development or design. The short-term project motivation type is concerned with supporting cooperative development or design, but the relationship is not expected to endure, and so relational investment is kept to a minimum. Finally, the long-term partnership type is both cooperative and involves a significant relational investment. For example, the project may be intended to provide or support a significant level of operational integration between firms.

\textit{Figure 1: IOS Motivation Types}
3 MOTIVATION – PROCESS – OUTCOME CHAINS

We propose that the motivation behind an IOS project (the reason a project is initiated) determines the pattern of activities performed, but within the limits imposed by environmental affordances, and that each pattern will result in a firm obtaining or enhancing particular business capabilities. Figure 2 presents the model examined in this research. For IOS projects, it shows relationships among patterns of motivations, affordances, activities, and business capabilities.

In our model, motivation is not the same as business strategy. A business strategy is a general pattern of organizational behaviour (Miles & Snow 2003), whereas project motivation is the justification for a specific project. Because motivation expresses (or is closely related to) a specific deficiency, it is reasonable to assume that activities will be structured accordingly, but this is not to say that organisations always achieve what they intend, only that intentionality influences technology outcomes. This reasoning is consistent with evidence from studies of IT project behavior, which show that the specific problem and the way in which it is framed influence the types of issues considered in system investigation and the analysis activities performed (Keil 1995). Investigation and analysis, in turn, affects how the business problem is actually solved, and the specific solution implemented (Markus & Tanis 2000).

![Figure 2: IOS Motivation Model (Motivation, affordances, activities, capabilities)](image)

3.1 Affordances

Environmental affordances are possibilities for action created the environment, and so both allow and suggest particular actions. An affordance can be embodied in objects or social practices, but should not be confused with the object/practice. Rather, it is an opportunity presented by an environment to perform specific actions (Gibson 1977). For a project, environmental affordances can be internal or external (to the project). Internal affordances are created by characteristics of the project, such as experience or budget, but may also emerge through project activities (Markus & Tanis 2000). External affordances are circumstances and practices outside of the project including business strategy, the strategy and capabilities of external partners, and industry standards.

Business strategy is perhaps the most important external affordance (although partner strategy and capabilities will also play a role). The Miles and Snow (2003) typology of organizational strategy is used widely to describe four patterns of strategic behaviour: defenders, prospectors, analyzers and reactors. Defender organizations specialize in a market niche, and defend that niche to ensure a stable and secure market position. It is common for these organizations to be cost-focused, and have a high reliance on formal procedures. Prospectors focus on diversification and growth, and so are always on the lookout for new market opportunities. Analyzers combine defender and prospector strategies. Efficiency and flexibility are both important for these organizations. Reactors, the final category, do not have a stable strategy, but instead respond to market conditions on an ad-hoc basis.

3.2 Business Capabilities

Business capabilities, the final component of the model, represent project outcomes. At this point, specific appropriations are embedded in the technology but still latent (to be crystallized when the IOS is
used), and particular business capabilities enabled. The specific technical capabilities enabled depend on the technology implemented (or enhanced) during the project. However, because it is here that the IOS moves from development to the production environment, research into the relationship between IOS attributes and business outcomes is relevant. The relational investment dimension primarily describes whether these outcomes will enhance internal or external capabilities. A small relational investment implies an internal focus, for example improving efficiency, monitoring, and coordination within the firm, whereas a large relational investment implies a more external focus on enhancing inter-firm relationships, or improving monitoring, and coordination between firms (Child et al. 2005).

The IOS purpose dimension, at the top of Figure 1, describes activities as exchange focused or collaboration focused. Exchange-focused projects tend to result in operational improvements, particularly more efficient sales and inventory management processes, and better information which improves monitoring of performance and better coordination of supply-chain activities (Chatterjee & Ravichandran 2004). IOS-based communication here will be mainly unidirectional, and involve exchange of structured transaction-related data such as EDI documents (Barrett & Konsynski 1982). Collaboration focused projects attempt to integrate processes, and so involve collaboration and coordination work activities, not just outcomes (Markus & Christianse 2003). IOS-based communication here will be bi-directional, and may involve rich unstructured communications (Sánchez & Pérez 2005).

4 APPLICATION OF THEORY

Two motivation types, activity control and market position, are now explained in detail. They represent extreme relational investment positions, and so allow us to describe contrasting effects. These motivations are shown in Figure 1 within the exchange segment, and so represent motivations for exchange applications, perhaps the most common of all IOS applications.

4.1 Activity control

The activity control motive is a long-established reason for entering cooperative relationships (and IT projects in general. Essentially, organizations experiencing financial pressures try to reduce the cost of administrative activities to offset perceived weaknesses (Child et al. 2005). Activity control has been found to motivate many IOS implementations, with these systems designed to reduce the cost of document handling and storage, and to create indirect savings by lowering the incidence of data-handling errors and data-processing related delays in business processes (Riggins et al. 1994).

Initiation: If an IOS project is initiated as a cost-saving initiative, the business case for the project will be based on financial benefits, particularly cost-savings (Peffers et al. 1998). Johnston and Vitale (1988, p. 160) characterize the approach as being driven by the question “how do I automate what is being done?” rather than the more strategically driven question of “how could our firm's objectives best be accomplished?” The immediate consequence of this focus is that the project is a short-term investment requiring a quick payback. Examples of this approach are described in detail by Peffers et al. (1998) and Rahim et al. (2007), with IOS investment motivated by the goal of lowering data entry errors and labor costs. Automating achieved these goals, but long-term concerns such as improving information quality or strategic positioning were ignored.

Development: This type of project is concerned with short-term cost-efficiency, and so is operational rather than strategic. Project activities, costs, and the payback period will be specified in detail, and there will be a clear allocation of project responsibility. In the development/execution phase, project performance measures and rewards will also emphasize cost-control, with the result that project monitoring will involve frequent meetings and focus on the consumption of rather than delivery of outputs (Lockamy & Hit 1995). The emphasis on detail suggests that a predictable and highly structured methodology (e.g. SDLC) may be preferred, although due to the low-cost, short-term emphasis of this motivation, a highly time-focused light methodology, particularly Agile methods such as Scrum or Extreme Programming, may be more common (Rico 2007). Post-implementation, this motivation is likely to involve a formal review, but mainly in terms of whether the project was run efficiently.
Post-implementation: This motivation involves a transaction-focused project and a small relational investment. Business capability improvements will therefore be internally oriented (e.g. improved activity monitoring or process efficiency), and focus on operational systems, particularly inventory management and exchange systems. In addition, IOS-based communication will be essentially a unidirectional transfer of well-defined and highly structured transaction-related data such as EDI documents.

Risks: A problem with the activity control motivation, however, is projects that cannot be shown to reduce costs in the short-term will not be approved even if they will ultimately provide strategic benefits. In addition teams may be rewarded for completing a project quickly at the expense of quality.

4.2 Market position

Under the market position motivation, cooperation is a mechanism for changing relative dependencies within an alliance. The purpose of cooperation here is to increase or protect the “top line” revenue stream of the organization (and to build long-term profitability), as opposed to the expenditure control focus of the activity control motive. This motivation is therefore externally-focused. This type of cooperative motivation was first described by Emerson (1962) in his seminal paper on power-dependence relationships. It holds that the power-dependence status within an alliance is changed when an organization invests in relationship-specific assets to make its business partner dependent on it, thereby producing codependence in the relationship. This power strategy is also often described using transaction cost economics terminology, which characterizes these partnerships as constituting: (1) non-salvageable, relationship-specific investments such as customized processes, (2) substantial information exchange via more direct access to partner systems, and (3) interdependent technological and functional systems (Child et al. 2005, Zaheer & Venkatraman 1995). Subramani (2004) illustrates this motivation in his description of the development by a mattress manufacturer of a make-to-order and quick delivery IOS to help a retailer to reduce inventories while improving customer service. The retailer ultimately became reliant on the manufacturer’s system, and so helped to replace an arms-length relationship with a more idiosyncratic partnership.

Initiation: Overall, this type of project is concerned with long-term strategies (e.g. reduce underlying inefficiencies) and so framed as a strategic issue. Activities conducted in the investigation phase will therefore be concerned with how the project contributes to the firm’s ability to achieve its strategy.

Development: In the development/execution phase, an iterative methodology may be preferred to allow for input from both internal and external parties, and project performance (and rewards) will be based on results. Due to its strategic importance, this type of project will be championed by a senior figure, and external orientation means that the business partner will have substantial involvement.

Post-implementation: Post-implementation, this motivation is likely to involve progressive identification and elimination of problems, particularly by prototyping new ideas and enhancements to further enhance the system. As with the activity control motive, IOS-based communication will support well-defined and highly structured transaction-related data such as EDI documents. However, communication between partners about the IOS (and related activities) will be ongoing.

Risks: This motivation also carries risks, however. Firstly, a long-term focus makes it easier to excuse poor project management, such as an extending deadline or a project that devours resources without ever reaching a conclusion (Keil 1995). Secondly, although long-term relationships tend to be highly beneficial, investing in the relationship may actually reduce long-term flexibility (Child et al. 2005).

Activities for these two motivation types are summarized in Table 1. Each is an ideal type, in that each describes project activities and outcomes that are theorized to be associated with a particular motivation. No actual project should therefore be expected to conform exactly to a theoretical account. Furthermore, the projects we describe as resulting from a given motivation are complex processes with multiple dimensions, but are theoretical exemplars, not categories of actual projects. The processes and outcomes we propose are, in effect, hypotheses regarding relationships between constructs. However, unlike the traditional hypothesis-testing approach, a typological theory such as ours does not
specify relationships between a unidimensional first-order construct and a dependent variable. Rather, it describes patterns among the constructs for each ideal type, and how each pattern produces specific observations for dependent variables (Doty & Glick 1994). Our theory should therefore be thought of as one that allows a researcher to assess the similarity of an actual project motivation to an ideal type, and on that basis to test relationships between the motivation and project activities.

Table 1: Summary of project activities for each IOS motive

5 RESEARCH METHOD

A multiple case study approach (two cases) was used in order to explicate theory using real IOS projects (Yin 2003). The unit of analysis is an IOS implementation project within an organisation, concentrating on the construct IOS motivation type. We focus in this paper on the "exchange" purpose within the IOS Motivation Type model, on the basis that transactional systems, such as EDI, are a dominant IOS application, and therefore of great practical significance (future work will report case studies for other motivation types). The two cases assessed represent the two motivation types theorized for the exchange purpose, and therefore provide theoretical replication (Yin 2003).

To allow us to assess whether differences in IOS project activities were a result of differences in motivation, we ensured that external and internal affordances to the projects were as similar as possible. This meant selecting firms that were as similar as possible. In particular, each had recently implemented a new IOS, operates at a similar level in the same industry (Tier 1 suppliers to automotive assemblers), and employs a similar organisational strategy (defender). Profiles of each of the two firms involved in the case studies are provided below.

In the data gathering phase, we were given full access to key decision-makers closely associated with the IOS implementation project (three senior managers with technical and/or business roles in each firm) who explained the specific issues that management was hoping to address, the implementation process, outcomes, and challenges faced. Data collected was first coded to indicate the construct discussed, and codes then analyzed using pattern matching logic (Yin 2003) to assess the whether the patterns predicted for each motivation corresponded to the patterns actually found in the case data. The case studies are considered to be exemplars of each of the two motivation types.

Carolina is a small-to-medium sized enterprise that operates out of three locations, two in a southern suburb of Melbourne, Australia, and one in South Carolina. It has a turnover of around $US 10M, is privately owned, employs approximately 120 staff, and manufactures dies, metal-cast products, and injection-molded plastic components, primarily for the automotive industry. Information processing is
conducted using desktop computers, with most of the materials planning and other quantitative work performed using in-house developed Excel-based applications. Carolina’s production system is primarily based on just-in-time principles, with most production lines employing Kanban principles and supported by lean inventory management. Carolina produces for all major automotive assemblers, but is dependent on Toyota for the bulk of its business. The case study is concerned with a major IOS project involving the implementation of a Kanban-based supply components system for Toyota.

Clayton is the regional subsidiary of a major Tier 1 supplier and has business relationships with every local assembler as well as component retailers. The automotive division that is the focus of this study is located in Melbourne, and employs around 1,500 staff. Information processing is conducted using a sophisticated SAP-based system (installed in 2000), with many custom-developed routines and reports. EDI capability was initially implemented around 1995 at the request of major customers. This capability has been progressively extended in response to further requests from major suppliers and customers, and the company is gradually introducing EDI communications with smaller customers and suppliers. The production system is also based on just-in-time principles, with a mixture of Kanban production lines and MRP demand forecasting. Clayton is not completely dependent on any one customer, but neither does it see itself as being the dominant party in its relationships. The case study is concerned with a recent major IOS project involving a consignment stock system.

6 CASE STUDY DESCRIPTION

The business strategy as described by senior managers in both case firms corresponds closely to the defender type. Both businesses are specialized and operate in a mature industry (primarily motor vehicle parts manufacturing). For a defender, the main entrepreneurial challenge is to ensure a stable and secure market position in the long-term. They tend to protect their position by implementing and refining established and standardized technical processes to ensure that activities are highly efficient. This approach is evident in statements from managers of each company:

“We need to embrace lean manufacturing to become more cost-effective, and if we are cost-effective, Toyota is looking at its list of suppliers now. We have been told that they’re looking at us supplying on the next model, which is beyond 2011, so it’s almost a situation where we’re doing it for two reasons: for the ongoing success of the business, but also to appease Toyota. We want to be on the shortlist [of the ten preferred suppliers].” [Carolina Managing Director]

“In this company, you can’t get too far without convincing management that what you want to do will save some money. You will find that is probably the case in any automotive business because it is the toughest. Therefore the margins are minimal, but the turnover is huge. It is immediate and longer-term cost-savings we are after. So cost savings must be direct, like on every sale, and indirect, like in terms of running the business cheaper and responding to a customer’s requirements quickly. A happy customer means potential more customers, and more sales.” [Clayton Manager]

Defender projects are characterized by a focus on improving the efficiency of existing operations, and careful top-down planning. However, each firm is achieving this objective in a different way. Carolina has a “whole of business” approach that requires multiple areas (e.g. warehouse, manufacturing, purchasing, accounting, sales) to make complementary changes to processes. In addition, it is more concerned with eliminating waste in the long-term than controlling short-term project expenditure:

“[Toyota] tell us to do all this, but we have our own plans. We started on lean [manufacturing] before Toyota got involvement with our company. When they found out we had spent quite a lot of money putting lean [manufacturing processes] in, they brought us into their top 10 preferred companies and they’re now spending a lot of money with us [on process improvement projects].” [Carolina Managing Director]

“We use the 5S methodology [an iterative waste-elimination method]. …With just-in-time you have to be really tight. That’s why we can’t rush [the implementation] or we’ll fall apart. …it has cost us a fair bit so far. I don’t think we will recover the cost soon. The previous system was simpler for us. Eventually, when we go completely Kanban we will recover it.” [Production Manager]

Clayton, on the other hand, is very concerned about controlling project expenditure, and relies on frequent progress meetings, and strict adherence to a defined project methodology to ensure that projects finish on time and on-budget. There is little evidence of outside partner involvement.

“For every project we have to specify the benefits. This includes qualitative benefits and cost-recovery.
Then we have to provide the estimate of the cost as part of the budget preparation. Once everything has been approved, we create an internal order, with a budget. It says "this is how much we allocate for this project, this is the cost-centre". As the project is running, I will check cost against budget to see how we are going. How often we do a major review depends on the project. As part of the project preparation we actually specify how often we are going to review, not only cost, but any activity on the project compared with the plan. So for this project, which is an 8 million dollar project, we have what we call four gates: the critical milestones for the project. We review the plan, what was achieved, issues, risk analysis, and costs. We also do a weekly review where the team meets to discuss the implementation." [Clayton Manager]

Post-implementation, each has a different review and follow-up mechanism, and each even assesses the benefits in quite different ways. Clayton’s review mechanism, like project execution, is highly formal, but the benefits are seen in operational terms (not strategic), and so project success and evaluation of future opportunities are similarly operational:

“We also have post implementation follow-up 5 years after the project. What we do, for example, we look at technical issues. What sorts of errors do we get, what is the reason for those errors? Second part is looking at the benefits to the business. When we started EDI, we started seeing the benefits of it straight away. It is much more reliable, less error-prone than manual entry. Now when we finish an EDI process with one of our customers and they see the benefits of it, we go out and advertise it to our other customers, and say 'look we will both benefit if we go EDI.'" [Clayton Manager]

For Carolina, the continuous improvement philosophy adopted (5S) means that the project is under constant review, with frequent re-evaluation of performance, and regular prototyping of innovations. Benefits from the IOS are seen quite differently. For example, improved information and internal control, and a more secure customer relationship were cited at various points during the interview, but controlling the cost of administrative procedures was not mentioned at all:

"Definitely we have learned lessons from it. The idea of visual management and all that sort of stuff. I think we are taking as much as we can from it. The information we are getting is a lot better. I mean it has benefited us because it has smoothed our production out. It has gotten rid of the fluctuation, and as we slowly increase in demand, we can see what we need to do to cope.” [Carolina Production Manager]

7 CASE STUDY ANALYSIS

Table 2 summarises the above observations. Each case has been selected because it conforms closely to an ideal type: Clayton to *activity control*, and Carolina to *market position*. Both firms are trying to maintain good relationships with customers (to defend market share), and have justified projects on the basis of efficiency improvements, as one would expect of defenders. However, Clayton’s IOS project approval process required a detailed justification and to show immediate cost-savings with a short-term payback, whereas Carolina’s project was expected to cement the firm’s relationship with a major customer, and so protect or expand future revenue streams. In other words, Clayton’s initiation process is inward looking, attempting to meet objectives by minimizing process costs, and Carolina has an external focus in which it attempts to strengthen a relationship in the short-term, while hoping that “cost-downs” generated by the project will recover expenditure eventually. On this basis, Clayton’s motivation is more like the “activity control” type, and Carolina’s like the “market position” type.

Development activities are similarly distinct, and consistent with the respective pattern established in the initiation phase. That is, consistent with the internal focus of the activity control motivation, Clayton has little business partner involvement, inventory-control and IT were the only departments with any significant involvement (and only IT was involved in the actual development phase) and treats the project as more of an operational concern with stringent controls over time, expenditure, and activities. For Carolina, by contrast, the project is a strategic concern, evidenced by the seniority of the project owner, the significant (and expensive) preparatory work to ensure that the project does not fail, and the iterative method employed, which focuses monitoring efforts on results rather than inputs.

Finally, in the post-implementation period, Clayton is continuing its reliance on formal procedures, with a defined review cycle, and a well-defined process for identifying and fixing problems. Carolina, on the other hand, consistent with its outcome orientation, has no formal review procedure, but is instead monitoring production continuously to both address problems as they occur, and enhancing the system by prototyping new ideas (mainly adapting control techniques used by business partners).
Some risks are evident, however. For Clayton, the internal focus of projects (only cost-reduction projects are approved) may be problematic in the long run. In the short-term, the project reported may help Clayton to differentiate itself on the basis of cost, but that strategy is rarely sustainable (Miles & Snow 2003). Carolina’s long-term focus is also a problem, particularly given the difficulties facing the automotive industry as significant parts of the world experience a severe economic slowdown. In particular, by adopting a long-term focus, Carolina risks over-investing in efficiency and in binding its future to the success of a single business partner. A severe economic slow-down could mean that long-term expectations of growth will not be met, making recovery of short-term expenditure much less likely. In addition, any problems experienced by the business partner will now affect Carolina far more directly (although the alternative may nevertheless have been even worse).

Table 2: Summary of project activities observed for each case study

8 DISCUSSION, LIMITATIONS, AND CONCLUSION

Our motivation model (Figure 2) proposes that project activities and outcomes depend on the motivation and environmental affordances. According to this model, process and outcome are predicted by what the motivation is able to determine within the constraints of the environment. The two cases help to illustrate the effects of environmental affordances on project activities and business capabilities because both firms have essentially the same business strategy (defender) in the same industry (Tier 1 suppliers in the automotive industry), and both were engaged in a major IOS project. Both firms are highly cost-focused, but, consistent with the typology each has enacted that strategy differently.

A number of limitations must be acknowledged. Firstly, all typologies necessarily simplify reality, particularly ones based on ideal types because these ideals are theoretical abstractions. Indeed, the specific cases reported here were selected because they correspond quite closely to the ideal types described, and so help explicate concepts without any need to explain differences between theory and observations. This research should therefore not be thought of as a test of theory in the hypothetico-deductive tradition, but instead as a form of theory development with detailed explication in the form of multiple case studies. More complex situations that do not clearly belong to any one cell are bound to occur, and these are a challenge to interpret. The simplified view of reality is nevertheless beneficial because it can help explain the principles underlying more complex situations.
A second limitation relates to the top-down (theory-driven) nature of the analysis. Because case details have been gathered and then compared to existing theory, retrospective sense-making (in which people interpret facts selectively according to what is known about the world) is a potential threat to validity. To counter this threat, motivation has been identified on the basis of explicit statements by managers (i.e., the technology application and depth of relationship were apparent from the outset), all cases have been assessed using the same template (thereby limiting the ability to exclude contradictory facts), and recording a rich description of activities has allowed us to assess the manner in which each is consistent with theoretical principles (assessment is not based on an arbitrary yes/no decision).

A third limitation is our assumption that intent is fully clarified and specified (or clarifiable and specifiable). That this assumption will not hold in all instances is a boundary condition on the application of the theory, rather than a conceptual limitation. If intent is unclear or unknown, application of the principles will be difficult, but this does not render the ideal types invalid.

Our findings have several implications for practice. Firstly, the motivation to adopt a system appears to affect implementation activities, including the design of the system and how it will be used. This is significant for managers because such design choices, once implemented, are usually expensive and difficult to modify. Secondly, relying on the experiences of other firms as a basis for system implementation decisions is clearly risky without in-depth knowledge of a project, particularly of the motivation. That is, simply knowing that a given firm has a similar structure, strategy, or technology is not a sufficient basis to assess another firm’s implementation project.

The major theoretical contribution of this work is our framework for understanding the role of motivation in the activities conducted when implementing a system. Our research model illustrates how motivations affect activities and outcomes for an IOS project, and so informs decision makers about how low-level concerns (project aims) can influence which technology capabilities are actualised, and even long-term plans. In addition, in contrast to the common views of project alignment, our theory does not assume that if project activities are aligned with business strategy, business goals should be met. As a general rule, one would expect project goals and corporate strategy to be aligned, and for project impacts to be highest when this is the case. However, the cases presented here indicate that, although strategy is an environmental affordance that suggests particular activities and constrains others, a given project could be structured in a wide variety of ways that are all consistent with the strategy and yet present quite different outcomes, opportunities, and risks to the business. In other words, the high-level nature of strategy means that the boundaries for project outcomes are broad. It is therefore not enough to align a project with corporate strategy; managers must also understand the specific implications that a given motivation has for project activities.

The case evidence presented explicates our argument that motivation affects the pattern of activities performed in an IOS project. The theory applied here is the basis for a wider research program, currently in progress. In future work we will describe other motivations and provide case examples for each. It is important to note that although IOS technology is the specific focus of our program, there is no reason to suppose that the principles we propose do not apply equally to other IT projects.

Abstract

Software development projects still fail at an unacceptable rate although prior studies have identified critical success factors needed for project success. This study contributes to the project management literature by providing further insight into the nature and role of `top management support` (TMS), which is widely recognised as one critical factor in the success of software development projects. The study seeks insight into the nature and role of TMS from the perspective of software development project managers and their perceptions of actions required by top management in facilitating project success. A qualitative case-based approach was employed. Sixteen top management `actions` are identified, and subsequently framed by a conceptual model consisting of three top management roles: strategy, facilitate and lead. The study represents the first stage of an ongoing research program. The model will be tested in the Asia-Pacific region in the second stage. The expected final outcome of the research program is a framework that will support project environments by defining top management actions needed to support a software development project in different stages of the life of a project.

Keywords: top management support, critical success factors, project success, project manager, top manager, software development projects
1 INTRODUCTION

Software development is a highly complicated task with the involvement of many stakeholders and previous studies have indicated that low software development project success rates are a major concern (PMBOK, 2004; Reel, 1999; Meredith & Mantel, 2006). Many studies have been conducted to identify the factors that affect the success of projects, leading to a body of knowledge referred to as the Critical Success Factors (CSFs). Although the rate of project failure has declined with the application of accumulated knowledge, software development projects continue to fail at an unacceptably high rate (PMBOK, 2004; Schwalbe, 2006).

Academics and practitioners alike acknowledge the importance of CSFs (Reel, 1999; Butler & Fitzgerald, 2006). However, mere acquaintance with the factors does not bring about the skills or mastery needed to address them. There is evidence, for example, of critical success factors not being handled properly, leading to project failure (Young & Jordan, 2008). This evidence suggests that we do not yet understand well enough how we can lead a project to success by applying CSFs. This line of thought, in turn, raises questions, as to what constitutes a critical success factor, in terms of its component parts, and how the components should be successfully applied across the life of a project.

Top management support (TMS) is one important CSF. As revealed by many studies (Loonam & McDonagh, 2005; Nah et al., 2001; Krumwiede & Lavelle, 1998; Young & Jordan, 2008; Zwilkael, 2008a-b; Zwilkael et al., 2008) it is a main ingredient in the recipe for project success. The major goal of this study is to gain insight into what constitutes TMS from the perspective of project managers (PMs), by asking them what actions they consider are needed from top management (TM) to facilitate project success. This research theme has not been adequately addressed in prior studies.

The study described in this paper is the first stage of a two-stage research project. Here, we look at software development projects from the perspective of five project managers, using extensive interviews. The qualitative findings are built into a conceptual model. The study was conducted in Sri Lanka, the home country of the lead author.

The remainder of the paper is organized in the following way. First, the existing literature related to TMS is reviewed as theoretical background. The methodology is then presented, followed by the findings from the five case studies. The conceptual model and its future development is addressed in the discussion section, which is followed by the conclusion.

2 THEORETICAL BACKGROUND

2.1 Software development projects, project success and CSFs

Software development is pursued as projects (Schwalbe, 2006; Meredith & Mantel, 2006) and therefore draws on knowledge from both the software development discipline and project management. Project management refers to the application of knowledge and skills in the project environment to successfully complete project tasks (PMBOK, 2004). At present we have a very pressing problem in that most software projects are reported to have been unsuccessful in one aspect or another. Software projects are said to be high risk because they involve changing requirements, a variety of business domains, a variety of technical platforms and large amounts of monetary investments (Ropponen & Lyytinen, 2000; Cockburn, 2000; Schwalbe, 2006; Reel, 1999; Scott et al., 2006).

A project involves many stakeholders (Hartman & Ashrafl, 2002). Each one will have their own success criteria, and, therefore, project success is a multi faceted issue (Shenhar, Dvir & Levy, 1997;
Lim & Mohamed, 1999). It is interesting to note that some projects do not meet all predetermined criteria such as time, cost or scope, yet, are deemed to be successful as the client was happy with the project’s product. Previous studies describe project success as multi dimensional. Shenhar, Dvir, and Levy (1997) maintain that project success can be measured in terms of how well the following project outcomes are met: internal project efficiency, impact on the customer, business and direct success and preparing for the future. Others take a two dimensional, macro and micro, view of project success (Lim & Mohamed, 1999; Agarwal & Rathod, 2006). At the macro level the organization looks at project completion and customer satisfaction. At the micro level only project completion is deemed important.

CSFs are the factors identified as critical to the success of a project (Reel, 1999; Nah et al., 2001; Young & Jordan, 2008; Zwilkael, 2008; Hartman & Ashrafl, 2002; The Standish Group, 1995). Most prior studies portray the CSFs as derived from a practitioner’s perspective. However, there is evidence that the CSF concept is also a valid academic concept (Butler & Fitzgerald, 2006). However, very little work has been done to investigate the exact nature of each CSF. Some CSFs have been identified when projects were live (in progress), and others have been identified as important at the post-mortem phase of the project. Knowledge of CSFs is essential, as not attending to them when necessary may prove disastrous to the project. An example in this context would be if top management support was not rendered when needed. The lack of support may take the project down a perilous path, possibly ending in project failure (Young & Jordan, 2008; Schwalbe, 2006; Zwilkael, 2008a-b).

2.2 Top Management Support (TMS)

Agreement on a definition for TMS has yet to be achieved (McLagan, 1998; Loonam & McDonagh, 2005). Some authors define TMS as devoting time in proportion with the cost and potential benefits of a project (Young & Jordan, 2008). Others, however, define TMS as the degree to which top management understands the importance of the project function (Ragu-Nathan et al., 2004). Further, there is still a lack of consensus in the literature as to who comprises TM. Identification of TM may vary according to the organizational structure and with the size of the organization (Green, 1995; Sabherwal et al., 2006). Therefore the understanding of the term TM ranges from immediate superior to departmental manager, to director, CIO or even to the CEO. In the current study, we refer to the management one hierarchical level above the project managers as the TM.

Projects are managed by project managers and their definition in the management hierarchy is given as operational managers (Meredith & Mantel, 2006; Turner & Muller, 2005). They manage work on the project. However a project is part of an organization (Turner & Muller, 2003) and there is much interaction between the organization and the project. Project managers may require TMS for direction, advice or for escalation (Loonam & McDonagh, 2005; Nah et al., 2001; Krumwiede & Lavelle, 1998; Young & Jordan, 2008; Zwilkael, 2008a-b; Zwilkael et al., 2008) during the life of a project.

Prior studies indicate that project failure is strategic rather than technical (Cicmil & Hodgson, 2006). Many studies believe that top management support is essential and will most certainly increase the probability of software development project success (Schwalbe, 2006; Young & Jordan, 2008; Zwilkael, 2008a-b). Related findings from previous studies which concentrated on TMS include the critical success processes (CSPs) of TMS (Zwilkael, 2008a-b) and the introduction of a maturity model for TMS (Zwilkael et al., 2008). Although the CSPs are an interesting finding, the origins of these processes are not clear. For instance, some processes could be traced back to the top manager (e.g. project manager assignment), some to the project manager (e.g. use of new project tools and techniques) and others to the organization (e.g. project based organization). The maturity model for TMS is a subsequent development, depicting five stages of top management growth in an organization against the CSPs. This model would invariably inherit the attributes discussed above.

As interesting as the above findings are, there is a lack of critical analysis of actions required of top management, and how these actions could be understood at a theoretical level. Therefore, the authors
find it timely to undertake such a study from the perspective of project managers, who are of course ultimately responsible for project success.

3 METHODOLOGY

Five case studies were conducted to examine how TMS is viewed by project managers. Small, medium and large sized organisations were targeted in order to accommodate a range of views. The project managers were first asked to complete a short questionnaire about a project they could relate to including its level of success. The project success part of the questionnaire was based on the multidimensional project success model by Shenhar, Levy and Dvir (1997). The project managers took approximately ten to fifteen minutes to complete the questionnaire. The aim of the questionnaire was to draw attention to the project to be discussed. The projects we discussed had already been completed. Most of the project managers had multiple projects in their accounts. Therefore, we used this exercise to refresh their memory and assist in the subsequent discussion, as a road map teasing out specific practical examples, rather than discussing generally what was needed as TMS.

It was explained to the PMs that for the purpose of this endeavour ‘top management’ referred to their immediate supervisor(s) and the support needed from them. A semi-structured interview followed with emphasis on TMS requirements for project success. The notion of project success was also discussed, including what was meant by the term and other factors which were deemed to be important for project success. Supporting information regarding the project, from one hierarchical level above or below the project manager was sought for clarification of information and to rule out any bias in responses. In Cases 1, 3, 4 and 5 we had the opportunity to speak with a key team member, in Cases 2 and 3 we were able to undertake interviews with the departmental manager (the TM) in addition to the project manager. Ten such interviews ranging from 45 minutes to 1 hour 10 minutes were conducted. Table 1 provides details of the organizations and the projects studied.

Interviewees were encouraged to freely convey their perceptions. These discussions were recorded and later transcribed.

4 FINDINGS

Top management support was identified as important for project success. Three out of five project managers stated the fact explicitly. The two remaining project managers saw top management support as built into the organization’s business model. They said that the industry approved model adopted by the organization ensured TMS. So in the discussion they did not try to explicate the factor, but agreed that it was indeed very important. Table 2 presents a comparative analysis of key attributes of each case.

Interestingly, the understanding of project success differed according to each interviewee’s position in the organization. A key team member when asked why he thought the project was a success answered “we were able to give a product which satisfied the customer”, which relates to the micro level of success. The same question was answered by the project manager as “the customer is happy and we met time, cost and scope constraints”. The latter criteria relate to the macro level of success.

The project managers’ perceptions of what was required of TM to facilitate project success were analysed by the researchers and agreed upon after multiple passes through the transcripts. We also sought evidence that the understanding of these requirements was congruent across an organization, since we had access to either one hierarchical level above or below a project manager at each of the organizations studied. Sixteen requirements of TM were identified, and are described below.
1. **Participate in scope definitions**

   Project managers (Case 1) expected the top management from both the client and the performing organization to be involved in the definition of the scope of a project. PMs said that this prevents conflicts regarding requirements over the life of a project. The project manager of Case 3 described the top managers as gate keepers of scope who prevent scope creep.

2. **Build support in the organizational model**

   Having preferred or standard methods have helped project managers to successfully conduct project activities. As one project manager (Case 2) put it “when the customer realizes that we work with proven methods, they just fall in line”. One major aspect of these methods (Cases 2, 4 and 5) is to ensure client management participation alongside the client.

3. **Achieve a sustainable business model**

   One project manager (Case 5) who described his project’s product as not meeting customer satisfaction, pointed out that it was important that the top management looks at the sustainability of the business model employed, both in terms of revenue and workability. He pointed out that in the particular project under discussion three parallel versions were simultaneously developed and released to the customer and the customer was billed accordingly, providing good revenue. He went onto say said that, “because of this model the developers had to be constantly pulled out and plugged in where necessary making it difficult for them to concentrate, a sequential release mechanism would have been a more sustainable model, and the project would have had a better chance at success”.

4. **Provide guidance**

   Project managers, as middle level managers, are consistently pressured by operational constraints. They are well aware that they carry the responsibility of the project on their shoulders. So they expect and welcome guidance (Cases 1, 3 and 4). As one project manager put is “it is not just passive evaluation, but active participation. For instance they might say to fine tune the resource allocation”. More importantly one key team member pointed out that the TM should not let projects be orphans, but a part of the whole organization.

5. **Supply resources**

   Project managers saw it as very important that the TM supplied the required quantity and quality of skilled resources when necessary. One project manager (Case 1) said that it was helpful that the TM was able to get experts from different departments when they faced unforeseen technical issues. He said “all in all we were able to get help from others when we needed it”.

6. **Boost employee morale**

   TM attendance at team meetings, commending good work and offering opportunities to travel on project work was identified as having a positive effect on morale and project managers welcomed such support (Cases 2 and 3).

7. **Balance project assignments**

   Some project managers (Cases 2 and 5) said that they have multiple projects in their accounts and that this may sometimes get in the way of success of projects that are of lower priority.

   One project manager (Case 2) explained in relation to a project which did not meet the desired level of success, “I was involved in another major project and could not give this project the attention it needed”.

   Another project manager (Case 5) said that a normal working day for him lasted twelve to sixteen hours, and that he felt overloaded since he had many projects in his account. He said that “I would start with a stand up meeting and see what has to be done today, then I will attend to the mail which will take me up to lunch, by afternoon I would get feedback from the team about progress, I would
then attend to any communication needs and then update the tracking documentation. In the evening I would get an update when hiccups are shown, then I have to liaise and facilitate, for example hardware problems, HR or admin problems”.

8. **Prioritize**

Project managers (Cases 1 and 2) found that when a project is prioritized, it is much easier to receive required support from an organization. Soft and hard resources flow in and top management is available for any further requests and escalations.

9. **Watch status**

TMs are expected to remain vigilant in relation to the status of a project. This, according to Case 3, was expected from the top management of both the performing and client organizations.

10. **Having clear business objectives and stating them**

Project managers and in some cases key team members maintained that it was important for the TM to have an understanding of what the company is hoping to achieve from the project and to communicate the objectives to the project team (Cases 3 and 5).

11. **Make necessary information available**

According to one key team member (Case 4), it would have been easier to work with better knowledge/information than what was specified. He said “this would have prevented ambiguity of tasks and would have helped promote the success of the project”. This action and point 10 above are somewhat related. However they are elaborating on two different levels, i.e. the project level (action 10) and task level (action 11).

12. **Provide challenging work**

Project managers of Cases 2 and 3 brought out the fact that TM was expected to provide challenging work. This motivated staff and was also key to retaining skilled employees in the long term.

13. **Retention of key employees**

Project managers value and depend largely on capable skilled resources. Removing these skilled resources to other projects or not retaining them in the organisation, what ever the reason may be, is detrimental to the success of an ongoing project. As one project manager (Case 5) put it “I felt some attrition, for example when I wanted to retain some personnel and the management was not supportive”. He indicated that this was a cause for project failure.

14. **Review project plans**

Project managers expected TMs to review and formally accept project plans. Some project managers pointed out that this was beneficial in a number of ways, including securing TM buy-in and ownership at the top level for the project (Cases 1, 2 and 3).

It was also maintained that when revision of time or other constraint is needed, it is helpful to have top management involved in communicating the revisions to the client.

15. **Liaise with customer**

Customer perception of project involvement differs according to the level of management involved, in both the performing and the client organization. PMs reported that when action is needed and does not seem to happen, an escalation to the TM followed by a discussion between the peer levels of management of the performing and client organizations gets things moving (Cases 1 and 4).

In some cases top management was reported to have had close business relationships with the client prior to obtaining the project (Case 2), and this relationship had been beneficial in executing project tasks.

Proceedings ECIS 2009
16. Accept ownership and gain better understanding of project work

Case 2 brought out the fact that when TM from both the performing and the client organizations take ownership interest in the project, it helps project success. In some organizations the TM had a technical background and the project managers said that this was immensely helpful.

<table>
<thead>
<tr>
<th>Case 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>The organization is a campus, with own software development centre, using company standards. They develop software for internal and external customers. The development centre consists of 14 developers. Two developers were dedicated to the project and 1-2 quality assurance engineers were used as per the need. The application system was developed to assist tea auctioning. The project was given priority by the top management. The project was seen as a success because the customer was satisfied. The scope and budget were met. However, the time frame had to be revised but was accepted by the customer.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Case 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>The organization is a software development centre with many specialised areas branching out as departments. They develop software for external customers. The product strategy is to market a core product and bridge the gap between new customer requirements and the product. A project is employed for this purpose. The project was for the very first foreign customer and was prioritized. The organization has around one thousand (1000) developers employed. This project had 15 dedicated developers. Separate quality assurance was carried out with the involvement of 4 people. Implementation was done by 5 engineers. The application was an insurance system. The project was a success; the top manager describes meeting the customer requirements 100%. The customer has returned for new business and is now a reference site. The constraints for scope, cost and budget were met. The organization has level 4 certification in Software Engineering Institute’s (SEI) Capability Maturity Model Integrated (CMMI) and has also obtained certification by International standards organization (ISO 9001:2000).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Case 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>This Case is somewhat different from the others. We spoke to the software development department of a mobile service provider. This software department consists of 35 employees and is the customer. The project was conducted when the mobile service provider was switching mobile platforms, which is a rare occurrence. In order to provision the requested system to the new software environment the mobile service provider and the vendor had to work together on one project. This project is an example for involvement of multiple stakeholders. In its development phase alone four (4) parties were involved. Those being the supplier (4 developers), in-house developers (3-4 developers), telecom engineers and marketing and customer care. The project was declared a success by the customer. They said that the functional requirements and the time, cost and quality constraints were met.</td>
</tr>

</table>

<table>
<thead>
<tr>
<th>Case 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>The organization is a highly reputed software development centre. They are CMMI level 4 certified and have a large employee pool, i.e. over 3500. The project concerned, handles requests at disaster situations and then handles bills and payments related to the actions taken on those requests. The product was for a foreign customer. This involved 12 developers and 3 quality assurance (QA) engineers. The project was declared a success, primarily because the customer was happy and the internal constraints such as time, cost and scope were met. The organization also has metrics with set indexes to monitor a project. The operations manager defined the project success as acceptance of the product by the customer, smooth rollout of the production system, high value on the client score card and repeated business with the customer.</td>

| This project is from the same organization as Case 4. The project concerned is a document retention management system. The project manager spoken to was a senior consultant for delivery, a higher level manager playing the role of project manager. The project involved 10 developers and 2-3 QA...
Engineers. The project was declared a failure from the customer satisfaction perspective. However, the performing organization’s requirements had been met.

Table 1 - A brief summary of Cases studied

5 Discussion: Conceptual model, future plans & limitations

We are able to group the TMS actions identified above into the three categories of strategy, facilitate and lead (see Table 3). Knowledge gathered from past studies was used to drive the categorization. The researchers sat through a brainstorming session to come to a consensus on this exercise. The term strategy has been defined and spoken of by researchers as early as the 70’s (Porter, 1979). However, at the core of the various definitions that have ensued since that time, is the fact that strategy constitutes the actions to ensure long term success of the organization. Leaders are expected to take ownership and pride in their work and set examples (Green, 1995; Viswesvaran et al., 1998). A facilitator assists an existing process, and prior studies state that this is what is expected of top management at times (Sabherwal, 2006; Kearns, 2007).

Using the three categories introduced above, referred to as TMS ‘roles’ from here on in, a conceptual model (Figure 1) is presented. Project success is introduced into the model as the outcome of the successful execution of the three TMS roles, which are considered to be the explanatory factors. We refer to the combination of a project’s process and a project’s product success as project success. Our research is congruent with findings of previous studies, regarding the fact that project success is multifaceted.

This model is an important milestone in the context of the overall research program. It is of interest in the future to see how these TMS actions are applied in the project management processes (initiation, planning, executing, monitoring / control, and closure) and how they impact project success.

The information we grouped and present is from the perspective of practitioners i.e., project managers. We believe that socio-organizational theories from the academic world can be used to better understand the three TMS roles of strategy, facilitate and lead and when they are required. Further, we believe that different theories come into play with each of these roles. At present it is considered that the following theories may be important for the reasons given. Organizational theory may be related to strategy, as it is based mainly on human, physical, work and coordination attributes (Hodge, 1988). The facilitate role involves creating the conditions for ordered rule and collective action (Stoker, 1998) and, therefore, may be related to project governance (Forcadell, 2007; Ezzamel & Reed, 2008). Human management theory may underpin the lead role (Leskiw & Singh, 2007) since people, however skilled they are, have to be led in situations such as project environments where people are brought together for a limited timeframe to achieve a specific goal or goals (PMBOK, 2004).

The research question to be addressed at the next stage of our project is as follows: “how do the top management roles of strategizing, facilitating and leading apply to the project management processes, and what impact do they have on project success?”

We plan to identify constructs which are related to the above roles from current theory, and use this information to operationalize the conceptual model. Then we plan to go back into the industry with a questionnaire compiled using the conceptual model and survey, firstly project managers and then top management in relation to the model. Information will be sought from the perspective of each project management process. Each role may be important in every one of the processes and one or more may be more important in different processes.

Our aim is to contribute a framework; where the three roles, strategy, facilitate and lead will be used as one dimension and the project management processes initiation, planning, executing, monitoring / control, and closure as the other.

Table 2 – Comparative view of the Case attributes
It is shown in the literature (Correll, 1994) that top managers are not particularly available for operational management support on request, since they have busy schedules themselves. So it is of importance that both top managers and project managers realize that support will be needed during the life of the project. The framework that we aim to define will assist them in advance to identify and understand, when and what kind of action may be required. A theoretical insight into each element will further elaborate and justify the requirement for top management support. Therefore, this intended framework could be used as a tool to ensure top management support.

*Table 3- Analysis of the top management actions*

*Figure 1 - Conceptual model*

We see the following as limitations in this study. We were interested in researching TMS actions required for software development projects. Therefore, the majority of the organizations selected were from the software industry and as such our investigation did not investigate the relationship between TMS and the core business of the organizations. Although references to other projects were brought into the discussion, the factors needed as TMS are mostly limited to the projects that were studied in the five organizations involved. The investigation took place in one country only and, therefore, the findings may not be a generic representation. However, our plan is to extend the research to other Asia-Pacific countries, in the second stage. We have also not investigated in this stage, how the level of economic development and cultural aspects of a nation may affect TMS.
6 CONCLUSION

Many academics and practitioners believe that top management support is an important factor for the success of software development projects. This study examined five software development projects and is the first stage of an ongoing research program. We identified sixteen (16) specific actions needed by project managers as support from their immediate management. These actions were categorized into three groups (strategy, facilitate and lead) with the aid of prior literature and are identified as three important top management roles. The findings led to the development of a conceptual model with the three roles (strategy, facilitate and lead) identified as explanatory factors, and project success as the outcome.

The unique contribution from this paper is the conceptual model (Figure 1) based on the findings to date. There is promise in this framework, which not only looks at top management support roles, but can be built upon to examine the TM roles over the life of a project. The expanded framework planned for the second stage of this research program will have the capacity to explain and justify the top management actions required in each project management process using socio-organizational theories.

From Business Case to Value Case - Assessing the Organizational Value of IT Investments

Frisk, Elisabeth Jane Applied Information Technology, Gothenburg University, Sweden. elisabeth.frisk@ituniv.se

Abstract

Managers continually invest in new information technology (IT) but the question of organizational value still seems vague. One explanation is poor evaluation. In practice the Business Case including Return on Investment (ROI) still dominate. Information System research has noted for a long time that the Economic Approach is not sufficient and instead the Interpretative IT Evaluation Approach has been put forward. However, the approach has reached limited acceptance in practice and it has been noted that what to evaluate is a far more complex process than might first appear. The aim of this study is to articulate factors and criteria that are important to consider when assessing the organizational value of IT investments. This study is part of a Collaborative Practice Research project that took place 2005-2008 at three public organizations. The findings indicate that it is time to take a step from a Business Case to a Value Case. The Value Case is a pluralistic, a formative and a formalized approach that includes factors and criteria that have its base in prior research and have been further discussed and analyzed by the respondents. The Value Case also put management’s attention to effectiveness and efficiency, the task of management.

Keywords: IT assessment, IT investment, Management, Interpretative IT Evaluation
1. INTRODUCTION

IT investments are still high-risk projects. The newspapers repeatedly describe IT project failures costing the organizations millions of dollars. In Sweden, one organization in the health sector had to cancel one large IT project after the cost had exceeded the budget enormously (Järräng 2007). Also the regional social insurance office had giant runaway costs when implementing SAP (Järräng 2009). There have been similar findings in the UK public sector and the failures there have been related partly to insufficient management skills (Brown 2001). One explanation is the overreliance on financial business cases (Ward & Daniel 2006). Therefore, new knowledge is needed that can create increased understanding for other effects than the economic when introducing a new IT investment to the organization. Today the Business Case mostly including a Return on Investments is still the dominating approach when assessing the organizational value of an IT investment (Ward & Daniel 2006). Several researchers have criticized the economic approach due to that IT’s role has changed from automated processes to increased individual and group effectiveness, to organizational transformation and to collaborative partnership (Pearlson 2001). Instead interpretative IT evaluation, based on stakeholder groups’ perception of reality and a consideration of the context (why), content (what) and a process (how), has been put forward (Hamilton & Chervany 1981, Symons 1991, Walsham 1995, Jones & Huges 2001, Ward and Daniel 2006, Stockdale & Standing 2006). However, interpretative IT evaluation is rarely used and the reasons can be several. Stockdale and Standing (2006) note that; “A decision on what is to be evaluated is a far more complex process than might first appear and is significantly influenced by the stakeholders and by the context of the organization” (p. 1092). Due to lack of management skills and a complexity of what to evaluate it can be of interest to create increased understanding for what management perceives as useful to reflect upon, when assessing organizational value of IT investments. In the research field IT evaluation, methods and models based on economic and interpretative theory are the most discussed (Berghout and Remenyi 2005). The question is if these theories are sufficient or a step forward is needed. The aim of this study is to articulate factors and criteria that are important to consider when assessing the organizational value of IT investments. The goal is from a management perspective, to create increased understanding for different factors affecting organizational value of IT investments. The goal to IS research to develop an analyze tool that can support the content of IT evaluation in the interpretative IT evaluation approach. The following research question is raised: When assessing the organizational value of an IT investment, what factors and criteria should be reflected upon from a management perspective?

This study has a Collaborative Practice Research approach. It is based on managers’ perception about what should be reflected upon when evaluating organizational value of IT investments. The managers involved have experience from decision support systems aiming to save time in the operative work, give information about how to handle chemical accidents and provide better analysis of the operative work etc. The main purpose of these IT systems is foremost to provide the organization with better information related to the operative work. Further, IT systems are considered as social systems and “…has some recognized functionality but needs to be considered as a set of social objects. As a social object, its influence on organizational function and performance cannot be separated from expertise, jobs, processes or structures.” (Zammuto et al. 2007 p. 753).

This study involves three non-public organizations in Sweden. The organizations have a rather unique situation since the grant of money has its origin in a cost budget process that gives the frame for the approved costs. If one organization spends less money one year, they risk receiving fewer grants next year. In addition, the evaluation of IT investments in the public sector can be extra problematic since they work in collaboration with many different organizations, such as the police, ambulance, and health services.

In the next section, I will give a literature review. Then the organizational settings and research approach will be presented. Followed by the result of this study, a discussion, and a short conclusion.
2. ASSESSING THE VALUE OF IT INVESTMENTS

The problem of evaluating IT investments is framed as the productivity paradox. It originates from studies during the 1980s that found no connection between IT investments and productivity in the U.S economy. Productivity is a measure of efficiency, the use of resources (output, doing things right). The productivity paradox was originally stated by Solow and further developed and discussed by Brynjolfsson (Dedrick et al. 2003). Today there is evidence that IT provides positive impact on productivity and instead the attention has switched to IT and profitability (ibid). Profitability is described as the fulfillment of goals and measurement of effectiveness (outcome, doing the right things) (Lewis et al. 2007). The task of management is according to Lewis et al. (2007) to “administrating and coordinating resources effectively and efficiently in an effort to achieve the goals of the organization”. This is a rather rational view of the organization. However, both effectiveness (do the right things) and efficiency (do things right) are relevant measures to consider since the role of the involved organizations is described by Fire Rescue Agency as to deliver services (pre-determined goals) to citizens in an efficient way. Also, non-profit public organizations in Sweden have no traditional income and balance sheet that can evaluate the outcome of the organizations. It should be important to initially reflect upon the effectiveness (goals achievement, doing the right things) and the efficiency (use of resources, doing things right) before an IT investment is accepted. However, effectiveness and efficiency can include other factors than the economic since value is pluralistic (Guba & Lincoln 1990, Bannister 2001). This will be discussed in the next paragraph.

2.1 The Economic and the Interpretative Approach

The two most discussed IT evaluation approaches within the research field IT evaluation are the Economic and the Interpretative IT Evaluation Approach based on economic and interpretative theory (Berghout & Remenyi 2005). The Economic Approach is the most used method by management when assessing IT investments (Ward & Daniel 2006). There exists a plethora of different economic methods such as the capital budgeting methods: Pay Back, Internal Rate of Return (IRR) and Net Present Value (NPV). These methods is described as “the process of analyzing potential capital expenditures and deciding which investments the firm should undertake”. (Brigham & Gapenst 1996). To use these methods requires a consideration of aspects such as estimating expected cash in- and outflows and calculating the sum of the present values of the expected cash flows. Different kinds of information is attained such as, how long it will take for the investment to return invested capital, and calculating the interest costs for not borrowed capital in order to give a more accurate result of the investment etc. The methods are summative and do not give guidelines how to follow-up an investments along its life cycle. Thus, evaluate organizational value of IT investments with economic methods only gives information about efficiency and effectiveness from an economic view.

The Interpretative IT Evaluation Approach sees IT systems as both technical and social entities (Walsham 1995) and as the starting point for evaluating organizational value is the stakeholders’ perception of reality (Guba & Lincoln 1990, Symons 1991, Stockdale & Standing 2006). Examples of interpretative IT evaluation models are the CCP (content, context, process) framework and Benefit management (BM). The CCP framework focuses on the context (why), the content (what) and the process (how) (Symons 1991, Stockdale & Standing 2006). These concepts derive from Pettigrew’s conceptualization of organizational change (Symons 1991). Stockdale and Standing (2006) have described the context as explaining why the IT system is of importance. The content is based on the stakeholders’ perception of the value so their choice of criteria determines the content (ibid). The process is formative and follow up the IT investment along its life cycle. BM focuses on how to follow-up benefits in different steps along the IT investments life cycle. Thus, the Interpretative IT evaluation approach is contextual, the content is dependent on stakeholders’ choice of criteria, and the process is formative. Next it would be of interest to find out what prior research has been put forward as important factors and criteria to be reflected upon when assessing IT investments.
2.2 Beyond the Economic and the Interpretative IT Evaluation Approaches

The research field IT evaluation can in overall be described as fragmentary (Berghout & Remenyi 2005). IT evaluation includes a plethora of different factors and criteria directed to IT evaluation of IT investments. A well-known multi-criteria method is Information Economics developed by Parker and Benson (Robson 1997). Information Economics focuses on the business and the technology domain and include factors such as strategic match, competitive advantage, competitive response and organizational or project risk. Other factors suggested to reflect upon is strategic match. Strategic match is important since it creates awareness of whether the IT investment matches the strategic context (Kefi 2002). In addition, Ballantine & Stray (1999) argue for strategic alignment i.e. the IT investment should align with the IT strategy that in turn should be aligned with the business strategy. If strategic match not is done the IT, investment could be waste of money in the end. In addition, the effect of IT investments inside and outside the organization is consider as valuable input to the discussion of the organizational value. For instance, when considering collaborative and inter-organizational systems the surroundings of the organization should be analyzed (McCalla et al. 2003). Stefanoue (2001) writes that, understanding of organizational impact and change is required if any benefits are to be realized, since poor fitting of the system to the organization relates to an inability to respond to changes. In addition, costs of organizational change are required if any benefits are to be realized (ibid). Benefits are described as hard and soft, costs as direct and indirect (Love et al. 2005). Indirect benefits can occur due to further IT investments. Indirect costs are difficult to see and examples of such costs are user resistance; personal training; external consultants; additional applications and system downtime (Stefanou 2001). In addition, optional theory and uncertainties are mentioned as input to IT evaluation (Toffolon 2001). Stakeholders’ involvement gives a better understanding of benefits, value and suitability than traditional economic methods (Irani & Love 2001) and the functionality of the system (Khalifa et al. 2001). However, when it comes to stakeholders it is mainly the stakeholders of the system that are discussed and not the stakeholders of the organization. Still several IS researchers see the IT system primarily as a technical system and therefore the most important factor to consider (Gemmell and Pagano 2003, Choenni et al. 2003). Further, Clay et al. (2003) write that a project manager who has authority and experience will influence the outcome of an IT project in a positive way. Thus, prior research has provided knowledge about many factors and criteria that should be reflected upon when assessing IT investments.

3 RESEARCH APPROACH

3.1 Research site: The Fire Rescue Services

The Fire Rescue Service (FRS) is responsible for providing the population with services such as prevention, preparation, and response. The FRS is structured as a Fire Rescue Service (FRS) or as a Fire Rescue Alliance (FRA). The difference is that the former co-operates with the municipalities where it is situated. The latter consists of several FRS and acts as one municipality that assists the municipalities involved. The directorate of the confederation gives the economic pre-condition for FRS and FRA. The confederation is composed of politicians from one or several municipalities. The three involved organizations differ in structure and amount of employees. Organization A was a FRA, acted in a large city, included five municipalities, has 1000 employees, and 9 Fire Stations. Organization B was a FRS, acted in a large city, has 650 employees, and 9 Fire Stations. Organization C was a FRS, acted in a middle-sized municipality, has 100 employees, and 3 Fire Stations.

IT investments were initiated inside or outside the organizations. Initiatives outside could be initiated due to a new law or from the Rescue Services Agency, the government authority. Initiatives inside the organizations could come from anyone within the organization. In addition, initiatives come yearly when the budget process is running, all kind of requirements pop up, running track, IT system etc. Decisions on IT investments were decentralized, and were often taken on the departmental level. However, if the costs exceed a specific amount the Chief Manager of the FRS became responsible. Before such a decision, the board often discussed the IT investment and if it should be approved. If the
IT investment costs exceed regular budget restrictions, it becomes a political issue and the decision has to be supported by the local government committee, appointed by the local municipality. The individual decisions on IT investment were based on factors such as benefits, costs and technology. The benefits are often argued from the requester view and not from an organizational view. The cost calculations included mainly costs for IT hardware and software since the costs for using the organizations own resources was consider already taken. Thus, the focus is on the IT system and its possibilities and not on the need of the organization. Historically the organizations have had good economy and that has created a culture where the organizational value is not always in focus. Times have changed and in one organization, large savings are needed. So, evaluating organizational value of IT investments were perceived to be more important in the future.

3.2 Collaborative Practice Research

The research project was performed from 2005 to June 2008. It was a well-known problem that initiatives on IT investments are based on personal interest and have a technique focus. Instead, the perception among several of the respondents was that it was time to put the need of the organization in focus. After the initial interviews were the problem area was appreciated it was evident that IT evaluation was a management, IT evaluation and a conceptual problem.

The next step was to investigate the content, what should be evaluated, and how should the process be accomplished. The research approach was Collaborative Practice Research (CPR). CPR tries to fulfill the dual objectives, improving practice and contributes to the body of knowledge within the research (Mathiassen et al. 2002). CPR is pluralistic since it is difficult to control the research with only using action research (Mathiassen 2002). In addition, the researcher is dependent on how practice evolves and it is not easy to control the focus of the research outcome. Therefore, diverge activities support each other and give deeper understanding for the investigated phenomenon. The CPR-based process is developed by Mathiassen (2002) and is influenced by Susman and Evered, Checkland and McKay, and Marshall’s action research approach (ibid). The project has been done in collaboration between the researcher and management in the organizations involved. The CPR includes different stages, see table 1, and the stages of the research project are presented in the second column. This study focuses on point C in the second column.

Table 1. This research project, in comparison to Mathiassen et al. (2002) research project.

Thus, the findings are based on the respondents’ perceptions of reality and the interpretation of the researcher. My role was an “outside researcher” and during the workshops and interviews, I did try not to influence the participants in any direction. In the workshops, findings from prior IT evaluation research were discussed. I also took part of several meetings and documents such as a project model, an activity plan, introducing a new IT project, information concerning Balance Score Card etc.

3.2.1 Data collection and Data analysis

In organization A and B the IT manager selected the respondents that should attend the workshops. In organization C it was the manager for the operative work. These managers had awareness of who had
the experience from IT investments or assessing IT investments. The study involved at each organization six to seven managers from different levels. Managers attending the study were at top level: Chief Manager, Vice Chief Manager and IT Manager. At functional level, Managers of department were attending. At the operative level, Managers of the operative work force were involved. By management is meant someone who has an overall responsibility for the organization, the department, or for a team alternative the turnout.

The first workshop included two different meeting points. First, the findings from the interviews (see table 1, point A) were presented. Theses findings indicated that the missing value of IT investments was caused by lack of management control (lack of strategy and co-ordination), lack of understanding of the concept value (each stakeholders has his own perception), and lack of an appropriate formalized IT evaluation approach that consider context, content and a process. The findings were recognizable by the participants. Next, the IT evaluation, the economic and interpretative IT evaluation approach, and factors and criteria put forward by prior research were introduced. The presented factors and criteria were received in a positive way and were in accordance with management perceptions of what should be reflected upon when assessing the organizational value of IT investments. Along the discussion, I wrote down the factors and criteria that by the participants should to be part of an IT evaluation. It was also an agreement among the participants about the selected factors and criteria. I perceived that this exercise created learning to the participants and put structure on a complex issue. I finished the workshop by asking if they wanted to structure the selected factors and criteria in a word document, a power point presentation or in some other form. Two of the organizations wanted to structure the findings in a word document and the third organization wanted a power point presentation. The aim of the documents was to support the evaluation process of IT investments. In the second workshop, the respondents discussed the results from the first workshop. The workshop resulted to further development and modification of factors and criteria selected by the participants. I perceive that the modification occur due to that the respondents have had time to reflect upon the discussed factors and criteria and had developed an improved understanding for organizational value. Thus, the workshops trigger their own learning by reflecting upon factors and criteria related to organizational value. The last workshop was performed according to the second.

Each workshop and lasted approximately 2 hours. During the workshops, I took notes and after the workshop, I wrote down spontaneous reflections from the meetings. For the analysis, I used the notes from the paperboard and from my own reflections. For two of the organizations I summarized the chosen factors and criteria in a word document, called the Value Case. This Value Case was further modified during the workshops. For the third organization, the result was summarized in a power point presentation, named the Value Case. I also compared the results from all three organizations in order to analyze patterns of similarities and deviations. This analysis resulted in a Meta Value Case that included all factors and criteria suggested from the three organizations. Organization A and B wanted to learn from each other and took part of the Meta Value Case.

Care was taken to ensure that the findings were interpreted in accordance with the respondent’s perception regarding what factors and criteria that should be included in the value case. In order to validate the findings, the Meta Value Case were also presented for top managers at two others Fire Rescue Services not involved in the study. The results were favorably received in both organizations. The managers perceive that the document could support the IT evaluation process and increase the understanding for the organizational value of an IT investment.

4 ASSESSMENT FACTORS GENERATED BY PRACTICE

Management has in literature been described as “... the process of administrating and coordinating resources effectively and efficiently in an effort to achieve the goals of an organization” (Lewis 2007, p. 5). Such management approach can be extra important in non-profit public organizations that are goal driven.
In order to increase the understanding of the relevance of these factors they have been categorized into effectiveness (do the right things) and efficiency (do things right). The respondents suggested that the selected factors and criteria should be evaluated in an iterative process along the IT investments, life cycle and give continuously feedback about the relevance of the IT system.

4.1 The Rationale for Effectiveness, doing the right things

The respondents considered strategic match vital since the lack of strategic match has contributed to an ad-hoc development of IT. Strategic match can give management increased understanding of the relevance of new IT investments (doing the right thing). The respondents (functional and operational level) perceive that IT initiatives today are often based upon individual interests and not on the needs of the organization. “We don’t know the plans for the coming two years. This allows persons who are most anxious about new information systems or information technology to get their requests approved. The arguments are often based on personal interest and not on the needs of the organization” (Operational managers). “Unfortunately we give priority to individual desires instead of the total picture. We can’t agree on one brand of digital cameras or digital calendars” (IT manager). In addition, to include strategic match as a factor can give management increased understanding of the need of explicit strategies for the organization in order to be able to govern the public sector towards its mission. By the time of the workshops none of the organizations had evident strategies for the business, organization, or for IS and IT. In one of the organizations the IT Manager was waiting for the organizational strategy while the Vice Chief Manager was waiting for the IS and IT strategy. In two of the organizations, the Balance Scorecard was on the agenda. I perceive that two of the organizations tried to agree on what perspectives to include in order being able to doing benchmarking, but this seems like a problematic process. To introduce a Balance Score Card could facilitate the strategic match of an IT investment. In one organization, the IT manager refused to take responsibility for the operations of new IT investments since IT was introduced into the organization without discussing or informing the IT department. Not coordinating IT will give increased cost for running IT and the burden of work becomes unmanageable for the IT department. In addition, the managers perceive that IT is power and IT decisions are a political act, and a focus on strategic match can reduce power situations since the need and the value of the organization will be in focus.

Today FRS collaborates with organizations such as the police, the ambulance and the municipality so impact on the surroundings is an essential factor to reflect upon. Also, the impact on the citizens are vital since FRS/FRA work for the citizens’ best, but is often forgotten in the discussions about value (functional and operational level). Criteria such as politics, economy, society, and technology i.e. what is going on outside the organization should also be reflected upon in order to ensure that the organization would do the right things. The selected factors and criteria in the workshops concerning effectiveness are presented in table 2.

Table 2. Factors and criteria related to effectiveness.

4.2 The Rationale for Efficiency, doing things right.

Organizational impact is also essential since it opens up the understanding for the changes needed in the organization, and from that, quantitative and qualitative benefits could more easily be deduced. Also, a criterion like power is of interest since IT changes power structures. The respondents regarded
benefits to be difficult to make explicit and benefits should not only be an enumeration of quantitative and qualitative aspects but also be described with who receives the benefits. Managers perceive that the technology get to much attention: “The internal discussion often concerns technology, technical platform and the IT system, but questions should be raised such as, what needs to be developed, what do we want to achieve, and how should we proceed?” (A manager at functional level). Today cost calculations include costs of the hardware and software but not for the employee’s involvement, education, maintenance, support, for the project etc. According to some of the managers this can explain why the decisions-makers seem to have a habit of buying new IT instead of upgrading (IT manager). Factors as risks are necessary and in particular risk for the project, the organization and the technology. Also not involving the stakeholders can make it worse instead of improving. The IT system and criteria such as security, architecture, support, flexibility etc. are important. In addition, the respondents added project organizing in order to increase the IT project chance of succeeding, since the IT project is dependent on right timing and the ability to involve the right persons. Selected factors and criteria related to efficiency are summarized in table 3.

5 DISCUSSION: TOWARDS A VALUE CASE

Lewis et al. (2007) have described the role of management as “the process of administering and coordinating resources effectively and efficiently in an effort to achieve organizational goals” (p.5). This is very much in accordance with the opinions of several of the managers, a demand for an IT
evaluation approach that could shift attention from a technique and personal interest focus to organizational value based on effectiveness (do the right things) and efficiency (do things right).

One way to support managers’ consideration of effectiveness and efficiency in the IT evaluation process of IT investments is to introduce a Value Case. The Value Case takes one-step further from the Business Case and takes a formalized, pluralistic, contextual and formative view. The Value Case includes factors and criteria put forward by prior research and is further discussed by the involved managers.

5.1 Reflections on the Economic and Interpretative IT Evaluation Approach

The respondents argue as well as several researchers, Symmons (1991), Stockdale and Standing (2006), and Ward and Daniel (2006), that an economic perspective is not sufficient. However, the Interpretative IT Evaluation Approach was not sufficient either since the content needed support by pre-determined criteria that could increase the understanding of factors and criteria affecting effectiveness and efficiency i.e. the organizational value. Stockdale and Standing (2006) has also noted that what to evaluate is a far more complex process than first appear. It can be worth reflecting upon the consequences of using an Interpretative approach if the involved stakeholders lack experience and pre-knowledge of a new IT investment. Also, if pre-knowledge and experience of the IT system differ among the different stakeholder groups, how will that affect the discussions about organizational value. Since evaluating IT investments is described as a political process there is also a risk that the discussions of the organizational value of IT investments deal with individual interests from some stakeholders and other stakeholders lack arguments due to limited experience. A Value Case including a formalized, pluralistic, contextual and formative approach can support managers in a discussion of the organizational value and the appropriateness of the IT investment.

5.2 Towards a formalized, formative, contextual and a pluralistic Value Case

The involved managers argue that the understanding of organizational value can be improved by assessing factors and criteria related to both efficiency and effectiveness. The factors and criteria generated by the managers are presented and discussed in next section.

Effectiveness

- **Strategic match.** In accordance to Kefi (2002) the respondents said that before starting an IT project it is vital to match an IT-investment with the strategic context since it contributes to an increased awareness if the IT investment is “doing the right thing” for the organization. The respondents added criteria related to internal goals included in the Safety and Health Act.

- **Impact on the surroundings.** This factor was also considered important since the organizations cooperate with several other organizations such as the police, ambulance etc. McCalla et al. (2003) note that this can be particularly important when collaborative and inter-organizational systems are evaluated. The respondents also consider the traditional strategic criteria, politics, economy, society and technique relevant in order to create awareness of doing the right things.

Efficiency

- **Impact on the organization.** The respondents agree with Stefanoue (2001) that organizational impact must be considered if any benefits are to be realized. However, the respondents also emphasize the importance of analyzing the impact of an IT investment on the organization since that will facilitate the understanding of needed changes and in turn to whom the benefits relate.

- **Benefits.** In literature, several discussions concerned tangible, intangible, direct and indirect benefits (Love et al. 2005). The respondents were more interested in discussing quantitative and qualitative benefits and to whom the benefit was directed. The respondents said that it is important to consider the stakeholders of the organization in order to get a rich picture of who benefits from the new IT system. Due to individual interest of IT, it can be a risk of internal focus and the citizen perspective cast aside.
- **Costs.** Costs were of great interest since a better calculation could contribute to better understanding of total investment costs, running costs and for the selection between buying new or upgrading. The literature that discussed direct and indirect costs (Love et al. 2005) received less attention.
- **Risks.** The respondents discussed risks related to the organization, the IT project, the IT system, costs etc. Uncertainties and optional theory did not catch the respondents for further discussions.
- **The IT system.** Gemmell and Pagano (2003), and Choenni et al. (2003) have suggested some criteria, and those were received with recognition. Also, questions like, what will happen if the IT system breaks down and stop were discussed as important input to the value case.
- **Stakeholders’ opinion.** Irani and Love (2001) noted that stakeholders’ involvement incorporates increased understanding of benefits, value and suitability. Khalifa et al. (2001) write that the functionality of the IT system will also be improved. These statements are very much in accordance with the opinions of the respondents. They argue that stakeholder groups’ affected by the new IT system should be involved and interviewed so they can give their view of the new IT system.
- **Project organizing.** This perspective was not so well discussed in the literature; Clay et al. (2003) note the importance of a project champion. The respondents said that it is central to involve the right people and have the right timing in the IT project, also to clarify dependencies on other IT projects.

Factors and criteria discussed by the respondents as valuable input to the evaluation process when assessing the organizational value of IT investments are presented in table 4.

*Table 4. The Value Case*

The empirical findings of this study indicate that only using an interpretative IT evaluation approach don’t match the need of management. A step forward is needed since methods or models based on economic or interpretative theory are not sufficient from a management view when evaluating IT investments. That economic methods are not sufficient has been known for a long time. Instead the interpretative IT evaluation approach has by prior research been suggested. However, the content, what to evaluate, in the interpretative IT evaluation approach is based on stakeholders’ perception on reality. But if the managers lack experience or pre-knowledge of a new IT system, such approach can be limited. The risk is that factors related to efficiency and effectiveness, the task of managements is not on the agenda. In non-profit organizations in the public sector the consideration of efficiency and
effectiveness can be extra important since several of the organizations are foremost goal driven. The empirical findings showed that several managers lack understanding of what should be assessed in order to achieve organizational value. The Value Case gives managers a possibility to discuss and reflect upon important factors related to the organizational value of IT investments. Hopefully, a Value Case can support managers and reduce the risks to IT projects failures since increased understanding will be achieved about how the IT investments match the strategy, the effects on and outside the organization.

As Stockdale and Standing (2006) write; “A decision on what is to be evaluated is a far more complex process than might first appear and is significantly influenced by the stakeholders and by the context of the organization” (p. 1092). In future research, it would be of interest to continue to discuss the content of IT evaluation and hopefully provide an analyze tool. Such analyze tool can for managers increase the understanding of how an organization will be affected by a new IT investment, and essential factors and criteria to reflect upon when assessing organizational value of IT investments? It is time to take a step from an IT system focus, focusing on the stakeholders of the IT system, to a organizational focus and foremost create understanding for how they will interact.

6 CONCLUSION

Prior IS research has concluded that only an economic view is not sufficient when evaluating organizational value of the IT investments. Instead an interpretative IT evaluation approach has been put forward. The content is based on the stakeholders’ perceptions on reality. But if the stakeholders lack experience or the strategic view and organizational goals are not evident, how will organizational value be evaluated? What to evaluate has by prior research been described as more complex than it might appear. The empirical findings show that the involved managers perceive that assessment of organizational value of an IT investment can be improved if the content of IT evaluation can be supported by pre-determined factors related to effectiveness and efficiency. Therefore, in this study a Value Case is developed that puts management’s attention to effectiveness (doing the right things) and efficiency (doing things right). The Value Case has a pluralistic, a formative and a formalized view. Gives managers a possibility to discuss and reflect upon factors related to how the IT investment will affect the organization and its surroundings and thereby create better understanding of the organizational value of the IT investments. The discussed factors are strategic match, impact on the organization and its surroundings, benefits, costs, risks, the IT system as such, the stakeholders’ view of the system, and project organizing. Hopefully future research will continue to discuss the content of IT evaluation and what should be reflected upon in order to facilitate for managers the assessing organizational value of IT investments.

^Department of Information Systems, The University of Melbourne, Australia.

Abstract

Many organizations now purchase and customize software rather than build information systems. In this light, some argue that high-level data modeling no longer has a role. In this paper, we examine the contemporary relevance of high-level data modeling. We addressed this issue by asking 21 experienced data-modeling practitioners to reflect on their work and to give their opinions on trends and future directions in high-level data modeling. We analyzed transcripts of our interviews with them using Klein and Myers’s (1999) framework for qualitative research. We found considerable variation in the practice of high-level data modeling. We also found that high-level data modeling is still considered important, even though organizations ultimately may purchase off-the-shelf software. The reason is that high-level data modeling assists organizations to obtain clarity about IT project scope and requirements, thereby reducing the risk that costly implementation mistakes will be made.

Keywords: high-level data-modeling practice, conceptual data-modeling practice, logical data-modeling practice, enterprise systems, package selection.

1 INTRODUCTION

Historically, organizations have built information systems in-house to solve business problems, exploit business opportunities, support business processes, and enable new products or services to be delivered. In this context, part of the practice of building an information system involved analyzing the data needs of an organization so that databases could be designed and implemented to support the system. This requirement gave rise to the traditional database design life cycle of steps reported in contemporary textbooks (e.g., Teorey et al. 2006; Hoffer et al. 2005) and attempts to develop relevant theory to support database design (e.g., Batra 2007; Codd 1970; Wand and Weber 2002).

The steps commonly articulated in database design (e.g., Teorey et al. 2006; Hoffer et al. 2005) and more broadly addressed in systems analysis (e.g., Kendall and Kendall 2004) include two that are often called conceptual data modeling and logical data modeling. Together, these steps are sometimes called high-level data modeling. They are undertaken before physical data modeling, which involves taking into account a target database management system and a hardware/software platform.

In this research, our focus is on conceptual and logical data modeling (i.e., high-level data modeling). Both steps involve constructing and using data models to represent, clarify, define, and relate important business phenomena. Often the distinction between the two steps revolves around the need in logical data modeling to consider key challenges with and to avoid common flaws in database implementation. In contrast, conceptual data modeling focuses much more on the meaning, use, and definition of and relationships among key business entities.

The motivation for our research is that the need for, purposes of, and activities involved in high-level data modeling appear to be changing significantly. For instance:
Many information systems are now considered to be a commodity. As a result, organizations often no longer build information systems. Instead, they buy ready-made packages to support their information systems needs (Davenport 1998; Shang and Seddon 2002). Often these packages require extensive configuration and customization (Markus and Tanis 2000).

To support managerial decision-making, many organizations now build data warehouses and use various business-intelligence tools that obtain data taken directly from business transactions (Kimball et al. 1998; Wixom and Watson 2001).

The strategic importance of data is increasing, especially at the corporate level (e.g., Shanks 1997). For instance, acquisition and merger activities are unlikely to be successful if information systems cannot be integrated.

Patterns are playing an increasingly important role in contemporary high-level modeling (e.g., Batra, 2005; Hay, 2006; Silverston 2001a, 2001b). Furthermore, a number of industry-standard data models are now appearing (e.g., in health services, http://www.hl7.org/, telecommunications, http://www.tmforum.org/, and supply-chain management, http://www.supply-chain.org/).

These changes affect the practice of high-level data modeling. Historically, some research has been done on data modeling practices (e.g., Batra and Marakas 1995; Floyd 1986; Necco et al. 1987). A paucity of research exists, however, in relation to contemporary high-level data modeling practice. Some work has been done on design and development methodologies (e.g., Kautz et al. 2004) and process modeling (e.g., Chang et al. 2001), but little work has been done on data modeling broadly or high-level data modeling specifically.

In response to a paucity of research on conceptual modelling practice, Davies et al. (2006) conducted a survey of conceptual modeling practitioners in Australia. They had two objectives (p. 359): (a) “to obtain empirical data that conceptual modeling is indeed being performed now and into the foreseeable future in IS practice in Australia”; and (b) “to find out what are the principal tools, techniques, and purposes for which conceptual modeling is performed currently in Australia.” Their focus was conceptual modeling broadly, including process and workflow modeling additional to data modeling. They found that (p. 376) “[d]atabase design and management remains the highest average purpose for use of modeling techniques,” and that the reasons for continued use of all conceptual-modeling approaches included “communication…to/from stakeholders, internal knowledge…of techniques, user expectations management, understanding models integration into the business, and tool/software deficiencies.” The limited qualitative data that came from the survey constrained the depth with which current practice and future trends in data modeling practice could be studied.

In this research, our goal was to explore current practices and trends in high-level data modeling in some depth. We conducted field research in which we undertook semi-structured interviews with 21 highly experienced practitioners to obtain their views about high-level data modeling. We sought a deep understanding of the reasons behind the answers they provided to our questions. Specifically, we used the following broad questions as a “scaffold” for the interviews we conducted with them:

- Why is high-level data modeling undertaken?
- What high-level data-modeling activities are undertaken?
- How are high-level data-modeling activities undertaken?
- Who is involved in undertaking high-level data-modeling activities?
- What quality-assurance measures are used in high-level data modeling?
- What is the future of high-level data modeling?

We canvassed these questions with our interviewees in a fairly informal way. Our concern was to use the questions to elicit and trigger their opinions and reflections rather than to impose a rigid structure on our interactions with them. We wanted to understand the nature and purposes of the activities they undertook and the meaning they ascribed to high-level data modelling (Neumann 2007, pp. 276-278).
The remainder of the paper proceeds as follows. First, we discuss our research method. Next, we present our results in relation to each of our research questions. We then summarize our findings. Finally, we present some implications of and some strengths and limitations of our research.

2 RESEARCH METHOD

Because our research is exploratory, we adopted an interpretative research method. In this light, we followed Klein and Myers’ (1999) principles for the conduct of interpretative research (Table 1). During 2007 and 2008, we carried out interviews with 21 experienced data-modeling professionals engaged in high-level data modelling. Each interview lasted about 90 minutes. All interviews were transcribed. Using techniques from Miles and Huberman (1994), we then sought to make sense of interviewees’ experiences with and views about high-level data modeling. Specifically, we employed a descriptive matrix to relate comments made by our interviewees to our broad research questions.

<table>

Table 2. Overview of research interviewees

We sought interviewees by making presentations to local chapters of the Data Management Association (DAMA) and Data Warehousing Association (DWA) in three cities. We explained the nature of our research, its purposes, the assistance we required, and the qualifications of individuals from whom we sought assistance. We obtained contact details from individuals who indicated they were willing to assist us. In some cases, to comply with ethics restrictions, we used ‘snowballing’ whereby individuals asked other data modelers to contact us to indicate their willingness to participate in our research. Subsequently, we scheduled interviews with all who had agreed to assist us.

3 RESULTS

The following subsections present our findings in relation to each of our major research questions. We provide illustrative quotations to support our findings. Quotations are labelled as, for example, I#4, which means a quote from Interviewee 4’s transcript.

3.1 Reasons for Undertaking High-Level Modeling

Previous research has considered conceptual modeling as a precursor to logical modeling, which in turn leads to physical data modeling. This sequence assumes that an application supported by a database will be built. Interviewees had alternative views on reasons why conceptual modeling was now undertaken by organizations.

Scoping for proposed projects was the most-common reason given for preparing a conceptual model. I#4, who is a highly experienced modeler, stated that rigor is unimportant in conceptual modeling. He commented that the primary purpose of the conceptual models he prepared was to scope the project. Furthermore, he argued that conceptual models are not prepared with the objective of “getting towards implementation or working out business rules.” I#6 also considered that articulating rigorous business requirements was unnecessary at the conceptual-model level. Instead, conceptual modeling was done just to “scope the next level of activity.” I#2 describes a model as a “means to the end” with a project’s scope report as a likely associated key deliverable. I#1 described “scope as possibly the key part of the conceptual model.”

I#5 said she created conceptual models for two purposes. First, she used them to build an enterprise data model, which she described as not necessarily leading to the immediate purchase of a package or development of a bespoke system. Instead, a conceptual model was a resource that had “many
purposes.” Second, sometimes she used an application conceptual data model for a “particular application” development. Others reinforced this view. For example, I#3 described how a quality conceptual model and organizational overview helped direct an organization’s selection and purchase of package software and development of applications. In particular, the model and overview helped avoid the pitfalls of systems that evolve independently. He argued that it was better to have the applications “logically conforming to some overarching model than to have them evolve independently and then try and put them together, which is where we’re at today.” Similarly, I#1 spoke of using high-level data models to find “pain points” with proposed systems and thereby to manage risk.

The need for integrated information systems, particularly data warehouses, was the driver for some to undertake entity definition work at the conceptual level. In these contexts, interviewees stressed the need for entity definition resolution. Interviewees found potential in conceptual models for transcending individual projects. They were long-term resources that could be used to help integrate and plan an organization’s informational needs, projects, applications, and data-warehouse activities.

Without a conceptual model to guide configuration, I#3 argued that configuring a package becomes more expensive and error prone. He commented that lack of a conceptual model to provide guidance during package configuration led to arguments about the meaning of data among different departments in an organization. He gave an example where an organization found it could migrate only 30 percent of data from six billing systems to a new system because of the lack of agreed data definitions. The result was seven systems that lacked interoperability. He was not alone in this observation.

I#1, who has supervised many teams on major projects for decades, argued that high-level data modeling is needed to help avoid major problems for organizations by guiding the evolution of data needs. “I see the design documents as a key resource for the company.” While business evolves over time, I#7 argued that conceptual modeling done correctly often needed only fine tuning over time.

3.2 Types of High-Level Data Modeling Activities Undertaken

Interviewees had different views about the nature of conceptual versus logical models. Each particular view appears to be linked to the depth of the project they were undertaking, the domain in which they were modeling, and the complexity or size of the organization they were modeling.

Although interviewees varied in the activities they undertook at the two levels (and sometimes varied in the modeling activities they undertook at these two levels between projects), most considered preparation of conceptual models to be a phase that was distinct from preparation of logical models. Specifically, they indicated the logical level involved adding more details to the model (e.g., keys and attributes) and resolving many-to-many relationships. During the preparation of a logical model, I#4 said that he added more detail to a conceptual model and “nailed down the rules.” I#6 commented that rigor in a conceptual model was unimportant. He indicated that his logical or “subject” models had keys and relationships, but his conceptual or “enterprise” models had no keys or relationships.

Those interviewees who constructed enterprise conceptual models did not fully articulate their models. For instance, a fully articulated ER (entity-relationship) diagram would have keys, attributes, and fully resolved many-to-many relationships. On those occasions where he used ER diagrams, I#1 was clear that relationship resolution did not occur at the conceptual-modeling level. Instead, his focus was on identifying “scope” and “pain points” and achieving some agreement about entity definition.

Most interviewees indicated that the largest amount of work at the conceptual-model level involved getting agreement on definitions. I#4 said this task as “difficult.” I#3 commented that obtaining agreement on name definitions was not always possible, and he described it as an ongoing job. Nonetheless, he argued that obtaining agreement on name definitions was important because it meant that business requirements between departments could be understood better and more easily integrated. I#15 thought it important to get the right stakeholders with expertise because it was “a question of confidence in the answer” and he could “manage expectations.” I#7 endeavors to have one agreed definition for each entity and attribute to ensure “multiple departments are speaking the
same language.” She said it is a mistake to allow different departments or applications to have different definitions. I#10 spoke about the importance of consensus about data definitions: “Build up a glossary and say if we’ve got two different terms for them and maybe let’s think of a term that covers the general, both of them but just trying to agree on the same language.”

I#5 indicated she focuses on definitions needing resolution. She also looks for key performance indicators, as these often needed definitional agreement. I#5 indicated she had recently completed a project to help the client get a “structured business vocabulary” as a first step. The client then followed through with an articulation of business rules using the agreed vocabulary.

Whether entity definition occurred at the conceptual or logical level varied among interviewees and the types of projects they undertook. I#8 indicated he did not undertake entity definitions during conceptual modeling but rather left this task for “techies.” Instead, he gave a “description of what these areas of information are.” Most interviewees considered that attaining some agreement on entity definitions was a key part of conceptual model work, however. For example, at the conceptual-model level, I#1 argued the main deliverables were the model and entity definitions. At the logical level, he would include some key attributes. Many interviewees thought a large part of conceptual modeling was establishing business vocabulary or metadata in the form of data definitions relating to business rules. The client organization could then use these definitions as a business “language” for communication across divisions and applications.

I#9 had a different view, however, about the link between conceptual models, logical models, and physical models. He commented, “they (a client) took that as a logical design which they put into physical code and they got it straight from the conceptual model. Now is that blurring the boundaries?” Even during his conceptual modeling work, he included a high level of detail in the models he prepared, primarily because he relied substantially on previously developed data modeling patterns. I#12 also included high levels of detail in the models he developed. I#15 had changed his mind about the role for logical data models by saying that “the physical needs to be supported.”

Model completion usually was not expected. I#5 said she only represented a few types of phenomena in a conceptual model. Sometimes she might prepare just a simple conceptual model with a few key entities and definitions as a basis for communication among stakeholders in some domain. At other times in small projects, she prepared a conceptual model that included attributes and relationships (which she described as eventually constituting a logical model). She described her most-recent project as being supervised by an experienced modeler who expected rigor. On this project, she had to include detail like relationships at the conceptual level. Moreover, her conceptual model had to link coherently to a logical model that included keys and other “technical information.”

Some interviewees said they undertook sub-typing of entities in their models. For instance, I#3 described sub-typing at the logical level as time consuming and expensive. Nonetheless, he felt the clarification of business rules saved much time in implementation. I#14 avoided sub-typing, however, because when he explained “sub-class, sub-typing, and bringing in sort of universal data modeling type concepts” to business personnel, “they get lost.” By way of contrast, he emphasized the need for abstraction: “So you’ve got to move up a level there and think of that level and that’s important.”

### 3.3 Ways in Which High-Level Data Modeling is Undertaken

All except one interviewee used workshops to garner the business information required for the data models they needed to construct. Attendees at the workshops were almost always representatives of the business. Some interviewees emphasized that workshops also helped to obtain agreement among client representatives about priorities and definitions of business objects or metadata. For instance, I#11 commented: “Often it’s good for us to get into the workshop and try and thrash out some of the nitty gritties with a lot of business units because often they have conflicting priorities.”

Helping participants feel comfortable during workshops was a reason behind some interviewees’ choice of material or methodology. For instance, rather than using software tools to build a model,
I#7 indicated she uses whiteboards and hand-drawings to help client representatives feel relaxed and to build the model in conjunction with them. I#10 follows a similar approach: “Really, to be truthful I tend to start off with a whiteboard and some people sitting around and saying what are the concepts.”

Some interviewees use standard data model patterns that they customize to suit the context in which they are working. For instance, I#1 argued, “You do not need to reinvent the wheel.” He had specialized in banks and telecommunication companies where transactional relational databases are common. He had used the Financial Services Data Model, which is a proprietary data model developed for the banking and finance sector.

I#9 was the strongest advocate for the use of patterns. He commented that he used patterns “I guess, in ever-increasing amounts of detail. I can knock together, and this is going to frighten you, I can knock together an enterprise-wide conceptual model in probably 30 to 60 minutes. And you say you’re joking, but I can interact with senior management and start to talk and their eyes light up when they realize, hey you understand and all I’m doing is patterns.” I#14 is also a strong believer in patterns: “I’m a great believer in utilizing what other people have done.” I#12 did not use patterns, but he reused models he had developed during previous engagements with clients.

I#8 said that he started with a straw-man pattern and looked for disagreement with it, because he frequently had only a few days to complete a model. He commented that he often had already decided what package was likely to suit his client’s business. As a result, he would look to make only slight adjustments to the patterns he used. He saw patterns as a fast means of getting input from end users. I#10 also sometimes used a straw-man approach: “The other way is probably a bit more common…come up with a straw-man yourself and then go through and sort of say well is this right.”

One of the more-experienced interviewees, I#4, replied that he used patterns only occasionally and used them only in the sense of capturing previous experience. He indicated that he discarded them quickly, however, if they did not fit the context. I#7 found dangers when presenting models prior to eliciting business requirements. She warned that end users might simply accept a pattern without sufficient reflection on its accuracy and completeness. As a result, she emphasized the importance of starting with a clean whiteboard and working with end users to create their own model.

I#3 was the most outspoken against patterns. He argued that it was “best practice” not to assume similarities among models and to commence modeling with an open mind. He referred to recent experiences with patterns in which he found that “a US telco is very different from an Australian telco.” Despite the fact that telecommunication companies often offer similar products, he found that they applied different business rules that required different models. He had found that patterns did not save time and led to important omissions in data definitions. I#5 commented that some proprietary data models were too expensive for some organizations to purchase.

I#19, who has worked primarily in government, was keen to identify “reference sets” in his modeling workshops. He indicated that he “would source (reference data) from somewhere else.” Examples he gave included “countries of the world,” “area codes,” and “telephone prefixes.”

3.4 Participants in High-Level Data Modeling

Interviewees were split as to whether IT professionals should be included in workshops. If IT professionals were present, however, interviewees held a common view—namely, that IT professionals should play little or no role in the discussions that ensued in a workshop. Instead, IT professionals should play the role primarily of observers.

I#5 voiced one perspective saying she “does not deal with IT folks… I may have some present but only as observers.” I#18 preferred “to concentrate on the business problem.” Others had regrets like I#6: “I wish I did work with people at that (the technical) level, but consultants come in.”
3.5 Quality-Assurance Practices in High-Level Data Modeling

Throughout our interviews, it became clear that quality-assurance practices like audits, walkthroughs, reviews, metrics, and documentation standards received little attention during high-level data modeling. Our findings stand in contrast to the modeling standards now in force in organizations such as the U.S. Defense Department (where UML has been adopted as the conceptual-modeling standard). Interviewees stressed that model correctness and completeness were important for high-level data modeling, but that standards were not defined clearly. For instance, interviewees selected a modeling methodology depending on the project, personal leanings, or their client’s preferences. Moreover, conformity with standards was often impossible because of time constraints imposed on them.

We asked interviewees how their models were validated and updated. Many indicated they were hired as consultants and were not given time to validate and correct their models. For the most part, any validation that occurred was an outcome of interactions among attendees at modeling workshops.

I#7 aims to get consensus about correct and complete business requirements and data definitions despite the fact that “a lot of companies are not willing to invest that time.” She indicated that some organizations were willing to devote only an hour or two to model validation. I#8 acknowledged that getting agreed data definitions was pivotal to quality and validation concerns. Nonetheless, he argued that trying to get agreement on definitions quickly was “counterproductive.” His view is that during modeling he must “understand business and not techno stuff.” He prefers to get a “description of what these areas of information are” rather than an agreed definition because “we can’t let things drag on.”

Interviewees involved with data-warehousing projects seemed to have more opportunities to validate and update their models. For instance, I#5 said she was responsible for updating her conceptual models if errors and omissions were found during logical-level modeling. Similarly, I#7 remains engaged until the “physical-build” stages of a warehousing project. She oversees quality checks that she suggests for her logical model. Her model is updated when errors and omissions are found.

With governments, I#4 indicated he has been given the chance to undertake quality reviews. He went through many cycles of feedback with stakeholders until differences relating to the models he had prepared were resolved. Nonetheless, for most of his projects, achieving correct and complete high-level data models was not considered important. He commented, “you do not really worry about getting it perfect,” because once the model is used it becomes evident how it should be “tweaked.” I#8 went further and stated that aiming to get most data definitions right at the conceptual level is “counterproductive.” He felt definitions and relationships should be left for “techies.”

Interviewees were asked about the tools they used to enhance the quality of their models, such as tools to check syntax and reverse engineer models based on existing systems. They responded that they used whatever tools their client organization wanted or provided. Few mentioned use of expensive tools. Those who did often had large government organizations as their clients. For instance, I#6 described liking the “Mega” tools, and commented that “System Architect” was “brilliant.” Nonetheless, he indicated that these tools often require full-time personnel to support their use because they are highly complex.

I#6 said that he preferred to use the types of tools that allow his models to be linked with other models (including physical models) and ultimately with the data that populates his models. He described the tools as not so much CASE (computer-aided software/system engineering) tools but as tools to manage business areas on many levels. He stated that use of these tools enhanced the quality of models because they facilitate validation and update of the models—they allow a system’s requirements and architecture to be integrated and considered from several perspectives. In relation to the projects he undertook, I#6 pointed out a trend toward increasing demands of cohesiveness between (a) different organizations models, and (b) business and technology. He observed that some data-modeling tools were evolving to support this trend.
I#5 sees herself as exceptional among modelers in her attempts to provide metadata about each object in her models. She spoke of a procedure whereby a “series of assertions” derived from a model was presented to stakeholders for validation as a thorough, best-practice technique. Her experience with using this approach, however, was that business people were unable to understand it or refused to devote time to it. Instead, like I#16, she recommended using a walkthrough with stakeholders that focused primarily on entities. I#18 used quasi-assertions in which he would “explain each one of those relationships both backward and forward and find out... is this correct or is it not correct?”

Like I#5, I#3 seeks to cross-reference metadata definitions with business rules to test the validity of his models. He was the only interviewee who expressed his ability to undertake model validation in a fairly formal way. He used the most-extensive procedures to validate his models. For him, quality was also about exploring business requirements rather than using presupposed patterns. He uses three validation techniques. (1) He presents his model to stakeholders for feedback and questions and resolves errors, omissions, and ambiguities. (2) He describes the business rules in a spreadsheet and asks stakeholders to check their validity. (3) He asks stakeholders to check his model through scenarios. He particularly focuses on the validity of subtypes in his models.

In short, our interviewees indicated that they had only limited influence over quality-assurance procedures. Unlike other areas of IT practice where quality checks, metrics, validations, updates, and reviews are now standard, they often are not features of high-level data-modeling environments. Moreover, quality problems appear to be compounded by a general lack of stakeholder input and interaction and the distribution of modeling activities across different IT professionals.

### 3.6 Future of High-Level Data Modeling

Interviewees were emphatic and unanimous about the ongoing need for high-level data modeling. Several argued that “erroneous ideas” about the declining importance of high-level data modeling were “driven from the package industry.” I#7 argued that good high-level data models save millions of dollars by avoiding the purchase of inappropriate, sometimes expensive, software systems. I#1 indicated that a package might not fit all business requirements. He believes that knowledge of the overall business requirements is necessary to make an informed decision about package purchases, especially expensive packages.

I#5 believes a resurgence in high-level data modelling is occurring, driven partly by greater use of Service Oriented Architectures (SOAs), which are a relatively low-cost approach to aid application integration across organizations. I#5 is working increasingly with “information architects,” who have been appointed by their organizations to achieve the goal of better data management. I#5 argued that pressures to develop high-level models quickly were counterproductive to the growing need of “providing an enterprise asset for the organization.”

I#3 commented that systems integration and interoperability were now a high priority for many organizations. He argued that high-quality, high-level data models help with the development of applications systems and the purchase of packaged software. They enable organizations to avoid the pitfalls associated with bespoke systems that are developed independently. Moreover, they help ensure that packages can be integrated with other systems in the organization. In the absence of high-quality high-level data models, I#3 argued “some really expensive failures” can result.

I#7 argued that high-level data models were increasingly important to effective strategic planning. Some types of organizational strategy required systems integration. In this regard, I#6 said that the need for integrated information systems required organization-level data management, which in turn was linked to a trend toward increasingly big and complex organizations and applications.

I#6 argued that the assets of an organization are “in the requirements and design,” because nowadays one can “auto generate code” or “select packages.” Therefore, he believes that increasing emphasis will be placed on developing high-quality design documents and data models. He also stressed the importance of governance to support high-level data modeling. He has observed many times that
models “fell apart” when good governance structures and procedures were not in place and working. He explained that a clear governance structure effectively allows discrepancies among high-level data models to be resolved and an organization to own changes that it makes to its data models. He now prefers to work only for organizations that have effective governance in place. 1#6 argued that effective governance occurs, however, only when a leader recognizes the importance of clearly stating business process requirements and is willing to devote resources to support quality business analysis.

I#21 was circumspect about the role that high-level data models could play in package selection by helping to drive a “side-by-side functionality capability check” between the package and requirements. I#19 cited a specific example of how data modeling helped build a requirements document where the package vendor “knew exactly what our requirements were at a data level, at the process level, at the use-cases.” Another project took nine months longer than expected where the vendor “saw us coming a mile away... because the requirements were not clear” after I#19 had warned the internal client “you need to have models for this.”

Where companies continue to build bespoke systems, agile methodologies are now in the ascendancy. Those data modelers who used agile methodologies identified advantages and challenges. I#20 sees a key role for high-level data modeling and observed that sometimes “what falls off the bottom of agile prototyping is the underlying model,” which means it is difficult to extract data into warehouses. I#21, who is also experienced with agile methodologies, said that “we use a tool to gather the stories and exercise the model... on how well it supports the business functionality... (and if it) can actually support the business processes.”

4 SUMMARY OF FINDINGS

Table 3 is a descriptive matrix that summarizes major themes (Miles and Huberman 1994, p. 246) we identified in the responses provided by interviewees to our research questions.

<table>
<thead>
<tr>
<th>Research Question</th>
<th>Findings/Themes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Why undertake high-level data modeling?</td>
<td>To scope projects, build enterprise data models, guide the evolution of an organization’s data needs, select and configure packages, manage project risk, and develop applications.</td>
</tr>
<tr>
<td>What high-level data-modeling activities are undertaken?</td>
<td>Building conceptual data models in which entities and sometimes relationships are defined. Building logical data models in which attributes and keys are defined. Gaining agreement on entity definitions.</td>
</tr>
<tr>
<td>How are high-level data-modeling activities undertaken?</td>
<td>Via workshops and sometimes by using patterns, past models that the modeler has developed, industry-standard data models, and CASE tools (often those tools mandated by the client).</td>
</tr>
<tr>
<td>Who is involved in high-level data-modeling activities?</td>
<td>Modeler and most often key business stakeholders.</td>
</tr>
<tr>
<td>What quality-assurance measures are used in high-level data modeling?</td>
<td>Quality-assurance activities are limited due to lack of client resources and enthusiasm.</td>
</tr>
<tr>
<td>What is the future of high-level data modeling?</td>
<td>To articulate business requirements before package selection, help manage data that needs to be integrated in service-oriented architectures, and improve the effectiveness of strategies that lead to system integration in large, complex organizations by clearly defining data to be integrated.</td>
</tr>
</tbody>
</table>

Table 3. Summary of results

In our view, these themes enable us to characterize contemporary high-level data-modeling practice in the following way:

- Relative to the past, most high-level data modeling is now undertaken with much-less emphasis on database design. Instead, the goals are to (a) identify critical business concepts and their relationships, and (b) provide guidance for projects, especially in terms of a project’s scope.
• Group techniques dominate contemporary high-level data modeling. Experienced modelers play the important role of facilitating stakeholder discourse. They assist stakeholders to share ideas and information, negotiate outcomes, and establish shared vocabularies. IT professionals are seldom included as active stakeholders in group activities.
• High-level data modeling increasingly is used to underpin package selection, data-warehouse design, and enterprise planning.
• Quality assurance in relation to high-level data models often is not undertaken as a distinct activity. Instead, it is an active process that occurs, somewhat subliminally, during workshops. To some extent, it is facilitated by using industry-standard data models and data-model patterns.
• Experienced data modelers see an ongoing and more-important role for high-level data modeling.

5 IMPLICATIONS, STRENGTHS, AND LIMITATIONS

Our findings have implications for research, teaching, and practice. For research, it is clear that the objectives of and practices associated with high-level data modeling are changing. A deeper understanding is needed of the motivation for and nature of these changes and the likely ways they will unfold. Our findings show that variations exist in the views of and activities undertaken by practitioners. A deeper understanding of why these variations exist is required. Ultimately, theories are needed to account for the variations.

For teaching, we believe high-level data modeling still needs to be an important part of the curriculum taught to intending IT professionals. Moreover, it appears that conceptual modeling, logical modeling, and physical modeling increasingly are becoming distinct areas of expertise and practice. While students need to understand how these three types of data modeling are related, it may be advantageous for them to develop higher levels of competence in one particular type of data modeling.

For practice, we believe the management of organizations should revisit the role that high-level data modeling plays in their planning activities and the operations of their organizations. In some organizations, this role seems to have become diminished, mainly because of some of the rhetoric around package software (e.g., that packages obviate the need for detailed requirements specifications and thus data models). Our findings show that high-level data modeling is transcending its traditional roles in system development and playing an increasingly important role in strategy and planning.

A strength of our research is that it is one of few studies investigating how highly skilled practitioners undertake high-level data modeling. It is also novel because it explores the under-researched role of high-level data modeling in the post-bespoke-systems era. Because we have used an interpretive approach to the analysis of data collected in our research, we believe we have obtained rich insights into the current practice of high-level data modeling. Thus, our research should inform both researchers and practitioners.

A limitation of our research is that we have obtained only the opinions and reflections of our interviewees. We did not observe them directly, and we recognize that espoused theories may not reflect theories-in-use (Argyris and Schön 1974). Furthermore, because we interviewed only active experienced data modelers, our results potentially are biased toward emphasizing the ongoing importance of high-level data modeling.

Abstract

Distributed construction of conceptual models may lead to a set of problems when these models are to be compared or integrated. Different kinds of comparison conflicts are known (e.g. naming conflicts or structural conflicts), the resolution of which is subject of different approaches. However, the ex-post resolution of naming conflicts raises subsequent problems that origin from semantic diversities of namings – even if they are syntactically the same. Therefore, we propose an approach that allows for avoiding naming conflicts in conceptual models already during modelling. This way, the ex-post resolution of naming conflicts becomes obsolete. In order to realise this approach we combine domain thesauri as lexical conventions for the use of terms, and linguistic grammars as conventions for valid phrase structures. The approach is generic in order to make it reusable for any conceptual modelling language.

Keywords: Conceptual Modelling, Model Comparison, Domain Thesaurus, Computational Linguistics
1 INTRODUCTION

Since IS modelling projects are often large-scaled, the required models are increasingly constructed in a distributed way in order to boost the efficiency of modelling (vom Brocke & Thomas 2006). I.e., different modellers participate in the modelling process developing different model parts – maybe at different places and at a different time. Furthermore, domain experts are increasingly integrated in the modelling process to comply with domain requirements as much as possible – an approach that is commonly known as End-user Development (Wulf & Jarke 2004; Fischer et al. 2004). Distributed modelling becomes more and more mainstream. This applies not only intra-corporately but also in the form of so-called modelling communities, e.g. the Open Model Initiative (Frank & Strecker 2007).

Empirical studies show that model sections developed in the course of distributed modelling can vary heavily concerning terms and abstraction level (Hadar & Soffer 2006). Therefore, the comparability of the regarded models cannot be guaranteed. Comparison conflicts may occur, which are commonly divided into naming conflicts and structural conflicts (Pfeiffer 2008). Consequently, the integration of the different model sections into one total model representing the original modelling issue may be extremely laborious. Usually, model parts are consolidated manually and with attendance of all modellers in order to reach a consensus. Sometimes, external consultants are involved additionally (Phalp & Shepperd 2000; Vergidis & Tiwari & Majeed 2008). Thus, the original sub-goal of distributed modelling – i.e. the increased modelling efficiency – may be missed.

Summarising, a considerable problem of distributed modelling is the insufficient comparability of conceptual models. In order to solve this problem, approaches are required that are able to assure comparability. In literature, there exist many contributions that propose approaches for resolving comparison conflicts subsequent to modelling (cf. Section 2).

The goal of this article is to introduce an approach that ensures the comparability of conceptual models by avoiding potential comparison conflicts already during modelling. This way, we prevent semantic problems that result from the ex-post resolution of conflicts. This article focuses on naming conflicts. We define naming conventions for elements of modelling languages and ensure their compliance by an automated, methodical guiding during modelling. The conventions are set up using the domain terms and the phrase structures that are defined as valid in the regarded modelling context. As a formal specification basis, we use thesauri that provide term conventions not only for nouns but also for verbs and adjectives. These thesauri also include descriptions of a term’s meaning. In order to provide conventions for phrase structures, we use the Head-driven Phrase Structure Grammar (HPSG) (Pollard & Sag 1994), a formal grammar for the specification of natural language syntaxes. During modelling, model element names are validated simultaneously against both the term and phrase structure conventions. Our approach is generic so that it can be applied to any conceptual modelling language.

Our approach is suitable for modelling situations, where it is possible to provide all involved stakeholders with the necessary information about the modelling conventions, i.e. modelling projects that are determined regarding organization and/or business domain. These modelling situations usually apply in companies, corporate groups or modelling communities.

The paper is structured as follows. First, we analyse related work in Section 2 and discuss the research gap that led to the development of the approach presented in this paper. Furthermore, we outline the research methodology used. In Section 3, we introduce a conceptual framework for the specification and enforcement of naming conventions. The feasibility of our approach is shown exemplarily with a demonstrator software in Section 4. Furthermore, an explorative analysis of real-world process modelling projects shows the potential of the approach reducing ambiguities in process models. We conclude the paper in Section 5 and motivate further research addressing e.g. the conflict classes not yet covered by this approach.
2 FOUNDATIONS

2.1 Related Work

Early approaches of the 1980s and 1990s discussing the resolution of naming conflicts address the integration of company databases and use the underlying schemas as a starting point (Batini & Lenzerini 1984; Batini & Lenzerini & Navathe 1986; Bhargava & Kimbrough & Krishnan 1991; Lawrence & Barker 2001). Hence, these approaches focus on data modelling languages, mostly dialects of the Entity-Relationship Model (ERM) (Chen 1976). Names of schema elements are compared and, this way, similarities are revealed. The authors state that such a semantic comparison can exclusively happen manually. Moreover, only single nouns are considered as names. In contrast, in common modelling languages and especially in process modelling languages, names are used that consist of sentence fragments containing terms of any word class. This aspect is not regarded by schema integration approaches. Thus, they are only suitable for the mentioned data modelling languages.

Other approaches make use of ontologies (Gruber 1993; Guarino 1998) in order to address the problem of semantic comparison of names. These approaches act under the assumption that there exists a “generally accepted” ontology describing a certain modelling domain. It is assumed that all considered models of this domain comply with its ontology, i.e. that modellers had a thorough knowledge of the ontology. E.g., Höfferer (2007) connects domain ontologies to the terms that are used as element names in conceptual models. This way, he establishes relationships between elements of different models that are to be compared and identifies similarities. In addition to ontologies, Ehrig, Koschmider, and Oberweis (2007) define combined similarity measures that consist of syntactic and semantic parts. These serve as a basis for the decision whether or not the model elements compared are equivalent. Consequently, it is argued that if identical terms – or those that are defined as synonymous within the ontology – are used in different models and by different modellers, they can be considered as semantically identical as well (Koschmider & Oberweis 2005; Sabetzadeh et al. 2007).

However, solely the circumstance that two modellers act in the same business domain does not guarantee at all that they share the same or an equivalent understanding of business terms. If a “generally accepted” ontology is available, it is suitable for model comparison if and only if it is explicated and can be accessed by all involved modellers already during the modelling process. Furthermore, in order to ensure comparability of the models, modellers have to comply strictly with the ontology. Most approaches make the implicit assumption that these preconditions are already given rather than addressing a methodical support. So far, there exist only few approaches that address such a support. Greco et al. (2004) propose adopting terms from existing ontologies for process models manually. However, due to manual adoption, correctness cannot be assured. Born, Dörr, and Weber (2007) propose semi-automated adoption of model element names. However, they restrict their approach to BPMN models (White & Miers 2008).

In order to avoid the problems of ontology based approaches, Pfeiffer (2008) suggests integrating domain semantics into modelling languages, i.e. the names of model elements are preset. Thus, he proposes domain-oriented building block-based process modelling languages. With the PICTURE modelling approach, he concretises them for the domain of public administration. Since PICTURE consists exclusively of 26 process building blocks with defined semantics, naming conflicts are a priori impossible. As the author states himself, this language class is restricted to mainly linear business processes.

Only few approaches, mainly from the German speaking area, suggest standardised phrases for model element names in order to increase the clarity of process models. The phrase standards are summed up as modelling conventions. E.g., Rosemann (1996) and Kugeler (2000) propose particular phrase structure guidelines for names of process activities (e.g. <verb, imperative> + <noun>; in particular e.g. “check invoice”). Moreover, the authors propose so-called Technical Term Models (Rosemann 2003) that have to be designed previously to process modelling and that specify the terms to be used within the phrases. Therefore, the scope of Technical Term Models is restricted to nouns. Similar approaches provided by Koschmider and Oberweis (2005) and Sabetzadeh et al. (2007) propose preposi-
tioning generally accepted vocabulary. Further approaches recommend connecting names of model elements to online dictionaries in order to establish semantic relationships of terms (Rizopolous & McBrien 2005; Bögl & Kobler & Schrefl 2008). These online dictionaries consist of extensive collections of English nouns, verbs, and adjectives as well as their semantic relationships. Actually, the proposed approaches are promising regarding increased comparability of conceptual models since all of them aim at standardising names for model elements prior to modelling. However, up to now, a methodical realisation is missing.

To sum up, we identify the following need for development towards avoiding naming conflicts in comparing conceptual models: Up to now, methodical support for (1) the formal specification of naming conventions for all word classes and (2) the formal specification of phrase structure conventions is missing. Furthermore, there exists neither methodical support for (3) the integration of conventions in modelling languages nor (4) for guiding modellers in order to comply with the conventions.

In order to realise such a methodical support, we propose an approach that consists of (1) a formalism to specify thesauri covering nouns, verbs, and adjectives, (2) a grammar to specify phrase structures that can hold terms specified as valid within the term models, (3) a framework to integrate these naming conventions with modelling languages, and (4) a procedure to guide modellers automatically in complying with the conventions.

2.2 Research Methodology

The research methodology followed here complies with the Design Science approach (Hevner et al. 2004) that deals with the construction of scientific artefacts like methods, languages, models, or implementations. Following the Design Science approach, it is necessary to assure that the research addresses a relevant problem. This has to be proven. Furthermore, the artefacts to be constructed have to represent an innovative contribution to the existing knowledge base within the actual research discipline. I.e., similar or identical solutions must not be already available. Subsequent to the construction of the artefacts, these have to be evaluated in order to prove their fulfilment of the research goals.

In this contribution the scientific artefact is the modelling approach outlined in Section 1. This artefact aims at solving the relevant problem of the lacking comparability of conceptual models that are developed in a distributed way (cf. Section 1). Related work does not provide appropriate solutions up to now (cf. Section 2). Hence, the approach presented here (cf. Section 3) makes an innovative contribution to the existing knowledge base. In order to evaluate the approach, we have implemented a demonstrator software that shows the general applicability of the approach. Furthermore, we have conducted an explorative study that shows the potential of the approach (cf. Section 4). Additional evaluations concerning efficiency and acceptance issues will be performed in future studies (cf. Section 5).

3 A FRAMEWORK FOR THE SPECIFICATION AND ENFORCEMENT OF NAMING CONVENTIONS

3.1 Procedure Model

In order to provide a framework for naming conventions, we propose the usage of a domain language that is used for naming model elements in a certain modelling context (i.e. a specific modelling domain, project, or company). This domain language is a subset of the respective natural language (here: English) used in the modelling context. The domain language consists of a set of valid domain terms that are allowed to be used for model element names exclusively. The set of domain terms is a subset of all terms available in the respective natural language. Furthermore, every natural language has a certain syntax that determines the set of grammatically correct phrases. In our framework, we restrict the syntax of the respective natural language as well. I.e., the possibilities to construct sentences for model element names are limited. In summary, we restrict the grammar of a natural language in order to provide a formal basis for naming model elements (cf. Figure 1).
Natural language grammars are usually defined by a formalism that consists of a lexicon and a syntax specification (Mitkov 2003). This grammar is complemented with naming conventions, which again consist of term and phrase structure conventions. Term conventions are specified by a domain thesaurus containing domain terms with a precise specification of their synonym, homonym, and word formation relationships as well as a textual description of their meaning. It is connected to the natural language’s lexicon. Moreover, valid phrase structures are specified by phrase structure conventions. Hence, the natural language is customised for the needs of a specific modelling context. This allows for subsequent validation of the model element names and the enforcement of naming conventions. A conceptual overview of the naming conventions’ specification is given in Section 3.2.

The domain thesaurus can be created from scratch, or by reusing possibly existing thesauri or glossaries. Contrary to most common domain ontologies, which consist of nouns (e.g. “invoice”) or atomic domain concepts (e.g. “check invoice”), the thesaurus used here includes single nouns, verbs, and adjectives that are interrelated. Other word classes are generally domain independent. Thus, as they are already included in the lexicon, they do not need to be explicitly specified in the thesaurus. The terms in the thesaurus are linked to their synonyms, homonyms, and linguistic derivation in the lexicon. This additional term-related information can be obtained from linguistic services, which already exist for different natural languages. WordNet (http://wordnet.princeton.edu) is such a lexicon service for the English language providing an online interface. Therefore, in case of a later violation of the naming conventions by the modeller, synonymous valid terms can be automatically identified and recommended. The terms specified should be provided with short textual semantic descriptions, allowing modellers to look up the exact meaning of a term. The thesaurus should not be changed during a modelling project in order not to violate the consistency of application. When online services are used, the option of creating a local copy should be analysed.

Before starting a modelling project, the naming conventions have to be specified once for every modelling context. However, already existing conventions can be reused. Naming conventions are modelling language specific. For example, functions in Event-driven Process Chains (EPC) are labelled with activities (e.g. `<verb, imperative> + <noun>`; in particular e.g. “check invoice”) and events are labelled with states (e.g. `<noun> + <verb, past participle>`; in particular e.g. “invoice checked”) (Scheer 2000). For each model element type at least one phrase structure convention has to be defined. For the sake of applicability, the conventions should be specified in a manner, which is compatible with the formalism of the natural language grammar.

The conventions should be defined by a project team consisting of domain experts and modelling experts. I.e. the stakeholders responsible for the conventions should have thorough knowledge of the actual modelling context in order to reach a consensus. Most commonly, the thesaurus part of the conventions already exists in terms of corporate or domain-specific glossaries (e.g. http://www.automo-
During modelling, the model element names entered are verified simultaneously against the specified modelling context-specific grammar. On the one hand, the structure of an entered model element name is validated against the customised syntax specification. On the other hand, it is checked whether the used terms are allowed. Nouns, verbs, and adjectives are validated against the thesaurus. Other word classes are validated against the natural language lexicon.

In case of a positive validation, the entered model element name is declared as valid against the modelling context-specific grammar. In case of a violation of one or both criteria, alternative valid phrase structures and/or terms are suggested based on the user input. The modellers themselves have to decide, which of the recommendations fits their particular needs. By looking up the semantic descriptions of the terms, modellers can choose the appropriate one. Alternatively, they can choose a valid structure as a pattern and fill in the gaps with valid terms. However, the modeller should have the chance to propose a new term, which is then accepted temporarily. Hence, the modeller can continue without being distracted from his modelling session. It is then up to the modelling project expert team whether they accept the term or not. If the term is accepted, it is added to the thesaurus. Otherwise, the modeller is informed to revise the model element. Hereby, we ensure that equal model element names represent equal semantics, which is a precondition for comparability.

3.2 Conceptual Specification

In the following, we provide a conceptual framework for the specification and the enforcement of naming conventions using Entity-Relationship Models in (min,max)-notation (ISO 1982) (cf. Figure 2). Phrase structure conventions (PSC) are defined depending on distinct element types of conceptual modelling languages (e.g., activities in process models are named differently to events). Phrase structure conventions consist of phrase types or word types. A phrase type specifies the structure of a phrase, which can be used as a model element name. Therefore, a phrase type can be composed recursively of further phrase types or word types. Representing atomic elements of a phrase type, word types are acting as placeholders for particular words. An example of a word type is <noun, singular>, an example of a phrase type is <noun, singular> + <verb, infinitive>. The composition of phrase types is specified by the phrase type structure. At this, the allocation of sub-phrase types or word types to a phrase type and their position in the superordinated phrase type are defined. A word type consists of a distinct word class (noun, verb, adjective, adverb, article, pronoun, preposition, conjunction, or numeral) – and its inflection. Inflections are specialised as case, number, tense, gender, mood, person, and comparative, which are usually combined. E.g., a particular combined inflection is <3rd person, plural>. In respect to specific word classes, not every inflection is applicable. Based on the recursive composition of phrase types, the specification of arbitrary phrase structure conventions is possible.

Figure 2. Specification of Phrase Structure Conventions on Type Layer

Phrase structure conventions restrict the English syntax and thus limit modellers in their freedom of naming of model elements. In order to facilitate the synchronisation between the syntax of the natural
language and the applied phrase structure conventions, compatible formalisms for both syntax specifications are necessary. Hence, it should be possible to verify phrase structure conventions against the underlying natural language and to signal potential conflicts directly during the specification process. For this purpose, we establish the connection to an appropriate linguistic method in Section 3.3.

Independent from their corresponding word class, particular uninflected words are called lexemes (e.g. the verb “check”). Inflected words are called word forms (e.g. past participle “checked” of the lexeme “check”). Word forms are assigned to the corresponding word classes and inflections, i.e. their word types. Thus, word forms represent lexemes of a particular word type (cf. Figure 3).

![Figure 3. Specification of Term Conventions on Instance Layer](image)

In order to specify the domain thesaurus, allowed words are stored in the form of lexemes that are related by different word relationship types. They are specialised as homonym, synonym, and word formation relations. Word formation means that a lexeme originates from (an)other one(s) (e.g. the noun “control” originates from the verb “to control”). In case of synonym relations, one of the involved lexemes is marked as dominant to state that it is the valid one for the particular modelling context. Homonym relations are necessary in order to distinguish lexemes that consist of the same string but have a different meaning and to prevent errors during modelling. Word formation relations are used to search for appropriate alternatives when a modeller has used invalid terms and phrase structures. E.g., if the phrase “order clearance” violates the conventions, the alternative phrase “clear order” can be found via the word formation relation of “to clear” and “clearance”. Based on the word relationship types, lexical services (cf. Section 3.1) are connected to the domain thesaurus. To specify the actual meaning of a lexeme, a textual semantic description is added at least to each dominant lexeme. This way, modellers are enabled to check if the lexeme they have used actually fits the modelling issue.

### 3.3 Specification of Linguistic Restrictions

We make use of formalisms for the syntax specification of natural languages both for assuring correctness of specified phrase structure conventions and for identifying the structure and words of model element names. The latter is necessary in order to detect convention violations during modelling and to suppose alternative valid phrase structures and terms.

Such formalisms are mainly established in the field of computational linguistics. A well-known and widely accepted class of such formalisms are unification grammars (Mitkov 2003). All formalisms of this class have in common that syntax rules are specified in relation to phrase structures and their components. In unification grammars, feature structures are used to formalise syntax rules of a given language. A feature structure is a set of features and their values, which are structured hierarchically. It describes syntactical characteristics of a phrase structure. These phrase structures declare for a given natural language, which word types or sub phrase types can occur at which position within a phrase structure. An exemplary phrase structure consists of a phrase type, which is composed of two word types (cf. Figure 4). The word types are characterised by the features word class and inflection. Depending on the word class, the feature inflection is composed of further features. Possible features are number and case for the word class noun, and tense for the word class verb. The position of word types and phrase types within the phrase structure is defined by the given order. In the class of unifi-
cation grammars, the *Head-driven Phrase Structure Grammar (HPSG)* (Pollard & Sag 1994) is a widely established approach. Several formal specifications of natural languages based on HPSG are already available (cf. http://www.delph-in.net). A formal specification of the English syntax with HPSG was developed at the CSLI LinGo Lab of the University of Stanford (Copestake & Flickinger 2000).

In our approach, we use this HPSG-based syntax of the English language. Hence, the set of possible phrase structure conventions for model elements is a subset of the syntax of the English language based on HPSG. In the modelling process, the model element names have to comply with the conventions. Moreover, the used words have to comply with the domain thesaurus. In order to assure this, the model element names are parsed against the used words, their inflection, and their phrase structure. Corresponding parsing methods are available as a part of the *LinGo English Resource Grammar* (Copestake & Flickinger 2000). The parser is able to detect the lexeme, its word class and its inflection for each word using a lexicon. In our approach, the lexicon consists of the domain thesaurus that is connected to common lexical services. If the terms used within model element names do not comply with the conventions, alternative valid lexemes are searched in the domain thesaurus via the defined word relationships and are proposed in the appropriate inflection form for proper use. If a phrase structure is violated in turn, alternative valid phrase structures are proposed that contain the valid terms.

4 EVALUATION

4.1 Modelling Tool Support

To validate the applicability of our approach, we developed a modelling prototype. The way of navigating through the software and its handling corresponds with the procedures motivated in Section 3. Please note that the screenshots were adapted to English, since the prototype solely exists in German.
As a preliminary but unique step, the team responsible for constituting the domain grammar has to define the terms, which are allowed for the modelling context. Subsequently, the phrase structure conventions have to be specified. If the actual modelling context represents a domain which has been processed before, the existing set of terms and rules can be reused or adapted to the current requirements. Figure 5 shows an exemplary definition of domain verbs. It is sufficient to add the uninflected word, as the inflection can be looked up in the lexical services. Specifying nouns and adjectives is similar to specifying verbs. Word relationships like “synonym” or “word formation” can be defined between words. Besides the word relationships, the semantic descriptions are defined within the thesaurus editor as well.

![Figure 5. Specification of Domain Verbs](image)

Figure 5. Specification of Domain Verbs

In the next step, phrase structure conventions are defined and connected to those language elements for which they are valid. Figure 6 illustrates this with the example of EPCs. Here, phrase structure conventions are created for the model element type event. Concerning their semantics (but not their type), events of the EPC can be distinguished in trigger events and resulting events. The former ones trigger action in activities, the latter ones conclude activities. Different phrase structures can be attached to each of them in regard to their different semantics. An example for a trigger event is “Invoice is to be checked”, hence an appropriate phrase structure convention called “Trigger” is \(<\text{noun}> + \langle\text{"to be", simple present, 3rd person}\rangle + \langle\text{"to be", infinitive}\rangle + \langle\text{verb, past participle}\rangle\). With this phrase structure, a set of trigger events can be named. However, different aspects might require additional phrase structures to be defined. For result events, an adequate phrase structure is \(<\text{noun}> + \langle\text{verb, past participle}\rangle\), allowing phrases like “Invoice checked”.

Once generated, the phrase structure conventions in combination with the domain thesaurus are used during modelling. The modeller gets just-in-time hints as soon as he violates a convention (cf. Figure 7). First, he might have chosen invalid terms (e.g. bill instead of invoice or audit instead of check). As soon as a phrase is entered, it is parsed to determine its compliance with the naming conventions. Every term is transformed to its uninflected form and is compared to the domain thesaurus. If it is not found, synonymous valid terms are searched in the lexicon. If according alternatives are found, they are proposed to the modeller. Otherwise, the modeller has to rename the respective element – optionally by choosing a valid term from the domain thesaurus. Second, violations of phrase structure conventions are signalled, and alternative valid structures are proposed. Summarising, the name audit bill is suggested to be changed to Invoice is to be checked. Phrases corresponding with both the domain thesaurus and the phrase structure conventions are accepted without any feedback.
4.2 Explorative Analysis

Naming practices in process models provide evidence concerning the danger of naming conflicts as well as show the feasibility of approaches that aim at resolving or even avoiding them. In order to empirically evaluate our phrase structure conventions approach we conducted an exploratory empirical analysis. We analysed two process modelling projects consisting of overall 257 EPC models containing in turn overall 3918 elements (1827 functions and 2091 events). Within these modelling projects, modelling conventions were available in terms of glossaries and phrase structures. However, these conventions solely existed as textual recommendations rather than methodical support. All model element names were analysed and revised. We then manually analysed 280 phrase structure types, which occurred at least twice. These structures covered 1770 model element names in total. We were able to match the found structures to 47 identified phrase structure conventions, which had the same power of expression. E.g. we were able to express the same semantics concurrently achieving less naming variability. This analysis shows that having applied our approach would have substantially reduced naming differences and thus supported model comparability.

5 CONCLUSION AND OUTLOOK

Integrating naming conventions into conceptual modelling languages is promising for increasing the comparability of conceptual models. Two characteristics are significant to avoid common problems:

- Defining and providing naming conventions previously to modelling is the basis for avoiding naming conflicts rather than resolving them. Therefore, time-consuming alignment of namings in the course of model comparison becomes dispensable.
- Guiding the modeller automatically during modelling is of substantial importance, since only this way the compliance with the modelling conventions can be assured.

Certainly, specifying naming conventions in the proposed way is time-consuming. Our approach is therefore mainly suited for large-scaled modelling projects. Nevertheless, for every project, business domain or company, the conventions have to be specified only once and are reusable. Moreover, term models, thesauri, or glossaries that may already exist in companies or business domains can be reused.

Future research will focus on the further evaluation of the proposed approach. In the short-term, the approach will be instantiated for different modelling languages, different natural languages and different application scenarios. In particular, the capability of our approach to increase the efficiency of dis-
tributed conceptual modelling and its acceptance will be evaluated in empirical studies. In order to as-
sure the applicability of the approach, the demonstrator software will be enhanced in order to make it
usable in practice. In the course of evaluation, it will also be investigated if ambiguities play a role in
model element names. E.g. the sentence “They hit the man with a cane” is ambiguous, even if the
meanings of all of the used words are considered definite. Thus, we will analyse further conceptual
models and determine if phrase structures are common in conceptual modelling that promote ambi-
guities. A result of this analysis could be a recommendation to restrict phrase structure conventions to
phrases that do not lead to ambiguities.

Middle-term research will address further approaches in order to facilitate the comparison of models
that are developed in a distributed way. Here, the comparison of conceptual models based on the
model structure is a promising research area. Moreover, we will question if modelling conventions on
the basis of structure patterns that are provided at the beginning of modelling are able to increase the
comparability of conceptual models as well.

Abstract

It is intensively discussed in both science and practice how data quality (DQ) can be assured and improved. The growing relevance of DQ has revealed the need for adequate metrics because quantifying DQ is essential for planning quality measures in an economic manner. This paper analyses how DQ can be quantified with respect to the DQ dimension timeliness. Based on an existing approach, we design a new metric to quantify timeliness in a well-founded manner that considers so-called supplemental data (supplemental data are additional data attributes that allow drawing conclusions about the timeliness of the data attribute considered). In addition, it is possible to take the values of the metric into account when calculating expected values, an advantage that in turn leads to improved and comprehensible decision support. We evaluate the presented metric briefly with regard to requirements for designing DQ metrics from literature. Then, we illustrate the metric’s applicability as well as its practical benefit. In cooperation with a financial services provider, the metric was applied in the field of customer valuation in order to support the measurement of customer lifetime values.

Keywords: Data Quality, Data Quality Metrics, Design Research, Customer Valuation
1 INTRODUCTION

Both the benefit and the acceptance of application systems depend heavily on the quality of data processed and provided by these systems (Ballou et al. 1999, Fisher et al. 2003). Executives and employees need high-quality data in order to perform business, innovation, and decision-making processes properly (Al-Hakim 2007, Even et al. 2007). This in mind, it is not surprising that insufficient data quality (DQ) may lead to wrong decisions and correspondingly high costs. According to an international survey on DQ, 75% of all respondents have already made wrong decisions due to incorrect or outdated data. In addition, the respondents and their staff spend up to 30% of their working time on checking the quality of data provided (Harris Interactive 2006). Therefore, ensuring completeness, correctness, and timeliness of data – these properties are known as DQ dimensions (Wang et al. 1995) – still remains an important problem for many companies (Ballou et al. 1998, Jiang et al. 2007). Non-surprisingly, many scientific papers (e.g. Ballou et al. 1998, Even et al. 2007, Lee et al. 2002, Parssian et al. 2004, Pipino et al. 2002, Wang 1998) deal with the question of how DQ can be quantified. This is essential for analysing the economic effects of poor or improved DQ as well as for realising DQ measures considering cost-benefit aspects (e.g. Heinrich et al. 2007a, Pipino et al. 2002).

In the following, we propose a metric for the DQ dimension timeliness. The reason is that – according to several studies – timeliness is a serious issue in DQ management (Klein et al. 2007, Yu et al. 2007). Therefore, this dimension has already been discussed from both a scientific and a practical point of view (e.g. Al-Hakim 2007, Klein et al. 2007, Knight et al. 2005, Lee et al. 2002, Wand et al. 1996).

Referring to the guidelines for conducting design science research defined by Hevner et al. (2004), we consider the metric for timeliness as our artifact and organize the paper as follows: After discussing the relevance of the problem, section 2 briefly compiles the related work regarding timeliness and identifies the research gap. Our contribution is a novel approach to quantify timeliness. Hence, a metric is proposed in section 3 which is based on probabilistic considerations. This metric enables to quantify timeliness in a well-founded manner and to consider so-called supplemental data (supplemental data are additional data attributes that allow drawing conclusions about the timeliness of the data attribute considered). In section 4, we illustrate the application of the new approach and its practical benefit by means of an extensive real world example in the field of customer valuation at a financial services provider. Section 5 summarizes our findings and critically reflects on the results.

2 RELATED WORK

In literature, there is a wide range of definitions with respect to the DQ dimension timeliness. In some publications, timeliness is also referred to as currency or recency. Table 1 contains some selected definitions.

<table>
<thead>

</table>

Table 1. Selected definitions of the DQ dimension timeliness
The main issue of most definitions is that timeliness expresses whether an attribute value stored in a database is still up-to-date. This means that an attribute value, which was correct when it was stored, still corresponds to the current value of its real world counterpart at the (later) instant when DQ is quantified. In other words, the attribute value has not become outdated (due to its temporal decline). This is also reflected in the authors’ approaches to quantify timeliness. In contrast to the DQ dimension correctness, quantifying timeliness does not necessarily require a real world test. Instead, a metric for timeliness should provide an estimation, not a verified statement under certainty (which is necessary for correctness), on whether an attribute value is still up-to-date. Heinrich et al. (2007a, b) refer to this fact explicitly. They interpret timeliness as the probability that an attribute value is still up-to-date. For huge data sets and when the shelf life of attribute values is not explicitly known, it seems to be quite reasonable to quantify timeliness by means of such an estimation. This is because comparing attribute values to their real world counterparts (real world test) is often by far too time- and cost-intensive and not practical at all.

In this context the following questions arise: (1) How can well-founded estimations for the timeliness of attribute values be derived? (2) Avoiding real world tests, what kind of data can alternatively be used for quantifying timeliness? Some authors mentioned above consider so-called attribute metadata. Such metadata are the instant \( t_0 \) when the attribute value’s corresponding real world counterpart was created (e.g. for an attribute value “student” of a data attribute “professional status”: the instant of the student’s enrolment, at which the data value “student” became valid), and the attribute value’s shelf life \( T \) (e.g. for the attribute value “student”: the duration of study that represents how long this value is valid). Depending on whether these metadata are known or not, we have to quantify the timeliness of an attribute value under certainty or uncertainty. According to the definition of timeliness given above, we have to quantify whether an attribute value still corresponds to the current value of its real world counterpart at the instant \( t_1 \) of quantifying DQ. In other words, we have to analyse whether \((t_1-t_0) \leq T\) holds. If the instant \( t_0 \) when the attribute value’s corresponding real world counterpart was created and the attribute value’s shelf life \( T \) are known (e.g. based on a temporal rule), it is possible to determine whether the attribute value is still up-to-date under certainty. In this case the value of the metric equals zero (minimum value) if \((t_1-t_0)>T\) holds (attribute value is outdated). Otherwise, we can definitely state that the attribute value considered still corresponds to the current value of its real world counterpart \((t_1-t_0) \leq T\) and the value of the metric equals one (maximum value). In contrast to this scenario of temporal rules, we will focus in the following on quantifying timeliness under uncertainty. This case is much more interesting (in the scenario under certainty you have to check only if \(t_1-t_0) \leq T\) holds) and often more realistic because the shelf life \(T\) of an attribute value is usually unknown. Thus, the question arises of how to accomplish well-founded estimations for the timeliness of data when the shelf life of attribute values is not known.

To improve the estimations for the timeliness of data and to enhance existing approaches, we follow the idea to use additionally other data attribute values \( w_i \) \((i=1, \ldots, n)\) to draw conclusions about the timeliness of an attribute value \( \omega \) considered (e.g. about its unknown shelf life \( T\)). In the following, the values \(w_i\), which are used to improve the estimation, are called supplemental data. A short example illustrates their importance: Figure 1 (based on data from Federal Statistical Office of Germany 2007, Heublein et al. 2003, Heublein et al. 2008) shows that the duration of study (including dropouts) – i.e. the shelf life \( T\) of the attribute value “student” – and the type of university (university vs. university of applied sciences) are statistically contingent. Consider a number of customers stored in a database whose professional status “student” was for example stored 5.5 years ago at the beginning of their studies of economics and social sciences (age \( t \) of the attribute values: \((t_1-t_0)=5.5\) years=11 semesters): Then it is expected that in average about 90% of the customers enrolled at a university of applied sciences have already finished their studies (see Figure 1). This means that the attribute value “student” is up-to-date for only 10% of them. In contrast, it is expected that only 66% of the customers enrolled at a university have already finished their studies (see Figure 1) – i.e. the attribute value “student” is still up-to-date for about 34% of them in average.
Consequently, supplemental data – like the type of university – are relevant for quantifying the timeliness of data. Thus, it seems to be necessary to consider not only attribute metadata, but also supplemental data. Below, we discuss how existing approaches deal with this kind of data.

We found the approaches by Hinrichs (2002), Ballou et al. (1998), Even et al. (2007), and Heinrich et al. (2007a) as these are – to the best of our knowledge – the only approaches which (1) design metrics for timeliness, (2) are formally noted, and (3) are based for the most part on a Quality of Conformance definition. Regarding (3), literature distinguishes two different concepts and definitions of quality: Quality of Design and Quality of Conformance (Heinrich et al. 2003, Juran 1998, Teboul 1991). Quality of Design denotes the degree of correspondence between the users’ requirements and the specification of the information system. In contrast, Quality of Conformance represents the degree of correspondence between the specification and the existing realization in the information systems (e.g. correspondence between a data schemata and a set of stored data values). In the following, we focus on metrics for quantifying Quality of Conformance as they can be applied in many different situations and are more reusable (because they are more independent from particular users’ requirements in a specific business context). Heinrich et al. (2009) have already analysed the approaches mentioned above and compared them with respect to six requirements (due to space restrictions we can not describe this here): Normalisation, Interval scale, Interpretability, Aggregation, Adaptivity, and Feasibility. This analysis revealed weaknesses particularly with respect to Adaptivity, which requires a metric to be adaptable to the context of a particular application in order to enable a goal-oriented quantification of DQ (for a detailed analysis see (Heinrich et al. 2009)).

Referring to Adaptivity, supplemental data are valuable to improve the quantification of timeliness in many fields of application. Just consider the example mentioned above (see Figure 1). The existing metrics by Hinrichs (2002), Ballou et al. (1998), Even et al. (2007), and Heinrich et al. (2007a) use metadata like instant of creation \( t_0 \) and shelf life \( T \). However, they do not use supplemental data. That is, values of data attributes – as in our example type of university and course (field of study) –, which are relevant for quantifying timeliness and improving estimations, cannot be considered at all so far. Concluding, further research is needed to design a metric for timeliness that supports supplemental data in a methodically well-founded way.

3 DESIGNING A NOVEL METRIC FOR TIMELINESS

In the following, we take the metric for timeliness defined by Heinrich et al. (2007a) as starting point. We do so because the metric is based on probabilistic theory and its value can be interpreted as the probability that the considered attribute value \( \omega \) is still up-to-date. Assuming a finite shelf life for an attribute value, the value of the metric and consequently the probability decrease when the age \( t = t_f - t_0 \) increases (and vice versa). In contrast, an infinite shelf life would lead to a situation that an attribute value acquired once is always up-to-date and never changes, which refers to a quantification under certainty and is therefore quite simple.
We generalize the metric proposed by Heinrich et al. (2007a) as follows: The metric quantifies the timeliness of an attribute value \( \omega \), which is characterized by the corresponding real world counterpart’s instant of creation \( t_0 \). Together with the instant \( t_1 \) of quantifying DQ (with \( t_1 \geq t_0 \)), it is possible to determine the age \( t \) of the attribute value \( \omega: t = t_1 - t_0 \). The limited shelf life \( T \in \mathbb{R}^+ \) is unknown and therefore defined as a continuous random variable. Consequently, timeliness is defined as the probability that the shelf life \( T \) is greater than or equal to the age \( t \) of the attribute value \( \omega \). Given the probability distribution function \( F_\omega(t) := P_\omega(T \leq t) \) of the shelf life \( T \), we define the metric for timeliness as follows:

\[
Q_{\text{Time}}^\omega(t) := P_\omega(T \geq t) = 1 - P_\omega(T < t) = 1 - F_\omega(t)
\]  

(1)

In the particular case of an exponential distribution, which is a typical distribution for lifetime and has already proven to be useful in quality management (especially for address data etc.), Heinrich et al. (2007a) define the metric as shown in (2). Assuming that the attribute value \( \omega \) is correct at the instant \( t_0 \) of its acquisition, we may use this instant \( t_0 \) to calculate the age \( t \) instead of the corresponding real world counterpart’s instant \( t_0 \) of creation. This is because the exponential distribution is memoryless in the following way: \( P(X \geq x + t | X \geq x) = P(X \geq t) \); i.e. the conditional probability that the attribute value becomes outdated in the next period of time is independent of its current age.

\[
Q_{\text{Time}}^\omega(t) := \exp(-\text{decline}(A) \cdot t)
\]  

(2)

The parameter \( \text{decline}(A) \) is the decline rate indicating how many of the attribute’s values become outdated on average within one period of time. For example, a value of \( \text{decline}(A)=0.2 \) has to be interpreted like this: on average 20% of the attribute’s values lose their validity within one period of time. Obviously, the definitions (1) and (2) do not support the use of supplemental data \( w_i \) \((i = 1, \ldots, n)\). Therefore, values of data attributes like type of university and course cannot be considered at all when quantifying timeliness of the attribute value “student”, for example.

To solve this problem, we developed the following idea: We redefine the metric for timeliness in term (1) to represent the conditional probability that the considered attribute value \( \omega \) is still up-to-date. Using the supplemental data \( w_i \) as conditions \( W_1 = w_1, \ldots, W_n = w_n \) when calculating the probability is a well-founded way to consider them. The values of the variables \( W_i \) (i.e. \( w_i \)) are known (they are stored in the database) and thus need not be modelled as random variables. However, they usually are subject to temporal decline as well. Hence, it is advantageous to model them – without loss of generality - as random variables, too. Given the distribution function \( F_\omega(t|W_1, ..., W_n) := P_\omega(T \leq t | W_1 = w_1, ..., W_n = w_n) \) with the supplemental data \( w_i \) \((i = 1, \ldots, n)\) we define the new metric for timeliness \( Q_{\text{Time}}^\omega(t, w_1, ..., w_n) \) as follows:

\[
Q_{\text{Time}}^\omega(t, w_1, ..., w_n) := P_\omega(T \geq t | W_1 = w_1, ..., W_n = w_n) = 1 - P_\omega(T < t | W_1 = w_1, ..., W_n = w_n)
\]

\[
= 1 - F_\omega(t | w_1, ..., w_n) = 1 - \int_0^t f_\omega(\theta | w_1, ..., w_n) d\theta
\]  

(3)

The conditional probability (=value of the metric) is calculated based on the complementary probability \( P_\omega(T < t | W_1 = w_1, ..., W_n = w_n) \) – which represents the probability that the attribute value is outdated at the instant \( t \) of quantifying DQ – and the distribution function \( F_\omega(t|w_1, ..., w_n) \). Thereby, the conditional distribution function is defined as the integral over the conditional probability density function \( f_\omega(\theta | w_1, ..., w_n) \). This function, in turn, is determined by the quotient of the combined probability density functions \( f_\omega(\theta, w_1, ..., w_n) \) and \( f_\omega(w_1, ..., w_n) \). As the complementary probability represents whether the attribute value \( \omega \) is outdated before the age \( t \) is reached, the definite integral is calculated for the interval \([0, t]\). This in mind, we can calculate the probability in our example that the stored attribute value “student” is still up-to-date for a certain customer considering supplemental data.
Before, we briefly evaluate whether the novel metric meets the requirements defined by Heinrich et al. (2007b).

The definition as a conditional probability ensures that the values of the novel metric are normalized to \([0; 1]\). Moreover, the metric is equal to one for attribute values with age \(t=0\) (i.e. \(t_1=t_0\): 
\[
Q_{\text{time}}(0, w_1, ..., w_n) = 1.
\]
This is reasonable because the attribute value \(\omega\) is correct at the corresponding real world counterpart’s instant \(t_0\) of creation (see definition of timeliness). Moreover, the values of the metric are limited to zero – due to their limited shelf life \(T\), the following equation holds:
\[
\lim_{t \to \infty} Q_{\text{time}}(t, w_1, ..., w_n) = 1 - \lim_{t \to \infty} F_{\omega}(t | w_1, ..., w_n) = 0.
\]
Thereby, a value of zero means, that the attribute value \(\omega\) is certainly outdated. Based on probability theory, the values of the metric are interval scaled and interpretable (as a probability). Moreover, the aggregation formulas defined by Heinrich et al. (2007b) can be applied as well. As mentioned earlier, the timeliness of an attribute value (e.g. professional status of a particular customer) can be calculated automatically to a large extent by using the formula above as well as SQL DML statements. This ensures that the metric meets Feasibility. The weighting factors in the aggregation formulas and designing the metric according to the shelf life of the attribute values support Adaptivity. However, the Adaptivity of the novel metric could be further improved – related to the metric proposed by Heinrich et al. (2007a) – by integrating supplemental data. In the next section, we illustrate this advantage by an example of a financial services provider.

## 4 PRACTICAL EVALUATION OF THE METRIC

In this section, we evaluate our metric for timeliness by means of a real use situation. Thereby, we analyse its applicability and practical benefit. We applied the metric at a German financial services provider (FSP) and especially focus on the question of how it can support the process of customer valuation. In the context of customer valuation, the customer lifetime value (CLV) is a widely accepted approach to valuate customers and is defined as the present value of all existing and future cash flows generated with a certain customer (cp. e.g. Berger et al. 1998). It is obvious that a high CLV has to be assessed very critically, when the input data used for calculation are (possibly) outdated. Thus, quantifying DQ is an important issue in this context. Due to confidentiality, all data are anonymised and modified. But the principal results still hold.

The FSP acts as an independent company aiming at advising its customers (mostly academics) holistically during a large part of their life cycle. Thus, the CLV is a starting point for many decisions and plays an important role. CLV calculation is based on several input data like customer’s age, current professional status (e.g. student) and course (e.g. engineering sciences). Such data attribute values – which were often acquired many years ago - are usually stored in the customer database.

In order to calculate CLVs, the FSP assumes that every customer passes through different phases of a typical customer life cycle. This customer life cycle starts at the instant of career entry because at this instant the FSP can start selling various products and services. The FSP then tries to determine a customer’s (typical) demand for each of these phases (e.g. retirement). On this base, it is possible to estimate the cash flows resulting from selling products and services in each phase and to calculate the CLV as an expected net present value. In this way, the cash flows and CLVs have already been quantified for several target groups during a former project. The results are a starting point for our example.

However, the FSP also focuses on students in order to acquire them before they become career starters (then their demand is usually especially high). Therefore, the FSP has a very large number of customers being students. These are stored in the database with professional status “student”, including course and instant of enrolment. But how should the CLVs of these customers be quantified? As most of the products cannot be sold to students, the staff of the FSP usually contact these customers quite sporadically (this finally leads to marginal, negative cash flows in this phase). As a result, a student’s instant of career entry is typically not known by the FSP. Nevertheless, it would be much too time- and labour-intensive to contact each customer in order to verify the correctness of the stored professional status.
sional status “student” (real world test). Therefore, it is necessary to quantify timeliness at a high level of automation and to avoid such real world tests. In the following, we describe two customer valuation procedures that were previously used by the FSP. Then, we discuss the application of the metric for timeliness.

According to the first procedure, the FSP calculated the CLV of customers with professional status “student” as follows: The attribute value for instant of enrolment was used to estimate the remaining duration of study by comparing the duration since the instant of enrolment with the average duration of study (in semesters). The latter was determined by using publicly available data about graduates and dropouts (Federal Statistical Office of Germany 2007, Heublein et al. 2003, Heublein et al. 2008): Accordingly, 64% of all students who finally graduated studied about 15.5 semesters on average, while the remaining 36% dropped out after 5.6 semesters on average. The FSP calculated an average duration of study of about 12 semesters (≈0.64*15.5 semesters+0.36*5.6 semesters). For this estimated remaining duration of study, the FSP calculated negative cash flows (note: as the FSP did not put DQ into question, the remaining duration of study was estimated with one semester, if the elapsed time since instant of enrolment was larger than or equal to the average duration of study). Starting from the instant of career entry, the FSP considered the CLV related to its life cycle approach. We briefly illustrate this simple procedure: Considering a customer, who enrolled in economics and social sciences in April 2003, a remaining duration of study of about 2 semesters is assumed by the FSP at the instant of customer valuation in April 2008 (computed by (average duration of study)-(duration since instant of enrolment)=12-10=2). For this period of time negative cash flows (here: € -150 per semester) were calculated. On the one hand, the CLV of a graduate in economics and social sciences is € 4,000 (net present value according to the lifecycle approach). On the other hand, the CLV of a dropout is only about € 2,000. This leads to a weighted average CLV of 0.64*€ 4,000+0.36*€ 2,000=€ 3,280. Table 2 summarizes the results of this procedure:

<table>
<thead>
<tr>
<th>Instant of enrolment</th>
<th>Instant of customer valuation</th>
<th>Duration since enrolment</th>
<th>Remaining duration of study (est.)</th>
<th>Cash flows of students (est.)</th>
<th>CLV at the instant of career entry (est.)</th>
<th>Calculated CLV at the instant of customer valuation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apr. 2003</td>
<td>Apr. 2008</td>
<td>10 semesters</td>
<td>2 semesters</td>
<td>€ -150/semester</td>
<td>€ 3,280</td>
<td>€ 2,554</td>
</tr>
</tbody>
</table>

Table 2. Customer valuation in the example (first procedure)

The example illustrates that the FSP (with a discount rate of 5% per semester) calculated a CLV of \[ \sum_{i=1}^{2} \frac{-150}{(1+0.05)^i} + \frac{3280}{(1+0.05)^3} \approx € 2,554 \] (net present value of the expected cash flows), which is quite low compared to the average CLV at the instant of career entry. The result is based on the implicit assumption that the customer will certainly be studying another two semesters before starting his/her career. All in all, this procedure is quite simple, but does by no means consider DQ aspects.

Therefore, the FSP began to modify the procedure and extended it by probabilistic considerations. First, the assumption of a fixed duration of study (of 12 semesters) for all students was avoided. Instead, a customer’s professional status “student” may remain or change (to “career entry/graduate” or “career entry/dropout”) in each period (semester). All three possible transitions are assigned with probabilities, considering the customer’s estimated remaining duration of study. By using this procedure, it is possible that the instant of career entry is before or after the average duration of study. Figure 2 illustrates the modified procedure, which is to large parts based on the concept of homogeneous Markov chains (cp. e.g. Pfeifer et al. 2000). Note: This concept implies that the transition probabilities (e.g. \( p_{stu.,stu.} \)) are identical for all periods considered (e.g. \( p_{stu.,stu.}(i)=p_{stu.,stu.}(i+1) \) for each period \( i \)). The FSP calculated the probability \( p_{stu.,stu.} \) for each customer so that the expected number of semesters, for
which a customer remains in professional status “student” \( \left( \sum_{i=1}^{\infty} i \cdot p_{\text{Stu},\text{Stu}} = \frac{p_{\text{Stu},\text{Stu}}}{(1 - p_{\text{Stu},\text{Stu}})^2} \right) \) was equal to the estimated remaining duration of study. Using this probability-based procedure and calculating the expected value to determine the CLV, it is considered that a customer may finish sooner or later than the average duration of study (variation).

![Diagram](image.png)

**Figure 2.** Possible transitions of the professional status “student” (modified procedure)

Taking into account the customer data in Table 2, the transition probability \( p_{\text{Stu},\text{Stu}} \) was determined to 50\% (this goes along with an expected remaining duration of study of 2 semesters). Interpreting this probability means that 50 out of 100 customers studying in the 10\(^{th}\) semester still remain students in the next semester and so on. The other 50 customers finish after the 10\(^{th}\) semester. They were separated – based on the shares mentioned above – in 32 (\( \approx 0.64 \times 50 \)) graduates and 18 (\( \approx 0.36 \times 50 \)) dropouts to determine \( p_{\text{Stu},\text{Grad}} \) and \( p_{\text{Stu},\text{Drop}} \). Summing up, a CLV of € 2,845 was determined by means of the modified procedure:

\[
\sum_{i=1}^{\infty} \left( \frac{0.50 \cdot \varepsilon - 150 + 0.32 \cdot \varepsilon \cdot 4,000 + 0.18 \cdot \varepsilon \cdot 2,000}{1 + 0.05} \right)^i
\]

Though avoiding the assumption of a uniform fixed duration of study (of 12 semesters), the modified procedure does not address DQ issues of input data yet. What is particularly noteworthy is the underlying assumption that each customer with the attribute value “student” is still a student at the instant of customer valuation (in the example in April 2008). Both procedures are based on this assumption. Therefore, the FSP ignored that the stored customer data could already be outdated at the instant of customer valuation. Exactly this was observed by the FSP when some customers were asked in summer 2008 with respect to their professional status (cp. ex post analysis below). As a consequence, we analysed how the designed metric for timeliness can be used to meet this issue. The basic idea is as follows:

Our metric for timeliness represents the probability that a customer with the attribute value “student” is still a student in the real world at the instant of customer valuation. This in mind, the values of the metric are appropriate for calculating the transition probabilities \( p_{\text{Stu},\text{Stu}}, p_{\text{Stu},\text{Grad}}, \) and \( p_{\text{Stu},\text{Drop}} \). Neglecting the limiting assumption of both former procedures, we first calculated the probability \( Q_{\text{Time}}(t,0) = Q_{\text{Time}}(t) \) that a customer is still studying at the instant of customer valuation (April 2008 = period 0). We did not consider supplemental data in the first step. The value of the metric had to be calculated at the instant of customer valuation considering the probabilities for graduation \( P_{\text{Grad}}(0) \) as well as for dropout \( P_{\text{Drop}}(0) \) up to that point in time: \( Q_{\text{Time}}(t,0) = 1 - (P_{\text{Grad}}(t,0) + P_{\text{Drop}}(t,0)) \). We similarly determined the transition probabilities for the following periods (semester). Since conditional probabilities were needed, we calculated \( p_{\text{Stu},\text{Stu}}(t,i) \) for each period \( i \) with \( i \geq 1 \) as follows:

\[
p_{\text{Stu},\text{Stu}}(t,i) = \frac{Q_{\text{Time}}(t,i)}{Q_{\text{Time}}(t,i-1)}
\]

In the next step, we determined the transition probabilities \( p_{\text{Stu},\text{Grad}}(t,i) \) and \( p_{\text{Stu},\text{Drop}}(t,i) \) taking into account the values of the metric, too. They represent conditional probabili-
ties for graduation and dropout respectively regarding period $i$

$$p_{\text{Stu,Grad}.(t,i)} = \frac{P_{\text{Grad}.(t,i)} - P_{\text{Grad}.(t,i-1)}}{Q_{\text{Time}.(t,i-1)}}$$

$$p_{\text{Stu,Drop}.(t,i)} = \frac{P_{\text{Drop}.(t,i)} - P_{\text{Drop}.(t,i-1)}}{Q_{\text{Time}.(t,i-1)}}$$

Summing up, we get $p_{\text{Stu,Stu}.(t,i)} + p_{\text{Stu,Grad}.(t,i)} + p_{\text{Stu,Drop}.(t,i)} = 1$ for each period $i$ (equivalent to $Q_{\text{Time}.(t,i)} = 1 - (P_{\text{Grad}.(t,i)} + P_{\text{Drop}.(t,i)})$).

Figure 3 illustrates the procedure considering the metric:
Considering dropouts for example, the cumulative relative frequencies by Heublein et al. (2008) for each type of university and each course can be used. Figure 4 shows the cumulative relative frequency distribution of dropouts (in relation to all dropouts) for economics and social sciences at universities. For example, approx. 25% of all dropouts occur within the first two semesters. All in all, the figure shows that the dropout rates with respect to all students of a semester are approx. constant (contrary to the absolute number of dropouts which is obviously decreasing). Hence, we can assume a constant relative decline rate and apply an exponential distribution. Using a least square estimation, we determined an exponential distribution with a decline rate of 0.165 (see Figure 4). The value of the coefficient of determination $R^2$ was calculated to 0.98, which shows a very good approximation. Therefore, $P_{\text{Drop}}(x)=0.19 \cdot (1-\exp(-0.165 \cdot x))$ denotes the probability that a student has already aborted his/her studies after $x$ semesters. Here, the factor 0.19 corresponds to the fraction of dropouts in relation to all students who have enrolled at universities in economics and social sciences.

![Figure 4. Cumulative relative frequency distribution of dropouts](image)

If we compare this result to the function $0.05 \cdot (1-\exp(-0.145 \cdot x))$, which was determined equally for students enrolled at universities in medical sciences, significant differences become apparent. Considering the first five semesters (i.e., $x=5$) for example, the probability $P_{\text{Drop}}(x)$ for economics and social sciences is 10.7% in contrast to just 2.6% for medical sciences. Such differences completely depend on the different supplemental data with respect to the data attribute course. We similarly computed the probability $P_{\text{Grad}}(x)$, which represents the cumulative probability that a customer with professional status “student” graduated after $x$ semesters. Here, it was necessary to assume a Weibull distribution (for this distribution see Heinrich et al. 2009). Then, we defined the metric $Q_{\text{Time}}^\text{grad}(t, w_1, \ldots, w_n)$ based on both probabilities and calculated its values for each customer and period automatically.

Table 3 lists some selected customers with the supplemental data (type of university and course) from the FSP’s customer database as well as the corresponding metric values $Q_{\text{Time}}^\text{grad}(t, w_1, \ldots, w_n)$.

Table 3. Supplemental data for selected customers and corresponding value of the metric
The differences between the values of the metric highlight the impact of supplemental data (since all other data are the same). For our example customer (see above), we get the following results when applying the procedure based on the new metric: The probability that the customer, who enrolled at a university in economics and social sciences in April 2004, is still a student at the instant of customer valuation (April 2008) is only 46%. In contrast, the probabilities that he/she has already graduated or aborted were calculated to 38% and 16% respectively. When using the previous procedures, it was not possible to determine such probabilities at all. Instead, it was assumed that the customer is still studying in April 2008. A further advantage of the metric is that we do not need to assume that the transition probabilities are constant over time (this is unrealistic). But, it is possible to determine customer-specific transition probabilities for each period automatically. Applying the new metric within the example, we got a CLV of €3,173 which is more than before due to 1), 2) and 3) (cp. above).

The importance of supplemental data can also be demonstrated by an ex post analysis. After the valuation in April 2008, the FSP instructed its sales staff to ask about the current professional status of customers who were stored as “student” in the database. For all customers who had already graduated or dropped out the staff had to acquire the instant of graduation or dropout. Otherwise professional status “student” was confirmed. Similar information was requested by the FSP in a campaign starting in May 2008. The FSP wanted to know from customers with professional status “student” whether and when their status had changed. All in all, the FSP and its staff changed the attribute value “student” for 1,510 customers until the end of August 2008. We analysed these customers by comparing their actual instant of graduation or dropout with the results and estimations of each procedure accomplished. According to the first and simple procedure the FSP assumed an average duration of study of 12 semesters. Thus, for each of the 1,510 customers we could determine when he/she would have been expected to finish his/her studies. Comparing these instants with the actual semester of graduation or dropout, we found that these conformed for only 130 out of 1,510 customers. In other words, in 91.4% of all cases, the estimation was actually incorrect. We also analysed the other probability-based procedures. For every instant of enrolment, we determined the corresponding number of students. On this basis, we calculated how many students would have been expected to graduate and dropout in each of the following semesters using the transition probabilities (see Figures 2 and 3). An example illustrates this: 157 customers out of all 1,510 customers enrolled in October 2002. With the transition probabilities \( p_{\text{Stu.,Stu.}}(0,1)=0.86, p_{\text{Stu.,Grad.}}(0,1)=0, \) and \( p_{\text{Stu.,Drop.}}(0,1)=0.14, \) we get no customer who expectedly graduates in the first semester (until Feb. 2003), 22 customers who dropout and 135 customers who continue their studies. We did such calculations for each probability-based procedure and compared the expected numbers with the actual numbers acquired by the FSP. This way we calculated the difference between the expected frequency distribution of each procedure and the actual frequency distribution of all 1,510 selected customers (number of faults=1,510-number of customers where actual and expected semester corresponded).

The results of the ex post analysis were the following: The second procedure, which does not consider DQ issues, had 1,136 faults (75.2%). For the third procedure, which includes the metric for timeliness without supplemental data, these faults could be reduced to 892 (59.1%). Finally, by using the last procedure, which is based on the novel metric for timeliness considering supplemental data (type of university and course), these results could be further improved to 710 faults (47.0%). Table 4 summarizes the findings of the ex post analysis (the number of faults is quite high for all procedures because we count every “minor” difference in terms of one semester as a fault):

<table>
<thead>
<tr>
<th>Number of analysed customers</th>
<th>Number of faults first procedure without DQ</th>
<th>Number of faults second procedure without DQ</th>
<th>Number of faults existing DQ metric</th>
<th>Number of faults novel DQ metric</th>
</tr>
</thead>
<tbody>
<tr>
<td>1,510 customers (100.0%)</td>
<td>1,380 customers (91.4%)</td>
<td>1,136 customers (75.2%)</td>
<td>892 customers (59.1%)</td>
<td>710 customers (47.0%)</td>
</tr>
</tbody>
</table>

*Table 4. Ex post analysis*
The analysis shows that using the metric for timeliness and considering supplemental data obviously improve the results. Focusing on DQ issues, we did not evaluate the CLVs, but the metrics for timeliness. Here, using the novel metric (instead of existing approaches) allows estimating transition probabilities better and therefore creates practical benefit to a significant extent.

Summing up, it can be stated that the example was intentionally kept simple in order to illustrate the practical benefit. It is possible to represent much more difficult issues considering further statuses besides “student”, “career entry/graduate”, and “career entry/dropout”. For customers whose professional status was acquired a long time ago other statuses seem to be reasonable (e.g. “junior consultant” or “senior consultant” instead of “career entry/graduate”). In addition, the new metric is valuable for determining the instant of career entry because such information can be used to contact customers in a more goal-oriented way. Figures like average duration of study are bad estimates here, especially considering good students. These students who are often characterised by a short duration of study would be contacted too late, though being more attractive for the FSP in many cases. Nevertheless, the simple example illustrates that quantifying DQ helps to improve customer valuation.

5 SUMMARY AND CONCLUSIONS

In this paper, we presented a novel metric for timeliness that is based on probabilistic considerations. Extending an existing approach, we take supplemental data into account and define the metric as the conditional probability that a considered data value is still up-to-date at the instant of quantifying DQ. Hence, quantifying timeliness can be done in a more accurate and methodically well-founded way. The metric’s practical benefits as well as its applicability were illustrated by a real use situation. In contrast to previous approaches, the new metric allows us to consider supplemental data. Here we work with conditional probabilities using supplemental data as conditions of the probability density function. The example illustrates the importance of supplemental data like type of university and course. Moreover, when designing the metric, we were able to avoid limiting assumptions concerning the probability distribution (a number of possible probability distributions is presented by Heinrich et al. 2009). This assures that the metric is appropriate for many attributes and their individual characteristics (such as constant, increasing or decreasing decline rates). In practice, the metric is valuable for calculating decision variables like the CLV. If companies rely on the CLV in order to manage customer relationships, outdated customer data may result in wrong decisions. The same holds for other fields of application (e.g. mobile services provider (cp. Heinrich et al. 2007a, b, 2009), financial services provider (cp. Heinrich et al. 2008), where such metrics for Quality of Conformance could be applied successfully.

Besides these findings, calculating the probability distribution function can be difficult in some cases: On the one hand, publicly available data (e.g. from Federal Statistical Offices or scientific institutions) can be applied to define the metric. On the other hand, internal data (e.g. from the data warehouse) may be analysed using statistical software such as SPSS to derive the probability distribution function. Moreover, interviews (as the FSP from the example did) and experts’ estimations are further instruments. However, quantifying correctness by means of a real world test for every single attribute value – which is an alternative to quantifying timeliness – is usually much more cost-intensive. Additionally, it has to be considered that a metric, which was developed once, can be reused frequently or adapted to several fields of application. The authors are working currently on a model-based economic approach for planning DQ measures. For implementing such a model, adequate DQ metrics are necessary. The approach presented here provides a basis for those purposes. Nevertheless, further metrics for other DQ dimensions should be developed and further research in this area is encouraged.

Abstract

As organizations increase their offshore software development efforts, they must develop new methods and models for handling the vast amount of knowledge involved in these projects. Successful knowledge management and transfer is considered key to the success of contemporary organizations. When transferring knowledge to other operating units of a multi national company, the overall goal is to successfully implement the knowledge sent to the receiver. Cultural differences however, can interfere with successful knowledge management intentions. This paper investigates storytelling as a tool to transfer knowledge between global corporate units. A case study on how this instrument is used to communicate knowledge between a German and an Indian IT company gives first insights into factors that influence implementation success.

Keywords: Knowledge Management, Storytelling, Case Study, Culture.
INTRODUCTION

Globalization has played a major role in developing businesses processes. Modern technology supports these transformations and allows members of global organizations to be involved in increasingly international cooperation. In the IT industry, more and more software development projects have been geographically distributed and happen in many different countries at the same time. Offshore software development has thus become a notable area of focus in the IT industry. Nowadays, we often speak about global or offshore software development when it comes to globally distributed development teams working together in different time zones, with different local language settings, with different cultural backgrounds and a different educational approach to software engineering.

1 THE NEED FOR KNOWLEDGE TRANSFER

As organizations increase their offshore software development efforts, they must develop new methods and models for handling the vast amount of knowledge involved in these projects (Desouza et al., 2006). ‘Knowledge management’ and ‘knowledge transfer’ become highly prominent in this scenario. ‘Knowledge management’ has many definitions, one of them being the process of continuously creating new knowledge, disseminating it widely through the organisation, and embodying it quickly in new products/services, technologies and systems (Takeuchi and Nonaka, 2004). ‘Knowledge transfer’ is basically giving background information on software projects to people who do not have it (Stellman and Greene, 2005).

The concept of knowledge transfer is difficult to capture, because there is no clear distinction between the transfer of knowledge and the creation of new knowledge (Bresman et al., 1999). It is customary to speak of the ‘transfer’ of knowledge between two distant units of a multi national company (MNC) or between two different functional units at the headquarters, between a vendor and a customer, or even between countries. The use of ‘transfer’ implies flow: knowledge ‘flows’ from its primary holder to the receiver (Doz and Santos, 1997).

Knowledge flows or knowledge transfer refers to the transfer of either expertise or external market information of global relevance, but not to the transfer of internal administrative information (Gupta and Govindarajan, 1991). Transferring knowledge means the transferring of operational knowledge. This can happen in the form of data, information, blueprints, parts, subassemblies, machines or other means to represent knowledge. It can also happen via persons, individual or teams (Doz and Santos, 1997).

Knowledge flows and knowledge transfers are strategically important to organizations for several reasons. They transmit localised know-how, which is generated in one sub-unit to other locations in the organization. Knowledge transfers also facilitate the co-ordination of work flows linking multiple, geographically dispersed sub-units. Furthermore they can enable organizations to capitalise on business opportunities requiring the collaboration of several sub-units. Knowledge flows are also crucial to the orchestrated execution of unified strategic responses to moves of competitors, customers, and suppliers. Finally knowledge flows enable the recognition and exploitation of economies of scale and scope (Schulz and Jobe, 2001).

The MNC faces various challenges with regard to internal knowledge transfer. Subsidiaries should be motivated to access and produce knowledge within the MNC, which means that relevant subsidiary knowledge has to be made accessible to those MNC units that need it. To do so communication needs to be established between those who need and those who possess knowledge. To achieve this goal the organization has to choose the best instruments of control, motivation and context (Foss and Pedersen, 2002).
Successfully identifying, analysing, specifying and documenting better requirements are very crucial; it becomes a higher priority in terms of its effectual transfer across boundaries in offshore software development cases. Differences in location specific work cultures like work ethic, importance of hierarchy and mode of communication can impact the transfer of the software requirements specifications.

When cautiously considering the inherent risks of globally distributed development (Aspray et al., 2007), co-ordination and communication issues are the most intense burdens compared to distance and time (Herbsleb, 2007). Moreover, issues on data and system security, contractual and intellectual property issues as well as concerns about losing domain knowledge play an important role (Carmel and Tija, 2005). But despite those risks, reasons to offshore are still persuasive with cost advantages as the dominant force (Carmel and Tija, 2005). Offshore strategies are further utilised to gain access to enormous skilled labour pools with a certain domain experience and to exploit time shift advantages by expanding the daily development cycle to different time zones.

Conveying this knowledge to counterparts working in a geographically distant, culturally differing country becomes an important issue to focus on. During such scenarios a lot of factors come into prominence that should be well taken care of. The crucial challenges are ‘knowledge transfer’ and ‘cultural’; it is important to inspect these problems and come up with a feasible solution in each case.

2 CROSS-CULTURAL KNOWLEDGE TRANSFER

Culture plays an important role in any team activity’s success (Bhat et al., 2006) and is associated with the knowledge transfer process. Understanding and dealing with the culture of the vendor country for the efficient transfer of specifications is one of the motivations for our research.

Knowledge management literature gives the impression that knowledge management operates in a kind of cultural vacuum. Diversity in terms of language, cultural and ethical background, gender and professional affiliation are considered to be one independent variable, which is in any case pushed to the side. This approach may be convenient for conceptualizing, but is very limited for practical purposes in the modern international business world (Holden, 2002). Hofstede (Hofstede, 1984) furthermore points out that geographical separation and cultural differences can lead to quasi-autonomous sub-organizations which may further lead to numerous problems of communication, co-ordination, control and motivation. Thus cultural differences within an MNC should not be neglected when discussing knowledge transfer and can be regarded as one of the barriers between company divisions and local units of the company (von Krogh et al., 2000, Davenport and Prusak, 1998). Knowledge transfer within units located in the same country can already be troublesome, but it is clear that the problem associated with transfer increases with geographical and cultural distance (Bresman et al., 1999). Li (Li, 1999) shows that communication between individuals in high-context countries and low-context countries differs significantly in the amount of information transferred.

Within knowledge transfer relationships between members of differing cultures interlocutors communicated less information than between members of the same cultural background. His results indicate that low-context/low-context communication relationships do not differ from high-context/high-context relationships in this term. These differences in the communication between high-context and low-context cultures lead to tremendous losses of relevant knowledge within the transfer process between these groups.

Contact and communication between different cultures is an inherent fact of offshoring, thus research on cross-cultural issues in this area is gaining more and more emphasis. Motivated by the immense negative influence of cross-cultural issues on the offshore performance in software development projects (Carmel and Tija, 2005), even information systems research is ‘seeking culture’ nowadays. As a conclusion, the common understanding of culture is that it is learned, associated with values and behaviours, shared by a group and passed from one generation to the next (MacGregor et al., 2005).
To explain cultural differences researchers make use of dimensions of cultural variations. Dimensions in this context are aspects of a culture which can be measured in relation to other cultures (Hofstede and Hofstede, 2004). Triandis provides an overview of the most popular cultural dimensions (Triandis, 1982). Referring to them helps to understand and explain why people from other cultures behave and think differently than we do. Therefore in the context of offshore software development and the necessary transfer of knowledge we need to analyse some of the typical dimensions to understand why the knowledge transfer is so complicated between team members from different cultures.

The findings of Hofstede and Hall are often discussed in the scientific community and based on their work we can build a model of the most important cultural obstacles that impede the performance of knowledge transfer. The following seven obstacles have been summarized and selected from the cultural orientations formulated by Hofstede and Hall (Hall, 1976, Hofstede, 1984). This selection is based on casual expert interviews in preparation for this research initiative.

Firstly the power dimension is one of the most important in any business context. The structure of power accounts for the expression of emotional distance between subordinates (Hofstede, 1984) and superiors where higher power cultures tend to have more autocratic managers (Hall, 1976, Hofstede, 1984). Individuals in such cultures are less likely to express disagreement with their supervisors. Less power-orientated cultures use participatory and consultative management styles. When both extremes have to collaborate in a knowledge transfer initiative cultural obstacles may emerge.

Secondly, relationship dimensions reflect the difference between individualism and collectivism. People from individualistic cultures tend to highly value personal freedom, privacy, and time (Hall, 1976, Hofstede, 1984). They are usually expected to look out for themselves, especially in a business context. For more collectivist-orientated cultures, group harmony is more important than personal ambition. At work they have a higher dependence on organization and a stronger desire for non-financial rewards. Some authors in the knowledge transfer community argue that individuals from collectivist cultures are better suited as knowledge transfer partners, because no financial reward is required.

Different cultures experience time dimensions differently. For certain groups deadlines are firm and literal, in other words people tend to be on time (e.g. stereotypical Germans and Americans). For others the interpretation of time is more flexible. A team of mixed cultures may find it hard to meet knowledge transfer milestones and to dedicate time for joint work sessions when one part of the team has a different understanding of when to meet a given objective. Since knowledge transfer in many cases, as in the transfer of implicit knowledge, requires that two individuals work together, a different understanding of how often and how rigorously to schedule joint meetings may slow the employee from the more ambitious culture. This would naturally be lead to frustration and conflict between the two parties.

Dimensions of uncertainty, as defined by Hofstede, represent the amount of uncertainty an individual tolerates. This is due to the fact that the business environment requires numerous decisions involving doubt and risk. Examining this perspective on the unknown will contribute a description of how people cope with ambiguity. Hofstede, for example has found that British people can handle uncertainty better then Germans (Carmel and Tija, 2005). A similar difference may also arise between German and Chinese workers.

Hofstede defines the ‘future’ dimension as how focused on the future a culture is. East Asian countries, including China, Korea, and Japan, tend to be very forward looking. The central purpose of orienting one’s work around the future or the long-term implies delaying present gratification or gains in return for future prosperity on a grander scale. Naturally, the opposite would be an emphasis on the present, where instant gratification would reign supreme, or on the past, where present ambitions are shaped by former achievements. In the context of knowledge transfer obstacles will present themselves when one group of workers invests much more time into the long-term objective of knowledge transfer than the other.
Such frustrating situations may become worse if the communication dimensions of the parties are also incompatible. Two classifications of communication orientation can be found in the relevant literature on culture in general: high- versus low-context communicators. Low-context cultures listen to what is said rather than how it is said while high-context cultures consider secondary factors such as one’s tone and peripheral and contextual information in order to understand each other. Given the fact that a knowledge transfer requires two individuals to communicate regularly often regarding entirely new concepts, different communication orientations can become significant obstacles for knowledge transfer. For example, a low context communicator might find it difficult to explain something to a high context communicator often interrupting him because he sensed, that his partner is bored and tries to convey interest by asking a confirming question.

Finally we identify information processing dimensions by the way cultural groups process information. East Asian cultures tend to see more relationships and connections between disparate pieces of data. Westerners distinguish more across categories and taxonomies in a rather disconnected approach. As with communication problems, an expert may find it difficult to explain an isolated metaphor to an individual thinking in terms of relationships.

These cultural dimensions help to understand the basic principles of cross-cultural communication and data processing. We concentrate our efforts on the first three dimensions, as we found storytelling to have a strong positive effect on intercultural problems in those areas, but a weaker effect on the other dimensions.

3 STORYTELLING

When transferring knowledge to other operating units of a MNC, the overall goal is to implement the knowledge sent successfully at the receiver’s unit (Sorensen and Snis, 2001). Therefore, a shared, explicit understanding of concepts, categories, and descriptors lays the foundation for effective communication and knowledge transfer in organizations (Zack, 1999).

The knowledge to be sent needs to be transferred in a format that can be understood by the receiver (Thomps, 2002). Unfortunately, most of the time the encoded messages cannot be considered universal, since they are culture-specific and arbitrary (Roth, 2001). This might not always be obvious during the communication process. Messages received from individuals of other cultures might have an outward similarity with messages of the home culture; their culture-specific differences are often ignored. This might also influence the transfer of knowledge negatively. Successful transfer of knowledge must thus be based on a collaboratively established consensus among the participants (Sorensen and Snis, 2001) and can improve relationships among organizational communities if there is a commonly acknowledged context in which the significance given by the users to the symbols are unique (Dupouet and Laguecir, 2002).

Ever since human beings have communicated and socially interacted with each other, stories have played a vital role in exchanging and propagating complex ideas and disclosing knowledge. In every culture, different stories exist and have been used to preserve and pass on knowledge from generation to generation. Stories are in a certain intrinsic sense interesting, because they are an attractive high-priority memory booster. With purpose and a meaning behind it, stories will draw and grasp the attention of any audience and in this sense will outperform any logical argument (Haghirian and Chini, 2003, Papadimitriou, 2003).

Stories and narratives are reports about company related incidents that happened in the past and that have a special meaning for the company. Davenport and Pruzak (Davenport and Prusak, 1998) claim the most efficient way of transferring knowledge is through a convincing narrative. People prefer to talk to their colleagues about their latest ideas (Birkinshaw, 2001). They tell stories to exchange knowledge. So narratives are used in order to transfer the complex contents of tacit knowledge (Snowden, 2002). An organizational story is defined as a detailed narrative of past management actions, employee interactions, or other intra- or extra-organizational events. These stories are usually
communicated informally within the organization. Normally, such stories consist of a plot, major characters and an outcome (Swap et al., 2001). Purposeful stories will be able to capture and hold the attention of the audience. They are rooted in truth and are self-propagating (Snowden, 1999). Snowden distinguishes between two kinds of storytelling: storytelling as a knowledge disclosure mechanism and storytelling to create meaning and understanding that can be a helpful tool in getting hold of the valuable tacit knowledge of members within the organization. Storytelling to create meaning and understanding creates metaphors to transfer knowledge in a more transparent way (Snowden, 1999).

Lately, much emphasis has been placed on stories within the organizational knowledge discussion and especially on stories as a tool for knowledge management. Based on studies on communities of practice, of technical knowledge transfer, e.g. Orrs study on Hewlett Packard technicians (1990), and on organizational sense-making processes, it is claimed that stories may fulfil a variety of functions such as the distribution of uncodified or tacit knowledge within knowledge management (Schreyogg and Geiger, 2005). Furthermore, stories allow the listener to comprehend new experiences and to create impressions about the persons, objects and beliefs of the storyteller. Stories help develop general attitudes and beliefs (Adaval and Wyer, 1998). Storytelling as a mechanism for disclosing knowledge can be a helpful tool to get hold of the valuable tacit knowledge within a project team. It creates a self-sustaining, low cost means by which knowledge can be captured on an ongoing basis (Haghirian and Chini, 2003).

These assumptions are based on an understanding of the knowledge taxonomy and address the socially and contextually-bound nature of knowledge, by which any formalised or explicit knowledge can only be understood through its tacit components. Therefore, knowledge can only be shared and understood successfully among people if, and only if, the participants involved share a general set of meanings, beliefs, values and a socially common interpretation. Stories do address the tacit part of knowledge and thus can be seen as a way to establish coherent structure of meaning and frames of references needed to interpret explicit forms of knowledge ending in an effective exchange (Meyer et al., 2005).

Organizationaly, stories emerge as a natural part of the day-to-day life, the routines, and the ongoing communication between individuals and groups. Not as a tool but rather unconsciously, they develop from events, extraordinary situations, successes and failures and are told and retold in everyday organizational life. Though during offshore software development, teams are geographically distributed and hence informal communications, spontaneous conversation and informal “corridor talks” are eliminated. This informal talk helps people stay aware of what is going on around them, what people are working on, what states various parts of the project are in, who has expertise in what area, and many other essential pieces of background information that enables teams to work together efficiently. In addition, different cultural and social backgrounds exist, resulting in an absent common meaning structure.

To bridge these gaps of culture, trust building, informal corridor talks and collaboration, we propose that storytelling may serve such a purpose. Stories have been used in all cultures to communicate values, norms etc. for centuries (Haghirian and Chini, 2003). Building on the findings of Hofstede and Hall, we can assume that organisations in high-context-cultures emphasise storytelling more. This is especially important for software offshore development because this usually involves low-context cultures in the western hemisphere and high-context Asian cultures.

Storytelling to create meaning and understanding creates metaphors to transfer knowledge in a more transparent way. They help to better transfer any information or formal knowledge in a sequential order, with priorities and including a chain of motivation or justification of the inherent transported tacit parts. This can be especially important in a cross-cultural context. People from high context cultures emphasise interpersonal relationships and developing trust as an important first step to any business transaction. In contrast, people from the low context cultures value logic, facts and directness. To be absolutely clear, they strive to use precise words and intend them to be taken literally (Hall, 1976). These very different styles of communication can more often than not cause misunderstandings and sometimes even failures in the intercultural communications process.
In addition to those communication difficulties, the effective and successful transfer of knowledge between people poses further difficulties. One reason is the ambiguous nature of knowledge itself as a result of the previously mentioned context and social embeddedness.

Especially for software offshore development, storytelling seems a promising tool for transferring tacit knowledge, as other instruments like social interaction between company members, traditions, routines and learning-by-doing are usually implausible due to geographical distance or the impossibility of face-to-face communication.

4 RESEARCH QUESTION AND METHODOLOGY

Storytelling is portrayed as an effective tool to communicate and transfer knowledge within cross-cultural teams. However, the case of transferring knowledge via stories in the IT industry has so far not been investigated.

The goal of our research is therefore to examine how telling successful organizational stories can be applied when communicating technological knowledge between geographically dispersed teams that also have different cultural backgrounds.

Since there is little evidence on knowledge transfer via stories and storytelling in a cross-cultural context we applied a qualitative research approach. This allows us to investigate a contemporary phenomenon within its real-life context where the relevant behaviour cannot be manipulated (Yin, 2002). The research is explanatory in nature and relies on an in-depth case study. The collection of data included interviews as primary sources and secondary information from documents and questionnaires regarding software development were used to assure triangulation.

The interviews were mainly conducted from winter 2007/08 through spring 2008. They involved both the client and the vendor, and were conducted each time with a project manager and developers in charge of the relevant project; in total we talked with 14 people. The interviews lasted 45 to 120 minutes. They were semi-structured to allow flexibility and to ensure that the researchers captured any interesting phenomena. Questions were formulated according to perceived performance of the projects, the project communication, the standards and details of the development process and the appearance of context-relevant information. The interviews were conducted with staff and senior management of each company, in Bangalore, India and Leipzig, Germany, together with a review of company documentation and formal presentation material. A number of telephone interviews were also conducted with vendor staff in the United Kingdom (a branch from the Indian company) and India. Gathered data currently includes approximately 90 hours of interviews.

To achieve an adequate level of validity we used multiple sources of evidence and had key interviewees as reviewers. Internal validity, needed for explanatory case studies, was obtained by using a pattern matching technique after coding the interviews. Causal chains are derived from the data analysis in order to later build a causal model (Miles and Huberman, 1994).

5 STORYTELLING AS A TOOL FOR KNOWLEDGE TRANSFER IN THE IT INDUSTRY

We present a case study in this section which will provide us with the result at the end of our research. With respect to the involved corporate partners we will not mention their real names. From a country perspective, India is still the global leader in providing offshore services (Kobayashi-Hillary, 2005). The subcontinent will continue to fulfill this role in the future due to its low labor costs and an abundance of skilled workers (Gott, 2007). We conducted an in-depth case study research involving an Indian vendor and a software company from Germany (client) in order to develop an understanding of the impact of storytelling during offshore software projects.
Here are some basic facts from the case background: the client team had 3 developers, one project manager and one unit manager. On the vendor site, the team had 6 developers, one project manager and one key account manager. Project duration was 8 months and the project was completed in August 2008. Both companies (client and vendor) could be classified as small to medium enterprises. The Indian company has 900 employees and is focused on software services and the client company has 40 employees and is specialised in IT Services for public companies.

The case involved a software development project that included further development and enhancement of an existing software application. Challenges included simultaneous ongoing development at both the client-site and the vendor-site. Therefore it was important for both parties to share the same vision of the products future roadmap. Both teams were urged to share their work experiences and challenges to be implemented in future work.

While focusing on the beginning and kickoff of the cooperation, storytelling was used mainly during the early phases on the project, using a variety of means of communications, e.g. face to face, via phone, chat, mail, and documents.

At the project start many documents and source code files had to be provided to the vendor. A kick-off meeting with members of both parties was held where the development vision was communicated, milestones and timelines were set and specific development tools were agreed upon. Not only the core facts related to the project had been communicated at this meeting but also soft facts like escalation chains and communication schedules for teleconferencing and instant messaging and especially the preconception of the client concerning the realisation of the project. One month after the project start the vendor provided the client with re-briefing and detailed requirement specifications in regards to the vendor’s processes. After the initial kickoff and during the starting phase, phone conferences were the primary form of communication. Here, stories were developed and transferred mainly for the Indian developers to enhance and facilitate the understanding of the development background of the product as well as the motivation, the history and related problems and solution. The focus was to transfer the client’s preconceptions and to determine a possible solution. In the ongoing process, the emphasis of the stories shifted towards the use of feedback rounds in which soft factors or problems became an issue. Here stories were used to bridge the difference in dealing with different approaches of problem solving, e.g. dealing with direct critique, and used to understand timing issues, e.g. meeting deadlines. Therefore, main themes of the stories were cultural differences, descriptions of different ways of collaborative work styles and team approaches integrating do’s and dont’s.

To give an example of such stories, one project manager told us the following story:

"Once I was the technical contact of an offshore project. The Indian company gave my contact data to one of their programmers and if he had any questions I was the person he communicated with. I’m a programmer myself so we share a certain degree of experience. But sometimes the Indian programmer asked an elementary question or could not solve a simple problem that made me think he lacks some basic programming skills. At one point (after several days on his part trying to solve a particular problem) he declared a certain task impossible when I knew it would be quite easy to accomplish. Using a web browser and typing the three keywords into Google gave the correct solution ranking first. So I sent him the article I found and an example of how to accomplish that particular task. I did not get an answer to that email but the next email merely stated the problem had been addressed."

The project manager used his experience from a former project to prepare the team with such stories to establish an open communication within the developer team. From that on, he could clearly ask the Indian team if they needed help. Further he told us many more stories he used in team communication and project set up. The integration of project experiences into the development of stories of both parties involved, the client and the Indian vendor, helped the Indian side, which at the beginning
seemed rather resistant to this management tool, to accept the stories. However, since only some of the developers were aware of the stories, this hindered the Indian team as a whole to take full advantage of the stories in all areas of the development process.

Stories were used at the beginning of the project to diminish issues related to cultural differences. They were also used to convey clear guidelines to the client’s counterparts for better communication. Facts explaining why things are done the way they are, the client’s expectations etc. were conveyed using stories. Regular meetings were scheduled and took place for tracking the project’s progress, noting any significant hindrances to the process. The client transformed his experiences into a story and conveyed it to the vendor, which made it easy for both sides to work collaboratively. These early data show results from instant messaging chat protocols, voice chats, interviews of involved team members of both client and vendor and project documentation.

6 LESSONS LEARNED

Based on our findings, we propose that storytelling can be used as an appropriate instrument for transferring knowledge especially in cross cultural contexts, where the differences in dealing between low context and high context cultures are remarkable. The following table shows a summary of the utilisation of storytelling during the case.

<table>

7 DISCUSSION AND CONCLUSION

With the help of our case study, we are making an attempt to explore and make use of the benefits the storytelling tool can provide in offshore projects. So far, the findings of the study show that it is a practical and beneficial solution in offshore situations to bridge cultural differences between the parties and members involved. Stories are not generic and are highly related to specific organisational and cultural conditions and therefore create a shared vision, sparking action, and fostering collaboration and understanding within the team. A deeper recognition and understanding of this
utilisable tool in IT organisations is still needed. This area of study must be examined closely with respect to its appropriateness in the knowledge management field. The limitation we see so far is a lack of storytelling cases in the field.

Further research aims to develop guidelines for a way of transferring collective experiences of source group to members of a target group by proper co-ordination and co-operation. Furthermore, research should be validated using additional cases and develop a framework for utilising storytelling as an instrument of knowledge transfer. Research may also focus on different aspects of the storytelling method such as the influence of oral vs. written communication on knowledge transfer, limitations of storytelling, and the role storytelling can play in decision making processes during knowledge transfer processes.

Abstract

This paper investigates online knowledge sharing behaviour in Baidu Knows, a platform sponsored by the largest search engine company Baidu in China. We developed a spider engine to collect data from over 2 million questions posted at Baidu Knows. The data collected allows us to profile registered members, to answer questions such as who are the main driving force of those online communities and their attributes, and who are the free-riders seldom posting and answering questions. We also test several hypotheses in explaining the motivations of knowledge sharing, and the quality of such knowledge sharing. Our results indicate that there is a large proportion of users who seldom answer questions, but always ask questions. Although their behaviour seems selfish at the surface, they are actually the key factors driving the growth of online knowledge sharing communities.

Keywords: knowledge-based community, shared knowledge, Web 2.0, empirical study
1. INTRODUCTION

Online communities are virtual spaces on the Internet where a group of people of similar interests communicate and interact collectively or individually to achieve certain goals. Its popularity has grown tremendously in recent years that in many instances online communities have become one of the main resources of knowledge seeking. The most famous and successful example is Wiki, the largest free encyclopedia in the world, where anyone can access its web pages to contribute or modify content. However, as its name indicates, the Wiki website is only useful for acquiring information about well-established encyclopedic subjects and thus lacks the flexibility for knowledge seeking of more general and practical types.

The model of seeking general and practical knowledge on the Internet has evolved substantially over years. Previously, Internet users actively sought knowledge via search engines, such as Google and Yahoo!. However, the search efficiency highly relies on the selection of keywords. Also the information obtained tends to be fragmented, incomplete and may even be wrong sometimes. When users are unfamiliar with the subject matter, or choose inappropriate keywords, the knowledge seeking process tends to be quite inefficient.

The broad class of Web 2.0 technologies attempts to improve upon the search process by establishing a passive way of acquiring knowledge. In this model, users can propose questions in virtual communities, and expect answers provided by other users. Once they find the right place in the knowledge sharing platform to post their questions, the rest is left for others to contribute answers. The questions range from highly specialized technical questions to everyday practical questions. Interestingly, in large knowledge sharing platforms, such as Yahoo! Answers and Baidu Knows, millions of online users are active in the community, spending time to read posts of others, and answer questions if possible.

Launched in June of 2005, Baidu Knows is China’s largest knowledge sharing platform. In Baidu Knows, the questions proposed by users are classified into over 500 categories at the time of this research, which are still increasing at a rapid pace everyday. Over 23.3 million questions and 22.8 million answers have been posted by the end of 2007. As a platform that was established only 2 years ago, Baidu Knows’ phenomenal success arguably plays an important role in Baidu’s competition with Google in the search engine arena in the Chinese Internet.

The success of the knowledge sharing platforms begs two important questions. First, why do people devote their time and effort to sharing their knowledge in virtual communities helping others, and who are they? Second, what is the quality of the answers provided and how useful are they? Obviously without the quantity and the quality of the answers, the usefulness of the knowledge sharing platform would dissipate, ultimately leading to reduced hit rates.

Despite the phenomenal growth of online knowledge sharing communities, there is surprisingly little empirical research about actual knowledge sharing patterns. Most prior studies use survey methods to investigate users’ knowledge sharing motivation. New online knowledge sharing communities enable a new way of knowledge sharing: users freely propose their questions and exchange opinions with members. However, the technology infrastructure alone cannot guarantee meaningful and constructive knowledge sharing behavior (Alavi and Leidner 1999). Its survival totally depends upon the “kindness of strangers” as previously suggested (Constant et al. 1996). This is in sharp contrast to conventional communities, where the main factors driving knowledge sharing are identified as strong ties (Wellman and Wortley 1990), co-location (Allen 1984, Kraut et al. 1990), demographic similarities (Pelled 1996), and status similarities (Cohen and Zhou 1991). However, Wasko and Faraj (2005) argue that these factors are not applicable in virtual communities, where participants are typically strangers, and do not always have demographic or status similarities.

---

1 Baidu is the largest search engine company in China.
Then why do people spend their valuable time and effort to contribute knowledge helping others? Prior studies postulated a variety of theories explaining knowledge contributions. Social capital is typically defined as “resources embedded in a social structure that are accessed and/or mobilized in purposive action” (Lin 2001, p. 29). Wasko and Faraj (2005) identified three forms of social capital related to knowledge sharing behavior in electronic networks. Chiu et al. (2006) also identified the influence of social capital on individual’s willingness to share knowledge. Another theory concerns the collective action. Wasko and Faraj (2005) theorized that in online communities, individuals voluntarily contribute their time, effort, and knowledge toward the collective benefits. Intrinsic benefits such as self-worth, social norm, social affiliation, and extrinsic benefits such as economic rewards, future promotion opportunities, can drive knowledge contributions (Ma and Agarwal 2007, Bock et al. 2005, Kankanhalli et al. 2005). Donath (1999) investigated Usenet newsgroup and concluded that identity plays a vital role in knowledge sharing behavior. The identity definition includes both the establishment of their own reputation and the recognition by others.

In this paper, we address knowledge sharing issues with empirical data collected from a spider engine that we developed. The data enables us to build a profile of those who post questions and those who answer questions. This allows us to address questions such as how many users are free-riders who seldom share their own knowledge while only asking questions, and who are the main contributors who are the driving force of the community? What are their main attributes, and whether knowledge sharing in different information categories exhibits different sharing patterns? With respect to the answer quality issue, we established a simple regression model to investigate the correlation between the quality of knowledge sharing and the characteristics of those who contribute knowledge. By analyzing users’ true knowledge sharing behavior, this study sheds light on how to induce, promote, and manage online knowledge sharing behavior.

The rest of the paper is organized as follows. Section 2 describes the spider engine and the data collection effort, followed by a profile analysis of different classes of users. Section 3 tests several hypotheses of different behavior among user groups in motivating knowledge sharing. Section 4 looks at the free-rider phenomenon. We also established a theoretical model that investigates the correlation between answer quality and the characteristics of those who contribute answers in section 5. Section 6 contains concluding remarks.

2. USER PROFILE ANALYSIS

To collect field data, we choose from two of the largest knowledge sharing platforms in the world, Baidu Knows and Yahoo! Answers. Interestingly, these two platforms adopt different mechanisms of how to reward users’ sharing behavior. Yahoo! Answers makes each question have the same Reward Points as answerers. Once the question is answered, the best answerer will get the Reward Points, which are given by Yahoo! Answers. In Baidu Knows, in contrast, askers could choose how many points they want to pay, and the Reward Points are deducted from askers’ cumulative points. Compared with Yahoo! Answers, Baidu Knows seems to provide more flexibility in motivating knowledge sharing. The comparison of these two mechanisms in driving their respective growth would be an interesting subject, but we will leave this issue to another research paper in the future.

We developed a spider engine to collect data in Baidu Knows as of December 2007. First we identified users who have asked or answered questions in one week from our sample in Baidu Knows’ Computer and Entertainment categories. Overall, we got 2,763 questions and 7,520 answers, with each question having an average of 2.72 answers. For the Computer category, there were 1,383 questions and 3,417 answers, averaging 2.47 answers per question. For the Entertainment category, there were 1,380 questions and 4,103 answers, averaging 2.97 answers per question. Detailed descriptive statistics of questions and answers are shown in the following Table 1:

---

2 This version reports data from Baidu Knows. Data from Yahoo! Answers will be incorporated in a forthcoming version.
The collected data contains past information of each user ID, which specifies three variables: No. of Answers, Reward Point and Best Answer Ratio. For privacy concerns, Baidu does not provide information about how many questions each ID has asked. We then collect all the information about these three variables for each user ID. The exact definition of these three variables are as follows:

- No. of Answers shows how many times each ID shared his or her knowledge with others.
- Reward Point tells how many points won by answering others’ questions.
- Best Answer Ratio is the ratio between the answers rated as the best answers by askers and the total number of questions one member answered.

Each user ID’s past history of asking and answering questions allows us to enlarge the sample size to include 2,114,930 questions. Based on the profile of questions posted and answered, we classify all members into several categories: top contributors, casual contributors and non-registered free riders.

Figure 1 illustrates the distribution of all registered members. Data along the x axis in Figure 1 is rank-ordered by the No. of Answers in the past, and the y axis is the No. of Answers provided by each corresponding registered member. These is clearly a concentration of users who often answered questions. Therefore we classify the top 10% of registered members as top contributors, who answered 1,618,161 questions in total, accounting for 76.6% of the total questions. Casual contributors are those registered members who answer questions occasionally. They account for 90% of the registered members. There are clearly also non-registered members of online knowledge sharing communities outside our sample. We define them as non-registered members who only come to the website to view questions and answers without contributing anything.

*Figure 1: Users’ Knowledge Sharing Pattern*
Past literature reports that knowledge contribution in Linux working groups follows a power distribution. Figure 1 seems to indicate the same pattern, as 10% of the members account for about three quarters of all answers. We test the power distribution for this dataset as well in SPSS. The power test is significant at 99% level.

Figure 2: Knowledge Sharing Pattern

Figure 2 above illustrates the distribution of member segments as defined previously. One interesting fact about top contributors is that not only the quantity but also the quality of their answers is higher than others. The quality of shared knowledge is measured by Best Answer Ratio. For each question proposed in Baidu Knows, askers are required to select and mark one best answer, if possible, from all the answers proposed by other members. The profile of each member contains the Best Answer Ratio, which shows the percentage of answers that are rated as the best among all answers provided by each member. The average Best Answer Ratio of top contributors is 20.9%, which is much higher than the 12.5% average for the rest. This indicates that top contributors appear to be the driving force of the knowledge sharing communities. They answer about three quarters of the total questions, and one fifth of their answers have been selected as the best answer by askers. On average, each of them has answered 2,021 questions, which is quite astonishing considering the two year time span of our sample data.

Interestingly, the data shows that top contributors can be further classified into two different subgroups by using the 1,000 Reward Points as the demarcation point. 85.3% of the top contributors’ Reward Points are less than 1,000, indicating that they asked less than 223 questions in the past. This is in sharp contrast to the 2,021 questions they answered. As a result, we call these members pure contributors, as they seem to be inclined to passing knowledge to others without expecting anything in return.

The second group of top contributors not only answers many questions but is also active knowledge seekers by asking many questions. 14.7% of the top contributors’ Reward Points are higher than 1000, with the average at 2,619, which means that they asked 589 questions on average in the past. We call these members active contributors and knowledge seekers. On one hand, they are keen on sharing knowledge with others. On the other hand, they are also active knowledge seekers, who frequently propose questions and give high rewards to answerers.

3 When we calculate the average Best Answer Ratio, we delete those members whose No. of Answer is less than 10.
Casual contributors are 90% of all registered members in the community. They answered 496,769 questions, accounting for 23.5% of the total questions. Both the quantity and the quality of their shared knowledge are inferior to that from the top contributors.

3. KNOWLEDGE SHARING MOTIVATIONS

Social exchange theory states that members engage in social interaction based on the expectation that it will lead in some way to social rewards, such as approval, status, and respect (Blau 1964). Ma and Agarwal (2007) theorized that participants share knowledge in online communities for both extrinsic benefits and intrinsic benefits. Donath (1999) proposed that in Usenet newsgroups, identity, both the establishment of their own reputation and the recognition of others, plays a vital role.

In knowledge sharing platforms, Reward Points could serve both as extrinsic award and intrinsic award. First, Reward Points act as the electronic money in the community. When members propose their questions, they need to pass some of their Reward Points to answerers. Second, Reward Points indicate the status of the member. In Baidu Knows, members are classified into 18 levels. Once members have accumulated certain Reward Points, they could be promoted to a higher level, indicating that they are more knowledgeable and have higher willingness to help others. As a result, high Reward Points can help members move up to higher levels and receive more esteem from others. This is hypothesis 1:

H1: Members share knowledge because of extrinsic and intrinsic motivations. The higher the Reward Points are associated with a question, the more answers it will get from others.

To check whether the Reward Points assigned to a question are related to Number of Answers it is likely to solicit, we use nonparametric test: Pearson’s r, Spearman’s rho, and Kendall’s tau_b. The results are reported in Table 2:

*** Significant at the 0.01 level (2-tailed)

Table 2. Nonparametric correlation between Reward Points and No. of Answers

Our results show that in both the Computer category and the Entertainment category, Reward Points are significantly correlated with No. of Answers. The strength of correlation is higher in the Computer category than that in the Entertainment category. Therefore, H1 is accepted.

People are not only pragmatic but also expressive of feelings, values, and self-identities (Baudura 1986, Schlenker 1985, Shamir 1991). In knowledge sharing communities, members could increase self-worth, personal identification with the organization, self-respect, respect from others, and feelings of commitment by helping others. Bandura (1986) posited that self-evaluation based on competence and social acceptance is an important source of intrinsic motivation that drives engagement in activities for the sake of the activity itself, rather than for external rewards. Wasko and Faraj (2000) also demonstrated that members may contribute knowledge within the collective because solving problems is challenging or fun, and because helping others is enjoyable. Therefore, we may expect that enjoyment of helping is one of the main motivations for members’ contribution to the collective.

In knowledge sharing platforms, some questions do not provide Reward Points to answerers. If such questions are still answered by other members, we may expect that the answerers reply such questions not for Reward Points, but for the joy they achieved during the helping process. Therefore, we propose the hypothesis 2:

H2: Some member share their knowledge because of the enjoyment of helping others.

Proceedings ECIS 2009
Overall, the Reward Points given out are very low. 47.86% of questions do not have any Reward Points. 92.8% of questions have Reward Points less than 30. Only 3.3% of the questions have Reward Points higher than 100, the highest being 200. Those questions having zero Reward Points have on average 1.91 answers, and only 17.8% of them are not answered. These results seem to indicate that some members are not motivated by extrinsic awards, but possibly by the enjoyment of helping others, thus confirming H2.

Although exchanges in electronic social networks occur through weak ties between strangers, there is evidence of reciprocal supportiveness (Wellman and Gulia 1999). In online communities, members tend to show generalized reciprocity. Scholars believe that in online communities with strong sharing social norms, members may offer their help either because that they may have been helped by others in the past or they may expect that some one in the community would help them if they have a question in the future. If reciprocal supportiveness is one motivation for members’ knowledge sharing behavior, a member’s helping tendency should be valued by others in the community. In other words, a member who used to help others should be more likely to get help from others compared with free riders. Therefore, we propose the following hypothesis

H3: Members who shared their knowledge more frequently in the past will get more responses when they post their questions.

We use the following regression function to check the correlation between members’ past answering behavior and the No. of answers they received when they propose their own questions. The result are reported in Table 3

\[ \text{No. of Answers} = \text{Reward Points} + \text{Asker’s No. of Answers in History} \]

Table 3. Regression Results for No. of Answers against Asker’s No., of Answers in History

This regression results show that No. of Answers is correlated with Reward Point, which of course confirms H1. However, Askers’ No. of Answers in History is not significantly correlated with No. of Answers a question gets. The result is quite important: members’ helping behavior does not pay off in terms of getting more answers when they need help in the future. No. of Answers in History indicates how many times a user helped others and contributed his/her knowledge. When this user calls for help and posts questions, others do not seem to value the asker’s past behavior. That means, the conclusion that people help others due to reciprocal supportiveness motivation cannot be drawn in the Baidu Knows sample data, thus rejecting H3.

When members ask for help in online communities, they usually send out their Reward Points to attract others to answer their questions. However, around half of the questions do not send out Reward Points and the askers can be viewed as free riders. Such phenomenon begs the question who tends to value more others’ knowledge sharing behavior?

Individual centrality concept defines that individuals who are centrally embedded in a collective have a high probability of direct ties with other members. They have a richer social capital. Such members can
exert more influence than others. They are more likely to cooperate with others and comply with group norms and expectations (Rogers and Kincaid 1981).

Members who frequently shared their knowledge and have high Best Answer Ratio are core members of the community. Members with high Best Answer Ratio are more connected to other members and have developed the habit of cooperation. They understand the efforts of sharing knowledge through their past experience. When they call for help from others, they tend to follow the sharing group norm and value the efforts of others. Therefore, we propose the following hypotheses:

H4: Members who shared their knowledge more frequently before will set high Reward Points when they post their own questions.

H5: Members who have high Best Answer Ratio will set high Reward Points when they post their own questions.

To check H4 and H5, we use nonparametric tests to check the correlation between Reward Points and No. of Answers in History, and Best Answer Ratio. The results are reported in Table 4 and Table 5 respectively.

Table 5. Correlation between Reward Points and Best Answer Ratio

The results show that Reward Points of questions in the Computer category are correlated with askers’ past behavior. In that category, members who answer more questions, or Members whose answers are frequently adopted by others as the best answer tend to set high Reward Points for their question. Therefore, H4 and H5 are accepted in the Computer category, while the same can not be said about the Entertainment category.

4. FREE RIDER BEHAVIOR

To investigate free rider behavior, we classify members into askers and answerers. Askers are defined as those members in the sample who have asked at least one question. Answerers are defined as those members who have answered at least one question. Table 6 shows the cumulative percentage of members’ past No. of Answers in the Computers category. According to their past behavior, 38.4% of askers never answered questions. 63.1% of askers answered less than 10 questions before. In contrast, only 1.3% of answerers never answered question before and answered their first question in our sample. Also, only 9.3% of answerers answered less than 10 questions before. Further more, 87.4% askers answered less than 100 questions, while only 43.6% answerers answered less than 100 questions.

</tr>
</tbody>
</table>

Table 7. The Cumulative Distribution of Past No. of Answers in Entertainment category

Such results clearly illustrate that askers show less willingness to help others compared with answerers. In both categories, askers show much less willingness to help than answerers. Around 35% to 40% askers in both categories are free-riders, as they never answered questions before. Around 60% askers in both categories answered less than 10 questions before. Although such members show more selfishness in contributing knowledge than others, it appears that they are actually the key factor to sustain the online community. They are active knowledge seekers and propose around 60% of questions. They value the answers from others and actively rate which one is the best. Because of the existence of such members, online community is able to sustain and prosper.

The free rider phenomenon may also be viewed from a box-plot of user behavior. We collect past behavior of askers and answerers and examine how many times each member have shared their knowledge before. The box-plot of the Computer category [Figure 3] and the Entertainment category [Figure 4] clearly show that answerers usually shared knowledge more frequently than askers. Moreover, answerers have much more outliers compared with askers, indicating that more answerers are extremely generous with respect to sharing their knowledge.

Figure 3. The Boxplot of the Computer Category
Besides the free rider behavior associated with askers and answerers, many other non-registered free riders are not included in our sample. Baidu Knows is an open community, that attracts users who did not register at Baidu Knows, but still browse the questions and answers in seeking knowledge. Baidu Knows also gets routed traffic from the regular Baidu search engine. Since this type of free rider behavior does not leave any trace in the community, it is difficult to investigate their behavior and assess their population size. We did surveys in two undergraduate and three postgraduate classes in a well-established university in China. All the students in these classes had visited Baidu Knows and browsed questions and answers. However, only one tenth of them were registered members in Baidu Knows. Such simple survey results indicate that the proportion of free riders in the knowledge sharing communities is much larger than that reflected in our sample.

5. QUALITY OF KNOWLEDGE SHARING

Quality of shared knowledge is one of the key factors determining whether the community will be sustainable over the long run. Those members who share high quality knowledge are the most valuable resources of the community. Who will share high quality knowledge? What are the characteristics of the members who share high quality knowledge? These are the questions we address in this section.

The self-verification concept, rooted in cognitive dissonance theory, suggests that people are more satisfied and likely to participate in a relationship when their salient identities are confirmed by others in a group (Swann 1983, Swann et al. 1987). Members who shared high quality knowledge obviously have higher Best Answer Ratio. Their sharing behavior is acknowledged by others. They will have a relatively high self verification than others and have higher motivation to help others in the future. Therefore, we suggest the following hypotheses:

H6: Members whose ratios of best answer are high will share knowledge more in the community.
H7: Members whose ratios of best answer are high will set high Reward Points for others.
H8: Answerers have higher ratios of best answer compared with askers.

To investigate who are sharing high quality knowledge in the community, we use the following regression function to examine the relationship between quality of shared knowledge and members’ characteristics.

<table>
<thead>
<tr>
<th>Y=Best answer ratio</th>

<td>7.877(0.323) t=24.357***</td>
<td></td>
</tr>
</tbody>
</table>

Figure 4. The Boxplot of the Entertainment Category
Table 8: The correlation between Best Answer Ratio and Reward Points

The regression results show some interesting findings: first, members answered more questions shared high quality knowledge as well. Second, members who shared high quality knowledge sent out more Reward Points, which means that they value others’ sharing behavior more. Third, compared with askers, answerers’ shared knowledge has high quality compared with askers’.

Such results indicate that those answerers who frequently answer questions are the most valuable resources in the community. They not only answered most questions but answered with higher quality. Also, we may envision a positive circulation formed in the community. Answerers who share high quality knowledge will be acknowledged by others and have high Best Answer Ratio. In return, those members are motivated due to the acknowledgment by other members, and thus will answer more questions. Further more, since they understand the efforts involved in sharing knowledge, they will send out high Reward Points to others when they propose their questions.

6. CONCLUDING REMARKS

This paper uses empirical data that we collected from a spider engine to investigate user profile, knowledge sharing motivations and quality of sharing knowledge in online communities. We found two groups of people are extremely important in driving the growth of these communities. First, the top contributors unselfishly answer other questions, contributing their own knowledge. Among these people, there are approximately 85% are pure contributors, seldom asking any questions. The second group of users are those who seldom answer questions, but always ask questions. Although their behavior seems selfish at the surface, they are actually the key factors driving the growth of online knowledge sharing communities. It is precisely because of these users’ questions that the online communities see reasons of existence.

Majority of free riders appear to be those non-registered members outside our sample. In order to spur further growth, organizers of online knowledge sharing communities may think of ways to have these free riders join the community.

We also investigated motivations of contributing knowledge. Although Reward Points and reciprocal-supportiveness are clear factors explaining knowledge sharing behavior, there are also many members who do not care about rewards. Our conjecture is that these members derive satisfaction from helping others as a motivation of contributing knowledge.

Unlike previous results, we found that members’ past behavior does not seem to be acknowledged by others. That is to say, those who have a history of helping others, do not seem to get above-average help from others when they need help. This may be because knowledge sharing communities are simply too large with too many members, and the bonding relationship seems to exist between members and the community itself, as opposed to between members. When users decide whether to answer a question, he may be more concerned about his relationship with the community, instead of the ID identity of the author of the question.

We also found that the value of shared knowledge sees a positive correlation with past behavior. Those members who historically contributed a lot tend to award members higher who answer their questions. These people are also the core members driving the growth of online communities.

Our study confirms the intrinsic and extrinsic motivations of knowledge contribution based on real member usage data, supplementing the survey methods that have been traditionally used in this type of studies. In future research, we plan to incorporate data from the Yahoo! Answers, to investigate different user behavior under the different reward mechanisms. We conjecture that there might be also different cultural factors in driving knowledge sharing behavior.

Abstract

Blogs are increasingly being used as collaboration tools in organizations. However the quality and accuracy of the posted messages in them are still causes for concern. This study proposes a research model to investigate the factors affecting trust in posted messages and the influence of such trust on knowledge use. It suggests that users’ intention to use trusted messages can act as a moderator variable in the relationship between trust and use of the collaboration tool.

Keywords: Blogs, Collaboration, Trust, Knowledge Use
1 INTRODUCTION

Organizations are increasingly adopting online collaboration tools as platforms where data, information, and knowledge about a particular topic can be shared among employees (Gordon, 2006). Blogs are relatively new forms of organizational online communication tools that are being increasingly used to promote internal collaboration as well as enhance knowledge sharing and use in organizations. However, the quality of messages shared on them is claimed to be average because some visitors may contribute useful information, while others may post irrelevant responses (Wen and Wen, 2006). The accuracy of posted message is also a critical concern (Cherry, 2003; Denning et al., 2005) because the messages may contain subjective opinions of the posters. The quality and accuracy of exchanged information has been shown in prior research to have a significant effect on user understanding and perceived effectiveness of communication (Daft and Lengel, 1986). In fact, the quality and accuracy of content on a Web site is a major factor influencing users’ trust towards the site (Mithas et al., 2007).

Therefore this research seeks to investigate what makes people trust the messages posted on Blogs and the effect this trust has on knowledge use. Understanding these relationships can be useful in redesigning the tools to achieve their maximum effective usage as well as justifying their adoption in organizations as a means to increase collaboration among employees.

The term Blog (i.e., Weblog) refers to an automated, personalized, and community-supported Web page, kept in reverse chronological order (Du and Wagner, 2007). It allows individuals to submit and share text, images, or video with others through the Internet or even a mobile phone (Bamford et al., 2006; Cemerlang et al., 2006). Common features of Blogs include searching, posting, and commenting on its messages. They differ from forums, message boards, newsgroups, and Wikis in that only the Blog owner is permitted to post entries, whereas readers are restricted to only comment on the posted entries (Gordon, 2006). The additional comments are appended to each posted message (Torrey et al., 2007). In terms of patterns to use, a Blog usually links to other Blogs in the same category or interest area.

Empirical research on Blogs has been limited. Although an initial study suggested that the primary purpose of using a Blog was as a personal journal, and its use for collaboration was fairly rare (Herring et al., 2004), more recent studies have shown the positive impact of Blogs on collaboration among users. Du and Wagner (2007) empirically examined the relationship between usage of Blogs for online learning and student learning performance. Their results suggest that effective use of Blogs promotes the constructivist models of learning by supporting both cognitive and social knowledge construction. Lin et al. (2006) studied the implementation of a Blog system in an international distance education course. Their findings suggest that Blogs are effective tools to document the student’s learning, to share experience and knowledge, and to have direct interaction with long distance peers.

2 THEORETICAL DEVELOPMENT

Several researchers have investigated the association of social networks with trust. Strength of ties is an aspect of social networks that correlates to a degree of trust. It can be measured by various criteria such as the length of time two actors spend together, the emotional intensity between two actors, the degree of trust and acquaintance, the frequency of interaction, or the time of relationship (Kristiansen, 2004). Strong ties bind actors who likely to be connected (Grannovetter, 1983). They exist for people with acquaintance such as family members, close friends, co-workers, etc. This study focuses on the strength of ties between the poster and reader of messages on corporate Blogs.

Many studies have shown that strong ties are important channels in transferring useful knowledge (Brass and Burkhardt, 1993; Droege and Anderson, 2003). Relationships between actors with strong ties, as a result, are beneficial. Levin and Cross (2004) claimed that when trust exists, people are more willing to give useful knowledge and also more willing to listen to and absorb others’ knowledge.
McGrath et al. (2003) found that software executives who were looking for advice tended to request people they knew well mostly from relationships formed through previous work settings, educational settings, or mutual contacts. In the current study, we measure the message reader’s perception about the relationship between the reader and the poster. It can be expected that messages posted on an online collaboration tool by an actor with strong ties to the reader will increase the reader’s trust on the message. Thus we hypothesize:

**H1: Greater strength of ties with message posters increases readers’ trust on posted messages.**

Reputation has been studied by many researchers in different perspectives. Barnett et al. (2006) defined corporate reputation as observers’ collective judgments of a corporation based on assessments of the financial, social, and environmental impacts attributed to the corporation over time. Helm (2005) proved that corporate reputation involved a variety of different measures and it correlated to stakeholders’ loyalty towards the company. Johnson et al. (1993) analyzed a relation between executive’s reputation and firm financial performance. They defined executive’s reputation as the expected value of true managerial ability conditional on all previous productivity observations.

Studies on reputation and trust have recently become important in information systems research, especially in the context of electronic markets. Reputation helps to build trust and cooperation among loosely connected and geographically dispersed economic agents (Dellarocas, 2006).

Reputation in this study refers to overall quality or character of the message poster as seen or judged by people in organization. In other words, reputation of the message poster is perceived as recognition by other people of some characteristics or abilities. According to the prior studies, it can be expected that messages on an online collaboration tool posted by a person with high reputation in an organization will increase the reader’s trust on the message. Thus:

**H2: Reputation of message posters increases readers’ trust on posted messages.**

Power has been researched for many years in multiple disciplines. An interesting study on interpersonal power was conducted by Garrison and Pate (1977). They measured power in different contexts, including the co-worker context. A co-worker is defined as someone a person has communicated with on a regular basis in the present job. The results of the study showed that perceptions of interpersonal power vary across the communication context. In the current study, power is conceived as relationships between two or more actors in which the behavior of one is affected by the behavior of the other (Jasperson et al., 2002). In other words, power is a perceived or attributed characteristic possessed by a social actor with a definite potential or capacity which may be used to influence or even control the behavior of others in some manner within some contexts (Brill, 1992). A person who holds more power can draw on rules and uses techniques of production and discipline through social relation (Backhouse et al., 2006). Regarding trust in online collaboration, it can be expected that messages posted on an online collaboration tool by a person who asserts more power will increase the reader’s trust on the message. Hence we hypothesize:

**H3: Power of message posters increases readers’ trust on posted messages.**

Apart from the characteristics of the message poster as mentioned above, features and elements used in posted messages are believed to affect trust and eventually the knowledge use of an online collaboration tool. In recent years, several studies have shown that Web site features and elements such as graphics, colors, links, tabular forms, frame location, background, navigation, organization, uniformity, etc. influence the beliefs and behaviors of Web customers (Song and Zahedi, 2005), user efficiency and frustration level (Pratt et al., 2004), and perceptions of customer service, information privacy, and product quality (Resnick and Montania, 2003). Interestingly, Everard and Galletta (2006) studied how Web site presentation flaws affect perceived site quality, trust, and intention to purchase from an online store. The flaws included poor aesthetics, quality, and reliability of a Website. Each of these flaws was found to prevent users from using the system in a meaningful manner.

Aesthetic aspects of a Web site should possess the same priority as the functionality aspects in Web design (Thorlacius, 2002). The organization of a Web site was found to have the greatest impact on the users’ experience visiting the site (Lynch and Horton, 2002). Several prior studies suggested that
customers are more likely to enjoy orderly Web sites due to ease of use and navigation (Song and Zahedi, 2005). In contrast, the poor style of Web sites was found to be inversely related to the users’ level of perceived quality, trust, and intentions to purchase from an online store (Everard and Galletta, 2006). The elements of a Web site’s poor style are graphical and visual elements such as background, font size, columns, words, line spacing, etc that interfere with reading. As a result, in this study, it is assumed that a poor style of posted messages on the online collaboration tool such as an unusual background color, font style, font size, words, line spacing, or frame layout, will reduce the reader’s trust on the message. Thus:

**H4: Poor style of posted messages decreases readers’ trust on posted messages.**

Incompleteness of a Web site is another factor that discourages confidence and trust of visitors (Everard and Galletta, 2006). Incompleteness refers to a Web site that includes obsolete content or links, non-loading pictures, or missing information. Information provided on a Web site should be accurate, detailed, up-to-date, and relevant (Li et al., 2002). A Website with high information quality provides valuable and helpful knowledge, leading to a larger audience (Chiu et al., 2005). On the contrary, incomplete sites can be risky and lead to negative impression of visitors. In online transactions, information incompleteness makes it difficult for buyers to assess sellers’ true characteristics and product quality, resulting in uncertainty perceptions about the transaction (Pavlou et al., 2007). For the current study, incompleteness of posted message on the online collaboration tool is likely to cause readers to become disappointed and not return. It can be expected that incompleteness of a posted message on the online collaboration tool will reduce the reader’s trust on the message. Thus:

**H5: Incompleteness of posted messages decreases readers’ trust on posted messages.**

A flaw that affects perceived site quality, trust, and intention to purchase from an online store includes typographical, grammatical, and factual errors (Everard and Galletta, 2006). Similar to incompleteness of Web sites, such errors distract users and make them suspect a generally poor quality of the system. Spelling errors may interfere with the user’s perception of the reliability of the information provided on the Web site (Liu and Ginther, 2001). Credibility in online communication is significant. It makes a competitive difference in an organization’s success (Booher, 2004). An experimental study on the effects of support conforming use of spelling and grammar in Computer-Mediated Communication (CMC) system found an increase of message persuasiveness (Wilson, 2005). In the current study, it is expected that language errors in a posted message on an online collaboration tool will reduce the reader’s trust on the message. Hence we hypothesize:

**H6: Errors of posted messages decrease readers’ trust on posted messages.**

Several studies have demonstrated that trust is a significant factor for organizational success. An organization that has a high level of trust environment promotes the exchange of valuable ideas between workers that will, in turn, leads to better firm performance (Collins and Smith, 2006). When trust among employees is low, individuals will be careful about exchanging information and ideas with one another. Trust has been shown to be a major factor in facilitating successful knowledge sharing (Kumar and Thondikulam, 2006) and R&D collaboration performance (Hurmelinna et al., 2005). Several prior studies, additionally, show that trust influences the intention to use or usage of information systems (IS) (Son et al., 2005; Kankanahalli et al., 2005; Salam et al., 2005).

**H7: Trust on posted messages increases readers’ use of the Blog tool.**

In the current study, intention to use trusted knowledge is defined as a degree of which a knowledge worker believes he or she has incorporated procedures for the capture and use of knowledge of various types into decision-making activities, routine, and otherwise and intends to use it (Kulkarni et al., 2006). Based on the findings of prior research, it can be expected that greater intention to use trusted knowledge will lead to a stronger relationship between trust and use of the tool whereas lower intention to use the knowledge will lead to a weaker relationship between trust and use of the tool.

**H8: Intention to use knowledge moderates the relationship between trust and knowledge use.**

The Research Model is shown in Figure 1.
3 RESEARCH METHOD

The study will utilize a Web-based field survey to collect data from organizations that are using Blogs for knowledge sharing among co-workers. Given that prior research on Blogs has largely relied on anecdotal information and not explored their use for organizational collaboration, the current research will aid further understanding on the subject.

The research questionnaire will include questions about (1) the collaboration tool used in the company; (2) trust in posted messages; (3) knowledge use; and (4) demographics. The questionnaire items have been derived from several prior studies in different disciplines such as psychology, IS, and management (Kulkarni et. al., 2006; Everard and Galletta, 2005; McKnight et. al., 2002; Levin and Cross, 2004; Evald et. al., 2006; Caruana, 2006; Garrison and Pate, 1977) with minor modifications.
made to fit the study’s context. Trust and knowledge use are measured using 5-point Likert scales. The questionnaire instructions, items, and sources can be found in Appendix A.

Ten organizations in China and Thailand that are currently using Blogs for collaboration will be contacted to participate in the study due to their accessibility to the researchers. A pilot study has been conducted with two subjects from different companies one based in China and the other in Thailand to assess the duration of a typical survey and to ensure that the questions would be correctly interpreted by the subjects. The first participant in the pilot recommended a translation of the questionnaire into Chinese to accommodate Chinese speakers, reduce the survey duration, and increase the response rate. The second participant recommended minor changes to the instrument which have been duly incorporated. The questionnaire has been translated to Chinese following the procedure recommended by Brislin (1986). One of the current study’s authors whose native language is Chinese translated the English questionnaire into Chinese and this translation was verified for accuracy by two other native Chinese speakers. Next, three different native Chinese speakers conversant with the English language, independently translated the revised Chinese version back to English. After the back-translation, the study’s authors compared the three back-translated English questionnaires with the original English version. No significant differences were found. Therefore, the revised Chinese version questionnaire will be posted online along with the English version for data collection. The data gathered will be analyzed using PLS-Graph 3.0 to test construct validity and the research hypotheses. Controls will be employed for the organization’s size, industry and national culture.

4 EXPECTED CONTRIBUTIONS AND LIMITATIONS

We believe that our research will be among the first studies to use quantitative methods to measure trust and knowledge use in organizational online collaboration tools such as Blogs. Because Blogs are not universally used in organizations, we believe our research could have implications for both early adopters and potential adopters. The results of the research could help early adopters better understand the factors that influence trust and knowledge use. Therefore, they could improve productivity within their organization by facilitating greater trust and knowledge use. The result will also help potential adopters understand the benefits of using Blogs, and how to implement them to maximize trust and knowledge use. Limitations in the current design are that the study utilizes a field survey with perceptual measures and single respondents. In-depth case studies could provide a richer context given that respondents may not accurately remember their social relations or simply provide socially acceptable answers to the questionnaires. However, given the limited research on the subject we believe our findings will inform future research that could utilize qualitative methods, objective measures and multiple respondents to overcome any response bias issues.

PROBLEM SOLVING PATTERNS IN DESIGN SCIENCE RESEARCH – LEARNING FROM ENGINEERING

Gericke, Anke, Institute of Information Management, University of St. Gallen, Müller-Friedberg-Strasse 8, 9000 St. Gallen, Switzerland, anke.gericke@unisg.ch

Abstract

Within information systems the design science research (DSR) paradigm aims at the development of useful artifacts, e.g. models or methods, with which relevant IS problems can be solved. In analogy to the engineering discipline construction processes have been proposed for DSR. Although different phases of such construction processes are explicated in several articles, contributions are missing that propose patterns/principles that support the constructor during the different phases of the construction process. Vaishnavi and Kuechler (2007) address this issue by proposing DSR patterns. Their contribution is a substantial one; however, it does not include comparable pattern approaches from the engineering discipline for the foundation of the proposed patterns. Bearing in mind that DSR has its roots in engineering, it is important to analyze so called problem solving patterns from engineering and to compare them to the DSR patterns. Using this as a basis, it is our research goal to examine whether it is possible to expand the existing DSR patterns to include patterns from engineering. As a result, 14 additional DSR patterns are proposed which originate from engineering, have not been discussed so far, but promise to be useful for DSR in information systems.

Keywords: Design Research, Design Science, Research Methodology
1 INTRODUCTION

1.1 Problem Statement

The information systems (IS) discipline differentiates two main research paradigms: behavioral research and design science research (DSR) (Hevner et al. 2004, p. 76). In contrast to behavioral research that focuses on the development of theories, DSR is a problem solving paradigm which does not only have its roots in the sciences of the artificial (Simon 1996) but also in the engineering discipline (Hevner et al. 2004, p. 76). The goal of the DSR discipline is the development of useful artifacts with which IS-related problems can be solved (March & Smith 1995, p. 253). Within DSR the artifact types of March & Smith (1995, p. 256 ff.), i.e. constructs, models, methods and instantiations, have been established as artifacts of the DSR discipline (e.g. cf. Hevner et al. 2004, Vahidov 2006, vom Brocke & Buddendiek 2006). Lately, design theories have been discussed as DSR artifacts as well (e.g. cf. Kuechler & Vaishnavi 2008, Venable 2006b).

For the development of such artifacts, construction processes have been proposed in analogy to the engineering discipline (e.g. cf. Pahl et al. 2007, p. 53). In recent years, the construction process developed by March & Smith (1995) has achieved wide acceptance (e.g. cf. Cao et al. 2006, Hevner et al. 2004, Venable 2006a). This construction process consists of a “build” (develop artifact) and an “evaluate” phase (evaluate artifact) (March & Smith 1995, p. 258 ff.). In addition, articles have been published (e.g. cf. Peffers et al. 2006, Rossi & Sein 2003, vom Brocke & Buddendiek 2006) that detail these phases, e.g. by explicitly defining an “identify a need” phase (Rossi & Sein 2003) which has to be conducted prior to the development of the artifact. Besides, Hevner et al. (2004, p. 82 ff.) propose seven DSR guidelines that assist researchers and reviewers to understand the requirements for effective DSR. Moreover, the literature analysis shows that some articles also put their focus on solution patterns, i.e. patterns that represent parts of the result of the construction process, but do not support the construction process itself. To give an example, Schermann et al. (2007) propose three patterns that form a design theory for IT service data management systems (result of the construction process).

It is doubtless that the identified contributions are very useful. However, there are hardly any contributions that contain patterns/principles guiding the constructor within the different phases of the construction process in order to solve the research problem through the development of a DSR artifact. Within our literature analysis we only identified the contribution of Vaishnavi & Kuechler (2007) who propose DSR patterns that support the constructor in each phase of the construction process, e.g. the “build” or the “evaluate” phase. In addition to the construction process further phases of the whole research process are supported as well. To give an example, Vaishnavi & Kuechler (2007) identified patterns for the “conclusion” phase, which assist researchers in writing up and publishing their results. Next to patterns that are assigned to a certain phase of the construction/research process, they also proposed so called meta patterns, such as “Brain Storming” or “Stimulating Creativity”, that support more than one or even all construction/research phases. Although the contribution of Vaishnavi & Kuechler (2007) is a substantial one, the underlying foundation of the identified patterns has not been made visible in their publication. Based on a statement of Vaishnavi, both authors have engineering backgrounds but did not use concrete engineering approaches for the foundation of the DSR patterns. Hence, for the proposition of their patterns DSR literature was used without including comparable approaches from engineering. Due to the fact that DSR has its roots in engineering – as e.g. stated by Hevner et al. (2004, p. 76) – it is important to analyze so called problem solving patterns from engineering and to compare them to the DSR patterns of Vaishnavi & Kuechler (2007). The identification of analogous patterns provides a solid foundation and improves the validity of the corresponding DSR

1 E-mail conversation with Vijay K. Vaishnavi between 1 Oct 2008 and 29 Oct 2008.
patterns as they are backed up by their root discipline. This comparison is following the line of arguments developed in (Gericke 2009). Based thereupon, in this paper it is our research goal to examine whether it is possible to expand the existing DSR patterns to include patterns from engineering.

1.2 Research Methodology

In the paper at hand, an argumentative analysis is used as research method to address the proposed research goal. In order to develop new DSR patterns based on patterns from the engineering discipline convincing arguments will be derived from literature/relevant research and presented in a logical as well as comprehensible order. Due to space limitations of this paper we focus on the “build” phase.

Before new DSR patterns can be developed, the DSR patterns of Vaishnavi & Kuechler (2007) and pattern approaches from the engineering discipline need to be analyzed. Therefore, a structuring approach already successfully used in both disciplines is used (for engineering e.g. cf. (Günzler & Vilbig 2003, Jarke et al. 2003), for method engineering (a sub-discipline of DSR) e.g. cf. (Brinkkemper 1996)): Following this approach the object or matter under consideration is structured regarding a product view and a process view. Applying this structuring approach to problem solving patterns implies, that patterns referring to the product, i.e. the result of a construction process, (“product view”) and patterns supporting the construction process itself (“process view”) can be differentiated.

Following the described research goal and research methodology we structured our paper as follows: In the second section we describe and analyze problem solving approaches/patterns from the engineering discipline. Thereafter, we introduce and analyze the DSR patterns of Vaishnavi and Kuechler (2007) in detail. In section 4 the results of the comparison of problem solving patterns from engineering and the DSR discipline are presented. Using this as a basis, we attempt to expand the DSR patterns by problem solving patterns from engineering. The paper closes with a summary and an outlook.

2 PROBLEM SOLVING PATTERNS IN ENGINEERING

In engineering it was already recognized in the beginning of the last century that the trial-and-error method is not the most efficient way to develop a problem solution (Altschuller 1986, p. 12, Orloff 2006, p. 34). Instead problem solving approaches should be used in order to reduce the number of errors and to solve problems more efficiently (Altschuller 2005, p. 36, Creţu 2007, p. 7, Teufelsdorfer & Conrad 1998, p. 14). Realizing this, Altschuller developed the TRIZ approach, which is the Russian acronym for the “Theory of Inventive Problem Solving” (TIPS) (e.g. cf. Altschuller 2005, Altschuller 2006, Altschuller & Shulyak 2002, Orloff 2006). This approach is well established – in academia as well as in industry (Altschuller 2005, p. 15 ff., Herb et al. 1998, p. 18). Many other approaches addressing inventive problem solving in engineering, such as WOIS (German acronym for contradiction-oriented innovation strategy), the PI concept (Concept of Problem-Oriented Invention) or SIT (Systematic Inventive Thinking), are based thereupon (Pannenbäcker 2007, Teufelsdorfer & Conrad 1998, p. 10). Beside TRIZ, other problem solving approaches have been developed as well (e.g. cf. Hürlimann 1981, Kelley 2003). However, they are either single contributions and/or did not achieve wider acceptance. That is why we restrict our focus to the TRIZ approach for the analysis at hand.

“TRIZ is a comprehensive, systematically organized invention knowledge and creative thinking methodology” (Creţu 2007, p. 8). The methods and concepts belonging to TRIZ can be divided into four independent groups (Gimpel et al. 2000, p. 7, Löbmann 2002): (1) Analysis (2) Knowledge (3) Analogy, and (4) Vision. The analysis group contains methods that are used to analyze problems and to overcome mental blocks. The second group refers to knowledge bases, e.g. a scientific effects database. The third group deals with analogies by containing different solution principles/patterns, e.g. 40 innovation principles used to overcome technical contradictions. Finally, the vision group describes development trends and contains e.g. the S-curves of evolution.
The 40 innovation principles belonging to the analogy group are one of the most famous concepts of TRIZ (Rietsch 2007, p. 14). They are patterns which support the constructor in solving technical problems efficiently and effectively (Chen & Lin 2008, p. 14, Rietsch 2007, p. 14 f.). The 40 innovation principles are empirically well founded, because they were derived from more than 40,000 reviewed and analyzed patents of inventions (Altschuller 2005, p. 137). Knowing this, the question arises whether these principles can be transferred to DSR since the DSR discipline cannot build on a comparable empirical basis which can be used to derive such principles/patterns. Though, next to their use in the engineering discipline these principles have already been transferred to other disciplines using conclusions by analogy. Examples can be found for management (Ruchti & Livotov 2001), marketing (Pustogow 2007), human resource management (Müller 2006), etc. Following this argumentation we transfer the innovation principles of TRIZ to the DSR discipline using conclusions by analogy. Regarding the transfer of the 40 innovation principles to other disciplines, Zobel (1991, p. 111) recognizes that the principles are not coequal, but that some principles are more universal than others. Following him such universal principles can be transferred to other disciplines whereas the remaining specific principles are of a rather technical nature and are less suitable to be transferred to other disciplines (Bannert & Warschat 2007, p. 64, Zobel 1991, p. 114 f.). That is why only 22 universal innovation principles will be considered in the following (Zobel 1991, p. 114 f.).

To give an overview of all 40 innovation principles, Table 1 contains their names and gives an exemplary description for every principle. A number (E1, E2, etc.) is assigned as well in order to ease recognition in the remainder of the paper. The last two columns refer to the analysis of the patterns which is presented at the end of this section. The 18 specific principles are shaded in grey and will not be considered in the remainder of this paper.

2 Zobel (1991, p. 114 f.) originally characterized 23 of the 40 innovation principles as universal. Due to the fact that the principle E18 “Mechanical Vibration” seems to be very specific for the engineering discipline we assign it to the category of specific principles and do not consider it any further.

¹ Problem Solving Pattern, ² Product View, ³ Process View

Table 1. Problem Solving Patterns in Engineering – The TRIZ Approach

After presenting the 40 innovation principles of TRIZ, we analyze them regarding the proposed structuring of “product view” and “process view”. Studying the descriptions of the principles, e.g. E1 – “Divide an object into independent parts.” or E2 – “Extract the ‘disturbing’ part from an object …” (see Table 1), it becomes obvious that the innovation principles basically refer to the object, i.e. the result/product, of the construction process. Hence, the innovation principles of the TRIZ approach are patterns possessing a product view, as they refer to the product/artifact which will be developed in the construction process (see fourth column in Table 1). However, looking from a process perspective it can be realized that the innovation principles can also be interpreted as actions that have to be conducted in a construction process. That is why all innovation principles are also marked with an “X” in the “process view” column in Table 1.

3 PROBLEM SOLVING PATTERNS IN THE DESIGN SCIENCE RESEARCH DISCIPLINE

In DSR Vaishnavi & Kuechler (2007) were the first proposing problem solving patterns. Amongst patterns for other phases of the construction process, they identified 27 patterns that support the constructor in the “build” phase of the construction process. Each of these patterns is characterized by a name and described in various dimensions: (A) For each pattern the intended field of use is described. (B) This is followed by a short statement about the context and applicability of the pattern and (C) a description about how to use it. (D) This goes together with a short explanation about the consequences of the usage of the pattern. Most pattern descriptions are accompanied by (E) examples and (F) lists of sources/references. (G) Sometimes referrals to related patterns are stated as well.

To make an example, the pattern “Approaches for Building Theory” (DSR2) will be explained according to the above listed dimensions (Vaishnavi & Kuechler 2007, p. 122 f.). Due to space limitations (F) sources and references are omitted and the description of (E) examples is reduced to one example; referrals to (G) related patterns are not available for this pattern. This pattern is (A) intended to encourage researchers to obtain a general understanding of the different approaches for developing theories. This research pattern can be used after identifying and developing the research problem ((B) context and applicability). In order to develop theories the researcher can choose from four different general approaches: (1) hypothetical/deductive, (2) prototyping (hermeneutical/inductive), (3) case-based and (4) historical, whereas each general approach is described in more detail in the book of Vaishnavi & Kuechler (2007) ((C) description). As a (D) consequence of the use of this pattern, the researcher should assess the suitability of the taken general approach based on the research problem and research area. Maybe corrective actions are necessary in such a way that approaches have to be combined or completely new approaches have to be taken into consideration. As one (E) example the research of Chen (1976) is referenced as he used the hypothetical/deductive approach to build theory.

Table 2 contains an overview of the 27 pattern of Vaishnavi & Kuechler (2007) supporting the “build” phase of the construction process. Each pattern is listed by its name and a short description referring to the intent of the pattern. Analogous to the innovation principles of TRIZ each pattern is accompanied by a number (DSR1, DSR2, etc.) and two columns indicating the product or process view of a pattern.

1 Problem Solving Pattern, 2 Product View, 3 Process View

Table 2. Problem Solving Patterns in the “Build” Phase in DSR (Vaishnavi & Kuechler 2007)

In analogy to the innovation principles of the TRIZ approach, we analyze the DSR patterns of Vaishnavi & Kuechler (2007) regarding the proposed structuring of “product view” and “process view” as well. Studying the first pattern DSR1 “Theory Development” (see Table 2), it becomes obvious that this is a pattern containing a product view because it suggests that next to the solution, i.e. a construct, model, method or instantiation, another product, i.e. the underlying design theory, should be
explicated. Equivalent to the TRIZ principles this DSR pattern can also be regarded as a pattern containing a process view, because it can also be interpreted as an action that has to be conducted in a construction process. Studying the second pattern DSR2 “Approaches for Building Theory” reveals that this pattern only possesses as process view as it tries to support the researcher in obtaining a general understanding of the different approaches for developing theories throughout the construction process. In contrast to the process view of the pattern DSR1 at which the action is directly conducted on the later solution/product of the construction process, the process view of DSR pattern 2 refers to actions that a researcher conducts within a construction process but that are only indirectly related to the later result. The complete analysis of all DSR patterns shows that all DSR patterns contain a process view that is directly or indirectly related to the final solution/result and guides the researcher through the construction process (see Table 2). Furthermore, 13 of these 27 DSR patterns possess a product view as well. Irrespective of being directly or indirectly related to the result of the construction process, patterns that contain a process view will be in the focus of our research. Due to space limitations the product view of the above listed patterns is not compared or expanded any further.

### 4 VERIFICATION AND EXPANSION OF DESIGN SCIENCE RESEARCH PATTERNS

#### 4.1 Design Science Research Patterns Verified by the Engineering Discipline

So far the DSR patterns of Vaishnavi and Kuechler (2007) that support the build phase have been based on DSR literature. In order to back them up by their root discipline, they were compared to the 22 universal TRIZ innovation principles (cf. Gericke 2009). Thereby the focus was put on DSR patterns that refer to the process view (see Table 2). Based on the comparison of DSR patterns and the universal innovation principles of the TRIZ approach in (Gericke 2009), Table 3 shows the results of that comparison: Nine DSR patterns could be verified by TRIZ innovation principles of the engineering discipline, which builds the roots of DSR. In Table 3 the first two columns present DSR patterns. The next two columns contain the corresponding TRIZ principles. Finally in the fifth column an explanation about the comparison of the DSR and the TRIZ pattern is given.

Table 3. Comparison of Problem Solving Patterns in DSR and Engineering (TRIZ) (cf. Gericke 2009)

4.2 Transfer of TRIZ Patterns to the Design Science Research Approach

Based on the comparison of the patterns, we try to transfer the remaining 14 universal innovation principles of TRIZ to DSR. Studying the first remaining TRIZ principle E2 “Extraction”, disturbing parts or only the necessary part of an object should be extracted. Transferred to DSR this could be interpreted in such a way that the researcher has to concentrate on solvable parts of the research problem whereas unsolvable parts are (temporarily) not considered. Table 4 presents the results of the transfer of TRIZ patterns. In the first two columns of the table the remaining TRIZ principles are presented. The next two columns of the table contain the new DSR patterns (new number and new name of the pattern) that result from the transfer of the TRIZ principles. Finally in the fifth column an explanation is given on how the TRIZ principle can be used in DSR.

Table 4. Transfer of TRIZ Principles to DSR

The attempt to expand the existing DSR patterns by the remaining universal TRIZ innovation principles from the engineering discipline successfully resulted in 14 new DSR patterns. Hence, all 22 universal TRIZ innovation principles could either be used to back up existing DSR patterns or to serve as a basis for the derivation of new DSR patterns.

5 SUMMARY AND FURTHER RESEARCH

Analyzing the body of literature of DSR it became obvious that there are patterns/principles missing that guide a constructor within the different phases of the construction process. To address this issue, we took up the DSR patterns of Vaishnavi & Kuechler (2007). Due to the fact that their foundation is limited to DSR literature and comparable concepts from the engineering discipline, which form the roots of DSR, have not been used for their foundation, we analyzed problem solving patterns from the engineering discipline. TRIZ, which is the most established problem solving approach in this discipline, was chosen and the included 22 universal innovation principles presented and analyzed in detail.

To support the analysis of both, the problem solving patterns from TRIZ and the DSR patterns of Vaishnavi & Kuechler (2007), a structuring approach which differentiates between patterns referring to a product perspective (the result of the construction process) and patterns referring to a process perspective (the construction process itself) was used. All DSR patterns possess a process character, whereas only some of them contain a product view as well. In a next step, the DSR patterns referring to the process perspective were compared to the universal innovation principles of TRIZ trying to verify the DSR patterns. In doing so, nine DSR patterns could be verified (cf. Gericke 2009). Using this as a basis, we attempted to expand the DSR patterns of Vaishnavi & Kuechler (2007). The remaining 14 universal innovation principles of TRIZ were additionally transferred to the DSR discipline, i.e. the existing DSR patterns of Vaishnavi & Kuechler (2007) could be successfully expanded to include further patterns from the engineering discipline.

In further research works these new patterns should be evaluated. On the one hand, evidence for these new patterns should be adduced by analyzing existing DSR literature and trying to retrieve these patterns from former research. On the other hand, these patterns can be used in future construction processes and the extent to which the efficiency of the construction process was improved by their use should be evaluated. Furthermore it would be helpful and improve usability of the patterns if the new identified patterns would be described as detailed as the existing DSR patterns, e.g. by describing intent, context and applicability, consequences etc. of the patterns. In addition, further research could address the identification of further DSR patterns. First, it is possible to try to transfer the 18 specific innovation principles of TRIZ to the DSR discipline. Second, the DSR patterns referring to a product perspective could be expanded by including the TRIZ innovation principles. Finally, next to problem solving methodologies from the engineering discipline such approaches from other disciplines, e.g. psychology, could be included in DSR as well.

Proceedings ECIS 2009
Acknowledgment

I would like to thank Vijay K. Vaishnavi who supported me during the preparation of this paper by answering questions regarding the understanding of some patterns and the foundation of the DSR patterns. I am grateful to Tobias Bucher and Joachim Schelp for their support during different stages of the paper development including several valuable discussions. Many thanks go to the anonymous paper reviewers for their valuable feedback.

Abstract

Prior research has identified the similarity of Action Research (AR) and Design Science Research
(DSR). This paper analyses AR and DSR from several perspectives, including paradigmatic
assumptions of ontology, epistemology, methodology, and ethics, their research interests, and
activities. We identify that often AR does not share the paradigmatic assumptions and the research
interests of DSR, that some activities in DSR are always mutually exclusive from AR, and that there
may be no, little, or significant (but not total) overlaps between AR and DSR. Thus we judge that AR
and DSR are decisively dissimilar. We further identify several key problems with combining AR and
DSR based on the ethical requirement of researchers to identify and manage risks to research
stakeholders. Management of such risks is done by careful disclosure, identifying research limitations
or by choosing alternative methods than AR for accomplishing DSR.

Keywords: Action Research, Design Science Research, Research Paradigm, Ontology, Epistemology,
Research Methodology, Ethics.
1 INTRODUCTION

The recent attention to Design Science Research has led many commentators to consider the relationship between Action Research (AR) and Design Science Research (DSR) (e.g. Burstein and Gregor, 1999; Cole et al., 2005; Järvinen, 2007). Järvinen especially makes a strong case for DSR being similar to AR. He analyzed and aligned the matching activities and characteristics of both AR and DSR. He found that AR and DSR have five main activities in a research cycle, which match. He also identified seven characteristics of AR and six characteristics of DSR and shows how they match. Overall, he found AR and DSR to be very similar, and as a consequence suggests that AR as a qualitative research method has a wrong “home” and should be more closely associated with DSR.

We agree that AR and DSR share many features, but at the same time we view Järvinen’s conclusions as overly hasty. First, if we accept that, as DSR has been implicitly practiced in engineering for centuries and in Computer Science and Software Engineering for decades, it is hard to interpret that all this DSR has actually been AR. In our opinion, doing so would extend the concept of AR much too far (we will discuss the concepts of AR and DSR in the next section).

Second, in our opinion, Järvinen’s analyses of both AR and DSR are based on somewhat biased conceptions of AR and DSR. In the case of AR, he sees action researchers’ intent as to plan and take action in order to change a part of reality. His focus is on the practical problem solving interest side of AR, de-emphasizing its research interest side (McKay and Marshall 2001). This focus may bias his interpretation of AR toward one that aligns better with DSR. In the case of his interpretation of DSR, Järvinen relies heavily on van Aken (2004). Although van Aken (2004) distinguishes improvement problems and construction problems, his major interest lies in improvement problems rather in construction of complex artifacts. Solution concepts (van Aken 2004) – whether general or specific – to improvement problems often are not complex artifacts, although they may be implemented in a complex and messy organizational environment. As a consequence, building artifacts does not have as central a role in addressing improvement problems as it does in addressing construction problems. Järvinen’s focus on van Aken’s (2004) emphasis on improvement problems in DSR biases his interpretation of DSR toward one that aligns better with AR than DSR would align more generally.

The purpose of the present paper is to continue the discussion about the relationship between AR and DSR. We will argue that although AR and DSR are seemingly similar, they are quite different phenomena. This conclusion is based on two analyses. First in Section 3, we analyze the paradigmatic – ontological, epistemological, methodological and ethical – roots and assumptions of AR and DSR, finding that they are somewhat different, but not incompatible. For our second analysis, Section 4 will analyze the research interests and activities of AR and DSR, showing how, while they are again compatible and may significantly overlap, they are decisively different. Based on these analyses and some further literature, Section 5 will discuss some ethical problems and more pragmatic reasons to keep AR and DSR as separate, especially when the focus of DSR is building and testing innovative artifacts. These all revolve around the fact that when building innovative, cutting-edge artifacts, possible failure is always present. That may make it difficult and also risky to combine AR and DSR.

2 WHAT IS ACTION RESEARCH AND WHAT IS DESIGN SCIENCE RESEARCH?

In this section we delineate the conceptions of AR and DSR adopted in the present paper.

2.1 Action Research

Action Research has been widely discussed in the IS literature (e.g. Davison et al. 2004; Kock 2004; Lau 1999; McKay and Marshall 2001). The purpose here is not to repeat that discussion, but to summarize the interpretation of AR adopted in the present paper.
A widely adopted definition of AR by Rapoport (1970) characterizes it as follows: “Action research aims to contribute both to the practical concerns of people in an immediate problematic situation and to the goals of social science by joint collaboration within a mutually acceptable ethical framework”. According to this definition AR has a dual goal of contributing to practice and research at the same time. The definition also assumes that there is a concrete client involved. As a consequence, AR is highly context dependent while attempting to address the specific client’s concerns.

Action Research is not a homogenous whole, but includes a number of versions (Baskerville and Wood-Harper 1998; Chandler and Torbert 2003). This paper focuses on Canonical Action Research (CAR) (Davison 2004), which is based on five principles:

1. The principle of the researcher-client agreement
2. The principle of the cyclical process model
3. The principle of theory
4. The principle of change through action, and
5. The principle of learning through reflection

The definition of AR by Rapoport (1970) emphasizes the first principle. The cyclical model of Susman and Evered (1978) – diagnosing, action planning, action taking, evaluating, and specifying learning – is the most well-known example of the second principle. McKay and Marshall (2001) summarize other cyclical AR models and propose a dual cycle model in which the cycle of research interest and the cycle of problem solving interest proceed in parallel while closely interacting with each other. For the third principle Davison et al. (2004) note that a CAR project may begin with theory-free action learning, but suggest that action researchers need theory to guide and focus their activities. We agree that qualitative research project may start relatively theory-free, but not totally. However, “theory” is an ambiguous concept (Sutton and Staw 1995) with multiple meanings (Gregor 2006). Most often it refers to theories for predicting and explaining, which are rare in IS research. Therefore, in line with McKay and Marshall (2001), we would speak about theoretical frameworks rather than about theories.

The fourth principle, the principle of change through action, attempts to ensure that diagnosing the problem, action planning, action taking and evaluating are appropriately done so that one can expect an improvement in the client’s problematic situation (Davison et al. 2004). The final principle, the principle of learning through reflection, attempts to ensure that both researchers and the client examine what they have learned in an explicit, systematic and critical manner (Davison et al. 2004).

2.2 Design Science Research

To our knowledge, there is no widely accepted definition of Design Science Research. Vaishnavi and Kuechler (undated) characterize “Design Research” as “yet another "lens" or set of analytical techniques and perspectives (complementing the Positivist and Interpretive perspectives) for performing research in IS. Design research involves the analysis of the use and performance of designed artifacts to understand, explain and very frequently to improve on the behavior of aspects of Information Systems.” Hevner et al. (2004) note that the design science paradigm seeks to extend the boundaries of human and organizational capabilities by creating new and innovative artifacts, including constructs, models, methods, and instantiations (also as in March and Smith, 1995). Venable (2006) identified “solution technology invention” as the core of DSR. We are ready to define DSR as a research activity that invents or builds new, innovative artifacts for solving problems or achieving improvements, i.e. DSR creates new means for achieving some general (unsituated) goal, as its major research contributions. Such new and innovative artifacts create new reality, rather than explaining existing reality or helping to make sense of it.

When compared with AR, an essential difference is that DSR assumes neither any specific client nor joint collaboration between researchers and the client. One should note, however, that typically the developed artifact aims at addressing a class of problems (Walls et al. 1992) in a way that it is useful in addressing specific problems of a specific client. As a consequence, one could argue that DSR has would-be-clients who comprise “The set of all members of the generalised class of all people or
organizations who could potentially be motivated to solve instances of the generalised class of problem(s)” (Venable 2009) addressed by the DSR outcome (artifact).

Some researchers have advocated a ‘soft’ version of DSR. Venable and Travis (1999) and Venable (2006) argued that more qualitative methods, including AR, could be used for evaluation of DSR outcomes. Venable (2006) further noted that AR could be used across the entire DSR lifecycle (on the naturalistic evaluation side). Baskerville et al (2007) proposed the development of a Soft DSR approach to better accommodate risks in DSR, including poor problem understanding and the potential for evaluation to give rise to type I or type II errors. However, these ‘soft’ approaches to DSR still assume a general, unsituated goal or problem to be solved rather than the situated one inherent in AR.

More fundamentally, equating AR to DSR suffers from the category problem: AR is a research method while DSR is more a research orientation, within which one can use different research methods (including AR). See the various research methods identified for evaluating innovative solutions as part of DSR in Hevner et al (2004) or Venable (2006), the latter of which includes AR.

3 PARADIGMATIC ASSUMPTIONS OF AR AND DSR

One possibility to scrutinize similarities and differences between AR and DSR is to analyze their paradigmatic assumptions. The section introduces first the paradigmatic framework to be applied. After it AR and DSR are analyzed in turn using the framework and finally the results are summarized.

3.1 The paradigmatic framework

Adopting Burrell and Morgan (1978), Iivari (1991) analyzed paradigmatic assumptions of a number of IS development approaches. The analytical framework included ontology, epistemology, methodology and ethics of research. In the following we will apply this framework.

Burrell and Morgan (1978) distinguish two extremes in the case of ontology: realism vs. nominalism. Realism “postulates that the social world external to individual cognition is a real world made up of hard, tangible and relatively immutable structures. [...] For the realist, the social world exists independently of an individual's appreciation of it [...] the social world has an existence which is as hard and concrete as the natural world” (p. 4). Nominalism, on the other hand, “revolves around the assumption that the social world external to individual cognition is made of nothing more than names, concepts and labels which are used to structure reality [...]” (p. 4).

Similarly, Burrell and Morgan (1978) identity two epistemological positions: positivism vs. anti-positivism. Positivism seeks “to explain and predict what happens in the social world by searching for regularities, causal relationships between its constituent elements”, whereas anti-positivism maintains that the social world “can only be understood from the point of view of the individuals who are directly involved in the activities which are to be studied. Anti-positivists reject the standpoint of the ‘observer’, which characterizes positivist epistemology, as a valid vantage point for understanding human activities. They maintain that one can only 'understand' by occupying the frame of reference of the participant in action. One has to understand from the inside rather than the outside.” (p. 5).

In the case of methodology, Iivari (1991) distinguishes three categories: nomothetic methods, idiographic methods and constructive methods. The last category complements Burrell and Morgan’s distinction between nomothetic methods and idiographic methods. Focusing specifically on IS development, Iivari (1991) distinguished conceptual development and technical development in the context of constructive methods explaining that “Conceptual development as a category of constructive research methods refers to the development of various models and frameworks which do not describe any existing reality but rather help to create a new one, and which do not necessarily have any "physical" realization (e.g. IS development "methodologies"). Technical development produces as its outputs "physical" artifacts, the adjective "physical" being interpreted here broadly to include
executable software (e.g. CASE environments)” (Iivari 1991, p. 257). These characterizations attempted to capture specific research methods used in the development of the above artifacts.

In the case of ethics, Iivari (1991) distinguishes three ethical positions: means-end, interpretive, and critical. In the first case, research aims at providing means knowledge for achieving given ends (goals), without questioning the legitimacy of the ends. The interpretive stance questions the realism of the idea of human and organizational action as goal-directed action. Goal statements follow rather than precede action (cf. March and Olsen, 1976). They are reconstructed retrospectively to give meaning to action. According to Chua (1986), the aim of an “interpretivist scientist is to enrich people’s understanding of their action” and “how social order is produced and reproduced” (p. 615), and a critical scientist sees that research has “a critical imperative: the identification and removal of domination and ideological practice” (p. 622). As a consequence, critical research subjects goals (ends) to a critical analysis.

In the following we apply the above paradigmatic framework to analyze similarities and differences between AR and DSR.

3.2 Paradigmatic assumptions of Action Research

To our knowledge, the early article of Oquist (1978) and the recent article of Cassell and Johnson (2006) are the most serious attempts to analyze the philosophical assumptions of AR. Oquist (1978) analyzed the kind of knowledge AR produces and its relation to different schools of philosophy of science (Empiricism, Logical Positivism, Structuralism, Pragmatism and Dialectical Materialism). Although his main focus lies in the epistemology, his analyses also cover ontological and ethical assumptions. He concludes that AR is compatible with the assumptions of Pragmatism and Dialectical Materialism, but incompatible with those of Empiricism, Logical Positivism and Structuralism.

Cassell and Johnson (2006) argue that the diversity of AR is due to different philosophical assumptions adopted. More specifically, they discuss philosophical assumptions underlying five different approaches to AR, which they label “experimental”, “inductive”, “participatory action research”, “participatory”, and “deconstructive”. “Experimental” AR covers Lewinian and Tavistockian traditions of AR with realistic ontology and positivistic epistemology. Cassell and Johnson (2006) explain “inductive” AR as an approach in which “theory … is generated from the data (…) of thick descriptions of the patterns of subjective meanings that organizational actors use to make sense of their worlds, rather than entailing the testing of hypotheses deduced from a priori theory that causally explains what has been observed by the action researchers” (p. 793). They refer to grounded theory as an example of the inductive approach and discuss “action science” (Argyris et al. 1985) as an example of the “inductive” approach. “Participatory action research” in Cassell and Johnson (2006) refers to an AR approach in an organizational or corporate setting in which the researcher usually works in a consultancy role serving the corporate elite, while “participatory research”, typically informed by ‘critical theory’, “requires that those individuals and groups whose perspectives are ordinarily silenced in organizations must be given voice through action research” (p. 798). Finally, “deconstructive” AR is an emerging approach that is based on postmodernism. It assumes a plurality of incommensurable voices, implying that “any discursive closure, whether grounded on democratic consensus or otherwise, implies the arbitrary dominance of a particular discourse which serves to silence alternative possible voices” (p. 804). Quite interestingly, none of the five approaches discussed by Cassell and Johnson (2006) directly corresponds to CAR, but in our view the “inductive” approach is closest to it.

Based on Oquist (1978) and Cassell and Johnson (2006) and our own reading of AR, we conclude that the ontology of CAR is anti-realist. It does not see (social) reality as “hard, tangible and relatively immutable structures” (Burrell and Morgan 1978), but as socially constructed that can be changed. At the same time we do not interpret that AR necessarily adopts the extreme ontological position of nominalism. Therefore we characterize the ontological position of CAR as anti-realist.
Similarly, the epistemological position of CAR is mainly anti-positivist. Although an action researcher may search for regularities and causal relationships in the social world or may apply such when interpreting the world, CAR clearly recognizes the limits of such regularities. Each CAR project is unique and the case can only be understood from the point of view of the individuals who are directly involved in the activities which are to be studied. As a consequence, in accordance to Iivari (1991), we interpret that AR as a research method is clearly idiographic.

In the case of ethics, we interpret that CAR is mainly means-ends oriented, but can also be interpretive. The major reason is that CAR is typically oriented in solving or alleviating a specific client’s problems, as evidenced by the 5-step AR cycle proposed by Susman and Evered (1978). CAR can also be interpretive if evaluation focuses on rich understanding of meanings attached to the executed action and its intended and unintended consequences. To some extent differing from Oquist (1978), we do not see CAR as representing a critical approach in the sense that it would challenge existing power structures or structures of domination and would suggest radical changes in that meaning. The major reason is that CAR represents joint collaboration between researchers and the specific client, within a mutually acceptable ethical framework. It is extremely unlikely that the most powerful representatives of the client (its management) would be ready for such radical changes.

Assuming that CAR is closest to the “inductive” approach discussed by Cassell and Johnson (2006), our assessment differs from theirs in that they conclude that the “inductive” approach ultimately reflects positivistic epistemology. The positivistic epistemology manifests in the presupposition of neutral observational language, and in the privileged position of the researcher who is assumed to access empirically data from the independent reality. We agree with Cassell and Johnson (2006) in the sense that the positivistic epistemology is so deep-rooted in our conception of research and science that often times when one scratches the surface of seemingly anti-positivistic approach, positivistic ideas can be found beneath the surface. One should note, however, that we do not see positivism and anti-positivism as mutually exclusive, but a research approach may – possibly unconsciously - include ideas from both philosophical positions. In our view CAR implies a clear move towards anti-positivistic epistemology although it may include some positivistic ideas.

3.3 Paradigmatic assumptions of Design Science Research

The DSR literature only rarely discusses its paradigmatic assumptions. Iivari (2007) discusses DSR’s ontology based on Popper’s 3-world ontology, epistemology in terms of types of knowledge associated with DSR, distinctive constructive research methodology, and ethics, but does not focus on its assumptions specifically. Vaishnavi and Kuechler (undated) briefly discuss DSR’s ontology, epistemology, methodology and axiology (= ethics), contrasting DSR with positivism and interpretivism. Unlike Vaishnavi and Kuechler (undated), the present paper does not see DSR as a third “paradigm”, but as based on more or less “positivistic” or “interpretivist” assumptions. This is in line with Niehaves (2007) who has a detailed analysis of the epistemological assumptions of DSR, claiming that “interpretive” (non-positivistic) epistemology is highly relevant in the context of DSR.

We conclude that DSR may adopt a realistic or anti-realistic ontological position. DSR especially in engineering exemplifies the realistic position, but we do not see realism inherent to DSR. Markus et al. (2002) exemplifies this point – in our view it clearly adopts a non-realistic ontological position.

DSR may also adopt both positivistic and anti-positivistic epistemology. Much of DSR in engineering is based on positivistic epistemology. Although March and Smith (1995) and Hevner et al. (2004) have a positivistic epistemological bias (Niehaves 2007), we agree with Niehaves (2007) that the anti-positivistic epistemology is also relevant in DSR, especially in evaluation of developed artifacts. For example, Baskerville et al (2007) propose “Soft Design Science” and Venable (2006) and Venable and Travis (1999) identify interpretive methods as appropriate for naturalistic, in situ evaluation of DSR outputs. On the other hand, since DSR aims at producing general solution concepts (van Aken 2004) or meta-artifacts (Walls et al. 1991; Iivari 2003), which are more widely applicable than in a specific organizational context, DSR aims at general knowledge typical to the positivistic epistemology.
Methodologically, DSR may apply both nomothetic and idiographic methods, as the variety of design evaluation methods proposed by Hevner et al. (2004) implies. As explained above, Iivari (1991) suggested constructive research as a third category of methods. Since it focuses on building IT artifacts, it can be considered a distinctive category of methods in the case of DSR.

With respect to ethics, much (if not all) of DSR is means-end-oriented. The artifact to be developed is assumed to have some purpose (Hevner et al. 2004; Gregor and Jones 2007). However, Venable (2009) claims that Hevner et al. (2004) consider profit (utility) maximization as the ultimate goal of DSR and that, overall, they privilege managers as a stakeholder group on business organizations. In AR, one can also use interpretive evaluation studies that aim at a rich understanding of the meanings attached to the constructed artifact and its intended and unintended consequences in practice. However, DSR may more easily have a critical orientation. DSR may aim at developing new artifacts that challenge existing power structures of domination. The Scandinavian trade-unionist IS development approach, is an example this orientation (see Iivari et al. 1998).

3.4 Summary of the analyses

Table 1 summarizes the above analysis. It suggests that DSR is more varied in its paradigmatic assumptions than AR. Paradigmatically, AR can be considered a special case of DSR, yet keeping in mind that DSR by definition includes building new innovative artifacts (unlike AR). As a consequence, there is not necessarily any paradigmatic incommensurability problems between AR and DSR, so they can be applied together, especially if DSR adopts paradigmatic assumptions that are compatible with those of AR. We also believe that if DSR activities of building an artifact and its evaluation are separate, one can easily apply AR in the evaluation (Venable, 2006, Johnstone and Venable, 2008), even if the building of the artifact has been based on paradigmatic assumptions that differ from those of AR. For example, one may have engineered an artifact based on a positivistic epistemology reflecting a realistic ontology (e.g. laws of physics). The evaluation of the very same artifact may follow an anti-positivistic epistemology and an anti-realistic ontology. In fact, we believe that idiographic research methods reflecting an anti-positivistic epistemology are often justified when attempting to understand organizational or individual appropriation, usage and consequences of any technology in real life.

4 COMBINING AR AND DSR

As noted in Section 2 considering our conceptions of AR and DSR, by definition the research interest of DSR is to construct new and innovative ways to solve a class or classes of problems, thus creating new reality. AR does not necessarily share any such purpose. Much of AR is conducted to understand existing reality, such as the complex workings of organisational situations and human behaviour. These research interests are decidedly different.
We now turn our analysis to the activities of AR and DSR. To facilitate our analysis, we conceptualize of two broad classes of problems and solutions: purely technical problems and innovations and socio-technical problems and innovations. Furthermore, we assume that any solutions or innovations to purely technical problems do not have direct and complex implications for the socio-technical systems within which they will be embedded (other than monetary costs, which are always taken into consideration in any innovation). Therefore, there is little or no interest in such problems and innovations in the context of AR, although there can be considerable interest in the context of DSR. Rather, AR is exclusively interested in innovations with significant impacts on socio-technical systems and the human context. This distinction between purely technical and socio-technical problems and innovations is reflected in the potential activities or AR and DSR, which we will now analyse.

We base our analysis of AR and DSR activities on the model of DSR activities presented in Venable (2006), which extended the multi-methodological framework of Nunamaker (1990) and Venable and Travis (1999) to differentiate between Naturalistic and Artificial evaluation in DSR, as in Figure 1.

**Figure 1. Framework and Context for DSR (Venable, 2006).**

In Figure 1, AR is shown as one of several means of conducting naturalistic evaluation of a new and innovative “solution technology” (Venable, 2006). DSR can also (or alternatively) conduct artificial evaluation. Artificial evaluation may be all that is required for purely technical artifacts. Artificial evaluation is not part of or relevant to AR, which is a decisive difference between AR and DSR.

Using this framework to analyze the overlapping activities between AR and DSR, we can identify three different cases: (1) completely non-overlapping (in three different ways), (2) slightly overlapping, and (3) significantly overlapping. Note that we do not call the third case “fully overlapping”, because artificial evaluation will never be a part of AR, as described in the previous paragraph. We will consider each of these three cases in turn.

In the first case, AR and DSR activities will be completely non-overlapping. Here AR is not concerned at all with the DSR research interest of building and evaluating innovative artifacts. One such situation is where the problem solving interest of the client will be addressed without any technology or through the application of existing solutions without innovation. In the latter case AR may include design, but it is normal design practice rather than DSR. Here, in so far as the action researcher is concerned with
the efficiency or effectiveness of the solution technology, it is concerned with the client’s problem solving interest. This problem solving interest merely provides the context and opportunity to research other aspects of socio-technical systems, such as organisational or human behaviour.

A second situation in which there is no overlap (which we will call case 1b) is where the DSR is concerned with solving a purely technical problem. In this case, evaluation is primarily artificial and there is no need for naturalistic evaluation (applying AR, for instance).

A third situation in which there is no overlap (which we will call case 1c) is where the DSR is concerned with solving a socio-technical problem, but not arising in an AR context and where AR is not used for naturalistic evaluation. Evaluation may be conducted artificially and/or using other research methods for naturalistic evaluation, such as case studies or surveys. Note that such evaluation could complement, precede, or follow separate AR evaluations (see case 2 below).

The second case concerns the use of AR to evaluate DSR. In this case, the action researcher does not develop a new, innovative artifact or solution technology, but has the express purpose of evaluating an existing solution technology that is still of research interest. In this case, the research interest (or a major part of it) is the evaluation and a planned research outcome is statements about the efficiency, effectiveness, or efficacy of artifacts that have been proposed and developed by other researchers or practitioners. In this case, there is only slight overlap, which is limited to the naturalistic evaluation activities in Figure 1.

The third case (significant overlap) is where the action researcher actually is also conducting DSR, in that he/she is inventing a new, innovative artifacts or solution technology to better address the client’s problem solving interest (a socio-technical problem). In this case, the research interest includes the development and evaluation of the solution technology. In the framework shown in Figure 1, this would include the theory building, solution technology invention, and naturalistic evaluation activities.

Table 2 summarizes these three cases.

5 PRACTICAL PROBLEMS OF COMBINING AR AND DSR

Although AR and DSR are in principle compatible with each other, they may be difficult to combine for more practical reasons. In the following we shall discuss these difficulties in more detail.
As pointed out above, AR assumes collaboration between researchers and the client within a mutually acceptable ethical framework. This ethical framework may not be self-evident in an AR project, but if the AR is part of a larger DSR effort, it may be particularly difficult to achieve such agreement since the major parties, researchers vs. clients, may have widely opposing goals. DSR by definition attempts to construct new and innovative artifacts or solution technologies. As a consequence, it operates at the edge of the existing technology. Such cutting edge technology is not usually robust. Petrovski (1982) claims that failure is central to understanding engineering, and that lessons learned from failures can advance engineering knowledge more than all the successful cases. Similarly, DSR may push a new technology to its limit until it collapses. However, in AR the client’s interest is usually that the technology employed is proven and robust and does not disturb the performance of their work. Having a technology fail would be unlikely to be appropriate or agreeable to the client in an AR context.

Weedman (1998, 2008) describes such a conflict of interest in the Sequoia 2000 project. It was essentially a combined DSR and AR project, although she does not refer to AR in her two papers. The project comprised computer scientists who acted as researchers and earth scientists as users. She describes the conflict of interest when the technology was repeatedly pushed to the limit by computer scientists until it broke, with consequent costs to the users when the system crashed and the users’ work came to a halt.

In conclusion, DSR may apply a conscious “learning from failures” strategy when developing new, innovative artifacts. Although the goal of this “learning from failures” strategy is to develop more robust technology that would be safer for the potential users of the developed technology or artifact, one should note that new technology is always failure prone and risky. In such a case, the research interest of the researcher would conflict severely with the problem solving interest of the client. AR in the DSR context implies that potentially failure prone technology is applied in the real-life context. Depending on the nature of technology and situation, it is more or less risky to the client. The potential of risk to the clients or the public have led DSR in engineering and medicine to prioritize laboratory testing in the initial evaluation (testing) of the developed artifacts or technology. This initial testing is done clearly separated from potential clients, partially to reduce risks.

In terms of the framework from Venable (2006) in Figure 1 above, where there are significant risks, the evaluation of the developed artifacts (e.g. as in case 2 above) should be done artificially, if possible, before attempting to evaluate naturalistically, using AR, for example. One can identify two opposing aspects in AR as far as risks to the client are concerned. On one hand, the involvement of the researcher in choosing the appropriate solution technology and the provision of on-going guidance for the using client organization during the AR study may mitigate the risk to the client. On the other hand, the AR researcher is often an advocate of the solution technology, and therefore may be prepared to push the technology too far from the client’s viewpoint in order to make it work. To mitigate this the client should always have the right to quit, if it does not want to continue the AR project.

When AR overlaps significantly with DSR (as in case 3 in the previous section), the solution technology invention is “on the fly”, which is inherently more risky than careful and thorough development before moving on to a separate evaluation. Thus, in our view, the mixed invention and evaluation of a new solution technology combining AR and DSR should only be used in situations where the risk to the client (and other stakeholders) is acceptably low. Also, the mutually agreeable ethical framework for the research should identify and make clear the risk of developing and trying out something new and take steps to mitigate that risk.

Finally, as identified in Venable (2009) and Pries-Heje et al (2008), there are risks in DSR that new or innovative solutions, once published and made available to be adopted by the public, do place these other stakeholders at risk. It is necessarily the case that AR is conducted in a narrow context, which implies that a new solution technology is untried in other contexts. Steps therefore need to be taken to clarify the extent of the evaluation in the AR context and to decide and state whether risks are yet
acceptable for public consumption of new technologies. Alternatively, other research methods than AR might be more appropriate for conducting the DSR.

6 CONCLUSIONS

There has been a significant and ongoing theoretical discussion in the IS field as to the nature and compatibility of AR and DSR, some of which has claimed that the two are similar, if not identical. In this paper we have analyzed the similarities and differences between AR and DSR based on their respective paradigmatic roots and assumptions, their research interests, the overlaps in their activities, and potential problems in combining the two approaches. Our conclusion is that, while the two approaches are compatible (and their synergistic use warrants further development), their paradigmatic assumptions, research interests, and activities may differ dramatically, depending on the purpose of research. More fundamentally, their levels or categories as research orientation (DSR) or method (AR) are different. Thus, we find that their similarities are actually quite superficial and the two things are decisively different.

Considering the practical implications of this analysis, we further identify that the employment of AR in the conduct of DSR needs to be done with care, especially where there is the potential for significant risk to the client or other stakeholders. Steps need to be taken where new technologies are being evaluated with AR to ensure that the evaluation is done carefully and that the completeness of the evaluation is judged and reported with a view to its limitations and remaining risk. This is especially the case where the new technology is developed “on the fly” as part of an AR project.

Our further recommendation is that clear consideration of risks due to the untried nature of the technology must be part of an ethical framework to be agreed at the beginning of a joint AR and DSR project. This is not just for improving the likelihood of successful conduct of the research project, but is the ethical responsibility of the researcher. Such agreement must be reached with the full, informed, and uncoerced consent of the client. Steps should also be taken, where possible, to reduce the risk to the client by evaluating the technology beforehand using other evaluation methods.

Abstract

In parallel to widely accepted behavioural research, Design Research (DR) has emerged in Information Systems. Nonetheless, the debate about the scientificity of DR is still ongoing. In the course of this debate, the role of scientific progress has hardly been discussed. But, doubtlessly, scientific progress is regarded as one of the main aims of science; science can even be defined by scientific progress. Philosophy of science has therefore developed a variety of concepts for scientific progress mostly adapted to explanatory and/or predictive theories. Nonetheless, the output of DR differs from those theories; therefore, concepts developed cannot be applied to DR without further ado. In this paper, we propose a first concept for scientific progress of DR artefacts. Because of the complexity of the field we firstly restrict to the research question: What is scientific progress of DR artefacts? Progress is commonly defined as a transition from step A to B whereby B is “better” than A. The aim of our research is to identify criteria for concretizing what is “better” in the context of DR and to define criteria of progressive DR artefacts. We thereby identified the following five criteria: utility, internal consistency, external consistency, scope, and efficiency.

Keywords: Design Science, Design Research, Design Theory, Scientific Progress.
1 THE IMPORTANCE OF SCIENTIFIC PROGRESS TO DESIGN SCIENCE

In parallel to widely accepted positivistic research approaches, design research (DR) has emerged in Information Systems (IS) Research (Hevner et al. 2004) and in other management sciences, e. g. organisational science (van Aken 2004; Romme 2003; Romme & Endenburg 2006).1 In ISR, a variety of articles describing and reflecting the construction and evaluation of concrete DR artefacts have been published.2 In parallel to the construction of concrete artefacts, authors also reflected the nature of design oriented research as well as the construction and evaluation of DR artefacts in general.3

Although many advances have been done in Design Science (DS) in IS, the debate on the scientificity of DR is still ongoing. In the course of this debate, the role of scientific progress has hardly been discussed. However, scientific progress is regarded as one of the main aims of science; science can even be defined by scientific progress.4 Philosophy of science has developed a variety of concepts for scientific progress. But, in most cases, they were adapted to theories in natural sciences, later also to theories in other disciplines (e. g. social sciences). Nonetheless, the output of DR differs from explanatory and predictive theories (Gregor 2006; Romme 2003). Therefore, concepts developed in philosophy of science referring to “traditional theories”5 cannot be applied to DR artefacts without further ado.

The aim of this paper is to transfer results of the discussion about scientific progress led in Philosophy of Science to the field of DS in IS. This is doubtless a complex enterprise. Yet, there has not been conducted much research on scientific progress in DR; consequently, this paper can only be a first approach. At the beginning of such a research, it is necessary to advance stepwise. The aim of this paper is to develop a set of criteria of progress of DR artefacts. This research aim concerns the ontological understanding of DR artefacts. Gregor and Jones (2007) make a seminal contribution by synthesising the ontological understanding of design research artefacts in a broad literature review. We therefore take their work as a starting point for our investigations.

In order to transfer results from philosophy referring to traditional theories to DR artefacts, we firstly trace the complex discussion of scientific progress in philosophy of science briefly. Secondly, we describe the anatomy of DR theories in order to understand differences to traditional theories. Thirdly, we transfer concepts from philosophy of science referring to traditional theories to DR artefacts and identify criteria of progress of DR artefacts. Finally, we summarise the criteria identified and show the necessity of further research.

---

1 Different authors in management sciences and information systems have a different understanding of what they mean by “design”. Some authors emphasise on aesthetical aspects and on creativity (Ehn & Malmberg 1998; Stolterman 2008) whereas others emphasise on utility and an engineering-like construction (van Aken 2004; Hevner et al. 2004; Romme 2003). In this paper, we clearly emphasise on the utility of the artifact and an engineering-like construction process.

2 An overview of the articles published at the Design Science Research in Information Systems Conference (DESRIST) is summarised by Bucher & Winter (2008, table 1 and table 2).

3 According to Winter (2008, p. 471), in this article, we call the concrete construction of design research artefacts “Design Research”, the reflection on the nature of design research artefacts and on their construction and evaluation in general “Design Science”.

4 Kuhn (1970, p. 162) asks the rhetorical question: “Does a field make progress because it is a science, or is it a science because it makes progress?”

5 In the following, we call descriptive, explanatory, and predictive theories “traditional” in order to demarcate them from design theories (Gregor 2006).
Progressivity of science has always been discussed in philosophy of science. Early works on the subject were already published in the 19th century, e.g. by William Whewell (Losee 2004, pp. 7-27). As always in philosophy, the discussion of scientific progress is multifarious. However, in the entire discourse there is one consensus: Scientific progress is a normative concept. A step from stage A to B constitutes progress if B is better than A in respect to some standards or criteria (Bird 2008). Object of discussion is the nature of such standards or criteria.

It is impossible to entirely summarise that broad discussion in this short article. Instead, we restrict ourselves to three major schools in philosophy of science whose concept of scientific progress influenced other philosophers of science significantly (Kaiser 1991, p. 12): the Logical Empiricism by the philosophers of the Vienna Circle, the Critical Rationalism by Popper, and the descriptive approach to philosophy of science by Kuhn. Finally, we propose how to synthesise some of the concepts presented by referring to Scientific Structuralism.

2.1 Logical Empiricism

The emergence of the Logical Empiricism is often said to be the beginning of modern philosophy of science. The concept of science of the Logical Empiricism was developed by the philosophers of the Vienna Circle since the 1920s. The seminal contributions of Logical Empiricism to philosophy of science in general, and to the subject of scientific progress in particular, were a starting point for the discussion by many philosophers later-on. Thereby, the Deductive-Nomological model for scientific explanations by Hempel and Oppenheim (1948) is central for the conceptualisation of science by Logical Empiricism. A scientific explanation consists of an explanans and an explanandum logically deduced from the explanans. The explanandum consists of at least one statement of antecedent conditions and at least one general law. The explanandum is a description of the empirical phenomenon to be explained, cf. Figure 1 (Hempel & Oppenheim 1948, p. 138).

The scientific explanation by Hempel and Oppenheim can explain concrete phenomena, but also general laws. For instance, the general law L2 “All copper expands when heated.” (explanandum) can be explained by the more general law L1 “All metals expand when heated.” in conjunction with the antecedent condition “Copper is a metal.” (explanans). In the conception of logical empiricism, law L1 is progressive in comparison to L2 because it does not only explain all phenomena L2 can explain, but also phenomena that cannot be explained by L2, e.g. “Tin is a metal”, “This is tin.”, “Therefore, this expands when heated.” (explanandum).

6 The argumentation of subsections 2.1 and 2.2 refers to Craig Dilworth’s introductory book “Scientific Progress” (Dilworth 2007).
7 An example for explaining a concrete phenomenon is: “All copper expands when heated.” (general law), “This is copper.” (statement of antecedent condition), “Therefore, this expands when heated.” (explanandum).
tin expands when heated.” (Dilworth 2007, p. 21). Hempel (1962, p. 100 f.) gives the following example from history of science: “[T]he uniformity expressed by Galileo’s law for free fall can be explained by deduction from the general laws of mechanics and Newton’s law of gravitation, in conjunction with statements specifying the mass and radius of the earth.”

The concept of scientific progress by the Logical Empiricism is based on exactly that deduction of one less comprehensive theory from another more comprehensive one: the more comprehensive theory is then progressive compared to the less comprehensive one. This concept is based on the assumption of a continuity of scientific knowledge, such that proceeding theories logically entail their predecessors.

2.2 Critical Rationalism

The Popperian concept of scientific progress fundamentally differs from that of Logical Empiricism in exactly this point. Popper does not emphasise on continuity, but on contradiction. In response to the Logical Empiricism, he states: “[F]rom a logical point of view, Newton’s theory, strictly speaking, contradicts both Galileo’s and Kepler’s. […] For this reason it is impossible to derive Newton’s theory from either Galileo’s or Kepler’s or both, whether by deduction or induction” (Popper 1973, p. 198).

Whereas Logical Positivism is able to distinguish between more and less progressive theories, but not to explain conflicts of theories Popper’s concept can explain theory conflict; but, in a first step, it fails to distinguish more progressive theories from less progressive ones (Dilworth 2007, p. 26). As a concept of scientific progress is central for each concept of science, Popper claims two criteria that make a theory more progressive in comparison to another one: their content and their verisimilitude.

Popper’s “study of the content of a theory […] was based on the simple and obvious idea that the informative content of the conjunction, $ab$, […] will always be greater than, or at least equal to, that of any of its components. Let $a$ be the statement ‘It will rain on Friday’; $b$ the statement ‘It will be fine on Saturday’; and $ab$ the statement ‘It will rain on Friday and it will be fine on Saturday’: it is then obvious that the informative content of this last statement, the conjunction $ab$, will exceed that of its component $a$ and also that of its component $b$” (Popper 1963, pp. 217-218). For instance, according to Popper, Kepler’s or Galileo’s theory is logically less strong and testable compared to Newton’s one; therefore, Newton’s theory has a richer content and is progressive in relation to Kepler’s or Galileo’s one. Moreover, the content of a theory is inverse to its probability. Obviously, the probability of $ab$ is less than the probability of $a$ or the probability of $b$. Consequently, a less probable theory has a greater content and is therefore ceteris paribus (c. p.) progressive (Popper 1963, p. 218).

The second Popperian criterion for scientific progress, the verisimilitude of a theory, can be described by its nearness to the truth. According to Popper, truth of a theory cannot be attained, but rather approached. A theory $a$ is closer to truth than a theory $b$ if $a$ has more true consequences and less false ones than $b$ (Bird 2008).

2.3 Kuhn’s historical view

Whereas Logical Empiricism and Critical Rationalism have a prescriptive concept of science, i. e. they state how science should be, Kuhn develops a descriptive approach by analysing history of science, i. e. he describes how science factually is. Especially Feyerabend, seizing many suggestions by Kuhn, strongly criticises Popper’s emphasis on falsification and argues that falsification has nearly never been the reason for rejecting a theory (Feyerabend 1989, pp. 250-259).

Instead, Kuhn’s (1970) concept of Scientific Revolution is said to better describe science as it is. According to that concept, each scientific discipline starts in a pre-paradigmatic phase. There, its members even do not agree on fundamental aspects, e. g. they do not speak a common language. When such different fundaments are harmonised usually a phase of Normal Science begins. Normal science is based on a paradigm supported by the research community. Kuhn (1970, pp. 35-42) describes science in such a phase as “puzzle solving”: Normal science is often very efficient, but it does not pro-
duce revolutionary outcomes. Nevertheless, at some moment, scientists begin to question their common fundamentals, e.g. core theories that are suddenly unable to explain newly detected phenomena. A crisis begins and leads to a scientific revolution. New theories are developed and tested until an appropriate candidate for explaining the newly detected phenomena is agreed on. Then again, a period of normal science begins until a new crisis appears.

After a scientific revolution, it might happen that the new paradigm cannot explain every phenomenon as good as the antecedent one (Kuhn 1970, pp. 99-100). Such a partial regress was called “Kuhn-loss” later-on (Bird 2008). Because of this Kuhn-loss, Kuhn’s understanding of scientific progress is not cumulative – as opposed to Logical Positivism and Critical Rationalism. Kuhn moreover denies any concept of nearness to truth. In his point of view, science develops rather evolutionarily, i.e. science develops like an organism that continuously adapts itself to its environment (Kuhn 1970, pp. 170-173).

Kuhn’s and Feyerabend’s conception of scientific progress is strongly marked by their incommensurability thesis. In everyday speech, “incommensurable” means not to have a common standard of measurement. Kuhn uses this term by referring to theories. His view is that a theory is always evaluated by comparing it to a paradigm. Therefore; the standards of theory evaluation are not permanent because paradigms change; they are not theory-independent because they involve a comparison to a (paradigm) theory; and they are not based on rules because they involve perceived relations of similarity (Bird 2008). Consequently, it is very difficult – if not impossible – to compare two theories.

Kuhn differentiates three types of incommensurability (Bird 2008): methodological incommensurability, observational incommensurability, and semantic incommensurability. Firstly, methodological incommensurability is caused by the fact that theories are always evaluated in reference to a paradigm. Therefore, theories having evolved in two different paradigms are not evaluated on the same basis. Secondly, observational incommensurability is caused by theory-dependency of observation. One basis for Kuhn’s argumentation is the gestalt-switch theory developed by Hanson (1958). Hanson uses the example of a picture called bird-antelope (Hanson 1958, p. 87). Usually, at a first view, the observer of that picture sees a bird. But, when somebody tells the observer that it can also be seen as an antelope, the observer usually begins to see an antelope, too. Hanson concludes our perception to be strongly influenced by our previous knowledge. Kuhn (1970, pp. 113-115) transfers Hanson’s discovery to theories and states that all observation is always conducted in the light of the theories of the accepted paradigm. Therefore, observation depends on theory. Consequently, observations conducted against the background of two paradigms cannot be easily compared with each other. This is called observational incommensurability. Lastly, semantic incommensurability is based on a change of the meaning of theoretical terms when a paradigm changes (Bird 2008). For example, the meaning of the word “mass” has slightly changed when Einstein formulated the theory of relativity. In the Newtonian mechanics, mass is a constant concept – e.g. a skyrocket on earth and on moon were considered to have the same mass. Einstein, in contrast, denies mass to be constant by stating that mass and energy are equivalent to each other ($E=mc^2$). Such slight changes in the meaning of theoretical terms also make comparisons of two theories difficult.

Despite all difficulties revealed by Kuhn, he identifies five characteristics “of a good theory” (Kuhn 1977, p. 321):

“First, a theory should be accurate: within its domain, that is, consequences deducible from a theory should be in demonstrated agreement with the results of existing experiments and observations. Second, a theory should be consistent, not only internally or with itself, but also with other currently accepted theories applicable to related aspects of nature. Third, it should have broad scope: in particular, a theory's consequences should extend far beyond the particular observations, laws, or subtheories it was initially designed to explain. Fourth, and closely related, it should be simple, bringing order to phenomena that in its absence would be individually isolated and, as a set, confused. Fifth – a somewhat less standard item, but one of special importance to actual scientific decisions – a theory should be fruitful of new research findings: it should, that is, disclose new phe-
nomena or previously unnoted relationships among those already known” (Kuhn 1977, pp. 321-322).

Kuhn (1977, p. 322) later-on explains that accuracy is important, but would be insufficient as a single criterion. Accuracy comprises explanatory and predictive power.

Nevertheless, two critical remarks referring to these criteria are made by Kuhn himself. Firstly, they are individually imprecise: individuals might differ about their application to concrete cases. Secondly, “when deployed together, they repeatedly prove to conflict with one another” (Kuhn 1977, p. 322).

2.4 Criteria for Scientific Progress

The three important approaches in philosophy of science presented in the preceding sections can hardly be harmonized. Philosophers of science often call the three positions the “Bermuda Triangle of Philosophy of Science”. If one tries to take a position inside that triangle, i.e. to harmonize aspects of at least two of the three positions, he will be caught by a vortex he cannot escape from any more (Kaiser 1991, p. 12). Being aware of this problem, we do not even try to harmonize the three positions - this task should be undertaken by philosophy.

Nonetheless, in order to be able to transfer the results of the discussion in philosophy of science to IS design theories, it is necessary to summarize the three approaches. We propose a set of criteria relevant for the discussion on scientific progress. The summary is illustrated in Table 1.
