Some of the criteria listed in Table 1 are redundant. The criterion C1 stemming from logical empiricism, i.e. the logical deducibility, is strongly based on an idea of continuity in science that is denied by the two other authors. Nonetheless, if a theory T2 is logically deducible from a theory T1, the scope of theory T1 is broader than the scope (C6) of T2 (or at least as broad as it). Moreover, the special notion of “content” formed by Popper (1973) implies that a theory with a higher content is more accurate than another with a lesser one. Therefore, there is also a relationship between content and accuracy.

The closeness to truth (C3) has some similarities to the accuracy of the theory. Kuhn avoids the term of truth in order to be independent of strong ontological and epistemological positions. The term “truth”, at least if following the correspondence theory of truth, necessitates a position of a scientific realist. Kuhn does not explicitly take such a realist position. Instead, he emphasizes the explanatory
and predictive power of theories and thereby adopts an instrumentalist view. Closeness to truth for a scientific realist is accuracy for a scientific instrumentalist.

We can conclude that the criteria mentioned by Kuhn (1977, pp. 321-322) are – as he states himself – exhaustive in the sense that they cover the criteria we extracted from Logical Empiricism and from Critical Rationalism. Consequently, we will use the following criteria for our further argumentation: accuracy, internal consistency, external consistency, scope, simplicity, and fruitfulness of new research findings.

3 THE NATURE OF DESIGN RESEARCH THEORY

In order to be able to transfer concepts of scientific progress developed for theories in natural sciences to IS DS, the differences between the outcomes of natural sciences and those of design research should be explained. Many publications in DS dealt with epistemological aspects of DR, e.g. with epistemological aspects of the construction and evaluation of design research. Compared to research about epistemological aspects, ontological aspects of design research in IS have been neglected. Nonetheless, in recent years, some authors emphasised on ontological aspects of DR. A seminal article on the “Anatomy of a Design Theory” was published by Gregor and Jones (2007) in which they described core components of an IS design theory.

3.1 On the output of DR: Design Research Artefacts or Design Theories?

Gregor and Jones (2007) write about theories as main outcome of DR. Up to now, there is no consensus whether DR should theorise (e.g. Hevner et al. 2004; Kuechler & Vaishnavi 2008a; Kuechler & Vaishnavi 2008b; Venable 2006; Walls & Widmeyer & El Sawy 1992) or not (e.g. March & Smith 1995). The proponents argue that “[d]eveloping theory is what we are meant to do as academic researchers […]. Theories are practical because they allow knowledge to be accumulated in a systematic manner and this accumulated knowledge enlightens professional practice” (Gregor 2006, p. 613).

Most authors understand design theory as a “utility theory” (Venable 2006) prescribing “how a design process can be carried out in a way which is both effective and feasible” (Walls & Widmeyer & El Sawy 1992). A design theory is a mean to communicate, justify, and develop knowledge in DS cumulatively (Gregor & Jones 2007).

In our paper, we clearly argue for theorising in DR. A synthesis of design knowledge in theories helps to compare results and makes it easier to proof scientific progress, as we will see later-on. Nonetheless, Frank’s (2006) approach is very helpful because it allows us to take a second perspective on design research.

3.2 Components of a Design Theory according to Gregor and Jones (2007)

Gregor and Jones (2007) detail the anatomy of a design theory. Their publication is thereby oriented at a paper published by Walls et al. (1992). The core elements of a design theory identified by Gregor and Jones (2007, p. 322) are listed in Table 2 and explained in the following:

(1) **Purpose and scope** are the characteristic elements of a design theory. Whereas the scope is also relevant for “traditional theories” the purpose is specific to design theories as they are “utility theories” (Venable 2006).

(2) **Constructs** represent the entities of interest in the design theory. Frank (2006) also emphasises on the language the artefact is represented in; he thereby differentiates formal, semi-formal, and natural languages. Constructs are also elements of traditional theories as Dubin (1978) states.
### Core components

1) **Purpose and scope** (the *causa finalis*)
   - "What the system is for," the set of meta-requirements or goals that specifies the type of artefact to which the theory applies and in conjunction also defines the scope, or boundaries, of the theory.

2) **Constructs** (the *causa materialis*)
   - Representations of the entities of interest in the theory.

3) **Principle of form and function** (the *causa formalis*)
   - The abstract “blueprint” or architecture that describes an IS artefact, either product or method/intervention.

4) **Artefact mutability**
   - The changes in state of the artefact anticipated in the theory, that is, what degree of artefact change is encompassed by the theory.

5) **Testable propositions**
   - Truth statements about the design theory.

6) **Justificatory knowledge**
   - The underlying knowledge or theory from the natural or social or design sciences that gives a basis and explanation for the design (kernel theories).

### Additional components

7) **Principles of implementation** (the *causa efficiens*)
   - A description of processes for implementing the theory (either product or method) in specific contexts.

8) **Expository instantiation**
   - A physical implementation of the artefact that can assist in representing the theory both as an expository device and for purposes of testing.

---

**Table 2:** Components of an IS Design Theory (Gregor & Jones 2007, p. 322)

(3) **Principles of form and function** constitute the architecture of an IS artefact. Principles of form and function also exist for traditional theories: Dubin (1978) refers to “laws of interaction” in reference to traditional theories.

(4) The **artefact mutability** refers to changes in the state of the artefact anticipated in the theory, e.g. suggestions for improving the approach in further works. For traditional theories, there is no equivalent to artefact mutability.

(5) **Testable propositions** are truth statements about the design theory. They are a central element of traditional theories; Dubin (Dubin 1978) names them simply “propositions”.

(6) **Justificatory knowledge** is the underlying knowledge or theory from natural or social sciences. Frank (2006) differentiates a variety of justification methods depending on different underlying concepts of truth: correspondence theory of truth, coherence theory of truth, and consensus theory of truth. For each of them, he mentions at least one validation method: for correspondence theory of truth experiment, field study, or case study; for coherence theory literature analysis; and for consensus theory of truth (virtual) discourse according to Habermas (1984). Dubin (1978) does not mention an equivalent element for traditional theories. According to Gregor and Jones (2007), this is due to the fact that Dubin, being realist, explicitly does not emphasize on explanation.

(7) **Principles of implementation** describe the process for implementing the theory in a specific context. This includes situational adaptation of artefacts (cf. Bucher et al. 2007). For traditional theories, Dubin (1978) does not mention an equivalent.

(8) **Expository instantiations** of the theory are physical implementations of the artefact. Often, they are used for testing the artefact. As well as principles of implementation, Gregor and Jones consider them as optional. Frank (Frank 2006) mentions “prototyping” as one method for justifying the artefact. In traditional theories, hypotheses and empirical indicators are very similar to an expository instantiation (Dubin 1978).
4 CRITERIA OF SCIENTIFIC PROGRESS OF DESIGN THEORIES

After having shortly summarised aspects of scientific progress from philosophy of science in section 2 and structural components of DR artefacts and DR theories respectively in section 3, we now transfer the criteria originally created for explanatory and predictive theories to DS. We thereby take, as a starting point, the five criteria for scientific progress by Kuhn (1977, pp. 322-323) which are, as explained in section 2.4, under some presuppositions exhaustive: accuracy, consistency, scope, simplicity, and fruitfulness of new research findings.

**Accuracy** of a theory in natural sciences is composed by its explanatory and predictive power. Theories in DS do not aim at explaining or predicting, but at being useful. Design Theories are therefore also called utility theories (Venable 2006).

Nonetheless, utility is mentioned as a component of DR [theory] neither by Frank nor by Gregor and Jones. They both mention the purpose of an artefact. The usefulness of an artefact can be defined as its ability to fulfil its purpose if the purpose itself is useful, i.e. relevant. The testable propositions claimed by Gregor and Jones operationalise the usefulness of the artefact. If the testable propositions are exhaustive, the accuracy of a DR theory corresponds to the truth of its testable propositions.

By **consistency**, Kuhn (1977, pp. 321-322) means both internal and external consistency.

The **internal consistency** of a design theory involves nearly all its components. One necessary internal consistency has already been mentioned: the consistency between testable propositions and the purpose of the artefact. The purpose of the artefact should be its leading property because the identity of an artefact is strongly linked to its purpose. The only component of a design theory which cannot be consistent to its purpose is its scope – both concepts are orthogonal one to another. Moreover, the testable propositions should be consistent to all other components of a design theory. A special role in determining the consistency of an artefact is played by its principles of form and function, i.e. its architecture. They give an overview of the artefact and facilitate internal consistency checks.

By **external consistency**, Kuhn means consistency with “other currently accepted theories applicable to related aspects of nature” (Kuhn 1977, p. 322). A design theory should therefore be consistent to both other accepted IS design theories and behavioural theories in IS. External consistency should be shown by a literature review. For external consistency; Gregor and Jones (2007) identify the design theory component of justificatory knowledge; Frank (2006) mentions adequacy according to the correspondence theory of truth.

The broader the **scope** of a theory the better is the theory. The scope of a theory should not only be mentioned, but it should also be justified. The internal consistency of a theory necessitates that testable propositions are formulated and tested such that the whole scope of the theory is covered.

**Simplicity** is often claimed as a quality factor of theories. Already, William of Ockham said that entities must not be multiplied beyond necessity. Albert Einstein stated to make everything as simple as possible, but not simpler. Simplicity is related to the explanatory power of theories. A complex explanation might be correct, but also might be that complex that it cannot be understood any more. Both, simplicity and explanatory power lead to understanding. In DS theory, understanding is not the primary goal, but utility. The utility of a DR artefact or of a design theory is only slightly affected when it is complex, but strongly when it is expensive, i.e. inefficient. Therefore, the efficiency of a utility theory is the equivalent to the simplicity of an explanatory theory. Simplicity, however, is still important: An efficient design theory implies its simplicity. As the understanding of the theory is time consuming for the practitioner who wants to apply it, an unnecessarily complex theory is inefficient compared to a simpler one.

The efficiency of a design theory should mainly be shown by formulating and testing propositions that show the efficiency of the artefact. The simplicity of a design theory (in the narrow sense of the word...
simplicity) mainly refers to the constructs, i.e. the language used, and to the principle of form and function of the artefact, i.e. its architecture.

The **fruitfulness of a design theory for further research** is a criterion that is only mentioned by Kuhn, i.e. neither by Logical Empiricism nor by Critical Rationalism. The fruitfulness for further research is – as Kuhn says himself – compared to the other criteria “a less standard item” (Kuhn 1977, p. 322). Fruitfulness for further research can only be determined in a historical analysis of a theory. Therefore, it is difficult to relate fruitfulness for further research to actual components of a design theory.

In summary, progress is a normative concept and can be defined as a transition from stage $A$ to stage $B$ whereby $B$ is better than $A$ in respect to certain criteria (Niiniluoto 2007). In order to identify such criteria for DS, we took five criteria for theories in natural sciences formulated by Kuhn (1977, pp. 322-323) and transferred them to DS. Four of these five criteria could be meaningfully transferred to DS and put in relation to components of a design theory. Some of the criteria changed in meaning. The final quality criteria for a “good” design theory are utility, internal consistency, external consistency, scope, and efficiency.

### 5 FINAL REFLECTION AND OUTLOOK

Scientific progress is a core aim of science. The subject therefore has been treated by philosophy of science for many years. The evolution from Logical Empiricism whose concept is based upon the relatively naïve assumption of continuity in science over the concept of scientific progress by Critical Rationalism to the historical, i.e. descriptive, view by Kuhn shows not only the complexity and diversity of the subject, but makes us also understand that the question of scientific progress is not even finally solved in philosophy of science.

In this paper, five criteria by Kuhn (1977, pp. 322-323) are applied to the structure of design theory. In summary, a good design theory is useful, internally and externally consistent, it has a broad scope, and its artefact is efficient. A theory $T_1$ that is better in at least one of these criteria and not worse in another criterion compared to a theory $T_2$ is progressive in reference to $T_2$.

The discussion of the problems related to scientific progress formulated by Kuhn (1970), i.e. the methodological, observational, and semantic incommensurability, have shown that scientific progress is a very complex concept. We can learn from Kuhn that it is important to consider the paradigm in which a theory is formulated. A theory can only be evaluated towards such a paradigm. Therefore, it is necessary to know actual paradigms. In order to detect such paradigms, rigorous historical research is necessary (Mason & McKenney & Copeland 1997). It is arguable whether, in our discipline, we are by now in a phase of normal science or still in a pre-paradigmatic phase. A common language is a fundamental requirement for a discipline in a phase of normal science. Such a common language does not broadly exist. Research about different language communities clearly shows that (Schelp & Winter 2008; Schelp & Winter 2009). Such research is very fruitful for IS because it allows for a better understanding of our research outcomes. Difficulties arising from different paradigms in reference to the discussion of scientific progress in IS DS could not be sufficiently discussed in this article. More research in this field is necessary.

Moreover, the subject of scientific progress was only treated on an ontological level. We proposed a criteria-based definition of scientific progress in DS. Besides research focussing on paradigms IS, at least three more research questions concerning scientific progress in design science follow: Firstly, an epistemological question can be posed: How can we detect scientific progress in DS? The criteria developed are a good basis for answering such a question. Moreover, at least two praxeological questions follow: How can we ameliorate DR processes in order to simplify the detection of scientific progress; are new guidelines in addition to those proposed by Hevner et al. (2004) helpful or even necessary? Lastly, we can ask how to construct artefacts that are progressive.

Abstract

Enterprises are facing a challenging dilemma. In order to be able to accommodate peak loads on their IT systems, they must maintain large computing clusters, which lie idle most of the time. At the same time, IT departments are under constant pressure to cut down on hard- and software expenses. Grid technology offers a promising way out of this dilemma by allowing the dynamic sharing both within enterprises as well as across organizational boundaries. This sharing approach, however, requires proper economic incentives. This paper is concerned with the determination of dynamic market-based prices. Due to their simplicity, so-called pay-as-bid mechanisms have become popular. This paper is novel as we provide an in-depth analysis of two such pay-as-bid mechanisms – Proportional Share and a discriminatory pay-as-bid mechanism – for the case of three users, thus extending previous work by Sanghavi and Hajek (2004) and Stößer et al. (2008). This analysis is important as we show that the nice results for two users cannot be retained once three or more users are present. Even worse, we show that these results can even be reversed if we move to games with more than two players.

Keywords: Pay-as-bid Mechanisms, Game-theoretic Analysis, Distributed Resource Allocation.
1 INTRODUCTION

Increasingly complex applications require massive amounts of processing power while exhibiting fluctuating utilization patterns. One example for such applications are CAx applications such as Computer Aided Engineering and Computer Aided Design or so-called “digital factory applications”, e.g. for production planning. As a result, companies pile up resources to accommodate few peak loads on their systems. In a meta-study, Carr (2005) reports that data centers are only using between 10-35% of their available processing power, leading to tremendous inefficiencies. This development is exacerbated by intra-organizational boundaries. Even business units and departments within one enterprise are unwilling to share idle resources with other units.

Grid technology offers a promising way out of this dilemma. Using virtualization technologies, physical resources can be dynamically assigned to applications according to these applications’ priority. Thus, if a unit experiences a peak load on its system, it can accommodate this peak load on remote resources, and analogously, in case an organizational unit temporarily has idle resources, it can host applications of other units. These applications can be forced out and moved to other resources as soon as the unit falls short of resources itself. In essence, Grid technology yields more efficient resource utilization as the system load is distributed across all organizational units. This sharing approach, however, requires proper economic incentives. Organizational units will only contribute their resources to the Grid if they get something in return. At the same time, units need to charge resource usage to avoid excessive usage. Both issues can be addressed by introducing dynamic prices. This paper is concerned with the determination of dynamic prices that are simple enough to be useful in Grids. Due to their simplicity, so-called pay-as-bid mechanisms have become popular – the user simply pays what he bid, and receives a share of the resource according to some specific allocation rule which relates this user’s bid to the other users’ bids.

This paper is novel as we provide an in-depth analysis of two such pay-as-bid mechanisms – Proportional Share and a discriminatory pay-as-bid mechanism – for the case of three users, thus extending previous work by Sanghavi and Hajek (2004) and Stößer et al. (2008). This analysis is important as we show that the nice results for two users cannot be retained once three or more users are present. Even worse, we show that these results can even be reversed if we move to games with more than two players.

This paper is structured as follows. In Section 2, we introduce a sample scenario which illustrates the business case for Grids. Section 3 discusses previous work on Grid market mechanisms. At the core of this paper, Section 4 provides a game-theoretic analysis of Proportional Share and the discriminatory pay-as-bid mechanism introduced by Sanghavi and Hajek (2004). In Section 5, we discuss our analytic results. Subsequently, Section 6 concludes the paper and points to future research directions.

2 MOTIVATIONAL SCENARIO

In the following, we showcase a scenario where market mechanisms create value in real business cases. The scenario is TXTDemand, an application by TXT e-solutions’ for forecasting demand and replenishment within a supply chain. The application combines CPU intense forecasting algorithms as well as algorithms for the analysis of historic data and current sales data with interactive revision tools. In a typical business scenario, a customer is running the application daily for defining demand and replenishment strategies. During the night batches process the previous days’ sales data to define initial forecast plans. For example, the replenishment module generates optimized replenishment plans, taking historic inventory levels, future demand forecasts and the type of the market into

\[http://www.txtgroup.com/\]
consideration. The plans are analyzed and refined by the user at the other day in the interactive mode. The rationale for user interaction in the planning process is that users have more in-depth knowledge about the context. For example, if a certain fair takes place for the first time, the replenishment plan generated from historical data are most likely ignoring this. The user can, hence, significantly improve the replenishment plan by conducting as-if scenario analyses, refining the automatically produced plan.

The calculations of the replenishment module are particularly resource demanding when used in real business due to the very large amounts of data surpassing several hundred millions of entries. Grid computing can help by distributing the calculations on several machines. By pooling resources of several providers, the costs for IT infrastructure can be significantly reduced. Since the calculations are so demanding, the total cost of ownership for one company alone would make the use of the forecasting module unprofitable. It is the pooling of resources in a Grid that amortizes the use of the replenishment module. As the pure sharing of resources without compensation is hampered by free-riding behavior, market mechanisms seem to work well, establishing the right incentives for the participants.

The market mechanisms need to cope with the peculiarities of the domain. We identify two main requirements for the market mechanism. In case of interactive applications, the requests for Grid resources depend on daily human interactions. Thus there can be unpredictable peaks of requests, occurring at any second. This requires from the mechanism to attain an allocation of resources in near real-time. Furthermore, from a technical viewpoint, avoiding starvation is an important objective. In scheduling theory, starvation denotes the fact that low-priority tasks are prevented from doing any progress because all resources are assigned to other higher-value tasks. Combining the economic and the technical viewpoint, it can be desirable to give “better” service to high-value applications but to also give at least “some” service to low-value applications.

3 RELATED WORK

A bulk of mechanisms has been proposed for Grid resource allocation (see Wolski et al. (2001) and Neumann et al. (2008) for surveys). In AuYoung et al. (2004), Bapna et al. (2006) and Schnizler et al. (2006), the scheduling problem in Grids is formalized as a combinatorial allocation problem. Bapna et al. (2006) and Stößer et al. (2007) present greedy heuristics to mitigate the resulting computational complexity. While these mechanisms allow for dependencies between multiple Grid resources (e.g. CPU and memory), they are based on strong informational assumptions, such as complete knowledge about the time constraints and resource requirements of applications. However, in practice the users themselves will only have fuzzy knowledge about this information, as can be seen when comparing the user estimates and actual runtimes and resource requirements in workload traces from supercomputers.

A fundamentally different approach is taken by mechanisms that continuously assign resource shares to applications. These shares are continuously updated as new user requests are submitted or tasks are completed, thus allowing for real-time allocations. With an allocation rule purely based on economic reasoning (e.g. the prominent Vickrey auction), all available resources would be given to one single user, with the highest valuation. However, this will lead to the starvation of other tasks with lower value. Consequently, considering the requirements of our scenario, in this work we will consider two different allocation mechanisms: Proportional Share (Chun and Culler 2000, Lai et al. 2004) and the discriminatory pay-as-bid mechanism by Sanghavi and Hajek (2004).

Proportional Share is well understood and has been implemented by Hewlett Packard in its Tycoon system (Lai et al.). If user $i$ reports a valuation of $w_i$, he will receive a fraction of the resources amounting to $\frac{w_i}{\sum_{j=1}^{n} w_j}$.

Proceedings ECIS 2009
The discriminatory pay-as-bid mechanism has been proposed by Sanghavi and Hajek (2004) for bandwidth allocation in computer networks. It works slightly different than Proportional Share, giving a discount to the high-value user, thus resulting in a lower unit price than the low-value users. The idea is to encourage the high-value user to bid close to his true valuation rather than to shade down his bid. We will denote the allocated share for each user \( i \) of \( n \) users for Proportional Share with \( \tau_{ps}^i = \frac{w_i}{\sum_{j=1}^{n} w_j} \) and the Sanghavi-Hajek allocation rule with \( \tau_{sh}^i = \frac{w_i}{w_{\text{max}}} \int_0^1 \prod_{j \neq i} \left( 1 - s \frac{w_j}{w_{\text{max}}} \right) ds \).

Sun Microsystems is considering to integrate the latter mechanism into their Sun Grid Engine (Stößer et al. 2008).

4 THE MODEL

One of the main goals of this work is to compare the performance of the two given allocation mechanisms and thus to conclude which of these may be more appropriate for use in typical Grid scenarios. Clearly our work is abstract and can be applied to other domains as well though in this work we restrict our attention to Grids as the mechanisms can be applied there reasonably.

In general the performance of mechanisms can be measured analytically, through simulations or with laboratory experiments. In this work though we will focus on analytical evaluation since it is well known that a common metric for measuring a mechanisms performance analytically is given by computing the performance ratio in its Nash equilibrium. Therefore we outline the setting used in our work and give a short introduction into Nash equilibria followed by the main analysis of the Nash equilibria of the two allocation mechanisms, Proportional Share and Sanghavi-Hajek. We will analyze under which conditions (multiple or unique) Nash equilibria exist for the case of more than two users. It is well known that the results from 2-player games cannot always be generalized to n-player games. Since this applies to our analysis as well, we will consider three players first, showing the tremendous challenges and difficulties as well as the rigorous conditions one encounters even for the simple case of one additional player.

4.1 The Setting

We assume there is an auction with one seller who offers a perfectly divisible good (i.e. there are no constraints in how many parts the good may be split up nor the size of these parts) and \( n \) buyers, each one offering a bid \( w_i \) and receiving a share through the utilized allocation mechanism \( \tau \). Let \( w = (w_1, ..., w_n) \) be the vector of bids given by the users. We also assume \( w_i \geq 0 \) for \( i = 1, ..., n \) with at least one \( w_i > 0 \), since a positive \( w_i \) represents the payment made by user \( i \). At this point we may already say, that we can exclude any Nash equilibria, where negative bids \( w_i \) are submitted, since this would mean that user \( i \) would receive a payment by the seller for his allocated part of the good and thus would turn into a seller, also leading to a contradiction to the assumption of a given non-negative payment vector. The vector \( x = (x_1, ..., x_n) \), \( x_i \in \mathbb{R}_+^0 \), \( \sum_{i=1}^{n} x_i = 1 \), denotes the actual allocation, where the shares \( x_i \) for each user are allocated according to the allocation mechanism \( \tau_{sh} \) for the Sanghavi-Hajek mechanism and \( \tau_{ps} \) for Proportional Share respectively, where each mechanism depends on the payment vector \( w \). Furthermore we assume in line with auction theory (Mas-Colell et al. 1995) that each user has a quasi-linear utility function \( u_i(x) = v_i x_i - c(x_i) \), with \( v_i \in \mathbb{R}_+^n \) denoting the valuation of user \( i \) for the good and \( c(x_i) = p_i x_i \) the linear price function, where \( p_i \) denotes user \( i \)’s unit price, i.e. the price user \( i \) would have to pay if she were awarded with the whole resources. As was shown in Johari and Tsitsiklis (2004), when evaluation the worst-case-performance ratio in our setting, it is enough to look at linear utility functions.

Additionally we use in our setting a so-called pay-as-bid pricing scheme, so that we have \( c(x_i) = p_i x_i = w_i, i = 1, ..., n \). Thus we can reformulate the utility functions to \( u_i(w) = v_i \tau_i(w) - w_i \).
4.2 Nash Equilibria

Since the main goal of this section is to analyze the possible Nash equilibria for the several given allocation mechanisms for two, three and \( n \) users, the concept and the idea behind this equilibrium needs to be clear. One of the main goals of mechanism design is to construct these mechanisms in a way that they are incentive compatible, i.e. each user bids his true valuation of the good and has no advantage of reporting false valuations, because it will not lead to any improvement for him. In this situation the concept of Nash equilibria is widely used (cf. Sanghavi and Hajek 2004).

**Definition 1. (Nash equilibrium)** A bid vector \( \mathbf{w}^{NE} \) is a *Nash equilibrium*, if \( u_i(\mathbf{w}_i^{NE}) \geq u_i(\mathbf{w}_i, \mathbf{w}_-^{NE}) \) for all \( i = 1, \ldots, n \), meaning that no user \( i \) can benefit by unilaterally deviating from his equilibrium bid \( \mathbf{w}_i^{NE} \).

For a given allocation mechanism there may exist no, one unique or several Nash equilibria. We will analyze under what conditions we may retrieve no equilibrium but by changing the realizations of the users bids and/or valuations slightly we obtain a unique or several Nash equilibria. Also we have not only to worry about multiple Nash equilibria but also acceptable (i.e. feasible) ones, meaning that we will not accept any solution resulting in a contradiction to our assumptions as already pointed out above. Having said this we will speak of a feasible Nash equilibrium if an equilibrium chosen out of a given set of several Nash equilibria fulfills all taken assumptions and leads to no contradiction at all. Therefore for any possible solution we have to check afterwards if the foregoing assumptions and conditions still hold.

Given the term of a Nash equilibrium we may define the performance ratio of an allocation mechanism:

**Definition 2. (Performance ratio)** Suppose a set of \( n \) users each having a utility function \( u_i \) and a provider selling the perfectly divisible good with a utility function \( u_p \). Let the bid vector \( \mathbf{w}^{NE} \) be a Nash equilibrium. Then the *performance ratio* of a given allocation mechanism \( \tau \) is given by

\[
\frac{u(\tau(\mathbf{w}^{NE}))}{u^*} = \frac{\sum_{i=1}^{n} u_i(\tau(\mathbf{w}^{NE})) + u_p(\tau(\mathbf{w}^{NE}))}{u^*}
\]

where \( u^* \) denotes the theoretical optimum giving the whole good to the user with the highest bid.

The subsequent analysis will be along the following lines: We will compute the resulting Nash equilibria for \( n \) users (\( n \in \{2, 3\} \)) for the Sanghavi-Hajek as well as the Proportional Share mechanism. We will show under which conditions these equilibria exist and to what outcome (utility function) they entail. For this we use the following, well known proposition:

**Proposition 3.** For a set of given users \( i, i = 1, \ldots, n \), the payment vector \( \mathbf{w}^{NE} \) is a Nash equilibrium, if and only if \( \frac{\partial u_i(w^{NE})}{\partial w_i^{NE}} = 0 \) for all \( i = 1, \ldots, n \).

Proposition 3 simply means that every agent maximizes his own utility in conjunction with all bids given by the other agents.

4.3 Two Users

Stößer et al. (2008) analyze the case with two requesters. We will briefly report the main results for the sake of completeness. We assume that the two users have the valuations \( v_1 \) and \( v_2 \) and without loss of generality user 2’s valuation is not less than user 1’s, i.e. \( v_1 \leq v_2 \).

**Lemma 4.** In the Nash equilibrium \( \mathbf{w}^{NE} \) of the pay-as-bid mechanism \( \tau^{sh} \), user 1 bids \( w_1^{NE} = \frac{v_1^2}{2v_2} \) and receives a share of \( \tau^{sh}_1(\mathbf{w}^{NE}) = \frac{v_1}{2v_2} \), whereas user 2 bids \( w_2^{NE} = \frac{v_1}{2} \), thus receiving \( \tau^{sh}_2(\mathbf{w}^{NE}) = 1 - \frac{v_1}{2v_2} \).
Inserting the above results in the utility functions \( u_i \) for every user \( i \), shows that the low-value user receives zero utility, while the high-value user has \( u_2(w^{NE}) = v_2 - v_1 \).

**Lemma 5.** In the Nash equilibrium \( w^{NE} \) of the pay-as-bid mechanism \( \tau^{PS} \), user 1 bids \( w_1^{NE} = \frac{v_1 v_2}{v_1 + v_2} \) and receives a share of \( \tau_1^{PS}(w^{NE}) = \frac{v_1}{v_1 + v_2} \), whereas user 2 bids \( w_2^{NE} = \frac{v_2}{v_1 + v_2} \), thus receiving \( \tau_2^{PS}(w^{NE}) = \frac{v_2}{v_1 + v_2} \).

Consequently, for two users there exists a unique Nash equilibrium without implying further restrictions on the valuations \( v_i \) of the users. Unfortunately, as we will show below, this does not hold any longer for three or more users.

### 4.4 Three Users

Now we will show our results for three users followed by additional examples demonstrating that our argumentation is not based on an empty set but that there exist scenarios allowing us to apply our analytic results. To illustrate our approach for each proposition we sketch the proofs which are straightforward but very in the appendix. We begin with the results of our analysis for the proportional Share mechanism for three users and subsequently move to the Sanghavi-Hajek mechanism.

#### 4.4.1 Proportional Share

In this section we will analyze whether there exist a unique Nash equilibrium when there are three users present. Our main result is captured by Proposition 6, which is quite powerful, as it shows the conditions for which feasible Nash equilibria exist.

**Proposition 6.** For three users with quasi-linear value functions there exists no unique Nash equilibrium for the Proportional Share allocation mechanism. Given the restrictions

\[
v_3 \geq \frac{v_1 v_2}{v_1 + v_2}, \quad v_2 \geq \sqrt{v_1 w_1} \quad \text{and} \quad v_1 \geq w_2 + w_3
\]

there exists a feasible equilibrium.

**Proof.** See Appendix.

Proposition 6 illustrates clearly that there does not exist a unique but two Nash equilibria, from which only one is feasible as it avoids payments from the seller to the user. The restrictions imply certain conditions (i.e. lower bounds) on the realizations of the valuations of the users but are not unlikely to happen in real-world scenarios, since they though being strong are nevertheless easy to check and fulfill. For the sake of simplicity we state them as a composition of constraints between the bids and the valuations, but since the bids depend unambiguously on the valuations only, more complex terms may be stated just using the users valuations. For more details we refer the reader to the appendix.

**Example 7.** We will give two simple examples, which illustrate this proposition. Assume there is a provider offering a certain amount of Terabytes of storage and three users having their own valuation and willing to pay a certain amount to achieve a share of the storage. The valuations are common knowledge and each user bids strategically trying to maximize his own utility.

- **a)** We assume the valuations to be \( v_1 = 1, v_2 = 2 \) and \( v_3 = 3 \). Using the results above we can compute the only payment vector \( w = \left( \frac{-12}{121}, \frac{60}{121}, \frac{84}{121} \right) \). The negative value of \( w_1 \) is the result of the third condition of the above proposition not being fulfilled, as \( w_2 + w_3 = \frac{144}{121} > 1 = v_1 \). Thus there exists no Nash equilibrium even for this simple case.

- **b)** Changing the valuations given in a) slightly, yields us a feasible outcome and Nash equilibrium: Assuming that we have the realization of the valuation vector \( v = (2, 3, 4) \) this
yields \( w = \left( \frac{24}{169}, \frac{120}{169}, \frac{168}{169} \right) \) and the following vector of utilities \( u = \left( \frac{2}{169}, \frac{75}{169}, \frac{196}{169} \right) \) thus amounting to a total revenue for the provider of \( \sum_{i=1}^{3} w_i = \frac{273}{169} \).

### 4.4.2 Sanghavi-Hajek Mechanism

In this section we analyze Nash equilibria for the Sanghavi-Hajek mechanism. These results differ very much from the ones we achieved for the Proportional Share mechanism.

**Proposition 8.** For three users, the Sanghavi-Hajek allocation mechanism combined with a pay-as-bid pricing scheme and quasi-linear utility functions, we have

a) A unique Nash equilibrium for the realization \( v_3 = \frac{1}{3} \frac{v_1 v_2 (3(v_1 + v_2) + 4 \sqrt{v_1 v_2})}{9(v_1^2 + v_2^2) - 14v_1 v_2} \) and the condition \( \frac{8}{9} v_1 \leq v_2 \leq \frac{9}{8} v_1 \), resulting in zero utility for the lower-bidding users and non-negative utility for the highest-bidding user.

b) Multiple Nash equilibria for \( v_3 > \frac{1}{3} \frac{v_1 v_2 (3(v_1 + v_2) + 4 \sqrt{v_1 v_2})}{9(v_1^2 + v_2^2) - 14v_1 v_2} \) and the realizations of the valuations of the three users being so that \( 2w_{3 \pm} \leq v_i \leq 3w_{3 \pm} \) for \( i = 1, 2 \) holds.

**Proof.** See Appendix.

As we learn from Proposition 8, for the Sanghavi-Hajek mechanism a unique Nash equilibrium may exist, but occurs under very restrictive assumptions on the users valuations. We can state immediately that in a real-world scenario the exact realization of \( v_3 \) as given above for a unique equilibrium is very unlikely to happen and tends to converge to zero. This is due to the fact that users usually will have expectations only about the valuations of the other users. Multiple Nash equilibria may also exist under less restrictive conditions though these conditions as seen in Proposition 8 depend on the highest given bid \( w_3 \). A strict dependency on the valuations of the users only can’t be given since \( v_3 \) is not determined but can be chosen freely above the limit.

**Example 9.** To clarify our results, we give two short examples assuming the same scenario as already given in Example 7.

a) Taking into account the conditions involved for finding a unique Nash equilibrium, we assume the realizations of the valuations of the lower-bidding users to be \( v_1 = v_2 = 1 \) and \( v_3 = 2 + \frac{3}{2} \sqrt{2} \). Thus the users may bid the strategy \( w_3 = \frac{4 + 3 \sqrt{2}}{4 + 3 \sqrt{2}} \) and \( w_1 = w_2 = \frac{3(2 + \sqrt{2}) (4 + 3 \sqrt{2})}{6 (3 + 2 \sqrt{2})} \) resulting in a utility vector \( u = (0, 0, \frac{1}{12(3 + 2 \sqrt{2})}) \).

b) If given the valuation vector \( v = (3, 3, 5) \) all necessary conditions are satisfied, resulting in a zero utility for the lower-bidding users and a positive utility for the highest bidder.

It is obvious that the conditions necessary for having a Nash equilibrium for both allocation mechanisms are different. The question which arises now is if the conditions given for one mechanism are stronger than the ones of the other meaning that if we have given one Nash equilibrium of one mechanism we would obtain automatically an equilibrium of the second allocation mechanism and thus allowing us to compare these mechanisms one to another. Fortunately we have the following result:

**Corollary 10.** Assume a unique Nash equilibrium \( w^{NE} \) for the Sanghavi-Hajek mechanism. Then \( w^{NE} \) is also a feasible equilibrium for Proportional Share.

**Proof.** See Appendix.

With this we may now compare the performance ratio of the two given allocation mechanisms assuming we have the conditions fulfilled for a unique Nash equilibrium for Sanghavi-Hajek. Since
the proof is a simple computation and straightforward it is omitted. We just state the final result of our paper:

**Corollary 11.** Assume a unique Nash equilibrium $w^{NE}$ for the Sanghavi-Hajek mechanism. Then the performance ratio for the Proportional Share mechanism exceeds the ratio of the Sanghavi-Hajek mechanism for all feasible realizations of $v_1$ and $v_2$.

This outcome is very surprising indeed as it is in opposition to the result obtained by Stößer et al. (2008) for two users and will be discussed in the following section.

**Corollary 12.** Assume a unique Nash equilibrium $w^{NE}$ for the Sanghavi-Hajek mechanism. Then the revenue for the Proportional Share mechanism is exceeded by the revenue of the Sanghavi-Hajek mechanism for all feasible realizations of $v_1$ and $v_2$.

This result coincides with the work for 2-players done by Stößer et al (2008).

## 5 DISCUSSION

Our goal is to compare market mechanisms which can be integrated into existing Grid schedulers to achieve efficient resource allocations and dynamic prices. As pointed out earlier, there are three possible techniques to do such a comparison: game-theoretic analysis, numerical experiments, and laboratory experiments. In this paper, we report the results of our game-theoretic approach.

Earlier work on Proportional Share and the discriminatory pay-as-bid mechanism for the two user case has shown that the Sanghavi and Hajek mechanism is superior to Proportional Share with respect to overall efficiency and, given sufficiently close valuations of the two users, also as regards provider’s revenue (Stößer et al. 2008). The aim of our analysis in this paper was to generalize these results for more than two users. To this end, we need to model the user behavior, i.e. how the users bid based on their true valuations. We chose to ground our analysis on the assumptions of quasi-linear utility functions and the prominent solution concept of Nash equilibria. We were able to derive conditions on the existence of such equilibria for both the Proportional Share and the Sanghavi and Hajek mechanism. However, the interpretation of these equilibria for the Sanghavi and Hajek mechanism gives rise to four issues:

- The two low-bidding users are pushed to zero utility while the high-bidding user only achieves a slightly positive utility, meaning that the provider reaps almost all the welfare generated by the mechanism. This corresponds to the results of Stößer et al. (2008) for the two user case. Consequently, the users are indifferent to not participating in the mechanism. One possibly remedy could be that the provider gives a small kickback to the low-bidding users to encourage them to participate. It can be an interesting question for future research to investigate how this impacts the users’ strategic considerations.

- The user with the lowest valuation ends up being the highest bidder. We explain this somewhat paradoxical result by the fact that in order to achieve a (unique or feasible) Nash equilibrium we had to set up some (rigorous) restrictions on the valuations of the users. Obviously this cannot be done in real-world scenarios and though this procedure is legitimate from a mathematical point of view, it may result in odd economic interpretations.

- The unique Nash equilibrium comprises some interesting cross-dependencies between the given bids. Assume two users bid according to their equilibrium strategy. If one of the low-value users deviates from his bid, this will not affect his own utility, but instead result in a decrease of the other users’ utilities.

- Interestingly, as shown in Corollary 11, the analytic results for the performance ratio reverse if we move from a scenario with two users to a scenario with three users. While with two users the Sanghavi-Hajek mechanism always generates higher efficiency than Proportional Share, with three users Proportional Share dominates the Sanghavi-Hajek mechanism.
In summary, our analysis showed that complexity increases tremendously already when adding only one more user. We need to introduce strong restrictions on the users’ valuations in order to obtain feasible Nash equilibria, let alone unique equilibria. While the analytic approach is attractive due to its elegance, this strikingly shows the limitations of the analytic approach, as these equilibria are unlikely to occur in real-world scenarios.

This is exacerbated by the fact that we assume a scenario with complete information. In practice, users will at most have a rough estimate about the valuations of other users. Including such Bayesian solution concepts into our model would surely drive complexity beyond analytic feasibility.

In conclusion, we need to rely on numerical simulations and/or laboratory experiments when trying to analyze these mechanisms in more complex and realistic settings.

6 CONCLUSION & FUTURE WORK

In this article, we have approached the concept of scheduling in Grid systems from an economic viewpoint. Due to the strategic nature which is inherent to these systems, market-based schedulers are deemed promising to increase the efficiency of such systems, while at the same time providing incentives to contribute resources to the Grid. So-called pay-as-bid mechanisms score with their ease-of-use. Furthermore, they impose only a very low communicational and computational burden on the scheduling process and consequently allows for real-time allocations.

In this paper, we analyzed the Proportional Share mechanism and the discriminatory pay-as-bid mechanism by Sanghavi and Hajek (2004), two prominent proxies of such pay-as-bid mechanisms, thus extending previous work by Sanghavi and Hajek (2004) and Stößler et al. (2008). In order to study the performance of these mechanisms, e.g. as regards efficiency and provider’s revenue, we modeled the strategic behavior of rational users using the prominent solution concept of Nash equilibria. The result of this paper is twofold. We show that for three users, Nash equilibria can only be obtained under strong assumptions. Moreover, in case we have a Nash equilibrium which holds for both mechanisms, Proportional Share achieves higher efficiency than the Sanghavi-Hajek mechanism, thus reversing the results for two users.

This shows the limitations of the analytic approach in more complex and realistic settings, and strengthens the case for alternative techniques. In the future, we will analyze the mechanisms by means of numerical experiments. This will allow us to model agents with learning capabilities. It will also be interesting to compare these simple pay-as-bid mechanisms to combinatorial approaches to Grid resource allocation, which have been proposed by several authors (cf. Neumann et al. 2008 for an overview). Moreover, our analysis is set within a real-world scenario, the Biz2Grid project which we introduced earlier. We thus plan a prototypical implementation of a market-based scheduler, which will serve as proof of our concept.

References

7 APPENDIX

Proof of Proposition 6. Applying the conditions given in Proposition 3 leads us to the following system of equations, where for the sake of simplicity we write $w_i$ instead of $w_i^{NE}$ for the components of the strategic chosen Nash equilibrium payment vector:

$$w_1 = \sqrt{v_1 (w_2 + w_3)} - (w_2 + w_3), \quad w_2 = \sqrt{v_2 (w_1 + w_3)} - (w_1 + w_3) \quad \text{and}$$

$$w_3 = \sqrt{v_3 (w_1 + w_2)} - (w_1 + w_2).$$

Solving this system leads us to a unique value of $w_3$ and two possible options of $w_1$ and $w_2$:

$$w_3 = \frac{2v_1 v_2 v_3 (v_1 v_3 + v_2 v_3 - v_1 v_2)}{(v_1 v_2 + v_1 v_3 + v_2 v_3)^2}, \quad w_{2\pm} = \frac{v_2 (v_1 v_2 + \sqrt{v_1 v_2 (v_1 v_2 + 4w_3 (v_1 + v_2))}) - 2v_1 w_3 (v_1 + v_2)}{2 (v_1 + v_2)^2} \quad \text{and}$$

$$w_{1\pm} = \sqrt{v_1 (w_{2\pm} + w_3)} - (w_{2\pm} + w_3).$$

Clearly we have multiple Nash equilibria. In order to achieve a unique equilibrium we have to imply one condition on the valuation of user 3, i.e. $v_1 v_2 (v_1 v_2 + 4w_3 (v_1 + v_2)) = 0$ yields the condition $v_3 = \frac{1}{3} v_1 v_2$. Furthermore, we need to check whether or not all payments $w_i$ made by the users are non-negative, which is not given by the above equations. A simple computation shows us, that $w_3 \geq 0$ is equivalent to $v_3 \geq \frac{v_1 v_2}{v_1 + v_2}$, $w_2 \geq 0$ is equivalent to $v_2 \geq \sqrt{v_1} w_3$ and $w_1 \geq 0$ is equivalent to $v_1 \geq w_2 + w_3$. Of course all of these conditions may be expressed by the valuations $v_i$, $i = 1, ..., 3$, but results in much more complex inequations. This leads us directly to the conclusion that there is no unique Nash equilibrium for three users, since the realization of $v_3 = \frac{1}{3} v_1 v_2$ yields to the negative bid $w_3 < 0$, which is not feasible. Finally, it is straightforward, that for any positive value of $w_3$ we obtain $w_{2\pm} \leq 0$, hence we may discard the second solution and focus on $w_{14}$ and $w_{2+}$ though we may not speak of a unique equilibrium but rather of a feasible equilibrium.
Proof of Proposition 8. In order to be able to apply the mechanism, we have to determine the user who submitted the highest bid. Without loss of generalization we may assume an ascending order for the payment vector, thus being $w_3 = w_{\text{max}}$ the highest bid. Similar to the discussion of the Proportional Share allocation mechanism we have the following equation system

$$w_1 = \frac{3w_3(v_2 - 2w_3)}{v_2}, \quad w_2 = \frac{3w_3(v_1 - 2w_3)}{v_1}$$

and

$$v_3 = \frac{3w_3}{3w_3(w_1 + w_2) - 4w_1w_2},$$

which leads to two possible solutions of $w_3$:

$$w_3\pm = \frac{1}{48v_3}(9v_3(v_1 + v_2) - v_1v_2 \pm \sqrt{81v_3^2(v_1^2 + v_2^2 - \frac{9}{14}v_1v_2) - 18v_1v_2v_3(v_1 + v_2) + v_1^2v_2^2}).$$

It is obvious that in order to obtain a unique Nash equilibrium, the sum contained in the root has to be zero, hence we need to demand a further condition on one of the valuations. Choosing that valuation to be $v_3$, it has to be that

$$81v_3^2(v_1^2 + v_2^2 - \frac{9}{14}v_1v_2) - 18v_1v_2v_3(v_1 + v_2) + v_1^2v_2^2 = 0$$

is valid for all valuations $v_1$ and $v_2$ resulting in a direct dependency of $v_3$ from the other two valuations. We receive two possible solutions for $v_{3\pm} = \frac{1}{3}v_1v_2(3(v_1 + v_2) \pm 4\sqrt{2v_1v_2^2})$ and therefore forcing $v_3$ to be on a cone-like structure.

As it is seen, the second solution gives us, even for very high valuations of the remaining two users, a relatively low value of the third valuation, though we assumed the third user to be the highest bidder. Since this scenario appears to be an extremely unlikely case, we may discard the second solution and focus on the first. Therefore we have a unique solution for $v_3$ and thus for $w_3$, both depending only on the valuations of the first two, lower-bidding users. The question is, if that is the one and only restriction even though it is a very tough condition and may rarely be achieved in real-world applications. Unfortunately the answer is that we need even more restrictions, this time on the realizations of the valuations of the lower-bidding users to ensure $0 \leq w_i \leq w_{\text{max}}$ for $i = 1, 2$, since otherwise we would have a contradiction to our primary assumptions. A simple computation shows us that the first inequality holds, if $2v_1 \geq v_2$ and $2v_2 \geq v_1$, while the second inequality holds if $\frac{8}{9}v_1 \leq v_2 \leq \frac{9}{8}v_1$. Since we need both inequalities to hold and the second condition already implies the first one, we may focus thereon, which leaves only a narrow margin for the possible choices of $v_1$ and $v_2$. At this point we have to remark, that for any given valuations of the lower-bidding users, $v_3$ will take on a value which is less than any of this valuations, though we already have chosen the highest possible value according to our calculations. The maximum for $v_3$ will be reached exactly if $v_2 = \frac{9}{8}v_1$ or vice versa, since the lower-bidding users are symmetric, i.e. it does not matter who bids or valuates the good more than the other one, as long as they do not bid higher than the third user.

Using the results above, we may compute a solution under the given conditions on the valuations $v_i$, $i = 1, ..., 3$. Since the components of the resulting payment vector $w$ are relatively complex, we just state here the final result of the utility functions: For any given valuations $v_i$, $i = 1, 2$, of the lower-bidding users their utility functions equal zero, i.e. $u_i = 0$ for $i = 1, 2$ while the utility of the higher-bidding user is besides being relatively low, non-negative for $\frac{8}{9}v_1 \leq v_2 \leq \frac{9}{8}v_1$.

Finally, omitting the restriction of a unique Nash equilibrium we may analyze the case of two equilibria. As is seen in Figure 1 a unique equilibrium is achieved for $v_3$ being on the cone-like structure. For $v_3$ not holding that requirement we can distinguish between two cases: First, $v_3$ being inside the structure and second, $v_3$ taking a value outside the cone. For the first case, it is easily seen, that we have no Nash equilibrium at all, because we have to deal with a square root of a non-positive
value. In the second case, we may discard the possibility of \( v_3 \) taking a value below the structure because we assumed the third user to be the highest bidder and thus this choice seems odd. So we proceed with the following condition

\[
\frac{1}{3} v_1 v_2 (3(v_1 + v_2) + 4\sqrt{2}\sqrt{v_1 v_2})
\]

\[
\geq \frac{9}{9v_1^2 + v_2^2} - 14v_1 v_2
\]

which gives rise to two Nash equilibria depending on the choice of \( w_{3\pm} \). To ensure a feasible solution, i.e. \( 0 \leq w_i \leq w_{max} \) for \( i = 1, 2 \), a subsequent analysis shows that it has to hold that \( 2w_{3\pm} \leq w_i \leq 3w_{3\pm} \) for \( i = 1, 2 \) resulting in a zero utility for these users as well. At this point we may remark, that \( w_{3\pm} \) is ascending and limited for all choices of \( v_3 \) and converges so that we have

\[
\lim_{v_3 \to \infty} w_{3\pm} = \frac{3(v_1 + v_2) \pm \sqrt{9(v_1^2 + v_2^2) - 14v_1 v_2}}{16}.
\]

We see, that the above condition on the valuations of the lower-bidding users is based upon the value of \( w_{3\pm} \). Therefore, instead of being able to check the conditions just on the given valuations of the three users, we have to compute \( w_{3\pm} \) first, followed by a decision, which solution of \( w_3 \) to use. Having in mind the conditions on \( v_i \), \( i = 1, 2 \), gives rise to the consideration choosing strategically \( w_{3+} \) and discard \( w_{3-} \) though one cannot eliminate the possibility of a feasible equilibrium with the last realization.

*Proof of Corollary 10.* We just have to show that the conditions on the valuations of the users which are being implied by the unique Nash equilibrium satisfy also the conditions necessary for a feasible equilibrium for the Proportional Share mechanism. This is straightforward. We may fix without loss of generalization the valuation of the first user \( v_1 \). Then \( v_2 \) has to satisfy \( \frac{8}{9} v_1 \leq v_2 \leq \frac{9}{8} v_1 \). A simple analysis shows us that \( v_3 \), depending on the other valuations, is ascending and thus we choose the lowest possible value for \( v_3 \) with \( v_2 = \frac{8}{9} v_1 \). This yields \( v_3 = v_2 \) and thus the first condition \( v_3 \geq \frac{v_1 v_2}{v_1 + v_2} \) for Proportional Share holds. To check the second condition \( v_2 \geq \sqrt{v_1 w_3} \) we confirm that \( w_3 \) is ascending as well and with \( v_1 \) fixed and the above choice of \( v_2 = \frac{9}{8} v_1 \) this results in \( w_3 = \frac{3}{8} v_1 \) and the second condition holds as well. Since \( w_2 \) depending on \( w_3 \) is also ascending we continue with the above choice of \( w_3 \) and have \( w_2 = \frac{9}{32} v_1 \) which makes the third condition hold for all possible realizations of the valuations of the users implied by the conditions of the unique Nash equilibrium by the Sanghavi-Hajek mechanism thus concluding our proof.

Abstract

After exchanges and alternative trading venues have introduced electronic execution mechanisms worldwide, the focus of the securities trading industry shifted to the use of fully electronic trading engines by banks, brokers and their institutional customers. These Algorithmic Trading engines enable order submissions without human intervention based on quantitative models applying historical and real-time market data. Although there is a widespread discussion on the pros and cons of Algorithmic Trading and on its impact on market volatility and market quality, little is known on how algorithms actually place their orders in the market and whether and in which respect this differs from other order submissions. Based on a dataset that – for the first time – includes a specific flag to enable the identification of orders submitted by Algorithmic Trading engines, the paper investigates the extent of Algorithmic Trading activity and specifically their order placement strategies in comparison to human traders in the Xetra trading system. It is shown that Algorithmic Trading has become a relevant part of overall market activity and that Algorithmic Trading engines fundamentally differ from human traders in their order submission, modification and deletion behavior as they exploit real-time market data and latest market movements.

Keywords: Electronic Markets, Algorithmic Trading, Order Submission, Securities Trading.
1 INTRODUCTION

IT has triggered a significant transformation in securities trading: The electronification of market venues in Europe, i.e. exchange trading systems like Xetra (Deutsche Börse), SETS (London Stock Exchange) or NSC (Euronext Paris) took place in the late 1990s and enabled market participants (banks, brokers as well as their institutional and retail customers) to access electronic order books via remote access without the need for physical presence on an exchange floor. Now, a second electronic revolution in securities trading is taking place (Preuss 2007): market participants along the value chain started an arms race by automating their trading processes, specifically by applying Algorithmic Trading. Definitions of Algorithmic Trading conceptualize it as the general “use of computer algorithms to manage the trading process” (Hendershott et al. 2008, p.1) or as the “computerized execution of financial instruments following pre-specified rules and guidelines” (Kissell & Malamut 2006, p.12). Gomber & Gsell (2006, p.541) define it as a technology that “emulates a broker’s core competence of slicing a big order into a multiplicity of smaller orders and of timing these orders to minimize market impact via electronic means”. These algorithms determine ex ante or continuously the optimum volume of the (next) order slice and its time of submission to the market based on mathematical models and considering historical and real-time market data.

For Algorithmic Trading engines, speed of execution, availability of real-time market data and minimum latency have become key success factors as already milliseconds can make a difference. As the speed of data communication is limited by the speed of light, the best option for minimizing latency is to get physically closer to the market. Market operators therefore offer co-location services where market participants can place their trading servers adjacent to the technical infrastructure of the market itself and thus ensure low latency (a latency measurement methodology has been proposed by Budimir & Schweickert (2007)). The downside of this development for market operators is that they have to cope with increasing demands for speed and growing amounts of data and message traffic, i.e. higher investments to upgrade their infrastructure especially for peak loads. The load on market operators’ systems is steadily increasing as “Algorithmic Trading is the fastest growing source of order flow” (Preuss 2007, p.154). However, there is only little academic work on how Algorithmic Trading engines schedule their trading strategies and adapt their behavior to current market movements and whether or to which extent it is different to the trading behavior of (human) traders.

Based on a unique dataset that encompasses all order book activity in the 30 most liquid shares traded on Xetra, the electronic trading system of the Frankfurt Stock Exchange, this research aims at demonstrating the manifest differences in the order submission and deletion behavior of Algorithmic Trading engines versus other order flow submitters. This is facilitated as the dataset enables to distinguish between orders submitted by Algorithmic Trading systems and orders submitted by humans. In particular, differences in the order submission strategies and order aggressiveness as well as concerning update/deletion strategies are disclosed. In the following section 2, related work on Algorithmic Trading is discussed. Section 3 provides a brief overview of the application domain, describes the available dataset as well as the applied methodology. Section 4 presents the results obtained while the final section concludes and gives an outlook on future research in this field.

2 RELATED WORK

Algorithmic Trading systems typically aim at achieving or beating a specified benchmark with their executions and may be distinguished by their underlying benchmark, their aggressiveness or trading style as well as their adaptation behavior (Kissell & Malamut 2006). The volume-weighted average price (VWAP), which is calculated as the ratio of the value traded and the volume traded within a specified time horizon, commonly serves as a benchmark for (automated) trading (Domowitz & Yegerman 2005). The universe of possible strategies has been narrowed down to the efficient frontier of optimal trading strategies (Almgren & Chriss 2000, Almgren & Lorenz 2007). There is evidence
that strategies that are adaptive to market developments, i.e. that can vary their aggressiveness, are superior to static strategies (Almgren & Chriss 2000). Furthermore, Algorithmic Trading systems must avoid to be detected as this leaked information could be exploited by other market participants (Brunnermeier & Pedersen 2005). Research on aggressiveness of orders in general is given by Ranaldo (2004) who investigated how (human) traders adapt their behavior to changes in the order book. Empirical research found the execution quality of algorithms to be inferior to executions handled by a broker. Nevertheless, this underperformance can be overcompensated by the fact that algorithms are offered at lower fees than human order handling (Domowitz & Yegerman 2005), as no (expensive) human traders are involved. Due to the increased cost consciousness among market participants, algorithms have become an attractive alternative.

Little research is available that deals with the behavior of Algorithmic Trading systems and their impact on the market itself. Hendershot et al. (2008) showed that Algorithmic Trading has a positive impact on liquidity, while Gsell (2008) found evidence that it has potential to lower market volatility. Datasets similar to the one used for the research at hand have been analyzed by Prix et al. (2007) and (2008). The former analyzes the lifetime distribution of cancelled orders and finds systematic patterns, while the latter investigates cancellation and re-insertion structures in the Xetra order flow. The main distinction to those datasets and the novelty of the dataset used for this research is the information whether an order event was submitted by an Algorithmic Trading system or a human trader.

3 APPLICATION DOMAIN AND METHODOLOGY

3.1 Xetra – The electronic trading system of Deutsche Börse AG

The Frankfurt Stock Exchange, operated by Deutsche Börse AG, has launched the fully-electronic exchange trading system Xetra in 1997. It offers a range of market models that address different asset classes as well as securities with differing liquidity. For high-liquid shares Xetra offers the market model continuous trading. Continuous trading starts after an opening call auction and can be interrupted by one or several intraday call auctions. The trading day ends with a closing call auction.

For securities in the DAX index that constitutes the dataset of this research the timing is as follows: At 08:50 the call phase of the opening auction starts. In the call phase, the order book is partially open, as only the indicative auction price and volume (the volume and price at which would be executed if the call phase would end instantaneously) or best bid and offer and their volumes are disseminated. Instantly after the end of the call phase, the auction price is determined according to the principle of most executable volume (Schwartz & Francioni 2004). All auction call phases feature a predefined length plus a random end of at most 30 seconds. This means, that for all DAX securities the price of the opening auction is determined between 09:00:00 and 09:00:30. After the opening auction, continuous trading starts and for each order immediately upon entry it is checked whether the new order is executable against orders on the other side of the order book. If no execution is possible or the order was not completely executed, the order is stored in the order book according to price-time priority. During continuous trading the order book is open, i.e. the limits, the accumulated volume per limit and the number of orders per limit are displayed. An intraday call auction interrupts continuous trading at 13:00. After the auction, continuous trading resumes until it is ended by the closing auction which starts at 17:30. To ensure price continuity, continuous trading may be contingently interrupted by volatility interruptions. In case the next potential price lies outside pre-defined price ranges, a volatility interruption stops continuous trading for an additional unscheduled call auction.

To submit their trading intentions, market participants use market or limit orders. Market orders are unlimited buy or sell orders, which are to be executed at the next price determined. Limit orders are buy or sell orders, which are to be executed at their specified limit or better. The buy limit order with the highest limit and the sell limit order with the lowest limit in the order book define the spread of the market. A buy (sell) limit order that is immediately executable due to a limit equal to or higher (lower) than the current best offer (bid) is also called “marketable limit order” as its result equals the result of
a market order, i.e. immediate execution. Therefore, market orders and limit orders that trigger immediate executions are called aggressive (or submitted by an aggressor), whilst limit orders that are not immediately executable and that are positioned in the order book are called non-aggressive (or submitted by a non-aggressor). An iceberg order is a hidden order type specified by a limit, an overall volume and a peak volume. The peak is the visible part of an iceberg and is introduced into the order book according to price-time priority. In continuous trading, as soon as the peak has been completely executed and hidden volume is still available, a new peak is entered into the book. For further information on order types and the market model for equity trading see Deutsche Börse AG (2008a).

3.2 The available dataset

The blue-chip index DAX comprises the 30 largest and most actively traded companies that are listed at the Frankfurt Stock Exchange. For these securities in 2007, 98% of the order book turnover on German exchanges was executed on the Xetra trading system (Deutsche Börse AG 2007). The dataset provided by Deutsche Börse AG encompasses all Xetra order book events for the DAX securities within the week from October 8th to 12th, 2007, comprising of 9,036,638 events in total and 593,857 trades with an overall value of € 33,019,307,823.5 6 in continuous trading and call auctions. For each single order book event a code is given that specifies the type of event that occurred. 46.6% of the events are order insertions, 0.9% are modifications, 34.6% are deletions. The number of modifications is rather low because in the Xetra trading system only a reduction of the order’s volume leads to a modification event retaining the time-stamp, as it does not affect price-time priority. All other changes to order parameters are mapped to a deletion event and a subsequent submission event of a ‘new’ (the modified) order applying a new timestamp. 11% of the events are full executions and 5.9% represent partial executions. The remaining 1% consist of other primarily technical events that are not relevant for the analysis. Each event is assigned a timestamp, identifiers for the affected securities and orders, characteristics of the order and event-specific fields, e.g. a price for an execution. The given timestamps have a precision of 1/100 second.

What makes the available dataset unique is an additional flag in the data that indicates whether the submitter of the order event has been an algorithm. As an order can only be modified by the submitter, all events corresponding to the same order will have the same flag, i.e. an order is either an Algorithmic Trading order or not. Deutsche Börse AG offers a special pricing model, the so-called Automated Trading Program (ATP), which charges a lower fee for automated trading. The exchange defines ATP transactions as “all transactions that have been generated by an electronic system of either the ATP member or the ATP member’s clients, whereby the electronic system has to determine two out of the three following order parameters: price (order type and/or order limit where applicable), timing (time of order entry) and quantity (quantity of the order in number of securities)” (Deutsche Börse AG 2008b, p.1). In this program, depending on the accumulated monthly ATP volume per ATP member, a marginal rebate of up to 60% of trading fees applies. To qualify for fee rebates offered by ATP, a member’s trading process has to fulfill some prerequisites. The thereby generated orders have to be channeled directly into the Xetra system without further manual intervention. To enable the application of lower trading fees the ATP orders furthermore must be submitted using a designated ATP Trader-ID. All order events that were submitted using such an ATP Trader-ID are tagged in the available data set. As the tag is anonymous it just gives the information whether this order event is an ATP event or not. It is not possible to pin down behavior to a specific ATP Trader-ID or to directly determine whether two different orders have been submitted by the same market participant or not. The requirements set by Deutsche Börse to qualify for ATP shall ensure that the users are machines, i.e. Algorithmic Traders. However, it cannot be ensured that vice versa all machines make actually use of the ATP fee rebate, i.e. an event not flagged as an ATP event (in the following: Non-ATP) may still have been submitted by an algorithm. Though, given that the fee rebates of ATP constitute a strong truth-telling incentive for market participants, one can assume the accuracy of the ATP flag to be high.
3.3 Methodology

Based on the succession of order events in the dataset, the state of each instrument’s order book has been reconstructed event-by-event for each single point of time in the observation period according to the matching rules effective on Xetra. The executions determined based on this order book reconstruction have been validated against the actual executions reported in the dataset to ensure the reconstruction’s accuracy. The reconstruction enables to investigate order events relative to the current order book situation, i.e. in continuous trading submissions or deletions of orders may be assessed in the context of the best bid and offer limits (the spread) prevailing at the time of the event.

Chi-square tests are applied to test whether the obtained results are stochastically dependent on the ATP and Non-ATP classification, i.e. whether there are significant differences in the unveiled behaviour.

4 RESULTS – STRATEGIES OF ALGORITHMIC TRADING ENGINES VERSUS HUMAN TRADERS

The analysis targets at comparing the trading strategies of Algorithmic Trading engines and human traders in several dimensions and to answer the following research questions in this context:

1. What is the overall extent of Algorithmic Trading activity relative to human traders’ activity?

2. Does Algorithmic Trading activity, i.e. do actual orders submitted by Algorithmic Trading engines, reflect their technical ability to monitor and exploit real-time market movements and market information when algorithms execute orders aggressively?

3. Does Algorithmic Trading activity, i.e. do actual orders submitted by Algorithmic Trading engines, reflect their technical ability to monitor and exploit real-time market movements and market information when algorithms position non-aggressive orders in the order book?

The focus for the analysis of the research questions is laid on the continuous trading phases as auctions with their call phases of up to ten minutes without any executions exhibit a different trading behavior. The volumes executed in auctions would distort the time-series analysis as they concentrate large execution volumes at a single point of time. Within the dataset 13.4% of overall executed shares (volume) are executed in call auctions, representing 14.0% of the total traded value (in €). These figures include call auctions triggered by volatility interruptions. Within the observation period, five volatility interruptions occurred in different securities executing a total of 46,068 shares representing less than 0.01% of the overall value traded. The analysis of Algorithmic Trading behavior in auctions will be subject to future research. Therefore, the results presented here refer to continuous trading that represents 97% of the overall trading time.

Research question 1: What is the overall extent of Algorithmic Trading activity relative to human traders’ activity?

The activity of ATP traders can be analyzed from two perspectives. On the one hand there is the sheer amount of events (traffic on the electronic trading system) that can be analyzed comparing ATP and Non-ATP events. On the other hand, the focus may be laid on the actual executions by algorithms, i.e. the trading activity, rather than on the mere technical events. Table 1 summarizes the events (see the first two columns for ATP and Non-ATP) and actual executions (see columns 3 to 6 for ATP and Non-ATP) occurring during continuous trading per security. It shows that Algorithmic Trading constitutes a relevant part of overall system traffic and also of actual trading activity. In the observation period, the overall share of ATP events is 52.3% and for only five out of the 30 securities the share of ATP events is below 50%. Fresenius Medical Care with 69.0% has the highest rate of ATP events while Volkswagen has the lowest rate (35.8%). Concerning the actual execution events, i.e. partial or complete executions, ATP has a share of 54.7% whereby Linde has the highest rate of ATP execution events with 65.0% while Deutsche Telekom has the lowest with 42.9%.

The value associated with ATP trading is 43.0% on average for all securities. As execution events are considered in Table 1, the traded value is double-counted; once for the buyer and once for the seller. 52.7% of the orders entered during continuous trading are ATP orders. ATP and Non-ATP submission exhibit a similar share of aggressive orders (ATP: 14.6%; Non-ATP: 11.2%) (order data not shown additionally in Table 1 to assure readability).

In the following a deeper analysis distinguishing aggressor and non-aggressor orders is performed: If aggressive executions are considered (Table 2), in total 56% of all executions are triggered by an ATP order as the aggressor. Linde has the highest share of ATP aggressor executions as for 68.4% an ATP trader was the aggressor. Further E.ON catches attention, as about two out of three executions were triggered by ATP orders, which sum up to 63.6% of the total value traded. For Deutsche Post only 30.5% of the executed value has been triggered by aggressive ATP orders. Please note that for the execution perspective of aggressors, the traded value is only single-counted.

Table 2. Number of executions and executed value for ATP- and Non-ATP aggressors in continuous trading

Table 2 further discloses that though across all securities 56.0% of all executions are triggered by aggressive ATP orders, they represent only 46.2% of the totally traded value. The average value per
executed order for ATP aggressor executions is 39,444 € and the average value per executed order for Non-ATP aggressor executions is 58,512 €. There are two possible explanations:

1) **ATP users have more partial executions**

A possible explanation for the fact that more executions result in less executed volume would be that aggressive Algorithmic Trading orders have more partial executions boosting their total number of executions. If the algorithms submit orders that hit orders at several price levels, this would result in several executions and the value per execution would be lowered. However, this argument does not hold true. This can be checked by measuring the number of different timestamps for the respective executions as multiple executions at the same timestamp represent partial executions. As there are 332,437 ATP aggressor executions at only 278,374 different timestamps, 19.4% of the aggressor orders seem to cause executions at several price levels. But for the Non-ATP aggressors there are 260,965 executions at 209,919 distinct timestamps indicating that 24.3% of Non-ATP aggressor orders cause more than one execution.

2) **Algorithms submit more but smaller orders**

Assuming that the algorithms can monitor changes in the order book and react in real-time and given that they still get what they saw when their order is arriving at the market, algorithms look for advantageous limits in the order book and snap at the chance and execute the best bid or offer. As the top of the book most often is thin – as the most volume is just behind the best bid and offer – this results in more but smaller executions. Furthermore the smaller executions lead to less market impact than larger executions that would potentially hit more than one price level.

For non-aggressor orders, Table 3 presents evidence that ATP non-aggressor orders (i.e. limit orders that are not immediately executable) are also smaller than their Non-ATP counterparts as it depicts the average order volumes and average order values (order volume times order limit). The surplus of Non-ATP orders’ average value over ATP orders’ average value is 143.5% for all securities. The values for the individual instruments range from 40.6% (Linde) to 455.7% (Volkswagen). Please note that iceberg orders and their peaks have not been considered for the calculation of the averages.

</table>
Concerning research question 1, the data reveals that Algorithmic Trading is a relevant part of technical events, actual executions as well as order submissions. Algorithms tend to use smaller order volumes both for aggressive as well as for non-aggressive orders than (human) Non-ATP counterparts.

Research question 2: Does Algorithmic Trading activity, i.e. do actual orders submitted by Algorithmic Trading engines, reflect their technical ability to monitor and exploit real-time market movements and market information when algorithms execute orders aggressively?

Research question 2 relates to the (aggressive) execution behavior of algorithms and is addressed in two dimensions: 2a) concerning the usage of order types by algorithms versus human traders and 2b) concerning the submitted limits in case of aggressive limit orders by algorithms versus human traders.

2a) If ATP traders would be more aggressive one might assume that they will utilize market orders to a larger extent than Non-ATP traders. As Table 4 points out, this is not the case, as although there is a similar number of ATP and Non-ATP orders involved in continuous trading, only 6.2% of the market orders have been submitted by ATP users. A straightforward chi-square test shows that the null-hypothesis of equal likelihood for ATP and Non-ATP participants to either utilize limited orders (limit and iceberg orders) or market orders can be rejected at a p-value of 0.01, which reveals a highly significant difference. The vast majority of ATP submitted orders are limit orders, as an aggressive strategy can be implemented with limit orders and a smart setting of the limits as well. Such a strategy is eased by speed and low latency to monitor market movements in real-time and to react with minimum delay – a prerequisite that can be matched by machines.

2b) In the following the focus is laid on how algorithms set order limits in relation to the prevailing order book situation when implementing an aggressive strategy. Although ATP and Non-ATP exhibit a similar share of aggressive orders (ATP: 14.6%, Non-ATP: 11.2%; see research question 1), the applied limits relative to current best bids and offers differ clearly (Table 5). 67.8% of all order submissions that exactly match the best bid or offer are ATP orders. Nearly two thirds of the other aggressive submissions are Non-ATP orders. For ATP orders, even 85.1% of the aggressive orders are limited exactly to the best available limit in the order book. A chi-square test shows that the null-hypothesis of equal likelihood of ATP and Non-ATP orders to submit exact limit matches can be rejected at a p-value of 0.01, i.e. reveals a highly significant difference.
Further, 17.7% of aggressive ATP orders are also exactly matching the volume available at the best limit (Non-ATP: 7.9%). Out of all submissions that exactly match the opposite side’s limit and volume 76.7% are ATP orders. For high-liquid securities, such as Siemens or E.ON, this proportion is even higher (92.1% respectively 91.9%). Referring to research question 2, these results indicate that ATP orders’ limits and volumes are based on a real-time monitoring of the market and are set based on latest market movements.

Research question 3: Does Algorithmic Trading activity, i.e. do actual orders submitted by Algorithmic Trading engines, reflect their technical ability to monitor and exploit real-time market movements and market information when algorithms position non-aggressive orders in the order book?

Research question 3 relates to the (non-aggressive) submission behavior and can be addressed in two dimensions: 3a) concerning the positioning of non-aggressive orders by algorithms versus human traders relative to the current best bids or best offers and 3b) concerning the adaptation of limits by algorithms versus human traders in case of changing best bids or best offers.

3a) Table 6 points out the different positioning of non-aggressive ATP and Non-ATP orders. Of the non-aggressive orders that improve the spread, 75.9% are ATP orders, while of the orders that do not affect the spread 62.5% are Non-ATP. A chi-square test (null-hypothesis: equal likelihood of ATP and Non-ATP orders to improve the spread) can be rejected at a p-value of 0.01, i.e. again reveals a highly significant difference among ATP and Non-ATP orders. The different order positioning behavior can also be seen from the weighted-average absolute variation in cents by which orders narrow the spread. ATP orders improve the best limit on average by 1.38 cents while Non-ATP orders improve it by 1.95 cents, i.e. algorithms are able to position orders at the top of the book with a lower concession in terms of price improvement.

3b) As shown above, ATP market participants limit the majority of their non-aggressive order in a way to be at the spread by either adding volume to the existing spread limit or setting a better limit. As these orders are positioned at the top of the book, i.e. they have a high likelihood of execution, it is of interest to investigate their further lifetime. The following table 7 depicts what happens to orders that are part of the spread when their lifetime ends. The absolute figures reveal that there are by far more ATP orders that end their lifetime being at the spread. As for table 7 the distribution of the termination reasons is in the focus, the percentages are calculated in relation to all termination reasons at the spread for each ATP and Non-ATP. About two thirds of Non-ATP orders end their lifetime at the spread by getting executed, while about one third gets deleted. For ATP orders these ratios are nearly vice versa. 63.2% of the ATP orders that end their lifetime being part of the spread are deleted. Again,
a chi-square test (null-hypothesis: equal likelihood of ATP and Non-ATP orders to be terminated by execution; p-value of 0.01) reveals a highly significant difference between ATP and Non-ATP orders.

The third and sixth column (table 7) list the average time in milliseconds, that the orders were continuously part of the spread before termination. The average survival times for orders terminated by execution are similar. This meets the expectation, as for executions the survival time is determined by other (aggressive) orders and therefore can not be influenced by the order positioned at the spread. However, for deleted Non-ATP orders the survival time is nearly twice the one for deleted ATP orders. 63.2% of ATP orders are deleted on average 6.519 seconds after becoming part of the spread. At a first glance it seems as if ATP users initially submit orders at the spread and then get cold feet and delete their orders to avoid execution. But what seems to be a deletion is actually a modification, as within the Xetra market model only a reduction of order volume does not affect price-time priority while all other modifications are mapped to a deletion event and a subsequent submission event for the ‘new’ modified order. For 26.9% of the ATP orders deleted at the spread there is an ATP submission event of a new order in the same instrument at exactly the same timestamp, with the same direction (buy or sell) and exactly the same volume (Non-ATP: 23.2%). If the restrictions are relaxed (up to 1 second delay, +/-5% volume), there is a corresponding submission event for 40.2% of the ATP deletions (Non-ATP: 33.4%) out of which 115,331 again improve the spread (Non-ATP: 16,822). This indicates that ATP traders want their orders to be at the top of the book. Therefore, they emulate pegging orders at their front end (an order type where the limit tracks the best bid or offer and moves with the market) as this order type – contrary to other markets – is not provided by the Xetra back-end.

Table 7. Survival time and termination reason for orders at the spread

To sum up the data analyzed concerning research question 3, the results indicate that ATP traders are more aware of the current spread, as they more often reflect the current best bid or offer when limiting their orders, and that their orders about three times more often narrow the current spread. Furthermore, they control their orders relative to the current market situation and delete and reinsert their orders based on changes in the current spread more extensively than Non-ATP traders do.

5 CONCLUSION

The detailed implementations of Algorithmic Trading systems are not published as these constitute important intellectual property rights of investment firms and are a key component of their business models both for proprietary trading and when providing algorithms to customers (regularly as a black box). Therefore, only little is known about how Algorithmic Trading engines schedule their trading and adapt to current market movements. Based on a unique dataset from a market operator that includes a tag enabling to distinguish Algorithmic Trading engines and human traders, the order submission behavior of both groups has been compared. An implication for theory is the result that the submission and deletion behavior of Algorithmic Trading systems (statistically) significantly differs from other market participants’. Evidence has been presented that they submit orders that are noticeably smaller. Additionally they show the ability to monitor their orders and modify them to be at the top of the book. Applying chi-square tests shows that Algorithmic Trading behavior is fundamentally different to human trading concerning the use of order types, the positioning of limits in case of executions and submissions as well as their modification/deletion behavior. These results let us conclude that Algorithmic Trading systems capitalize on their advantageous ability to process high-
speed data feeds and react instantaneously to market movements by submitting corresponding orders or modifying existing ones.

Future research based on the dataset will both investigate order submission strategies in auctions and the contribution of Algorithmic Trading engines to overall market liquidity. This contributes not only to the understanding of the algorithmic implementations but also has theoretical implications for market design and market surveillance issues. Furthermore, the understanding of algorithmic behavior has practical implications, as it enables to identify potential functional or technical bottlenecks.

COORDINATING SERVICE COMPOSITION

The fundamental paradigm shift from traditional value chains to agile service value networks implies new economic and organizational challenges. As coordination mechanisms, auctions have proven to perform quite well in situations where intangible and heterogeneous goods are traded. Nevertheless, traditional approaches in the area of multiattribute combinatorial auctions are not quite suitable to enable the trade of composite services. A flawless service execution and therefore the requester's valuation highly depends on the accurate sequence of the functional parts of the composition, meaning that in contrary to service bundles, composite services only generate value through a valid order of their components. We present an abstract model as a formalization of a service value network. The model comprehends a graph-based mechanism design to allocate multiattribute service offers within the network, to impose penalties for non-performance and to determine prices for complex services. The mechanism and the bidding language support various types of QoS attributes and their (semantic) aggregation. We analytically show that this variant is incentive compatible with respect to all dimensions of the service offer (quality and price).

Keywords: Mechanism Design, Coordination, Service Value Network, Pricing Model, Semantics.

The research was funded by means of the German Federal Ministry of Economy and Technology under the promotional reference “01MQ07012”.

1 INTRODUCTION

The paradigm shift from a product- to a service-oriented economy fosters the movement of complete industries from vertical integration to horizontal specialization. Hierarchically organized firms start to cooperate in firmly-coupled strategic networks with stable inter-organizational ties, recently exploring the benefits of moving to more loosely-coupled configurations of legally independent firms. In theory, complex products or services can be produced by a single vertically integrated company. But in this case the company is not able to focus on its core competencies, having to cover the whole spectrum of the value chain. Also, it has to burden all risks in a complex, changing and uncertain environment by itself. This is why companies tend to engage in networked value creation which allows participants to focus on their strengths. At the same time rapid innovation in the ICT sector enables promising opportunities in B2B communication which also supports the current trend. However, especially in complex and highly dynamic industries, forming value networks – especially business webs with their open structure – is more than an attractive strategic alternative. Prominent advocates of this new paradigm are (Tapscott et al., 2000, Hagel III, 1996, Zerdick et al., 2000, Steiner, 2005). As (Tapscott et al., 2000, Steiner, 2005) express it, business webs bring together mutually networked, permanently changing legally independent actors in customer centric, mostly heterarchical organizational forms in order to create (joint) value for customers. Specialized firms co-operetively contribute modules to an overall value proposition under the presence of network externalities. A prime example for such highly dynamic fields of application is the internet of services. We briefly outline the advantages of business webs related to modularization and specialization (Zerdick et al., 2000): Concentration on core competencies strengthens specialization (C1); Sharing the risk involved (C2); High level of flexibility (C3); Modularization brings potential for innovation and allows for rapid market penetration (C4); Fruitful interplay of competition and partnership (C5).

Auctions have proven to perform well under these conditions to coordinate value generation while addressing mentioned network characteristics. Nevertheless traditional approaches in the area of multiattribute combinatorial auctions are not quite suitable to enable the trade of composite services. Auctions for composite services are much more complex than simple procuring auctions, where the suppliers themselves offer a full solution to the procurer. In composite services, this is not the case, as a flawless service execution and therefore the requester's valuation highly depends on the accurate sequence of its functional parts, meaning that in contrary to service bundles, composite services only generate value through a valid order of their components.

As a coordination mechanism in networked economies we propose a multidimensional procurement auction for trading composite services. We present a graph-based model that captures the main components and characteristics of service value networks. Based on this model we introduced a mechanism design that enables allocation and pricing of service components that together form a requested complex service. The mechanism is capable of handling a wide range of aggregation operations for service attributes also supporting rich semantic approaches for dealing with complex non-functional service specifications. Due to the combinatorial restrictions imposed by the underlying graph topology and the absence of capacity constraints, the winner determination problem can be solved in polynomial time which is a crucial issue when it comes to implementing online systems. We furthermore show that the proposed mechanism is individual rational, allocation efficient and incentive compatible with respect to QoS characteristics and prices of service offers. Hence, reporting the true type regarding configuration and price is a weakly dominant strategy for all service providers.

This paper is structured as follows: The next section gives a brief overview over the literature. Section 3 illustrates the idea of on-demand service procurement in networked economies based on an integration scenario from SAP BusinessByDesign. In Section 4 we propose a multidimensional procurement auction for trading composite services based on an abstract model of a service value network. The mechanism comprehends a multiattribute bidding language (Section 4.1) and the central allocation function (Section 4.2). Section 4.3 demonstrates the semantic aggregation of service
attributes and the auction conduction by providing a numerical example. An extension regarding service level guarantees and penalties for non-performance is introduced in Section 4.4. In Section 4.5 we analytically show the providers’ bidding strategies and valuable properties of proposed mechanism design. Section 5 concludes with a summary, the practical realization of our approach and future work.

2 RELATED WORK

Recently, an enormous body of work has been done that investigates problems of coordination from a game theoretic and computer science perspective (Papadimitriou, 2001). Especially the discipline of mechanism design that focuses on the problem to coordinate self-interested participants in pursuing an overall goal (Nisan and Ronen, 2001). The authors design suitable mechanisms to standard optimization problems in the area of task scheduling and routing. In incentive compatible mechanisms agents are incentivized to choose the strategy of revealing their true type. Incentive compatible mechanisms such as the celebrated Vickrey-Clarke-Groves (VCG) mechanism are firstly introduced and extensively investigated by (Clarke, 1971, Groves, 1973, Vickrey, 1961). It is important to notice that incentive compatibility in VCG-based mechanisms may fail in repeated games (Binmore and Swierzbinski, 2000) due to the possibility to learn from past situations and adjust ones strategy in a trial-and-error process.

Most of the research has been done with respect to truth-telling of one-dimensional types. The field of designing incentive compatible mechanisms, that induce truth-telling of multidimensional properties of goods or services, still lacks deeper research. A thorough analysis and investigation in the area of multidimensional auctions and the design of optimal scoring rules has been done in (Branco, 1997, Che et al., 1993). In (Bichler and Kalagnanam, 2005) the winner determination problem in configurable multiattribute auctions is investigated from an operational research perspective without accounting for mechanism design aspects such as incentive compatibility. In (Parkes and Kalagnanam, 2002, Parkes and Kalagnanam, 2005) the authors introduce iterative multiattribute procurement auctions focusing on mechanism design issues and solving the multiattribute allocation problem. Preferences for multidimensional goods and multidimensional types in scoring auctions are extensively investigated in (Asker and Cantillon, 2008) and extended to combinatorial auctions in (Müller et al., 2008). Nevertheless their work does not consider value chains and sequences of services as well as their technically feasible interrelations in order to coordinate value generation in service networks. All of these approaches assume bundles of goods in scenarios where the sequence and order does not matter and therefore cannot be applied to composite services that only fulfil their objectives in the right sequence of execution.

Nevertheless, combinatorial auctions yield major drawbacks regarding computational feasibility that result from an NP-hard complexity. Computational feasibility implies a trade-off between optimality and valuable mechanism properties such as incentive compatibility. Several authors propose approximate solutions for incentive compatible mechanisms to overcome issues of computational complexity (Nisan and Ronen, 2007, Ronen, 2001, Ronen and Lehmann, 2005). Path auctions as a subset of combinatorial auctions reduce complexity through predefining all feasible service combinations in an underlying graph topology and are investigated in (Archer and Tardos, 2007, Feigenbaum et al., 2006, Hershberger and Suri, 2001). In their work, path auctions are utilized for pricing and routing in networks of resources such as computation or electricity. Application-related issues of auctions to optimal routing are examined by (Feldman et al., 2005, Maille and Tuffin, 2007). All of these approaches deal with the utility services layer according to the service classification in (Blau et al., 2008) and hence do not cover the problems related to complex services.
3 BUSINESS SCENARIO

To illustrate the idea of a service value network we introduce a business scenario which is actually delivered to customers as part of SAP’s BusinessByDesign\(^1\). The scenario consists of modular service components that can be provided by decentralized service providers. The integration scenario “Service Request and Order Management” (cp Figure 1) describes operational processes in a customer service based on service requests, service orders and service confirmations. From an end-to-end perspective the scenario includes the integration into related applications such as logistics planning and execution, invoicing and payment, as well as financial accounting.

![Figure 1 Business Process "Service Request and Order Management"](image)

A service value network is formed by many decentralized service providers that contribute to the achievement of an overall goal. In our scenario this goal is the flawless execution of a business scenario in order to provide defined functionality to the customer. From now on we call this overall goal a complex service. Recalling the main characteristics of service value networks there are many service providers that offer differentiated and specialized services covering various types of functionality within the network. In our scenario the functionality of each component can be modularized and therefore performed by different software-as-a-service providers as depicted in Table 1. The rapid upcoming of on-demand service providers shows the high degree of innovation and market penetration as a result of modularization (C4). Service providers offer specialized services and concentrate on their core competencies (C1). Each service provider is responsible for a certain part of the overall functionality which consequently spreads the risk of an erroneous business process over all contributing service providers (C2). Furthermore they partly grant access to their own resource supporting the realization of the overall business scenario (C5). The potential of substituting service providers on demand enables flexibility and rapid reaction on changing market requirements (C3).

\(^1\) http://www.sap.com/solutions/sme/businessbydesign/
4 ABSTRACT MODEL & MECHANISM DESIGN

A service value network is represented by an $k$-partite, directed and acyclic graph $G = (V, E)$. Each partition $v_1, \ldots, v_k$ of the graph represents a functionality cluster that entails services that provide the same functionality (substitutes). The set of $N$ nodes $V = \{v_1, \ldots, v_N\}$ represents the set of service offers with $v$ is an arbitrary service offer. Services are offered by a set of $Q$ Service Providers $S = \{s_1, \ldots, s_Q\}$ with $s$ is an arbitrary service provider. The ownership information $\sigma: S \rightarrow V$ that reveals which service provider owns which service within the network is public knowledge. There are two designated nodes $v_s$ and $v_f$ standing for source and sink in the network. The set of $M$ edges $E = \{e_1, \ldots, e_M\}$ denotes service compatibilities and interoperabilities such that $e_j$ represents interoperability of service $j$ with service $i$ and their sequence of execution. A service configuration $A_j$ of service $j$ is fully characterized by a set of attributes $A_j = \{a_j^1, \ldots, a_j^l\}$ where $a_j^l$ is an attribute value of attribute type $l$ of service $j$’s configuration. Let furthermore $c_j(e_j, A_j)$ denote a cost function that maps service $j$’s configuration to corresponding costs such that $c: E \times A \rightarrow R$. $c_j$ denotes costs that the service provider who owns service $j$ has to bear for developing a service that is interoperable with service $i$ (development and production costs) and for performing it during execution (execution costs). Configuration and costs are private knowledge to the service provider who owns a particular service (type). If two services are not interoperable at all, they are not connected within the network. Value is created through the network by performing a sequence of services that form a connected path from source to sink. We call such created value a complex service. Let $F$ denote the set of all feasible paths from source to sink. Every $f \in F$ represents a possible instantiation of the complex service. $F_i$ represents the set of all feasible paths from source to sink without node $i$ and its incoming and outgoing edges. Let $F_i$ be the set of all feasible paths from source to sink that entail node $i$. In our model we focus on the core process of realizing an overall goal without going into process-related details such as parallel or cyclic components. We apply a business and management-oriented view addressing the question of how an overall goal can be achieved maximizing the systems welfare and to dynamically determine prices.

4.1 Bidding Language

As a formalization of information objects which are exchanged during auction conduction we introduce a bidding language based on bidding languages for products with multiple attributes as discussed in (Engel et al., 2006). Our formalization is aligned to multiattribute auction theory as presented in (Parkes and Kalagnanam, 2002, Ronen and Lehmann, 2005) and assures compliance with the WS-Agreement specification in order to enable realization in decentralized environments such as the Web.

A service requester wants to purchase a complex service $f$ which is characterized by a configuration $A_f$. The importance of certain attributes and prices of a requested complex service is idiosyncratic and depends on the preferences of the requester. The requester's preferences are represented by a utility function $U$ of the form:

$$ U_f(a, \Lambda, A, \mathcal{P}) = aS(A_f) - T_f $$

$T_f$ denotes the sum of all transfer payments the requester has to transact to service providers that contribute to the complex service such that $T_f = \sum_{e\in f} t_e$. The configuration $A_f$ of the complex service is the aggregation of all attribute values of contributing services on the path $f$ such that
\( A_j = (A_j', ..., A_j') \) with \( A_j' = \oplus_{a \in A_j} a_j' \). The aggregation of attributes values depends on their type (i.e. encryption can be aggregated by an AND operator whereas response time is aggregated by a sum operator). Different methods for aggregating service attributes are presented in Section 4.3.

The scoring rule \( S(A_j) = \left( \sum_{l=1}^{L} \lambda_l A_j^l \right) \) represents the requester’s valuation for a configuration \( A_j \) of the complex service represented by path \( f \). The scoring rule is specified by a set of weights \( \Lambda = \{\lambda_1, ..., \lambda_L\} \) with \( \sum_{l=1}^{L} \lambda_l = 1 \) that defines the requester’s preferences of each attribute type analog to the definition of scoring rules in (Asker and Cantillon, 2008). To assure comparability of attribute values from different attribute types the aggregated attribute values \( A_j^l \) are mapped on an interval \([0;1]\). \( T_f \) represents the overall price of the complex service. \( \alpha \) can be interpreted as the willingness to pay for an optimal configuration \( S(A_j) = 1 \) based on the requester’s score. In other words \( \alpha \) defines the substitution rate between configuration and price based on the requester’s preferences.

Definition 1. Multiattribute Service Request

A request for a complex service is a vector of the form

\[ R := (G,F,\alpha,\Lambda,\Gamma) \]

with \( G \) represents a complex service network, \( F \) represents all feasible paths from source to sink that form a possible instantiation of a complex service, \( \Lambda \) the requester’s preferences and \( \alpha \) the willingness to pay. \( \Gamma \) denotes the set of lower and upper boundaries for each attribute type.

A service offer consists of an announced service configuration \( A_j \) and a corresponding price bid \( p_y \) that a service provider wants to charge for service \( j \) being invoked depending on the predecessor service \( i \) such that \( b_y(e_y) = (A_j, p_y) \) is a service offer bid for invocation of service \( j \) which interoperable with a predecessor service \( i \) with \( b : E \rightarrow A \times R \). A service provider \( s \) bids for all incoming edges to every service it owns.

Definition 2. Multiattribute Service Offer

A multiattribute service offer is a bid matrix of the form

\[ B' := \begin{cases} b_y(e_y) = (A_j, p_y), & i \in \tau(f), j \in \sigma(s) \\ 0, & \text{otherwise} \end{cases} \]

with \( \tau(v) \) denotes the set of all predecessor services to service \( v \) with \( \tau : V \rightarrow V \) and \( \sigma(s) \) the set of all services owned by service provider \( s \).

4.2 Mechanism Design

The mechanism maximizes welfare by allocating a path \( f^* \) within the service value network that yields the highest overall utility. Let \( \mathcal{U}_f \) denote welfare induced by path \( f \) with \( \mathcal{U}_f = \alpha S(A_j) - P_f \).

\[ o := \arg\max_{f \in F} \mathcal{U}_f \]

Let \( \mathcal{U}^* \) denote the utility of the winning path meaning the utility of a path \( f^* \) that maximizes welfare. Let \( \mathcal{U}_f^* \) denote the utility of a path \( f^*_s \) that yields a maximum overall utility in the reduced graph without every service owned by service provider \( s \) and its incoming and outgoing edges.
Every service provider $s$ receives a payment or transfer $t^i = \sum_{i \in \sigma(s), j \in \sigma^c(s)} t^i_j$ for all services it owns which are on the winning path. A payment $t^i_j$ for service $j$ corresponds to the monetary equivalent of the utility gap between the “winning path” and “second best path”. In other words a monetary equivalent to the utility service $j$ contributes to the systems welfare. This monetary equivalent represents the price that service provider $s$ could have charged without losing her participation in the winning allocation.

(5) $t^i_j := p^i_j + (U^i - U^i_s)$

Consequently the payment function $t^i$ for service provider $s$ is defined as

(6) $t^i := \sum_{i \in \sigma(s)} \sum_{j \in \sigma^c(s)} p^i_j + (U^i - U^i_s), \text{ if } e^i_j \in o
\left\{ \begin{array}{ll}
0, & \text{otherwise}
\end{array} \right.$

Costs $c^i$ that service provider $s$ has to bear for performing offered and allocated services result accordingly:

(7) $c^i := \sum_{i \in \sigma(s)} \sum_{j \in \sigma^c(s)} c^i_j(e^i_j, A^i_j), \text{ if } e^i_j \in o
\left\{ \begin{array}{ll}
0, & \text{otherwise}
\end{array} \right.$

The solution to the allocation problem in (4) can be computed in polynomial time using well-known graph algorithms to determine the "shortest" within a network such as the Dijkstra algorithm. Using a Fibonacci heap data structure the time complexity can be reduced to $O(n \log(n) + m)$ with $m$ is the number of edges and $n$ the number of nodes within the graph. According to the payment scheme in (6) the allocation must be computed twice: Based on the graph with the service offerings of the service provider receiving the payment and without its participation. In the second case the graph can be pre-processed and reduced by all service offerings owned by the service provider that receives the payment. After the reduction the shortest path can be computed accordingly which yields the same time complexity. In contrary to the NP-hard complexity in general combinatorial auctions this is a valuable achievement that enables the conduction of our auction in online systems.

4.3 Aggregation and Preference Mapping of Service Attributes

In order to determine the overall score for a provider based on its scoring function, the attribute values of the complex service have to be computed. Recall, the type of function for aggregating attribute value highly depends on the attribute type. Traditional quality of service attributes such as response time for example can be aggregated with basic mathematic operations such a sum operator. Table 2 shows different types of aggregation functions for multiple attribute types exemplarily. For example, the overall throughput of a complex service that consists of multiple service components is determined by the lowest throughput rate within the allocation and can therefore be computed using a minimum operator.

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Aggregation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$l$</td>
<td>$\oplus_{a \in f} d^l_j$</td>
</tr>
<tr>

<td>$\sum_{a \in f} a^r_{j}$</td>
</tr>
<tr>
<td>Encryption Type (et)</td>
<td>$\land_{a \in f} a^e_{j}$</td>
</tr>
<tr>
<td>Error Rate (er)</td>
<td>$\max_{a \in f} a^e_{j}$</td>
</tr>
</tbody>
</table>
Table 2. Aggregation Functions for Different Types of Attributes

Nevertheless, only considering basic quality of service attributes is not sufficient for dealing with complex non-functional service characteristics that express rich semantic information. The auction mechanism must be capable of aggregating a broad range of descriptive service attributes that express multiple quality aspects. The following example depicted in Figure 2 shows a service value network with four service offers and three possible paths from source to sink (top, middle, bottom).

Figure 2 Numerical Example

For simplicity and without loss of generality we assume that each service provider owns only a single service. Price values on the edges represent price bids announced by service providers. Each service configuration consists of attribute values for the types encryption \(a^e\) and probability of success \(a^s\). Attribute values are aggregated according to the aggregation operations in Table 2. Encryption types are derived from the concepts in the security algorithm ontology as illustrated in Figure 3.
The service requester announces its willingness to pay and weights for each attribute type representing its scoring function such that $\lambda_p = 0.2$, $\lambda_m = 0.8$ and $\alpha = 100$. Furthermore it specifies the *individual encryption* attribute type in first order logic:

$$\text{IndividualEncryption}(x) \leftarrow (\text{BlockCipher}(x) \wedge \text{hasKeyLength}(x, k) \wedge \text{isGreaterOrEqual}(k, '128')) \lor (\text{AsymmetricAlgorithm}(x) \wedge \text{hasKeyLength}(x, k) \wedge \text{isGreaterOrEqual}(k, '256'))$$

The mechanism allocates service offers on a path from source to sink based on the service request and announced multiattribute offers according to (4). The welfare level, generated by each allocation evolves as follows:

- Middle: $\mathcal{U}_{middle}^f = 100(0.2(1 \wedge 1) + 0.8(0.9 \times 0.8)) - (13 + 17) = 47.6$
- Top: $\mathcal{U}_{top}^f = 100(0.2(1 \wedge 0) + 0.8(0.9 \times 0.7)) - (13 + 16) = 21.4$
- Bottom: $\mathcal{U}_{bottom}^f = 100(0.2(0 \wedge 1) + 0.8(0.9 \times 0.8)) - (10 + 20) = 27.6$

Therefore $f_{middle}$ is allocated as it yields the highest welfare and each service provider that owns a service on it receives a payment according to (6) such that $t^1 = 13 + (47.6 - 27.6) = 33$ and $t^4 = 17 + (47.6 - 21.4) = 43.2$. The transfer is designed to compensate service providers for their contribution to the system’s welfare which implies that i.e. provider 1 could have bid a price of 33 without having lost its participation in the allocation.

### 4.4 Verification of Service-Level-Agreements

As introduced in Section 4.1 service providers’ bids contain a configuration and a price component. The allocation function maximizes welfare based on the achieved quality for the service requester and the costs that occur on the producer’s side. This shows that the announced quality also determines the likelihood of being allocated which might induce and incentive for service providers to lie about their configuration. Therefore proposed mechanism is extended with a so called ex-post verification term which is explained in detail in this section.

Let $a^j_l$ be the announced attribute value of attribute type $l$ of service $j$’s configuration. Furthermore let $\tilde{a}^j_l$ be the actual attribute value of attribute type $l$ realized ex-post by service $j$ during execution. $\tilde{U}^f$ is the overall winning path utility with the actual realized attribute values $\tilde{a}^j_1, ..., \tilde{a}^j_l$ of service $j$.

Auctioning services based on a platform approach opens up the possibility of ex-post verification. This means that the actual delivered quality of participating services can be measured and monitored after execution. Therefore we can ex-ante enforce a true announcement of quality to be delivered by verifying it ex-post. According to the *Compensation-and-Bonus Mechanism* introduced in (Nisan and Ronen, 2001) a compensation function is constructed as follows

$$\Delta f_j = \begin{cases} (\tilde{U}^f - \tilde{U}^j), & \text{if } e_j \in o \\ 0, & \text{otherwise} \end{cases}$$

The compensation function represents the utility gap that results from the utility difference of the announced attribute values and the actual performed ones from the service requester's perspective. In other words the gap that results from the utility loss the systems incurs because of the service provider's untruthful announcement. The monetary equivalent to this utility gap according to the requester’s preferences represents the penalty payment the service provider has to bear for deviating from the announced attribute values. This negative consequence can be interpreted as a contractual penalty for not realizing specified service-level-agreements as defined in (Salle and Bartolini, 2004).

Taking the compensation function into account the payment function is extended as follows:
4.5 An Analytical Analysis of Bidding Strategies of Service Providers

The bidding strategy of each service provider comprehends a price announcement and a corresponding service configuration consisting of a set of attribute values as introduced in the Section 4.1. In this section we analytically analyze providers’ bidding strategies in proposed mechanism design:

**Lemma 1.** In a Multiattribute Verification Mechanism for each service provider $s \in S$ the reward is independent from its bids consisting of the announced attribute values $a^s_1, \ldots, a^s_L$ and the announced prices $p_{ij} \forall i \in \tau(j), \forall j \in \sigma(s)$.

**Proof of Lemma 1.** Assuming without loss of generality that service provider $s$ only owns one service $z$ with a configuration $A_z$. $F_z$ denotes the set of all feasible paths from source to sink without service $z$ and its incoming and outgoing edges. We denote $f^*$ as the path which is allocated by $o$. Let $U'_z$ be the utility of path $f^*$ in the graph with service $z$. Let $U_z$ be the utility of path $f'_z$ in the reduced graph without service $z$ and its incoming and outgoing edges. Let $U'_{z}(e_{s})$ denote the utility of path $f'_{s}$ with $e_{s} \in f'_{s}$. $U'_z$ is the overall winning path utility with the actual realized attribute values $\hat{a}_1^s, \ldots, \hat{a}_L^s$ of service $z$. An invocation $e_{s}$ of service $z$ is allocated by $o$ iff $U'_z(e_{s}) \geq U_z$. In this case the profit of service provider $s$ evolves as follows:

$$\pi^s = p_{s}^a + t^s - c^s$$

$$\pi^s = p_{s}^a + (U'_z - U_z) - c_{s}(e_{s}, \hat{A}_z)$$

$$\pi^s = p_{s}^a + ((U'_z - U_z) - (U'_z - U'_z)) - c_{s}(e_{s}, \hat{A}_z)$$

$$\pi^s = p_{s}^a + (U'_z - U_z) - c_{s}(e_{s}, \hat{A}_z)$$

$$\pi^s = \left(\alpha \left( \sum_{l=1}^{L} \check{A}_l \right) - \sum_{e_{s} \in \tau(j)} p_{ij} - U_z\right) - c_{s}(e_{s}, \hat{A}_z)$$

Equation (10) shows that once a service $z$ is allocated, its reward is independent from its announced price $p_{s}$ and all announced attribute values $a^s_1, \ldots, a^s_L$. In other words $s$’s bid does not have an impact on the transfer function $t^s$. □

**Theorem 1.** In a Multiattribute Verification Mechanism, for each service provider $s \in S$ the bidding strategy $b_{ij}(e_{s}) = (A_{ij}, p_{ij})$ with $\hat{a}^s_l = a^s_l \forall l \in L, p_{ij} = c_{ij}(e_{s}, \hat{A}_z)$ (truth telling with respect to configuration and price) $\forall i \in \tau(j), \forall j \in \sigma(s)$ is a weakly dominant strategy.

**Proof of Theorem 1.** Lemma 1 shows that once service providers are allocated they are not able to influence their reward as $\pi$ is independent from the announced attribute values and prices. Nevertheless, bids have an impact on the chance of being allocated. Assuming without loss of generality that service provider $s$ only owns one service $z$ with a configuration $A_z$. A service provider $s$ wants to be allocated iff $\pi^s > 0$.
A possible solution that satisfies (11) is truth-telling with respect to configuration and price such that $p_a = c_a(e_a, \tilde{A})$ and $\mathcal{U}'(e_a) = \mathcal{U}'$. As shown in Lemma 1 service providers have no control about their reward once they are allocated which implies that any other possible solution besides truth-telling that satisfies (11) is not better than truth-telling. Hence, reporting attribute values $a'_1, \ldots, a'_l$ truthfully meaning that announced values are actually realized through execution such that $a'_l = a'_l \forall l \in L$ and consequently $\mathcal{U}'(e_a) = \mathcal{U}'^*$ as well as $p_a = c_a(e_a, \tilde{A})$ is a weakly dominant strategy.

Theorem 1 shows that the provider’s bidding strategy is determined through the mechanism design. Service providers act best (or at least as good as any other alternative) by reporting their services’ configurations and internal costs truthfully which is a valuable mechanism property from a requester’s perspective. This property assures that although all service providers act self-interested and therefore try to maximize their profit, their dominant strategy maximizes the system’s welfare and the requester receives a technical feasible instantiation of the desired complex service at a guaranteed service level. This is a valuable property as it tremendously lowers strategic complexity for service providers and fosters a trustful requester-provider-relationship. It is well-known in literature that incentive compatibility in VCG-based mechanisms may fail in repeated games (Binmore and Swierzbinski, 2000). Nevertheless, in service value networks we observe a high degree of dynamicity with respect to changing service providers, variable costs and network topologies. Thus, each auction setting is different from the preceding one which makes learning from past situations impossible and each game can therefore be treated as a one-shot game.

5 CONCLUSION

We proposed a multidimensional procurement auction for trading composite services in networked economies. We presented a graph-based model that captures the main components and characteristics of service value networks. Based on this model we introduced a mechanism design that enables allocation and pricing of service components that together form a requested complex service. However, auctions for composite services are much more complex than simple procuring auctions, where the suppliers themselves offer a full solution to the procurer. In composite services, this is not the case, as a flawless service execution and therefore the requestor’s valuation highly depends on the accurate sequence of its functional parts, meaning that in contrary to service bundles, composite services only generate value through a valid order of their components. The allocation is computed based on the requestor’s score for QoS characteristics of the complex service. At the same time, the mechanism is capable of handling a wide range of aggregation operations for service attributes also supporting rich semantic approaches for dealing with complex non-functional service specifications. Due to the combinatorial restrictions imposed by the underlying graph topology and the absence of capacity constraints, the winner determination problem can be solved in polynomial time which is a crucial issue when it comes to implementing online systems. We furthermore showed that proposed mechanism is individual rational, allocation efficient and incentive compatible with respect to QoS characteristics and prices of service offers. Hence, reporting the true type regarding configuration and price is a weakly dominant strategy for all service providers. This is a valuable property as it tremendously lowers strategic complexity for service providers and fosters a trustful requester-provider-relationship.
Proposed graph-based scoring auction is evaluated in the TEXO use case of the THESEUS² project. TEXO is a research project, within the Theseus research program initiated by the Federal Ministry of Economy and Technology (BMWi). Within the Theseus program, TEXO contributes to service economy by creating infrastructure components for business webs in the Internet of Services. Via intuitive interfaces and technical systems TEXO addresses the full lifecycle of these services from innovation to productive usage. Addressing these demands requires an interdisciplinary approach to create an integrated platform for the internet of services which supports all phases of the lifecycle. For all stakeholders and participants in such a service value network, innovative business models being as flexible as the network itself are required. Especially the novel requirements for pricing models are addressed by proposed graph-based multidimensional procurement auction. The auction mechanism is capable of allocating and pricing of composite services in an efficient and truthful manner. It enables flexible participation and switching for service providers and at the same time it does not require complete information about configurations, prices and interrelations from the service requester’s perspective which makes the mechanism favourable for ad-hoc and situational environments such as service value networks.

UNDERSTANDING THE MANIFOLD FORMS OF B2B INTEGRATION - A TRANSACTION COST PERSPECTIVE

Christine Legner, European Business School (EBS), Rheingaustr. 1, 65375 Oestrich-Winkel, Germany, christine.legner@ebs.edu

Abstract

The need for collaboration within value chains is rapidly increasing and drives enterprise to align and electronically integrate their business processes with their business partners. As technologies evolve, manifold forms of B2B integration have emerged – from e-mail communication to customer or supplier portals, the exchange of EDIFACT- to XML documents, and Web Services. Although service-oriented architectures (SOA) are considered the future of inter-organizational linkages, no empirical studies have been found which surveyed the impact of SOA on B2B integration costs and benefits. From a research perspective, we still lack a systematic analysis that explains how a specific B2B integration technology impacts the effectiveness of B2B integration.

Building on transaction cost theory, this research analyzes the different forms of B2B integration with regard to their impact on connectivity and coordination costs. Based on a field study from the automotive industry, it demonstrates that there is economic rationale for preferring supplier portals to machine-to-machine integration based on EDIFACT or XML messages. Compared to prior technologies, SOA reduces the costs of external integration by eliminating separate B2B integration infrastructures and improving connectivity of internal applications. However, we find that prior literature tends to overestimate the impact of open Internet and Web service technologies on connectivity costs.

Keywords: B2B integration, e-business, electronic data interchange, inter-organizational systems, transaction costs, Service-oriented architecture (SOA)
1 INTRODUCTION

The need for collaboration within value chains is rapidly increasing in many industries and drives enterprise to align and electronically integrate their business processes with their business partners. A huge growth of inter-organizational process integration is projected in the coming years due to the following three factors. First, enterprises increasingly realize that they gain competitive advantage by intensifying their customer interactions, concentrating on core competencies and augmenting the level of external sourcing (Dyer and Singh 1998; Venkatraman and Henderson 1998). This is underpinned by prominent examples from the automotive industry (Dannenberg and Kleinhans 2004) and financial services (Sydow et al. 1998). Second, companies have significantly increased internal process and systems integration over the past decade which is considered a major enabler of external integration (Zhu et al. 2006; Zhu et al. 2004). Third, inter-organizational systems technology has been completely overhauled since the mid 1990s by the emergence of the Internet. Today, the Internet provides a widely accepted infrastructure for e-business. Web services and service-oriented architectures (SOA) have emerged as an enhanced concept for integration in heterogeneous environments and are expected to stimulate inter-organizational process integration (Daniel and White 2005; Hagel and Brown 2001).

Inter-organizational systems (IOS) have been intensively studied since the 1960s, when the online airline ticketing system SABRE and other early forms of IOS established electronic linkages between business partners. Despite the vast body of IOS research that analyzes characteristics and benefits of B2B integration (e.g. Choudhury 1997; Massetti and Zmud 1996; Mukhopadhyay and Kekre 2002; Saeed et al. 2005), little research has been conducted so far with regard to analyzing and comparing the different forms of B2B integration and their effectiveness. While there is consent that the use of electronic channels reduces transaction costs (Grover et al. 2002; Malone et al. 1987), it is not well understood how technology choices affect the savings. In collaborative B2B relationships, business partners negotiate mid- to long-term contractual agreements that govern a larger number of transactions (Christiaanse et al. 2004; Clemons and Row 1992; Grover et al. 2002). As they seek investments in electronic linkages in order to reduce high-perceived transaction costs, they have the choice between manifold B2B integration options, from e-mail communication to customer or supplier portals, the exchange of EDIFACT- to XML documents, and Web Services. This paper takes on these challenges and aims at answering the following research questions:

1. How do different forms of B2B integration impact transaction costs in B2B relationships?
2. Is there empirical evidence that Web services and SOA overcome the shortcomings of prior forms of B2B integration and thereby are more likely to experience broad adoption?

Building on transaction cost theory and prior IOS literature, the author suggests distinguishing connectivity costs and coordination costs when analyzing the effectiveness of different forms of B2B integration. The resulting model has been applied in the automotive industry in order to explore the costs and benefits of B2B integration. While the field study presents a first attempt towards measuring transaction costs of electronic B2B relationships, the main contribution of this paper is the conceptual model and the operationalization of transaction cost elements. Hence, this research is intended to further stimulate the academic discourse on the effectiveness of B2B integration and the measurement of transaction costs in electronic B2B relationships.

The remainder of this article is structured as follows: The next section outlines the research methodology. From the review of prior research on IOS and transaction cost theory, we subsequently derive a conceptual model for analyzing different forms of B2B integration and their effectiveness. By applying the model in a field study in the automotive industry, we were able to explore the impact of five different forms of B2B integration on transaction costs. The article concludes with a summary of the insights related to current forms of B2B integration and the impact of service-oriented concepts.
2 RESEARCH METHOD

In view of the research objectives, we adopted an exploratory research design. Using transaction cost economics as a framework of analysis, the aim was to explore how the different forms of B2B integration impact the transaction costs. In a first step, a literature review was performed in order to systemize the different forms of IOS and to identify different transaction cost elements that characterize B2B integration. Given the lacking measurement approaches employed in the transaction cost literature, we derived a refined model that comprises the main transaction cost elements in B2B integration. The second step in the research process involved the collection and analysis of data that are related to the different forms of B2B integration and their impact on transaction costs. Since many industries either have limited experience with electronic integration or strongly rely on a dominant form of B2B integration (European Commission 2007), we had to carefully select a scenario that would provide the possibilities of analyzing and comparing different forms of B2B integration. In addition, accessibility of data was an important factor. For the purpose of gathering data from different B2B integration variants, we decided to focus on the specific scenario of engineering change management in the automotive industry. The following criteria were decisive: (1) The automotive industry has broad experience in B2B integration due to its long history in EDI-based supplier relationships. In this regard, automotive manufacturers and suppliers are aware of the various issues involved in B2B integration and can also be considered “IT-savvy”. (2) Engineering change management has been subject to a recent industry standardization initiative by the Association of German Automotive Manufacturers (VDA). This initiative resulted in VDA Recommendation 4965 which represents a well-documented and comprehensive industry standard. In view of the wide range of implementation variants, which range from manufacturer-neutral clients to EDI, automotive companies are pressing for solutions that have greater interoperability through SOA and Web services.

Over a period of 15 months, from October 2005 to February 2007, the author was heading a research team that conducted a field study in the automotive industry. As an active member of the VDA initiative on Engineering Change Management (VDA ECM), the research team participated in regular working meetings and contributed to the specification of XML messages. In addition, it supported a sub-group of the VDA initiative in designing a service-oriented architecture for the electronic integration of their engineering change management processes. This sub-group consisted of one automotive OEM and four suppliers, and was supported by several technology providers. This activity implied intensive collaboration between all participants. The results were a pilot implementation of the ECM scenarios based on SOA and an in-depth evaluation of the suggested approach compared to the more traditional forms of B2B integration. The evaluation was performed based on the conceptual model presented in this paper. It builds on the experiences from the pilot implementation and estimations that the automotive experts gained when realizing other B2B integration projects.

3 PRIOR RESEARCH

3.1 Inter-organizational Systems (IOS)

According to Johnston and Vitale (1988) and Hong (2002), inter-organizational systems (IOS) are network-based information systems that transcend organizational boundaries. The many different forms of IOS that exist currently reflect the evolution of B2B integration technologies. They range from the first EDI-based systems that were established in the 1960s to the Internet that gave raise to the concepts of e-business and e-commerce, and, more recently, Web services and Service-oriented Architectures. Many scholars argue that service-oriented concepts will provide a more cost-effective e-business platform than traditional EDI systems (Dorn et al. 2009; Legner and Vogel 2008). They are expected to cope better with the differences in semantics and pragmatics among the different actors,
and to replace the traditional document-centric approaches to B2B integration by a process-centric approach. IS researchers have proposed various categorization schemes and modes in order to systemize the different levels of external integration and their support for different types of supplier-buyer relationships (e.g. Choudhury 1997; Massetti and Zmud 1996; Mukhopadhyay and Kekre 2002; Saeed et al. 2005). IOS can be classified according to the type of electronic interaction that they support and the topology of the IT-supported inter-firm relationship (c.f. Table 1):

- The interaction type depends on the communication channel (Löwer 2005; McAfee 2005; Reimers 2001): Electronic human-human-interaction describes traditional forms of interaction between humans that are supported by electronic means, e.g. e-mail or video-conferencing. In the case of human-machine-interaction, external users are gaining direct access to shared data and applications. This is typically realized by Web front-ends or portals that bundle data and applications on the basis of users and roles. Machine-machine interaction finally describes the direct communication between two information systems which eliminates human intervention. It can be achieved by file transfer or by message exchange, which are both associated with asynchronous communication, as well as by service calls.

- The topology of the IT-enabled inter-firm relationship refers to the relationships between the business partners (Alt 2008). 1:1 connections represent dyadic relationships, e.g. between a customer and a supplier. Over time, they often evolve into 1:n or n:1 connections when a focal firm starts linking up with a larger number of (smaller) business partners. The shift to m:n relationships requires either the adherence to widely accepted standards (Damsgaard and Truex 2000) or the existence of an intermediary that facilitates multilateral electronic relationships (Giaglis et al. 2002).

Table 1. Categorization of Different Forms of IOS
3.2 Transaction Cost Theory

Transaction costs, originally developed by Coase (1937), are key in explaining the impact of electronic integration and assessing its benefits. According to transaction cost theory, the most efficient form of the inter- and intra-organizational structure minimizes transaction and production costs (Rindfleisch and Heide 1997). Although the use of IT is generally considered to reduce transaction costs (Malone et al. 1987), existing studies apply transaction cost theory rather at a conceptual rather than at a measurement level. Williamson (1985) initially proposed a division between ex-ante costs (costs prior to the execution of a transaction, i.e. partner search and contract negotiation) and ex-post costs (occurring during and after a transaction, i.e. policing and enforcement costs). With respect to the shortcomings of Williamson’s approach, Milgrom and Roberts (1992) propose the categorization of transaction costs into motivation and coordination costs which encompass the cost of obtaining information, the cost of coordinating the production process as well as the cost of measurement. Clemons and Row (1992) and Clemons et al. (1993) distinguish between two components of transaction costs, namely costs of coordination and costs of transaction risks. They argue that IT investments are asset-specific since they are idiosyncratic to the relationship with the other firm.

While the transaction cost-standpoint has been widely adopted in studies related to supply chain integration, outsourcing, and electronic markets, most studies are focussing on the negotiation and transaction phase. The relational perspective in transaction cost research (Christiaanse et al. 2004; Clemons and Row 1992; Grover et al. 2002) argues that it is too narrow to restrict the unit of analysis to a pure sales transaction (instead of the exchange relationship). In B2B networks, firms negotiate mid- to long-term contractual agreements that govern a larger number of transactions. In such relational structures, they may seek bilateral investments for setting up electronic linkages in order to reduce high-perceived transaction costs (Grover et al. 2002). In terms of transaction cost theory, this translates into asset-specific (or relationship-specific) investments and high transaction frequency.

4 CONCEPTUAL MODEL

Based on the relational perspective in transaction cost theory and propositions from IOS research, we suggest that two main cost elements characterize electronic B2B integration, namely connectivity and coordination costs (c.f. Table 2).

Connectivity costs denote non-recurring costs to establish an electronic business relationship. Prior literature on transaction costs emphasizes partner finding and contractual negotiation, i.e. the time spent by both transacting sides on agreeing on contractual terms. In the context of B2B integration, significant costs are incurred for the design and implementation costs of electronic process integration. Prior literature on IOS adoption emphasizes the effort to establish inter-organizational agreements (Kubicke 1992; McAfee 2005; Reimers 2001) and the internal costs incurred for implementing external process integration (Zhu et al. 2006). Since early IOS have mostly been built as proprietary systems, relationship-specific or asset-specific investments in joint infrastructure are considered to be more important in the case of older communication technology applications such as EDI and other proprietary networks. The use of open technologies, such as Web service- or XML-based applications, is expected to reduce asset-specific investments for firms (Christiaanse et al. 2004). Hence, the following cost elements that make up the connectivity costs of enterprise $i$ connecting with $n$ business partners can be derived:

$$C_{connect_i} = \sum_{j=1}^{n}(C_{P.agr.ij} + C_{P.impl.ij} + C_{IS.agr.ij} + C_{IS.impl.ij})$$

Costs occur for establishing inter-organizational agreements between two business partners $i$ and $j$ and for their subsequent (internal) implementation. Since we have to consider the organizational and the
technical aspects in setting up electronic B2B relationships, we distinguish costs at the process and IS layer. With regard to the process layer, the efforts in establishing an inter-organizational agreement on the process interaction between enterprises \(i\) and \(j\) result in \(c_{P,agr,ij}\). The costs for the internal implementation of the partner-specific process and organizational changes are denoted by \(c_{P,impl,ij}\). On the IS layer, \(c_{IS,agr,ij}\) are the costs for the inter-organizational agreement on the IS interface (or services) and communication infrastructure, whereas \(c_{IS,impl,ij}\) are the costs incurred for their implementation.

Coordination costs are the recurring costs to enable and execute a transaction. Electronic integration reduces coordination costs (Grover et al. 2002; Malone et al. 1987). However, if an IOS is used to automate an existing process, its effects are limited to reducing manual data processing and improving the reliability as well as the timeliness of information (Hoogewegen and Wagenaar 1996). As the firms progress to using IOS for closely coupling business processes between firms, they are able to realize additional benefits of vertical integration (Mukhopadhyay and Kekre 2002; Saeed et al. 2005; Zhu et al. 2004). The use of IOS is considered most beneficial if applied in cooperative relationships (Chatfield and Yetton 2000; Johnston and Vitale 1988) and accompanied by process innovation such as vendor-managed inventory or continuous replenishment in the retail and consumer goods industries (Clark and Stoddard 1996; Riggins and Mukhopadhyay 1994). The effectiveness of B2B integration can be measured by reduced coordination costs, i.e. the savings realized in executing and monitoring transactions. These savings depend on the number of transactions \(t_n\) conducted with all \(n\) business partners and the savings in coordination costs per transaction.

\[
\Delta C_{coord} = \sum_{j=1}^{n} \sum_{k=1}^{t_n} (\Delta C_{coord,ijk})
\]

Table 2. Transaction Cost Breakdown for Assessing B2B Integration

5 FIELD STUDY IN THE AUTOMOTIVE INDUSTRY

For the purpose of exploring the impact of different forms of B2B integration on transaction costs, the conceptual model has been applied in a field study in the automotive industry. The following section presents the findings of the study.
5.1 Background: Engineering Change Management in the Automotive Industry

Although it has been intensively studied for a long time, the automotive value chain is currently undergoing significant changes (Dannenberg and Kleinhans 2004; Doran et al. 2007; Seidel et al. 2005): Manufacturers are concentrating on branding and downstream activities such as marketing and after-sales, while tier-1 suppliers are increasingly taking over engineering, production and assembly of major components and even entire vehicles (Coronado Mondragon et al. 2006). Today, more than 65% of the value is created within the supplier network with a projected increase to 77% over the next decade (Dannenberg and Kleinhans 2004). With the changing roles in the automotive industry, the need for inter-organizational coordination increases and encompasses not only supply chain management, but also the innovation and product development processes. As part of product life cycle management, engineering change management refers to evaluating and deciding ideas for change as well as the implementation of the changes in development and production. Possible triggers include changes in product design or the elimination of quality and/or safety defects. Currently, suppliers are directly affected by approximately 30% of the more than 10 000 engineering changes an OEM processes per year. Engineering change management is the subject of current standardization efforts which have resulted in VDA Recommendation 4965 of the German Association of the Automotive Industry (VDA 2005) and which are currently brought to the international level.

5.2 Forms of B2B Integration

As part of the field study, five different forms of B2B integration have been analyzed. Interestingly, the group of automotive companies has never used intermediaries to electronically support interactions between OEMs and tier-1 suppliers, despite the intensive discussions in practitioner and academic publications about the role of Covisint and its recent shutdown. The companies had gained experiences with the following five different forms of B2B integration:

- **E-mail communication**: While e-mail communication represents the most widespread form of electronic interaction in the engineering change management scenario, it is mostly used to notify external partners about engineering changes and to share documents with them. Since no structured information is exchanged, e-mail communication corresponds to an electronic human-human interaction in a dyadic OEM-supplier relationship (1:1).

- **Portals**: In order to further automate and streamline their B2B interactions, OEMs have established supplier portals. These portals support interactions with suppliers and provide them with front-end access to the OEM’s internal applications, including engineering change management systems. Supplier portals are to be classified as human-machine interaction and support 1:n relationships between one OEM and its suppliers.

- **Message exchange based on individual data format**: This form of B2B integration is used if two firms bilaterally agree on a data format for exchanging engineering change messages electronically. It represents a dyadic relationship with bilateral agreements between the OEM and supplier (1:1).

- **Message exchange based on industry standard**: This option corresponds to the situation when the message format specified by the VDA ECM standard is used to electronically exchange engineering changes between business partners. In this case, multi-lateral agreements on ECM messages are a prerequisite (m:n).

- **SOA-based process integration based on industry standard**: The SOA-based approach allows for external process integration based on Web service calls. For the engineering change management scenario, the reference architecture outlined by Legner and Vogel (2008) translates the VDA recommendation into a public process model and public service interface (m:n). It has been subject of a pilot implementation.
As part of the field study, data was gathered based on prior experiences with these five forms of B2B integration and complemented with data gathered by VDA (2005). In the case of SOA-based connections, results from the pilot implementation were used. Table 3 presents an overview of the findings which will be discussed in more details in the following two sections.

5.3 Findings Related to Coordination Costs

As discussed earlier, the effectiveness of B2B integration depends on its effect on coordination costs, i.e. the savings in executing and monitoring transactions. In the specific case of engineering change management, the benefits of electronic integration only materialize if engineering changes are exchanged as structured messages that can be processed and imported into the company-specific engineering change management systems. The exchange of electronic messages significantly reduces the manual efforts that are caused by business partners requesting to comment on engineering changes by using their company-specific templates and terminology. With regard to coordination costs, no difference has been identified between the three forms of electronic machine-to-machine integration. Since all of them realize electronic system integration, the reduction in coordination costs amounts to 0.75 person-days per engineering change request (for both parties). On average, three external interactions are required for processing an engineering change request, with an estimated effort of 0.25 person-days for collecting and organizing information. Compared to machine-to-machine integration, the drawbacks from portal-based human-to-machine integration are obvious. Given that suppliers are required to manually re-enter data and to adopt the OEM-specific business and process logic, the estimated savings of 0.75 person-days only apply for the OEM.

5.4 Findings Related to Connectivity Costs

Connectivity costs are incurred for establishing inter-organizational agreements between the different parties and their subsequent (internal) implementation. While connectivity costs are insignificant in the case of e-mail communication, they are also a minor factor in the case of supplier portals where the OEM incurred most of the costs. However, connectivity costs represent an “entry barrier” when it comes to the establishment of machine-to-machine linkages between manufacturers and their suppliers. Table 3 presents the connectivity costs which we identified for the different forms of B2B integration in the engineering change management scenario. Estimations by the VDA ECM working group were used for quantifying the efforts related to inter-organizational agreements (here: $c_{P,agr,i}$ and $c_{IS,agr,i}$). It has proven impossible to further quantify the internal efforts for linking up $c_{P,impl,i}$ and $c_{IS,impl,i}$ since they largely depend on the internal processes and applications. However, Table 3 is quite informative in several ways: First, the inter-organizational agreements at the process level generate significantly more effort (15 days) than those at the IS level (5 days). Second, automotive companies experience that none of the approaches to B2B integration completely eliminates bilateral efforts. Even if public constructs are defined, some bilateral negotiations will be necessary to analyze and set up the collaboration (5 days). Third, Table 3 confirms that SOA-based process integration addresses the shortcomings of existing B2B integration approaches and significantly reduces the relationship-specific investments at process and IS level. Whereas the reduction of relation-specific investments compared to point-to-point connections is obvious, the comparison with the document-centric B2B standards is more interesting. The latter indicates significant relationship-specific costs for inter-organizational process alignment. In the case of SOA, these costs can be reduced if the vertical standard specifies public SOA constructs in the form of process and IS interface specifications. Finally, automotive experts stated that SOA will further reduce the IS-level implementation efforts although they have had difficulties to quantify these effects in the concrete case. They argue the following. (1) An SOA eliminates the need for maintaining a separate B2B integration infrastructure and is more scalable and flexible than existing adapters; (2) widely used Internet technologies will require less proprietary integration knowledge in the future; (3) strongly typed interfaces and process-centric integration allow for better testing and earlier error detection.

*Table 3. Assessment of Five Different Forms of B2B Integration From a Transaction Cost Perspective*
6 CONCLUSION

The contribution of this research is two-fold: First, it derives a model for assessing different forms of B2B integration and their impact on transaction costs of collaborative B2B relationships. By distinguishing connectivity and coordination costs, it provides a systematic view on the cost and benefit structures of different forms of B2B integration. It thereby captures the inherent differences that exist between machine-to-machine and human-to-machine interaction. While existing IOS research focuses mostly on benefits, this paper draws the attention to the fact that different forms of B2B integration require different ex-ante investments in order to generate benefits. The second contribution of this research is the comparison of different forms of B2B integration. This study demonstrates that there is economic rationale for preferring e-mail communication and supplier portals to more complex forms of machine-to-machine integration. While machine-to-machine integration is associated with the highest savings in coordination costs, it comes with significant investments in electronic connectivity. This explains some of the phenomena revealed by current statistics on e-business adoption (European Commission 2007). Asymmetric investments and benefits may exist for the different parties in electronic B2B relationships, notably in the case of B2B portals. When comparing SOA and Web Services to prior forms of B2B integration, we find that service-oriented concepts potentially increase the interoperability and scalability of electronic B2B relationships. This is due to their (1) leveraging of open Internet standards, (2) elimination of the need for maintaining a separate B2B integration infrastructure and (3) ease of integrating with internal applications. However, IS implementation efforts only account for a smaller part of the overall investments in external process integration, and SOA does not alter the problem of implementing organizational changes. Another interesting finding relates to the role of standardization which has been extensively discussed by prior IOS literature (Damsgaard and Truex 2000; Reimers and Li 2005; Zhu et al. 2006). According to the automotive industry’s experiences, vertical standards reduce connectivity costs and relationship-specific investments, but do not completely eliminate them. Besides the need for analyzing bilateral relationships prior to setting up electronic linkages, this is due to the costs incurred for implementing internal process and system changes in order to connect with external partners. On the other hand, the scope and quality of vertical standards significantly affect connectivity costs. If standardization goes beyond message definition and specifies process-level agreements, it further reduces connectivity costs.

There are several limitations to our research. The most important limitation lies in the explorative approach and the limited empirical base for assessing the alternative forms of B2B integration. Although we chose an industry and a scenario which provided rich data related to different forms of B2B integration, there is a risk that our findings are only applicable to this particular scenario. Another limitation of our research is due to the lacking availability of data on B2B integration costs. Our analysis relies on estimations from pilot and productive implementations. Future work is necessary to gather more empirical data and to validate our findings in other B2B scenarios and industry settings. While this study demonstrates that transactions cost theory provides a very valuable framework for analyzing the different forms of B2B integration, the suggested model only presents a first step towards measuring transaction costs. We hope that our findings stimulate further research and encourage further studies that elaborate on the distinction between connectivity and coordination costs. Since the different forms of B2B integration are still understudied, more conceptual and empirical research is needed to improve our understanding of B2B integration variants and their impact.

Abstract

The growth in e-commerce has been accompanied by a large number of disputes related to the online commercial interactions causing high litigation expenses and outstanding delays during the decision process. The distinct of such disputes in e-commerce have also led to the growth of online dispute resolution mechanisms, popularly known as ODR. In this paper, we provide an exploratory understanding and conceptualization of ODR. Based on the critical characteristics of ODR, we identify the various types of on-line transactions where ODR could be used and highlight its positive contribution in tackling these problems. Furthermore, we identify the key stakeholders as well as the secondary players in the ODR process and enunciate the roles played by them in order to move towards the development of an effective international on-line dispute resolution framework.

Keywords: On-line Dispute Resolution, ODR, e-negotiations, stakeholder analysis

1 INTRODUCTION

Since the advent of internet as a medium for online commerce, it has emerged as a critical medium for firms to interact and indulge in commercial transactions with their customers and business partners. Yet, the enormous growth in e-commerce and online transactions across the globe has been accompanied by a fallout arising from the number of disputes related to the online commercial interactions. The disputes have arisen for various reasons, but primarily due to the nature of e-commerce as an asynchronous mode for online transactions. The distinct of such disputes in e-commerce have also led to the growth of online dispute resolution mechanisms. A modern e-alternative to traditional lawsuits is the On-line Dispute Resolution (ODR) – a collection of online, out-of-court techniques, that in recent years has become one of the key areas in the legal world (Katsh, 1995, 2007).

The origins of ODR can be traced back in 1996, with the making of ‘Virtual Magistrate’ project (ICC 2004), due to issues that arose regarding Internet Service Providers’ rights and responsibilities. This was the first on-line arbitration system which was supported by the Chicago Kent Law School (Reed, 2007) and offered its free services to on-line users regarding defamatory postings and corrupted data files. Over a period of time, ODR has become popular among public and got termed as a ‘legal or business fad’ (Kaufmann et al., 2004). ODR’s basic purpose is to make justice more accessible, by improving the flawed parts of the justice process. In assessing the effectiveness of ODR, the Office for Developed and Transition Economies (Consumers International, 2000) identified that consumers were not using various ODR systems and there were recommendations for its avoidance.

Trust is recognized as an important, yet obscure concept in on-line transactions; however it has become more needed for effective online dispute resolution. Most of the disclosure policies and
agreements in online sites are unclear while several privacy infringements have also become commonplace (Schultz, 2004). Disputing parties when involved in dispute resolution complain about the level of protection of personal data, business secrets, contracts and their communication messages (Hornle, 2002). Moreover, there is an insufficient legal framework. On-line dispute resolution legislation or even an accepted cross-border dispute resolution regulation are absent adding to the complexities (Katsh and Rifkin, 2001). Government’s oversight and the need for ODR regulation are still emergent. In addition, the rapid evolution of on-line dispute resolution scheme will always demand immediate technological improvements and the development of software, programs and techniques, which remain unknown to legal practitioners.

This study is an exploratory effort to examine ODR mechanisms that exist in the current environment. More specifically, we perform a stakeholders’ analysis to examine multiple players, their interactions according to their actions and roles, in order to move towards the development of an effective international on-line dispute resolution framework. The key players, also known as the ODR’s principal stakeholders, which are examined are claimants, consumer associations, technical experts, ODR service providers, accreditation entities and the Government.

The contribution of the current research paper is important, as it is the basis for improving the means of dispute resolution, in order to be competent to settle on-line disputes whenever arise from cross-border commercial transactions. The development of a harmonized framework will play a part in achieving a constructive dispute resolution mechanism which will support e-commerce transactions to get improved and become more reliable. Also, it should ascertain that the quality of ‘on-line justice’ in meeting the claimants’ expectations.

2 ON-LINE DISPUTE RESOLUTION

According to the Internet World Stats (2008) report, the number of Internet users internationally on June 30th, 2008 was 1,463,632,361 compared to the world population, which is estimated at 6,676,120,288. In addition, most of the legal information gathered, known as ‘discovery’, exist in electronic form which is an evidence that proves attorneys’ need to use technology, despite their lack of interest in using electronic means of communication. Statistics point out that over 98% of lawsuits typically get settled through negotiation and out-of-court settlements (Boyer, 2007). The restrictions in the conventional legal environment and the evolution of World Wide Web (WWW) encouraged the emergence of on-line dispute resolution mechanisms (Kaufmann-Kobler and Schultz, 2004). In 2003, the United Nations Economic Commission for Europe (UNECE) Forum on ODR explained that the “rationale behind the early ODR programs was to leverage the cost-efficiency, accessibility, detemporalization and depersonalization of on-line interaction while preserving all of the procedural advantages presumed to be perfected in existing forms of face-to-face dispute resolution” (Choi 2003 p.1).

The ODR is not incorporated in any statutes, laws or regulations, since no legal framework supports this concept yet. The ODR is known as the ‘offspring’ of the traditional Alternative Dispute Resolution (ADR), which is the universal and long-existing ‘alternative’ movement to judicial process (Hornle, 2002). In broad terms, it is the branch of dispute resolution that is primarily enacted on an online medium (Hornle, 2002). It deals with the management of on-line and/or off-line disputes, depending whether they arise from interactions in cyberspace or in the off-line world respectively. This means that except for the participation of disputants and the intermediary’s intervention (third party), the ODR system is supported by digital technology also called the ‘Fourth Party’ (Katsh at al., 2001). The digital technology works as an ‘electronic ally, partner, collaborator’ (Katsh, 2002), by improving human capabilities with advanced electronic infrastructure and providing ways so that “dispute resolution expertise can be of value on-line” (Brannigan, 2003). The EU project of the Joint Research Commissions on the specifications for eXtensible Mark-up Language (XML) confirmed that ODR tools are a proof of the significance of technology in the evolution of Alternative Dispute Resolution, since it is a matter of interactivity (Keane et al., 2004).
In the Executive Summary of Final Recommendations of the American Bar Association Task Force on e-Commerce and ADR, ODR was described as the set of ADR techniques (mediation, arbitration, negotiation and conciliation) when integrated with “the use of the internet, websites, e-mail communications” (American Bar Association, 2002). In addition, on-line arbitration and on-line mediation are considered as ODR tools (Katsh, 1995). Moreover, Kaufmann and Schultz (2004) refer to other ODR techniques, such as automated negotiation’ (or ‘blind-binding’ or ‘assisted negotiation’ or ‘enhanced negotiation’ or ‘technologically facilitated negotiation’), where no service is offered by a neutral party since a computer software automatically settles the disputants bids-demands, as well as the ‘cyber tribunals’ (or virtual/wired courts). Ethan Katsh (1995) adds the terms of ‘on-line settlement’ that deals with insurance and financial claims and that of ‘on-line resolution of consumer complaints’. Additionally, Katsh (2007, p.105) suggests that ODR is “a network application that illustrates how, as data is generated by interactions between humans and machines, boundaries between dispute prevention and dispute resolution, or between dispute resolution and standard setting, may become less clear”. The ODR concept can also be found with other alternative terms, such as Virtual ADR, internet Dispute Resolution (iDR), electronic Dispute Resolution (eDR), electronic ADR (e-ADR) or on-line ADR (oADR) (Haloush, 2007, Raines et al., 2007).

3 A TYPOLOGY OF ON-LINE DISPUTE RESOLUTION

Based on the definitions and characteristics of ODR identified from prior literature, ODR processes can be offered for the settlement of disputes between Businesses and Consumers (B2C), Consumers and Consumers (C2C), Government and Citizens (G2C) and between businesses (B2B), as presented in Table 1.

3.1 B2C

There are several occasions where problems appear in B2C transactions. These problems could be handled in a cost effective way for both parties. Consumers could receive the same support in the on-line environment with the ones in the traditional markets in order to be confident before, during and after the transaction. This can be achieved through the development of an on-dispute resolution mechanism. For most professionals, who are involved in developing e-commerce platforms, dispute resolution is one discrete part of the overall e-trust environment.

3.2 C2C

Consumers are using intensively C2C portals such as virtual auctions to buy, sell or exchange products and services such as books, CDs, tickets etc. Unfortunately, the number of complaints in C2C commercial activities has increased dramatically over the last years. Initially, ODR has been used at web-sites for auctions, a type of business which is particularly vulnerable to conflicts, due to the fact that this transaction environment leaves ‘alone’ buyers and sellers to agree on after sales details. It is almost impossible to identify who is on the other side of the transaction especially because repeated relationships between buyers and sellers are rare. As a result, it is hard to trust because of lack of personal contact.

3.3 G2C

Due to the extensive involvement of the Government to various activities the range of disputes and the number of complaints is overwhelming (Ramasastry, 2004). ODR can be used by Governmental agencies and support the general move towards a model where citizens can handle several tasks by themselves such as paying parking tickets, requesting tax returns or informing change of their address. The above infrastructure could be extended for ODR purposes and this could resolve a large number of cases electronically without requiring citizens to reach physically administration authorities. More
specifically, if there is a repeated problem with pensions of 10,000 elderly citizens, instead of every
citizen to wait in long queues to fill in a form or speak to a public administrator he can file his
complaint electronically. If the complaint matches the information in a database, the problem can be
handled automatically. ODR can enhance citizen satisfaction towards Government since it resolves
several cases on an effective and user friendly way.

3.4 B2B

Because of their higher value, Business to Business transactions could use ODR mechanisms even
more effectively than in the B2C environment. B2B transactions have also to deal with trust issues
because of problems related to language, shipping and currency. Companies could use the ODR
mechanisms to avoid litigation expenses. Buyers and sellers in B2B usually repeat their transactions
and this provides an incentive to generate outcomes more effectively by using ODR in order to
continue collaborating in the future. The fact that organisations have legal identity and reputation also
works in favour of ODR. Another important element in B2B transactions is the fact that due to their
nature, during online exchanges both parties are buyers and sellers. As a result there is no problem
about who is going to pay the mediator’s fee which means there is no risk of bias.

<table>
<thead>
<tr>
<th>Relation</th>
<th>Problems</th>
<th>The use of ODR</th>
</tr>
</thead>
</table>
| B2C      | - Undermine the credibility of on-line market space  
- Damages the corporate brand and overall reputation  
- Consumers as well as businesses can not afford legal expenses and lawyers’ fees | - Increases the consumer confidence on-line  
- Keeps customers satisfied  
- Reduces corporate liabilities  
- Removes the risk of failed transactions  
- Increases customer loyalty |
| C2C      | - This environment leaves ‘alone’ buyers and sellers to agree on after sales details.  
- Hard to identify who is on the other side of the transaction  
- Lack of trust | - Minimizes the anonymity between individuals who use on-line C2C platforms to buy and sell their products and services as well as tackles disagreements effectively  
- Removes the risk of fake transactions |
| G2C      | - Conflicts arise during the delivery of Governmental services to citizens. Disputes over tax collection cases, benefits payments etc.  
- Time consuming and bureaucratic procedures discourage citizens from addressing for solution of their problems  
- Due to the extensive involvement of the Government to various activities the range of disputes and the number of complaints is overwhelming | - Could resolves electronically and automatically a large number of cases without requiring citizens to reach physically administration authorities  
- Avoids bureaucratic procedures on a time effective way  
- Can enhance citizen satisfaction towards Government and keeps society functioning smoothly  
- Can assist older individuals or people with special needs |
| B2B      | - Have to deal with trust issues because of problems related to language, shipping and currency  
- Damages their legal identity and reputation | - ODR could be used very effectively in this environment due to the high value of purchases as well as because buyers and sellers repeat their transactions  
- Could avoid litigation expenses  
- Buyers and sellers in B2B usually repeat their transactions |

4 STAKEHOLDERS’ ANALYSIS

4.1 Major ODR Stakeholders

Stakeholder Analysis (SA) has been widely applied in strategic management and corporate governance (Burgoyne, 1994; Donaldson and Preston, 1995), as well in information systems studies. Following Donaldson and Preston (1995) and Mitchell et al. (1997), we extend stakeholder analysis to the context of ODR. Stakeholder analysis will contribute in understanding the potential relations that may be created between the different players in ODR. In addition, it is a way of identifying possible conflicts of interests and presenting clearly the expectations of stakeholders in relation to the problems and the objectives of the research as a whole. Particularly, stakeholder analysis is “the process of systematically gathering and analyzing qualitative information to determine whose interests should be taken into account when developing and implementing a project” (Schmeer, 1999).

Technically, stakeholders’ analysis is used, because it supports in structuring at the best way the project design, understanding the whole system, by identifying and assessing the different stakeholders’ perspectives, actions and goals of the key actors to the research problem. It also matches all the gathered information which can then be analyzed properly and all the necessary ones may generate a single and sound framework of presented findings. In advance, it promises the chance of accomplishing a successful project. Specifically, such method targets at developing a model, an integrated mechanism of alternative dispute resolution applied in on-line transactions and thus, enhancing the on-line development of such dispute resolution mechanism.

Prior to the analysis, the major stakeholders will be identified and classified. In 1708, the word ‘stakeholder’ denoted the bet or the deposit (Clarke, 2004). Nowadays, stakeholder’s terminology refers to “anyone significantly affecting or being affected by someone else’s decision-making activity” (Chevalier, 2001). A stakeholder can either be a group of people or individuals or even organisations and institutions, which depending on the nature of their position and status can “significantly influence or be important to the success of the project” (Social Development Department, 1995) or “share a common interest” (ASA 2008) or this generic term that covers “all those people who have interest in the wellbeing of an area” (IDEA, 2008).

When the stakeholder influences significantly the project, then he considers being a powerful stakeholder (Social Development Department, 1995) either because of the position he holds in relation to the others stakeholders and his power “to control what decisions are made, facilitate its implementation or exert influence which affects the project negatively” (ASA 2008). In the current research, in order a stakeholder to be regarded as important, its interests and needs should be a priority. As a result, the decision regarding which players should be included in the stakeholders’ analysis depends on their major contribution and interest in the outcome to the current research.

The following stakeholder analysis’ table contains the list of the key ODR stakeholders that participate in the current research. These are the claimants, the governmental bodies, the ODR Service Providers, the ODR clearinghouses, the accreditation bodies, the technical experts and the consumer associations. The row data allows showing stakeholders’ relations and interactions between each other, regarding their roles and impact of intervention on the outcome of research, depending on their respective set of actions and goals in relation to the research problems addressed.

The following table (Table 2) provides an overview of the On-line Dispute Resolution stakeholders. In the following sections the key stakeholders are identified and their potential responses and objectives are analysed in detail.
### Table 2. Stakeholders’ Analysis for ODR

<table>

<th>Role</th>
<th>Actions</th>
<th>Objectives</th>
</tr>
</thead>
</table>
| **Claimants**           | Users / potential users of ODR            | - Seek out-of-court alternatives, cost and time effective solutions to tackle their disputes  
- Use ODR mechanisms to tackle their problems  
- Become familiar and aware of ODR mechanisms | - To strengthen consumer confidence in ODR mechanisms |
| **Government**          | - Legislates and enforces legislation     | - Produces legislation to safeguard commercial environment  
- Being responsible for implementation, enforcement, harmonization and awareness issues | - To progress effective enforcement of legislation nationally as well as internationally  
- To enhance harmonization in cross-border dispute settlements |
| **ODR Service Providers (ODRSP) or ODR Providers** | Facilitator of the dispute resolution | - Ensure processes (and systems) are capable to operate for an ODR process | - To provide assistance as a neutral third party in negotiating a mutually agreeable settlement to the parties  
- To be receptive to new advancements and adjust them to resolution processes by keeping pace with them |
| **ODR Clearinghouses**  |                                           | - Assist consumer and businesses in initiating electronic dispute resolution processes and provide necessary documentation  
- Recommend the best ODR provider  
- Provide a filtering service of complaints  
- Act as payment intermediary | - To control the quality and specificity of a mechanism for ODR providers  
- To act as central contact point internationally  
- To seek grant ODR providers access to larger markets  
- To assist consumers to overcome cross linguistic and cultural barriers  
- To develop a standard and multilingual on-line intake form for dispute submission (claimants and providers)  
- To develop a “good practice” framework where basic standards for ODR will be included in order to achieve global conformity among providers |
| **ODR Accreditation entities** |                                           |                                                                         |                                                                                                |

4.1.1 **Claimants**

According to the above table, one of the major stakeholders is the users of ODR. These could be claimants, such as individuals, business corporations and e-shops, or even the Government, that face a dispute with another party in the on-line or offline environment and ask for an e-alternative solution.
Claimants are requesting more efficient and creative negotiations instead of asking for compensations without achieving their goals. The central idea of all these mechanisms is to ‘shake the ego’ of the disputing parties and to discern the most appropriate solution for them. The desire of attaining a practical, speedy and cost-effective dispute resolution implies the use of ODR mechanism and requires claimants’ acquaintance and awareness of its function. What discourages them from trying this legal alternative relates to the absence of confidence in using such mechanism, no matter if things have improved since its emergence.

4.1.2 Government

The Government’s intervention is questionable under the concept of ODR, due to fact that the Internet is evolving so rapidly and it is not possible to keep pace with legislation. For that reason, self-regulation is preferable (Schultz, 2004). The e-disputes verify the existence of e-Government (eGov) or electronic governance, another equally important stakeholder that attracts business people, citizens, politicians and policy makers. In Governmental Departments, the ombudsman is the only offline intermediary who is used for administering maladministration (Local Government Ombudsman, 2008). When the Commission of European Communities referred to the role of e-Government (2003), it implied “the use of information and communication technologies in public administrations combined with organisational change and new skills in order to improve public services and democratic processes and strengthen support to public policies”. Leading e-Governmental bodies, in the USA, Australia, New Zealand, Singapore, Canada and the UK are responsible for implementing and enforcing laws, as well as providing funding for researching on ODR mechanism (UNPAN, 2002). Moreover, on-line Governments should accomplish the Government to Consumer (G2C), Government to Business (G2B) and Government to Government (G2G) interactions as well as equality of the digital divide, trust, privacy and security in administrative transactions with its citizens and businesses and the creation of broadband culture. The ODR procedures are controlled by Governmental initiatives. E-com trust’, ‘TRUSTe’, ‘Square Trade’ and ‘BBBO-n-line (Better Business Bureau On-line)’ are some of the initiatives which foster consumers’ believability and encourage them to trust private information. Their role is to check whether the corporations adhere to their privacy policies and consumer protection laws, thus approving their trust mark, their symbol to be attached to their business web-page. According to Consumers Affairs (2005), surveys like BBBO-n-line showed that such trust mark schemes are not even known by consumers. Governments’ presence is important in the progress of such research as it is the ‘ideal host’ (Rule, 2002). They can recommend ODR tools in the negotiation processes, bring the harmonization in cross-border dispute settlements and progress effective enforcement of ODR legislation internationally.

4.1.3 ODR Service Providers

Another key stakeholder is also the ODR Service Providers which consists of lawyers specialized in ODR. They can are either be in the form of non-Governmental or institutional bodies and offer e-dispute settlements. Conley’s (2005) survey presents the overall picture of ODR services and websites. Eighty-two out of one hundred and fifteen dispute resolution services are operational and with caseload over 1.5 million on-line and off-line disputes. Fifty-seven are distributed in North America, thirty-eight in Europe and sixteen in Asia. Some examples of non-Governmental bodies (Katsh, 2000) are Cybersettle (1996), Squaretrade (1999), Settlementonline (2007) and SmartSettle (1997). There are also institutional bodies, the London Court of International Arbitration (ICC, 2008), the American Arbitration Association (AAA, 2007) the World Intellectual Property Organization (WIPO, 1967) and the Chartered Institute of Arbitrators (CIArb, 1915). Their main aim is to assist in the “negotiation of a settlement mutually agreeable to the parties” (Department of Justice, 2009) as third-party neutrals-facilitators and make certain that every mechanism operates properly and is ready for the on-line resolution. The Internet Corporation for Assigned Names and Numbers (ICANN), a non-for-profit public-benefit corporation, approves only four providers, the Asian Domain Name Dispute Resolution Centre (ADNDRC), the National Arbitration Forum (NAF), World Intellectual...
Property Organization (WIPO) and the Czech Arbitration Court (CAC) (ICANN, 2008). For that reason, any e-arbitrator should improve his knowledge and skills, through the attendance of relative workshops and regular (on-line) training, which combines technology issues and on-line dispute resolution processes, in order to be capable to provide high quality and efficient resolutions.

4.1.4 Clearinghouses

The Clearinghouse is a stakeholder, who ensures that consumers have chosen the appropriate ODR provider. Though ODR clearinghouses are not yet well-developed, the following two bodies demonstrate cases on how a clearinghouse can make use of power over ODR providers: These are the ‘European Extra-Judicial Network’ (EEJ-Net) and the project of the International Chamber of Commerce (ICC) of a ‘Dispute Resolution Clearinghouse’. Clearinghouses have strategic role and can provide substantial contribution in the outcome of the above analysis, as they stand in a neuralgic position of the ODR mechanism, by being the (payment) intermediaries between the future claimants and the ODR providers. Not only they look for the most suitable e-arbitrator by launching electronic resolution for the interested disputing party, but also they check the filling of complaint forms and give the necessary documents and appropriate information when users consider whether to have on-line dispute settlement. What it must be achieved by the ODR clearinghouses is to accomplish acting as central contact point internationally. The clearinghouses will assist in handling internationally the linguistic and cultural problems that bother consumers. Furthermore, these accreditation independent entities can similarly control and verify the quality of ODR practitioners “on the basis of predefined and public criteria” (Schultz 2003, p.4). According to that, if practitioners are not in compliance, then these entities can prevent them from participating in the ODR arena. Besides, they can also support and assist policy makers through their practical experience. ICANN has a well-developed accreditation system the Uniform Domain Name Dispute Resolution Policy (UDRP) (ICANN, 2008). It is under consideration the possibility of establishing ODR appellate bodies, capable of reviewing decisions on-line, so as to exercise control over ODR resolvers by the end of the specific processes (Kaufmann-Kobler and Schultz, 2004).

4.2 Secondary ODR Players

ODR is also supported by technical experts and consumer associations, which are the secondary players, in order for the mechanisms to function properly (Table 3).

</tr>
</tbody>
</table>

Table 3 Secondary ODR players

Proceedings ECIS 2009
4.2.1 Technical Experts

An important post within ODR is held by the technical experts, who are responsible for developing and maintaining ODR infrastructure. A technical expert, “by virtue of training, education, profession, publication and experience, is believed to have special knowledge of a subject beyond the average person” (IT-Career-Coach.Com, 2007). His role is of great importance and concentration is given on their capabilities to advance the ODR infrastructure by developing more compatible software to the ones that already exist without altering or wiping them out. The main goal is that of building up a scheme for designing an advanced ODR infrastructure, which will offer higher security, faster connection, advanced interactivity and friendlier interface.

4.2.2 Consumer Associations

Consumer Associations’ contribution is noteworthy. Examples of associations are the Consumer International (CI), a federation of consumer groups (Consumers International, 2008), the Transatlantic Consumer Dialogue (TACD), a forum of sixty-five US and EU consumer organisations (2004) and the European Consumer’s Organization (BEUC) which comprises forty-one independent national consumer organisations from thirty European countries (2008). The above associations maintain electronic forums that act as reporting centres, and through that way they control by revealing feasible abuses, displaying irregularities and receiving complaints. They keep interested parties aware of what is happening in the marketplace by providing them with guidelines and consulting them for general issues that bothers them. Consequently, the consumer associations expect raising public awareness about ODR mechanisms and developing a database, as an information portal for claimants, with ODR cases. They can also act as a platform for consumers’ representation in international conferences and forums related to ODR.

5 INTERNATIONAL CO-OPERATION AMONG THE STAKEHOLDERS AND THE NEED FOR A UNITED APPROACH

International co-operation among the stakeholders of ODR is essential and could only be achieved through co-ordinated action. The Governmental bodies need to continue to participate and actively contribute to enhance the learning experience for the ODR players. Clearly one of the biggest problems with the use of ODR is its international character since several disputes may arise from distant locations, a fact that leads to the conclusion that the need for co-operation by ODR experts is essential. This will mean that authorities in Europe as well as internationally should work together and join training initiatives to progress International on-line ODR solutions. This will encourage communication and co-ordination between ODR Providers and technical experts to achieve efficient and effective ODR infrastructures as well as to investigate techniques and ways to address obstacles during an on-line dispute resolution case.

The key components of ODR could fall into three major categories; people, process and technology. Successful ODR sites should consider seriously about these three elements if they want to be successful. More specifically, people develop and power web-sites as well as ODR. No matter how advanced is the technology behind the site, it is important to consider that individuals will finally support and use it. ODR practitioners should develop specific skills before they start handling difficult disputes on-line. The arbitrator should learn how to manage the ODR platform in order to be able to respond and facilitate an on-line arbitration. In addition, he should be able to run through in depth simulations in the ODR platform before the system is ready for a live case. There is a significant value in educating everyone about the tools and techniques of ODR. More specifically, practitioners who are new in the field should be highly encouraged to interact and mentored by experienced neutrals.
regarding what type of language is more appropriate to be used in opening statements and ground rules with other neutrals.

There is no single solution or silver bullet that can be sufficient enough by itself to progress ODR. As a result, all stakeholders should be involved in the effort of developing ODR mechanisms which will be cost effective and easy to use. Even if the ODR technical infrastructure was effective, technology itself is not sufficient to develop an idealistic ODR mechanism. Different stakeholders (ODR Service Providers, Clearing Houses etc) need to co-operate in order to find an integrated solution to progress ODR mechanisms.

6 CONCLUSIONS

The rapid development of e-commerce has generated large numbers of online disputes between parties. These disputes undermine the credibility of online markets discouraging customers and organizations to engage in on-line transactions. The On-line Dispute Resolution mechanisms build trust in transactions, preserve relationships and reduce corporate liabilities. The development of technology plays a significant role for a successful On-line Dispute Resolution mechanism. However, the technology is the medium to an end and not an end in and of itself. There are some arbitrators who are highly skilled and efficient in face to face dispute resolution and they are not equally able to work in an on-line environment. In contrast, there are skillful arbitrators who will emerge as great ODR practitioners. ODR makes customers feel that they can purchase products and services on-line with confidence. In the near future adding links of external ODR services could be an industry standard among major e-commerce web-sites and will act as a means of giving on-line customers confidence. It is crucial for e-commerce to develop a trustful environment to support the building of confidence between parties. On-line Dispute Resolution is an essential component to achieve the above objective. Once consumers and organizations are aware that they could handle their cross differences which arise from their cross-border transactions in a cost effective way, then they will be willing to engage further.

Abstract

This paper discusses how several stakeholders in a public e-service development project consider a future e-service and expected changes in administrative processes and working routines. Our findings indicate a much more multifaceted view than the common win-win situation, with increased quality for citizens and increased efficiency for agencies, which is rhetorically put forth as an effect of public e-service implementation. We have studied a development project resulting in an e-service for handling student anonymity when marking written exams in higher education. In this case we have identified five distinct stakeholder groups related to this e-service: students, teachers, course administrators, exam guards, and the university at an agency level. All of them having certain expectations and fears about the new situation. By presenting this diversity in opinions we add further understanding to the notion of e-services as being more or less beneficial for certain stakeholders.

Keywords: Public e-services, e-government, stakeholders
1 INTRODUCTION

Public e-services demand secure information handling in order to build and maintain citizens’ confidence in public administration and in the long run also in democracy. We often see this issue being discussed in technological terms; e.g., how to develop secure IT solutions and how to handle integrity in public e-services (e.g., Argyrakis et al., 2003). In this paper we discuss how different actors apprehend an e-service under development, focusing on their perceived need for this e-service. An e-service, as well as any kind of service, is by definition intended to serve someone (Kelly et al., 2002). 

In this context of public e-services this means that an e-service should fulfill the needs of the citizens that are supposed to use the e-service. This is in accordance with Kelly et al. (2002) who identify services as meeting someone’s relatively enduring need for something.

In many e-government studies there is a focus on the roles of a government agency officer and a citizen who interact through, e.g., an Internet-based public e-service. These two roles are often taken for granted; the agency offers a communication medium to citizens who act as private persons towards the agency. In this paper, we use empirical findings from a case study in order to illustrate that this one-to-one relationship between government and citizen can be too simplified in order to explain the use of public e-services. Instead, we agree with Tranmüller and Wimmer (2000) who state that e-government involves many different stakeholder groups that need to be considered when developing e-services. In the present case we study the development of a public e-service for handling student anonymity during written exams at a Swedish university. The e-service is offered by the university, which has the agency role in this case. The e-service has several distinct user groups, both users working at the agency (teachers, administrators, and exam guards) and users acting in the role of citizens (students). This diversity in user roles implies that users of a public e-service are not a homogenous group. Instead, we argue that the stakeholder concept (e.g., Freeman, 1984), often used when describing and analysing private firms, can be fruitful to use in the e-government context as well.

The research question we focus on in this paper is how we can illustrate and understand different stakeholders’ perceptions of the public e-service during the development process. The perceptions can be expressed as anything from positive expectations to fears. We use empirical examples from the studied e-service development project in order to illustrate how stakeholder groups differ in their perceptions and consequently also in their feelings of relevance and need related to the e-service. By presenting this diversity in opinions we add further understanding to the notion of e-services as being more or less beneficial for certain stakeholders. By adopting a multifaceted perspective on stakeholders, public e-service development can be analyzed and understood in a way that takes several stakeholder groups’ needs into account. The purpose of the paper is thus to explore the effects of using the stakeholder concept when analyzing the development process of a public e-service. Our approach is supported by a study of Flak and Nordheim (2006) which indicates that few e-government studies so far have explicitly addressed the stakeholder complexity and its inherent challenges. However, we believe that the complexity is a potential strength in the development process that, handled in a constructive way, can result in more comprehensive and successful final e-services.

After this introduction, the paper is organized in the following way: In Section Two we discuss the theoretical concept of stakeholders in e-government. The research design is reported in Section Three. The empirical findings from our case study are presented in Section Four. In Section Five the findings are discussed. The paper is concluded in Section Six, in which we also make some statements about the need for further research efforts in this area.
2 STAKEHOLDERS IN E-GOVERNMENT

We use the stakeholder concept in order to discuss different user groups and other actor groups related to the studied public e-service. The stakeholder concept was used by Freeman (1984) in his seminal work with the definition of “any group or individual who can affect or is affected by the achievement of the organization’s objectives” (ibid., p. 46). The stakeholder concept was originally introduced and used in the context of a private firm. There are, however, several scholars who have discussed how the stakeholder concept can be applied to public contexts as well (e.g., Scholl, 2001; Pardo and Scholl, 2002; Chan et al., 2003; Flak and Rose, 2005; Flak and Nordheim, 2006). Scholl (2001) presents a literature review on how the stakeholder concept has been transferred from the private to the public context and used in e-government settings. He distinguishes both benefits and limitations, but concludes that even though the stakeholder theory origins from the private sector the stakeholder concept can be beneficial to use in e-government settings as well (ibid.). By dividing the actor roles into several stakeholders the understanding of citizen and government relations will broaden. Flak and Rose (2005) agree that stakeholder theory can be valuable to use in the e-government field, but they also argue that the stakeholder theory lacks theorization of the relationship between technology and stakeholders, which is important in order to understand e-government.

Mitchell et al. (1997) argue that a stakeholder possesses one or several of the attributes power, legitimacy and urgency. In their study, Mitchell et al. (ibid.) develop a typology of: 1) stakeholders who have power to influence the firm, 2) the legitimacy of the stakeholder’s relationship with the firm, and 3) urgency of the stakeholder’s claim on the firm. These three attributes are intertwined. Mitchell et al. (ibid., pp. 869-870) argue that “power gains authority through legitimacy, and it gains exercise through urgency [...] legitimacy gains rights through power and voice through urgency”. In an e-government context the attributes of stakeholders’ power, legitimacy, and urgency are also present. Chan et al. (2003) discuss how stakeholder theory can be used in order to manage stakeholder relations in e-government projects. They identify a lack of literature within the e-government field concerning strategic management of stakeholder relations, even though several scholars highlight this as an important issue to handle in order to reach success in e-government projects. This is also in line with Flak et al. (2003) who call for more research on how stakeholder theory can be adapted to the e-government field. This is taken a step further by Flak and Rose (2005) who propose a research agenda on stakeholder theory in e-government research, where for example issues such as external and internal stakeholders’ legitimacy as well as government agencies’ ethical duty to respect different stakeholders’ interests are put forth.

We do not intend to apply the entire stakeholder theory in the paper. Instead, we will explore the explanatory force of the stakeholder concept as such, by discussing and comparing the different stakeholders’ perceptions in our case. We follow Freeman’s (1984) definition above, and define a stakeholder as a person or group of persons who can affect or is affected by the public e-service and its surrounding processes. By discussing empirical findings related to different stakeholders the objective is that the analysis should become more comprehensive. This should help us view the studied phenomenon more critically, e.g., by contrasting different stakeholders’ experiences. Flak and Rose (2005) argue that applying stakeholder theory in e-government research could increase a critical stance.

Democracy depends in part on the trust in public institutions (Lauer, 2004). Therefore trust is an essential issue also in e-government research – an issue that can be related to and incorporated into the discussion and understanding of stakeholders. Several studies have explored the role of trust in the e-commerce area and the exploration in the area of e-government has just begun (Bélanger and Carter, 2008). Following Bélanger and Carter’s (ibid., p. 166) reasoning on the concept (based on Rotter, 1971) trust is defined as “an expectancy that the promise of an individual or group can be relied upon”. Social learning theory (ibid.) is the point of departure for the definition, which suggests that experiences of promised negative or positive reinforcements vary for different individuals and between different stakeholders. As a result, people develop expectancies that such reinforcements will occur when promised by other people. Komito (2005) claims that trust rarely is given unconditionally,
especially to governments composed of unknown and unaccountable individuals. Instead trust is earned. Trust has to be earned based on actual interactions that citizens have with particular agencies.

When we develop public e-services there is a risk that we put citizens’ trust in the e-service in the hands of the IT vendors (Lauer, 2004). On the other hand, taking different stakeholders into account during the development of new public e-services can increase the levels of trust and even solidarity and democracy. This means that there would be long-term benefits for civil society and also for, e.g., political participation (Komito, 2005). E-government has the potential to improve government transparency, responsiveness, and accountability, but will only be adopted if citizens deem them trustworthy (Bélanger and Carter, 2008). Trust as a concept has several different and interlinked dimensions, which we will only touch upon in this paper. One can for example discuss social trust, trust in administration and trust in technology. We use this division of trust in the paper in order to understand needs, opinions, etc. from different stakeholders. Bélanger and Carter (2008) provide a model where they divide trust into institution-based trust (e.g., trust in the Internet, such as secure data transmission, as an essential part of e-government) and trust in the government agency providing the e-service (which will highlight aspects such as organization and knowledge in the agency). Labels such as trust of the Internet and trust of the government are also present (ibid.). We label the two dimensions of trust as trust in administration (organization) and trust in technology when we analyze our empirical data.

RESEARCH DESIGN

In order to gain further understanding of how public e-services affect citizen and authority relations, we are conducting a research project in which we are analysing several public e-services from the perspective of trust, organization, and knowledge. The project is based on cooperation between researchers from the fields of information systems and public administration. The project aims to increase our joint understanding of how public e-services can be developed so that users (citizens as well as governmental users) have confidence in and competencies to handle these e-services, in a personal as well as an organizational context. Such e-services should also create democratic legitimacy and efficiency in the society.

2.1 The Case Study

In order to answer the question how we can illustrate and understand different stakeholders’ perceptions of public e-services during the development process, we analyze data from the first case study in the research project, which was performed at a Swedish university during the spring of 2008. The e-service under development is an e-service for handling student anonymity when marking written exams. At this university, 100,000 written exams are administered each year which makes this an extensive process. The e-service consists of several components; one part handling the information transfer from a student administrative IT system to a mobile palm solution that is used on site during the exam events, a web-based interface where students sign up for the exam and another web-based interface that the teachers and administrators use when reporting the results. The studied e-service comprises all these components and is, thus, used by several user groups during the exam process. The studied e-service differs from some public Internet e-services in the sense that it is closely integrated with the back-office IT system. We study all components in this paper.

The origin of the initiative to develop an e-service was student demands for a higher legal security in the marking process of written exams. Students argued that the teachers cannot be totally fair in their marks as long as they know who the student is. Students were afraid that some of them could be “punished” with a lower grade if they had been critical towards the teacher or that some of them would receive a higher grade than appropriate because the teacher liked them. Thus, the student demand for anonymity is in line with a general strive for equal opportunities in higher education; i.e., no one should be discriminated because of his or her sex, age, sexual orientation, ethnicity, religion or other faith, disability or social background. The student demand for anonymity was articulated through the students’ union and resulted in a strategic decision made by the university’s vice-chancellor that an e-
service should be developed to guarantee student anonymity during the marking process of all written exams. A project group was formed consisting of a project leader, systems developers, technical personnel, representatives of the exam guards and central examination administrators. A reference group was also organized consisting of representatives of the teachers, the students' union, and exam guards from all faculties. This implies that all identified stakeholders were represented in these two groups; students, teachers, course administrators, exam guards, and the university (represented by the project leader, systems developers, and technical personnel).

During the case study the authors followed the development project (the project group and the reference group) in their project activities. Data was generated in several different ways. One of the authors observed six project meetings and notes from these observations were taken. During the last project meeting respondent validation (Silverman, 2000) of the findings was accomplished. Data was also collected by observations of three information meetings open for university employees and in one systems training activity for exam guards. 14 representatives from all stakeholder groups have been interviewed during the case study; the project leader (1), course administrators (2), teachers (3), students (3), exam guards (2), and administrators at the students’ office (3). The interviews lasted for 30-60 minutes and were recorded. A focus group was also performed together with parts of the reference group (7 persons). This focus group meeting (approximately two hours) focused on the role of the reference group in the development project. Besides these data generation methods, project documentation as well as e-mails sent from university employees to the project group were also analyzed. Altogether this case study design (Yin, 1989) has resulted in rich empirical material focusing on the development project from several perspectives. The empirical data is of a qualitative nature and has been analyzed with an interpretive approach (e.g., Walsham, 2006). Of course, there are weaknesses in the chosen methods, for example that the presence of a researcher might influence the project meetings or that the choice of interview respondents could be biased. These are weaknesses of qualitative research approaches that always have to be considered. We argue, though, that our method and researcher triangulation (Miles and Huberman, 1994) is a way to confront and confine these weaknesses.

There are several motives for choosing the present case. First of all the development process was about to start when we got in contact with the university, which implied that we were able to follow the process from the start. We also have the possibility to return to the case for evaluations later on. The university also showed great interest and engagement in the research project which gave us valuable access to the case and opportunities to make a critical analysis of the situation. There is also a novelty interest concerning this kind of e-service since this seems to be the first one in Sweden with a direct link to the national IT system handling all information about students’ passed courses and exams (called the Ladok-system). There is a recent trend in Sweden to develop solutions for guaranteeing student anonymity in written exams, so other universities will probably follow this attempt.

2.2 The Process of Anonymous Written Exams

In this section we give a summarised description of the process of anonymous written exams. This includes both the e-service and the administrative routines surrounding the e-service. 1) A couple of times a year each course administrator registers all planned written exams within his or her responsibility area for next term in an IT system called TAL. 2) Based on the information in the TAL-system, a special unit at the university called the Examination Service books rooms and hires exam guards for the planned examinations. 3) Prior to the examination the student signs up for the event in a special (already existing) student web portal. An anonymous ID (called AID) is then created in the TAL-system. The AID is only valid for the specific student at this specific examination, and it is not accessible for the student at this moment. 4) Just before the examination starts, the exam guard downloads information about all students who have signed up for the present examination from the TAL-system to his or her palm. 5) The student gets his or her student identity card scanned in the exam guard’s palm and a list of all present students is created. 6) Then the exam guard gives the AID to each student. The student must write this AID instead of name and social security number on each page he or she completes during the exam. 7) When the student leaves the examination room he or she
gets the student identity card scanned once again. 8) When the examination is finished the exam guard transfers the information in the palm to the TAL-system. 9) Within 24 hours the teacher can create a web-based marking protocol based on this information. 10) When the teacher has completed the marking process he or she or a course administrator will register the grades for each AID in the e-service (which in turn transfers the data to the Ladok-system). 11) Finally, the teacher can print a list of the results where the students’ names are visible; i.e., once the written exam is marked and the results have been transferred to the Ladok-system by the e-service the identity of the student is revealed.

3 DIFFERENT STAKEHOLDERS’ EXPECTATIONS

We have identified five stakeholder groups in the studied case; students, teachers, course administrators, exam guards, and the university. In reference to the traditional view on e-government, the university represents the government agency in the case description below; i.e., the university management as well as project management. Each group expresses their particular expectations regarding the e-service under development. Below we present expectations and fears of each stakeholder group.

3.1 Students

The origin of this public e-service was students’ fear of not being treated in a fair way by the teachers when written exams are marked. Students claimed that they sometimes felt they were punished (by being given lower grades) if they expressed a critical attitude towards the course or the teacher. The students said that they would find it easier to criticize a teacher during a course if they felt that there was no risk for being punished during the examination. The students also stressed fairness as an important feature. It was not just the risk of being marked lower than expected that was seen as a problem, but also to get a higher mark than deserved. The students also saw a risk of being discriminated based on ethnicity or sex. The students we interviewed stated that the e-service, which ensures anonymity during examination, would increase their feeling of being secure from that kind of discrimination. In the interviews they emphasized the importance of perceived security. They made an important distinction between actual and perceived security by saying that maybe the marking process is actually done in a fair way already, but you must also perceive it as legally trustworthy. The e-service was seen as a means to perceive security in the process. The only fear the students mentioned regarding the e-service was that the timetable would not be met and doubts about whether the e-service would function as expected from the beginning. Altogether this stakeholder group was predominantly positive towards the e-service and the re-designed examination process.

3.2 Teachers

Some interviewed teachers did agree with the students’ opinion that this e-service could result in increased legal security – not only for the students, but also for themselves. With the e-service the examination process will become traceable and some of the interviewed teachers saw the traceability as a protection against future discrimination charges. On the other hand, they also expressed a fear to be forced into a certain pedagogical frame if technology (the e-service) was allowed to govern the examination process. The teachers were also afraid that a standardized process would result in decreased freedom of action for each individual teacher regarding their pedagogical design of courses. Another opinion was that this e-service could be seen as a sign of mistrust from the university. The teachers who stated this felt that their competence as fair examiners was questioned by introducing this e-service. One teacher went as far as stating that he would stop giving written exams in his courses due to this re-designed procedure. He objected to the idea that student anonymity would be of any good. Instead, he argued that he could only do a fair examination if he knew who the student was, e.g., in order to observe improvements in cases when a student failed the examination several times. The interviewed teachers were also afraid that this re-designed process would increase their workload and result in technical errors that would lead to chaotic situations and decreased legal justice. On the other hand, we also interviewed teachers who did not see student anonymity as an important issue, but
were positive towards the e-service as a tool for more efficient handling of the examination process (particularly for examinations with a large number of students).

3.3 Course Administrators

The course administrators that we interviewed were the ones with least understanding of the reasons behind the decision to develop the e-service. They stated that there had not been any problems concerning the marking process of written exams. They defended the integrity of “their” teachers as being fair examiners that did not discriminate any students. The administrators did not understand why the examination process could not continue as before. This group had not heard anything about the demands for student anonymity from the students’ union. Depending on how the examination process was performed at the course administrator’s department prior to the e-service development, they expected either an increased or a decreased workload due to the e-service. Administrators who thought that the teachers at their department would not learn how to use the web-based interface for result reporting expected their workload to increase, as they assumed that they would have to do this task instead. At the departments with a huge amount of written exams (e.g., the department of mathematics) the administrators were afraid that the automated routine for result reporting would lead to redundancy among administrators. They feared that this in worst case could lead to unemployment. Administrators who work at the students’ office are responsible for handing out the exams to the students after the marking is done. This group of administrators expected the process to become more stressful as the re-designed process will result in another way of sorting the written exams at the students’ office. The sorting will be based on dates and codes instead of names. This fear made this group of administrators very negative towards the e-service and the changed routines.

3.4 Exam Guards

The exam guards are a stakeholder group that is contracted by the university and temporarily hired for each examination. This group mainly consists of retired women who want to earn some extra money by working a few hours each month. Their responsibility is to supervise the students during the examination event in order to prevent cheating or the use of prohibited aid. It is this stakeholder group that faces the largest changes in their working process due to the e-service. Their work today is totally paper-based and the re-designed process implies that they will use a palm as their main working device. This group expressed fears that they will not be able to learn the new process and how to use the new technology. The degree of IT maturity is low in this group although it differs across individuals. The exam guards were afraid that the re-designed process will lead to increased time pressure during the examination, as the registration of each student in the palm will take some time. Their greatest fear concerned how they are supposed to solve technical problems that might occur, when they are alone in the classroom with a lot of students eager to start their examination. They were not sure what kind of help they can get and from whom. The exam guards also mentioned a positive expectation as they hope to be able to influence the examination process when the e-service is implemented. For example, they hope that the re-designed process will make it easier for them to refuse students who lack a valid student identity card to take part in the examination. These students are not allowed to do the examination, but now they are often difficult to reject when they are begging to participate. In the future process the student identity card must be scanned in the palm in order to get the AID, which means that no students can be permitted to participate if they lack this card.

3.5 The University

The e-service development was initiated by a vice-chancellor decision made after severe pressure from the students’ union. The main motive for the development project, articulated by the university, was to achieve increased legal examination security for students and teachers. Students should not risk to be favoured or discriminated and teachers should not risk to be accused of discrimination. Another expectation that the university has articulated is that the examination process will be more...
standardized thanks to the e-service. Today, the administrative process regarding written exams differs between departments. There are, e.g., many special solutions to get yet another opportunity to pass the exam, to get bonus points, etc. This implies that the regulations surrounding examination are not totally comparable across the university. Such differences are negative, according to the university, and should be removed. There is also some prestige in fulfilling this project expressed by university representatives. It seems as if this university will be the first one in Sweden to develop a solution with automatic information transfer to the national Ladok-system. The fact that the university can assure student anonymity in written exams is seen as a strong argument in the marketing of this university’s courses and educations. Obviously, the university is eager to launch this e-service as quick as possible in order to achieve a so called first mover advantage.

4 DISCUSSION

4.1 Identified Stakeholders’ Perceptions of the E-service

When comparing the expressed expectations from the identified stakeholder groups in the previous section, we find many differences in how our respondents view the future e-service and the changed examination process. In table 1, below, we summarise the main characteristics of each stakeholder group. Our findings obviously indicate differences regarding the stakeholders’ general impression of the development project. We also find differences regarding the stakeholders’ need for the e-service; i.e., whether the e-service corresponds to any expressed problem or not. The stakeholders have had differing influence on the development process and they will also be object for more or less evident changes in their working routines related to the examination process. Finally, we see differences concerning the expressed expectations and fears depending on stakeholder group.

Table 1 Stakeholder groups’ main perceptions in relation to the e-service

<table>
<thead>
<tr>
<th>Stakeholder group</th>
<th>General impression</th>
<th>Need for the e-service</th>
<th>Influence on e-service development</th>
<th>Affected by process changes</th>
<th>Expressed feelings</th>

<td>Initiated the development, representatives in the reference group</td>
<td>To some extent, but no critical changes</td>
<td>Improved situation, perceived security</td>
</tr>
<tr>
<td>Teachers</td>
<td>Negative, neutral or positive</td>
<td>No expressed need</td>
<td>Representatives in the reference group</td>
<td>Some changes, expect increased workload and technical problems</td>
<td>Questioned competence, a sign of mistrust, decreased freedom of action, improved efficiency and legal justice</td>
</tr>
<tr>
<td>Administrators</td>
<td>Very negative</td>
<td>No expressed need</td>
<td>Representatives in the project and reference groups</td>
<td>Changes that can lead to either increased workload or redundancy</td>
<td>Defend teachers’ competence, unnecessary system change</td>
</tr>
<tr>
<td>Exam guards</td>
<td>Negative or positive</td>
<td>No expressed need</td>
<td>Representatives in the project and reference groups</td>
<td>Severe changes due to introduction of IT</td>
<td>Increased need of technical competence, improved authority towards students</td>
</tr>
<tr>
<td>The university</td>
<td>Very positive</td>
<td>Prestige, marketing argument, standardization, answer to students’ demands</td>
<td>Manages the e-service development (in-house) and owns the development project</td>
<td>Positive standardization of processes, improved legal justice</td>
<td>Focus on rules, standardization and student recruitment – not on internal stakeholders</td>
</tr>
</tbody>
</table>

University representatives in the project group express difficulties regarding how to inform about the project, the future e-service and the process changes. They have arranged several open meetings for all university employees in order to inform and discuss this, but very few people have participated. At many departments there has been a widespread reluctance and skepticism towards the project. Based on our empirical findings there are several conceivable reasons for this situation. First of all, there have been prior attempts to develop an e-service for student anonymity which have failed due to technical problems. There is, thus, a history of failure that dilutes the present project and works as a breeding ground for mistrust among employees. The fact that three major stakeholder groups; i.e., teachers, administrators and exam guards, do not experience any problem that the e-service is supposed to solve is another important factor. Changes that do not correspond to an experienced problem
seem to be harder to accept. In this case, the lack of problem understanding must be focused and discussed in order to gain acceptance among these stakeholder groups. This is especially important since these stakeholder groups expect rather extensive changes in their working routines. Some of these expectations are valid, but others are exaggerated by rumors and lack of information. Since this project is performed in a large public organization (the university has several thousands of employees) the different stakeholder groups are only represented by a few persons in the project group and the reference group. These representatives have been successful to a varying degree in fulfilling their anchoring and informing responsibilities. Most teachers, administrators and exam guards have not been involved or informed about the project before the e-service was to be launched.

When focusing on the positive and negative feelings towards the e-service and the re-designed process that our respondents express, we discover some interesting patterns. The students, who as a group have been the one demanding student anonymity from the very beginning, express mostly positive expectations. They stress that the e-service will result in increased trust in a fair examination process. They distinguish between actual and perceived security; i.e., the examination process might be trustworthy even today but, as long as they do not perceive it to be a hundred percent reliable, they do not trust it. This division between the concepts of actual and perceived is discussed by Oscarson (2007) in relation to information systems security. His conclusion confirms our finding as he states that a high level of actual information systems security is not enough if an actor does not perceive it to be high as well (ibid.). It is also worth noticing that the students discuss increased trust in the process. On the other hand, the students we interviewed seemed to take rather little notice of possible technical problems that the implementation of the e-service could result in. Thus, they seem to rely on technology from the beginning.

On the other hand, the three stakeholder groups which are most negative towards the e-service and process changes (teachers, administrators, and exam guards) all seem to be mistrusting the technology and their own competence in relation to handling the technology (i.e., the e-service in the mobile device as well as the Internet-based part of the e-service). The exam guards express this feeling most distinctly, which of course is natural in relation to this group’s characteristics (consisting of many retired women with little prior IT experience). The administrators fear that the technology will change the conditions for their work in a dramatic way. Either it will result in much more work to do, since the teachers will delegate new tasks to their administrator, or it will make some administrators superfluous since the process will be much more effective. Both these scenarios might come true, depending on how the departments handle the examination process today. This is a result of the standardization that the university intends to create through the e-service. This kind of uncertainty about future effects of organizational changes is inevitable in many cases and do cause worry among employees. Facts and information are, thus, always better than rumours and guessing during change processes.

Another serious finding is the statement from some teachers that they regard the e-service as a sign of mistrust in their competence as examiners. The administrators also defend the teachers’ competence and underpin this feeling of mistrust in competence. There seems to be a mix of general reluctance towards changes – “we have always examined without student anonymity and I don’t see the need for this to change now”, fear to deteriorate pedagogical ideas in the courses leading to decreased quality – “I don’t want to get forced into any pedagogical frame that does not fit my course”, and a feeling that the university wants to decrease teachers’ freedom of action – “don’t they have trust in me as a fair examiner anymore?”. What we see here are signs of changes in competence needs in different stakeholder groups. The exam guards must learn how to handle the mobile device, and the teachers and the administrators must learn to interact with the Internet-based interface. Some tasks will be conducted by another group than before, some new tasks will occur and others will disappear.

When focusing on feelings expressed by representatives for the university at an agency level, it is obvious that these experiences are mainly directed towards external issues. The main aim for developing the e-service was fulfilling the students’ demand for anonymity. The process changes necessary in order to develop the e-service also serve the purpose of reaching a more standardized
examination process at the university level. Standardization is seen as a means to assure legal justice
and high quality in the examination process. Another hope put forth is that the e-service and the re-
designed examination process will lead to a good reputation among presumptive students, which will
be positive for future student recruitment. All together, it is obvious that the university focuses on
external issues related to the e-service development, but seems to have underestimated some internal
issues such as different user groups’ experiences and fears.

Our findings provide a good example of how an aim of increased standardization, accomplished
through adjustment in processes as well as formalization of actions performed through an e-service,
has effects on different stakeholders’ perceptions and expectations. Students experience increased
confidence in a fair marking process and therefore trust for the administration (i.e. the university).
Internal user groups experience mistrust in technology, in their competence and in their employer’s
appreciation of their achievements. The university management experiences increased possibilities to
fulfill the rules of legal justice and hope for competition advantages.

4.2 Stakeholders in Public E-services

By dividing our respondents into several distinct stakeholder groups it becomes apparent that there are
differences between these groups’ apprehensions of the e-service under development. We find that
stakeholders can possess diverse characteristics in relation to each other and the studied e-service. If
we adopt the concepts of urgency, power, and legitimacy, introduced by Mitchell et al. (1997), on our
case we get the following picture: The students raised a demand for student anonymity – this demand
was urgent and as it was supported by the students’ union it was also powerful. The university decided
to meet this demand by initiating the e-service development project – the university obviously has the
power and legitimacy to do this. Since other universities were about to start similar projects this was
also seen as an urgent project to initiate. The teachers did not experience any urgency regarding this
matter and they felt their power as examiners being somewhat weakened by student anonymity as their
legitimacy as fair decision-makers could be questioned. The administrators had similar characteristics
as the teachers (low power, urgency and legitimacy), but they also feared more serious effects such as
redundancy or increased workload. The exam guards did not express any notions of high urgency
related to the e-service, but some exam guards mentioned that the e-service and the process might
strengthen their authority towards students. The e-service might, thus, give them the power to refuse
students without valid student identity cards to do the exam. The exam guards had rather low legitima-
cy in the examination process since they are only hired for a certain examination event and easy to
replace. Without using the full explanation power of Mitchell’s et al. (ibid.) typology, it is obvious that
the concepts of power, legitimacy and urgency can be fruitful to apply to e-government cases as well.

By conducting a stakeholder centered analysis of expectations and fears concerning the e-service
under development we get a more thorough view of the process. If we had adopted the traditional, and
in some sense simplified, view of a government agency and a citizen interacting through an e-service,
we would have focused on the university and the students. Both these actors are positive towards the
e-service and the changed examination process and focusing on them would, thus, not have given us
full understanding of the complexity of the situation. A more detailed analysis divided on all identified
stakeholders seems to be a suitable way to gain a broader and more critical picture of public e-service
development. This finding is also supported by Scholl’s (2001) study. Stakeholder analysis in
combination with identifying different objects for trust (technology and organization, cf. Bélanger and
Carter, 2008) is also promising in order to gain a more multifaceted view of e-services, but needs to be
further elaborated on in future studies.

There is a vital difference in this studied case compared to many other public e-services. Usually a
user can decide not to use a certain e-service. Government agencies cannot exclude other communica-
tion channels as they must assure that all citizens are able to interact with the agency regardless of
access to a certain medium or capability of using the medium due to other circumstances. This is not
the fact in the present case. The identified stakeholder groups cannot choose whether to use the e-
service or not – they have to adapt to this re-designed process and they have to use the developed IT device. The only stakeholder group that might have any potential choice is the teachers who possibly could choose to refrain from having written exams in their courses and, e.g., use other approaches, such as essays, other reports etc., in order to exam students.

5 CONCLUSIONS

This paper’s main contribution is lessons learned from applying the stakeholder concept in an e-government setting. Our intention has been to illustrate and understand different stakeholders’ perceptions of a public e-service during the development process. A crucial conclusion that can be drawn from this study is that an appropriate understanding of an e-service’s internal and external stakeholder groups is important in order to get an adequate view of the complexity often related to the use of a public e-service. There is often a stakeholder group that is supposed to be served by the e-service (c.f. Goldkuhl, 2007), but this group cannot be the only one in focus. The e-service is developed to generate public value (Grimsley and Meehan, 2007) to citizens, but given that several stakeholder groups are related to an e-service, the sometimes complex relations between these groups must also be understood. Chan et al. (2003) show how some stakeholders are dependent on an e-service while other stakeholders are necessary for the e-service. This results in complicated stakeholder relations that need to be identified, understood and managed in a proper way. Stakeholders also differ in their power, legitimacy and urgency towards the e-service (Mitchell et al., 1997). The focus on internal stakeholders without any explicit need for the e-service (i.e., no outspoken need to be served) provided us with a more nuanced and critical understanding of the studied process. A more traditional focus on the citizen (the student) and the government agency (the university) would instead have indicated a more simplified win-win situation. This is an important lesson to learn in order to understand the effects of e-government implementations.

We have identified several, sometimes conflicting, expectations concerning the studied e-service which seem to be possible to explain by a history of previous e-service failures, no correspondence between the e-service and experienced needs among several stakeholder groups, and lack of information and involvement in the development process. A superior goal for this e-service development initiative was to create a more secure and fair marking process; i.e., to improve the legal justice surrounding written exams. Obviously, the feeling of anonymity was apprehended by the students as an important factor – their trust in the administration should increase if they know that their exam would be treated anonymously. Trust in technology (the e-service), on the other hand, was discussed by other stakeholder groups but mainly in terms of mistrust.

This study provides us with some illustrations of how e-service development can create different expectations within the stakeholder groups. The intention has been to add further understanding to the discussion of different stakeholders in e-government. Increased understanding of this complexity can help us develop public e-services that balance different stakeholders’ needs in a successful way. Our intention has not been to give any statistically valid explanations of the studied phenomena. The characteristics we have found in this case (e.g., the notion of need for the e-service) have to be followed up and compared to other cases. We plan to return to the case when the e-service has been used for some time, in order to evaluate whether different stakeholder groups’ expectations and fears have been realized or not. This will add a longitudinal dimension to our analysis and to further results. Another important theme for further studies is trust (in technology and organization); in the analysis above we have not highlighted trust, only used the concept as one aspect of a stakeholder analysis.

Abstract

This research-in-progress paper investigates the impact of social structures in virtual worlds (VWs) on the diffusion of innovations within them. Research has illustrated that innovation diffusion takes place within virtual worlds. VWs facilitate the emergence of purposeful communities which support the (often real-world) activities of their members including the development and adoption of innovations. Thus, VWs alter the social structures in which their users are embedded and the manner in which they communicate, both of which are thought to influence the diffusion of technical innovations amongst individuals. Though technical innovation is at the heart of Information Systems (IS) research, empirical research investigating innovation in the networked age is in its infancy. Thus, this paper presents a framework of propositions in relation to the impact of social structures on the diffusion of innovations within VWs and proposes the use of social network analysis to investigate these propositions.

Keywords: Virtual worlds, innovation, diffusion, social network analysis

1 INTRODUCTION

The Internet is on the cusp of an evolutionary leap and today’s virtual worlds (VWs) are seen as a sign of things to come (Driver 2008). Despite multidisciplinary interest in them, research investigating VWs is in its infancy. A review of extant literature reveals considerable conceptual imprecision surrounding VWs (Boellstorff 2008; Fetscherin, Lattemann et al. 2008); several terms are used to describe them, including virtual environment, synthetic world, and Web 3D; but concise definitions are “hard to find” (Boellstorff 2008, p. 17). As a result, the task of understanding VWs and innovation processes within them is difficult. Nevertheless, the need to do so is clear: approximately nineteen million people now participate in VWs (Jackson and Favier 2008) and more than US$200m is spent annually on virtual goods (Castronova 2005). In Second Life (SL®) alone, residents spent more than 28 million cumulative hours inworld in February 2008, created 200 terabytes of digital goods, with 50,000 businesses claiming profits (CPA 2008). Well known examples of innovative projects in Second Life include the artificial ecosystem Svarga, the audiovisual sculptures at Ramonia and Studio Wikitecture.

This study focuses on the diffusion of innovations in virtual worlds. The importance of innovation for organizational competitiveness is well recognized (Chesbrough 2003) and articulated (e.g. Tushman and Anderson 1986; Henderson and Clark 1990). Innovation diffusion is concerned with the communication of an innovation amongst members of a social system (Rogers 2003, p. 6). The formation, development and operation of VW communities are
influenced by their spatial and graphical properties, functional capabilities, communications and social networking mechanisms. Social Network Analysis (SNA) is deemed an appropriate vehicle to investigate innovation diffusion in VWs. The application of network models represents a “promising avenue” for innovation research (Cowan 2005). Rogers (2003, p. 361) suggests that adopting relationships as the unit of analysis represents the first step in overcoming the individual blame bias within extant diffusion studies and calls for study of the “network turbocharger effects”, defined as “the additional variance… explained by network variables beyond the direct effect of the individual level variables”. SNA recognizes the embeddedness of actors in social systems and holds that “the structure of relations among actors and the location of individual actors in the network have important behavioural, perceptual, and attitudinal consequences” (Knoke and Kuklinski 1982, p. 13). It has already been successfully used to study innovation adoption and diffusion (e.g. Coleman, Katz et al. 1966; Abrahamson and Rosenkopf 1997).

The study makes several contributions to IS research. It contributes a VW definition, derived from a review and extension of existing literature. It addresses a phenomenon (i.e. virtual worlds) of multidisciplinary interest and cross domain potential including simulation and communication (The New Media Consortium 2007; Atlas 2008); education and research (Bailenson 2002; Dickey 2005; Boulos, Hetherington et al. 2007; Duffy 2008); marketing and commerce (Castronova 2005; Hemp 2006; Driver 2008). It contributes to theory by presenting seven propositions regarding the impact of social networks on the diffusion of innovations in VWs. Once tested, these will provide insight into VWs and the diffusion of innovations. The paper is structured as follows. VWs are introduced, characterized and defined. Innovation diffusion and social network analysis are discussed in relation to virtual worlds. Finally, the paper presents a framework of propositions and concludes with a brief overview of how this study is operationalized.

2 VIRTUAL WORLDS

This section provides an overview of VWs and derives a definition of them which utilizes and extends extant literature, revealing them to be shared, interactive, immersive environments where participants can communicate, collaborate, innovate and trade. Today, it is estimated that approximately nineteen million people participate in VWs (Jackson and Favier 2008) and that more than $200 million a year is spent on virtual goods (Castronova 2005). VWs have evolved over three decades (Bartle 2004; Fetscherin, Lattemann et al. 2008) so despite their apparent novelty, they have important histories (Boellstorff 2008). Ever influenced by virtual reality and gaming, virtual worlds have become more graphically sophisticated over time (Sivan 2008), and continue to incorporate media of increasing richness. The origins of VWs can be traced to the release of MUD (multi-user DUNGEN1) in 1978. The first mainstream social world (AberMUD) was released in 1989 and MOO (1990) introduced the first fully functioning scripting language into a socially oriented world (Bartle 2004). It is commonly held that VWs progressed from text based to graphical environments, but several graphical environments were written in the 1960s (for instance PLATO (1960s); Avatar (1979); Island of Kesmai (1981)). The first three dimensional virtual world (Meridian) was released in 1996. As the Web evolved into a more explicit architecture of participation, VW users leveraged the vivid “opportunities for communication, collaboration, and cooperation” afforded by VWs (Fetscherin, Lattemann et al. 2008, p. 232) to deliver user-generated content far beyond that envisaged in Web 2.0 narratives. There was released in 2003 with its own currency (Therebucks), purchasable with ‘real’ money (Brown and Bell 2004). Second Life, released in 2003, incorporated “Linden Dollars” and was

1 DUNGEN referred to the Fortran port used to play the game and is not actually a reference to the game Dungeons and Dragons (Bartle, 2004, p. 5)
billed as a “3D online digital world imaged, created, & owned by its residents” (Second life, 2007). The extent to which these mechanisms influence creativity in VWs is an open question.

Given the multidisciplinary interest in VWs (Fetscherin, Lattemann et al. 2008), the absence of clear definitions and an agreed upon terminology is to be expected. What follows is the articulation of a new definition of VWs as shared, interactive, immersive environments where participants can communicate, collaborate, innovate and trade. VWs are environments and are referred to as places (e.g. Curtis 1992; Bartle 2004; Boellstorff 2008); spaces; environments (e.g. Bartle 2004; Mennecke, Roche et al. 2007); and simulations (Bartle 2004) of real or imaginary environments (Hagsand 1996). Bartle (2004, p. 475) argues that VWs are “a set of locations… People go to places, do things there, and then they go home”. In other words, they are navigable (Hagsand 1996). In defining them as spaces, authors emphasize that these locations are not contiguously bound. Virtual world spaces can therefore include: (1) core public space (2) private space (private access but connected to public core) (3) private spaces (disconnected from public core) requiring teleportation (4) multi-scale spaces that break the rules of realism (e.g. a house inside a grandfather clock) (Dodge and Kitchin cited in Bartle 2004). VWs have their own “rules that enable players to effect changes to them”— in other words, they have their own “physics” (Bartle 2004, p. 3). A common misconception of VWs is that they are media: but as (Bartle 2004, p. 475) points out, a “medium is a channel open for communication with a (large) number of individuals. Although most VWs do contain channels, they are not themselves channels.

VWs are shared (Hagsand 1996), multi-user (Hagsand 1996; Bartle 2004), massively multiplayer (Mennecke, Roche et al. 2007) or distributed (Hagsand 1996). Their users are referred to as users (Curtis 1992; Hagsand 1996) but also as inhabitants (Bartle 2004), residents and participants (Mennecke, Roche et al. 2007). Implicit in the assertion that VWs are shared is the notion that the worlds exist independently of a particular user’s presence within them. In other words, the worlds persist over time. Authors, seeking to emphasize the manner in which virtual world interactions are mediated by avatars, sometimes refer to ‘characters or ‘players’ (Bartle 2004). This has led to the confusion of VWs and online games. VWs contain games. However, just as “the Pasadena Rose Bowl is a stadium, not a game” (Bartle 2004, pp. 473-475), VWs are environments distinguishable from the activities taking place within them.

VWs are interactive (Hagsand 1996; Cagnina and Poian 2007). Users are represented “inworld” as intentionally (and often lavishly) crafted characters known as ‘avatars’. Participants interact with each other (Cagnina and Poian 2007) and engage in “socialization, entertainment, education, and commerce” (Menneke, Roche et al 2007). They also interact with the environment itself (Hagsand 1996; Bartle 2004; Cagnina and Poian 2007; Mennecke, Roche et al. 2007); building objects and embedding new functionalities. This functionality has enabled a new departure in user-generated content and has evolved to varying degrees in different VWs. Increasingly; people interact with ‘bots’ which have been built by other people within virtual worlds. Interactivity contributes to what has been termed social presence, defined as the degree of salience of another person in an interaction and the consequent salience of the interpersonal relationship (Short, Williams et al. 1976). Thus, key facets of VWs include “interconnection… social relationship… [and] network externalities” (Cagnina and Poian 2007).

VWs are immersive, where immersion is defined as that sense of “being there” or more formally as “a psychological state in which the individual perceives himself or herself to be enveloped by, included in, and interacting with an environment that provides a continuous stream of stimuli” (Bailenson 2002). In defining VWs as immersive environments, it is necessary to consider the relationship between VWs and virtual reality. Contemporary three dimensional VWs in particular, have been associated with the concept of Virtual Reality (VR) (Boellstorff 2008) and there is considerable overlap between descriptions of the two. For instance, VWs feature “immersion, interaction and imagination” (Zhu, Xiang et al. 2007) and McLellan (2003) defines
virtual reality as “interactive and evoking a feeling of immersion.” VR refers to (typically quite expensive) technological hardware, which is used to allow one to experience “worlds that never were and can never be” (Brooks in Biocca and Levy 1995, p. 6). VR technologies include (1) visual displays (2) graphics rendering systems (3) tracking systems and (4) database construction and maintenance systems (Brooks 1999, p. 16). The focus of VR research has traditionally been the technology itself and in increasing its “immersive and involving properties” rather than on the experience it creates (Steuer in Biocca and Levy 1995, p. 33). The immersion traditionally sought in the development of VR technologies is thus based on perceptual subterfuge or sensory realism leading to a “perceptually based illusion of non-mediation” (Lombard and Ditton 1997) within simulated environments. The immersiveness of these technologies has been defined as the “degree to which... [it] submerges the perceptual system of the user in computer-generated stimuli” (Biocca and Delaney in Biocca and Levy, p. 57). VWs are also immersive. But the technologies used are inexpensive and typically rely on desktop interfaces. The emphasis is less on the technologies used than on the worlds themselves (Bartle 2004; Boellstorff 2008, p. 5) and they “approximate aspects of reality – enough for the purposes of immersion” (Bartle 2004, p. 475). See Table 1 below for a list of prominent virtual worlds.

Table 1. Prominent virtual worlds listed in reverse chronological order

Second Life (SL) is seen as the de facto virtual world for commerce (Kim, Lyons et al. 2008). SL is the brainchild of Philip Rosedale and is managed by Linden Labs. SL is inhabited by millions of users and described as a user-generated content platform (Au 2008). Linden Labs describe it as “an online, 3D virtual world imagined and created by its residents” (Linden Research Inc 2008). Second Life is of particular interest because it embraces “strong economic and legal connections to the real world” in order to maximize the quality and quantity of its user-created content (Ondrejka 2005). Its key feature is the capability of its users to “collectively create” (Au 2008). Second Life residents have built replicas of real world locations, held “inworld” art openings, music concerts, and orchestral performances, and increasingly are using the medium to hold meetings, conferences, and teaching seminars (Jennings et al 2007) using a combination of built in text and voice chat features and streaming media. The infrastructure in Second Life is designed to facilitate a virtual economy, incorporating a Linden Dollar currency system and supports the ability to set objects as “for sale” or as replicable on demand (Jennings et al 2007). The steadily increasing volume of virtual goods and services sold in SL drove mainstream media coverage of SL and prompted the entry of a number of real world businesses into it in 2006 (Jennings et al
2007). Future plans to facilitate the development of its economy include the development of enterprise-safe VWs and universal avatars (which would allow users to “seamlessly travel” between worlds (IBM 2007); cf. Morgado 2009). Unresolved issues include the impact of virtual world economies on real world economies (see Castronova 2005); taxation, intellectual property rights and legal issues. The issue of digital property is also important because property rights are critical to strong markets, businesses, and innovation (Ondrejka 2005).

This study focuses on the potential impact of virtual worlds themselves on the diffusion of innovations within them. The role of virtual worlds in the creation and diffusion of innovations is of particular interest given the increased prevalence of networked innovation and the extent of collaborative and user driven innovation already manifest within them. Research is now needed to investigate the particular forms that innovation in virtual worlds takes and the processes at play as they diffuse through virtual world communities and social networks. To that end, the next section reviews literature on innovation and diffusion of innovation.

3 INNOVATION AND ITS DIFFUSION

This section provides an account of innovation and diffusion research. It introduces the concept of innovation, summarizes extant research streams, and identifies gaps in innovation studies to date. It argues for the adoption of a network perspective to investigate innovation in VWs.

Most broadly, innovation “combines factors in a new way” (Schumpeter 1939, pp. 87-88). It is commonly defined as an idea, practice, object or material artifact that is perceived as new by an individual or other unit of adoption” (e.g. West and Farr 1990; Damanpour and Gopalakrishnan 2001; Rogers 2003, p. 12). The idea is described as creative or meaningfully unique (e.g. Fang 2008); useful; original; or influential (Mayar cited in Paulus and Nijstad 2003). It generates value by solving techno-economic problems (Yayavaram and Ahuja 2008) and results in social change (Rogers 2003, p. xvi) or at least “challenges the present order” (Van de Ven, Angle et al. 2000).

Research has identified innovation types and characteristics (e.g. Zaltman 1973; Rogers 2003); and proposed innovation process models, at organizational (e.g. Utterback and Abernathy 1975), group (e.g. Osborn 1963; West in West and Farr 1990), and individual (Rogers 2003) levels. Authors have focused primarily on the factors affecting the rate of adoption of innovations (e.g. Moore and Benbasat 1991; Taylor and Todd 1995; Rogers 2003) and patterns of innovation diffusion (purposeful or passive) across space and/or time. Organizational level research dominates (King in West and Farr 1990, p. 52). However, results at an organizational level have been inconclusive and inconsistent (Wolfe 1994). Authors (e.g. West in West and Farr 1990; Paulus and Nijstad 2003) note the absence of group perspectives on innovation and creativity. Instead, emphasis is placed on individual reflection in creative accomplishments (Paulus and Nijstad 2003); individual antecedent research is typically cross-sectional; and few place facilitators or inhibitors in theoretical frameworks (King in West and Farr 1990).

The inattention to group level innovation research is understandable in light of phenomena including groupthink (premature consensus leading to suboptimal solutions) (cf. Janis 1972); diminished accountability (Karau and Williams 1993); diminished motivation (Karau and Williams 1993); deindividuation; production blocking; evaluation apprehension; and free riding in interacting groups (Diehl and Stroebe 1987). However, the role of groups in organizational life generally and innovation particularly (Paulus and Nijstad 2003) is increasingly acknowledged. In particular, evidence suggests that computer mediation enhances group performance. Dennis & Valacich (1993) find that large computer-based groups may outperform nominal groups (who tend to outperform groups) for brainstorming activities. Further, computer mediation may diminish the salience of social status variables resulting in greater and more even participation.
Thus, research bridging individual and group levels is needed. The application of network models to this task represents a “promising avenue” (Cowan 2005).

A number of criticisms have been levelled at innovation research. Innovation studies have done little to improve our understanding of innovation in decentralized contexts (Rogers 2003, p. 395). What we think of as single innovations are often the outcomes of lengthy processes involving interrelated innovations (Fagerberg, Mowery et al. 2004). Individual innovations do change (often drastically) over time (Kline and Rosenberg 1986, p. 283) as a result of reinvention, recombination (cf. Van de Ven, Angle et al. 2000; Yayavaram and Ahuja 2008), borrowing and imitation (cf. March and Simon 1958), functional interdependency (Rogers 2003, p. 162), and knowledge spillovers (Cohen and Levin 1989). But research often fails to address these issues (Rogers 2003). A focus on innovation diffusion patterns may shed light on these issues.

Innovation diffusion is defined as the process in which an innovation is communicated through certain channels over time among members of a social system (Rogers 2003, p. 5). Rogers (2003, p. xviii) argues that the diffusion of the Internet itself alters the diffusion of innovations because it changes the interpersonal networks through which information exchange about a new idea takes place. Ryan and Gross (1943) first classified adopters based on time of adoption: classifying adopters as innovators, early adopters, early majority, late majority and laggards. Innovation diffusion studies have investigated eight classes of dependent variable: the rate of adoption of innovations, the innovativeness of social system members (individuals or organizations), the role of opinion leadership, the role of communication channels, diffusion networks, the earliness of knowing about an innovation and the consequences of an innovation (Rogers 2003, pp. 98-99).

In the IS domain, the adoption of technical innovation has received attention resulting in several theories (cf. Davis 1989; Moore and Benbasat 1991; Venkatesh, Morris et al. 2003). These theories demonstrate the importance of adopter perception in adoption decisions, but are “for the most part silent on how users form initial attitudes about technologies” (Melone in Karahanna, Straub et al. 1999). The adoption of the relationship between individuals as the unit of analysis in future studies (cf. Rogers 2003, p. 361) may prove a first step in the understanding of this process. Rogers (2003, p. 361) also calls for the investigation of “network turbocharger effects”, defined as “the additional variance in a dependent variable explained by network variables beyond the direct effect of the individual level variables”. The application of network models represents a “promising avenue” for innovation research (Cowan 2005). Nonetheless, relatively few studies of innovation diffusion have adopted a social network analysis approach. Social network analysis (introduced below) represents a promising approach for the investigation of innovation diffusion in virtual worlds. The next section introduces social network analysis (SNA). It is a necessary prelude to the discussion of propositions which follows.

4 SOCIAL NETWORKS: THEORY AND ANALYSIS

Social networks are patterns of friendship, advice, communication or support which exist among members of a social system (Knoke and Kuklinski 1982; Scott 2000). A social network consists of finite set(s) of actors and relation(s) defined on them; the inclusion of relational information is a defining feature of a social network (Wasserman and Faust 1994, p. 20). Social Network Analysis (SNA) was developed to counteract the overemphasis of individual attributes in sociological research (Knoke and Kuklinski 1982). SNA holds that “the structure of relations among actors and the location of individual actors in the network have important behavioural, perceptual, and attitudinal consequences”; it explicitly recognizes the embeddedness of actors in social systems (Knoke and Kuklinski 1982, p. 13). SNA seeks to explain the behaviour of network elements in part by examining the interconnections amongst elements (Laumann 1994, p. 394). The hallmark of a network based explanation of a process is the inclusion of concepts
and information on relationships among units in a study: theoretical concepts and pertinent data are relational; structures are operationalized in terms of networks of linkages among units (Wasserman and Faust 1994, p. 6). Table 2 summarizes the social network constructs relevant to this study.

<table>

Table 2. Social Network constructs relevant to the diffusion of innovations in virtual worlds

The study of social networks has contributed to the development of social capital theories. Burt (1999) investigated the social capital of opinion leaders, whose role in the diffusion of innovations has been demonstrated by a number of empirical studies (cf. Rogers 2003). Burt (1992) examined the role of structural holes in social networks, postulating the existence of brokers who bridge those holes. Granovetter (1973) investigated the role of weak ties in the transmission of information across subgroups. Rogers (2003) developed the concept of localities and socialites and hypothesized that more cosmopolitan individuals would be comparatively more innovative. Lorrain and White’s (1971) investigation of the effect of social cohesion on individuals led to Burt’s (1987) analysis of social cohesion and equivalence in the context of social contagion.
In the next section, a number of propositions regarding the factors affecting innovation diffusion in virtual worlds are proposed and presented in the form of a theoretical framework.

5 PROPOSITIONS

This section derives seven propositions regarding the impact of virtual world social networks on the diffusion of innovations within them. These propositions are derived from a combination of virtual world observations (made in Second Life) and extant knowledge of social networks. The propositions are presented initially as a theoretical model (see figure 1 below); and pertain to three key aspects of the process and outcome of innovation diffusion, namely: (1) openness, (2) connectivity and (3) structural equivalence and social cohesion in virtual worlds. The seven propositions are organised under these three headings.

Figure 1. Preliminary model of the impact of VW social structure on the diffusion of innovations

5.1 Openness

People’s perceptions of each other shape their interactions. Indeed the weight they give each other’s opinions are often based on physical and social cues such as race, gender, age, or social standing (Weisband, Schneider et al. 1995). Previous research indicates that higher status group members dominate group activities but in computer mediated contexts, the salience of status effects is diminished, leading to greater participation (Weisband, Schneider et al. 1995). It is theorized that social status exists within VWs and is based on real world (where this information is disclosed) as well as virtual world factors (e.g. avatar appearance; newbie status).

However, the impact of social status on levels of interaction and participation is diminished in VWs leading to greater degrees of direct and equalized interactions.

Proposition 1: There are high levels of participation in the VW innovation diffusion process

Proposition 2: Easy access to detailed (even tacit) knowledge of innovations in VWs, due to direct exposure to opinion leaders and change agents results in rapid innovation diffusion

Computer mediated communication has typically been text-based and asynchronous with limited social presence (Wellman, Salaff et al. 1996). VWs facilitate high levels of presence, facilitating the formation of affective relations and personal contacts, which are thought to “provide more meaningful referents than broad social aggregates” (Gartrell 1987). Furthermore, as a result of high levels of participation in VWs, actors are more likely to have personal contact with high status members, including opinion leaders and change agents.
**Proposition 3:** High status actors, including opinion leaders, will have greater influence on individual adoption decisions in VWs than real worlds

### 5.2 Connectivity

Communication technologies within VWs are diverse and easy to employ. They support the ability to broadcast, locally or otherwise; multiplex communications (direct communications with multiple alters simultaneously using synchronous and asynchronous methods); and teleportation to spatially distant locations inworld. They therefore reduce the costs associated with maintaining a large number of relationships and may increase spatial as well as social proximity relative to the real world. This may facilitate the formation of large, (globally) dense social networks in VWs. Holes in social structure (referred to as structural holes) are thought to create competitive advantages for individuals whose networks span those holes (Burt 1992); to separate nonredundant sources of information; and to afford actors on either side of them the opportunity to increase their own social capital by brokering the flow of information across them (Burt 1999). Low costs associated with adding new linkages, greater network density and radiality as well as publicly available information on social structures in VWs decrease the likelihood that structural holes will be found in VW social networks and increase the ability of actors to circumnavigate them.

**Proposition 4:** Innovation diffusion in VWs is accelerated in VWS due to high availability of (novel) information and the relative ease of accessing it

- **Proposition 4(a):** VWs have high levels of network density and low levels of Betweenness
- **Proposition 4(b):** VW social networks have relatively short path lengths
- **Proposition 4(c):** VW actors demonstrate high levels of reachability and radiality
- **Proposition 4(d):** The existence and significance of structural holes in VWs is minimal
- **Proposition 4(e):** The existence of informational intermediaries in VWs is minimal and their ability to, and benefits associated with, controlling the flow of information in VW networks are reduced

### 5.3 Structural equivalence and social cohesion

Initial observation suggests that virtual world interactions are characterised by high levels of openness and connectivity. Empowered with social networking tools and freed from the spatial constraints of the actual world, users have greater control over the composition of their own social networks. Virtual worlds are theorized to allow structurally equivalent actors to come together to form purposeful and socially cohesive communities resulting in high levels of social contagion and homophily. Burt (1987) discusses social contagion in the context of innovation diffusion, suggesting that “something about the social structural circumstances of ego and alter makes them proximate such that ego’s evaluation of an innovation is sensitive to alter’s adoption”. Both contact and communication have been argued to make ego and alter proximate (Burt 1987). High levels of interaction lead to increased similarity (Gartrell 1987). Homophily is the principle that contact between similar people occurs at a higher rate than among dissimilar people (Rogers 2003). Prior research indicates that homophily increases the rate of innovation diffusion but inhibits the diffusion of innovations across subgroups (Rogers 2003).

**Proposition 5:** VW social networks feature high levels of innovation contagion

**Proposition 6:** VW social networks are homophilious increasing the rate of diffusion

**Proposition 7:** VW subgroup boundaries are permeable facilitating diffusion across subgroups
6 CONCLUSIONS AND FUTURE RESEARCH

The diffusion of innovations in VWs is of scientific and practical interest for several reasons. For many organisations, VWs represent significant commercial and educational opportunities. For these organizations, an understanding of how innovations are diffused within VWs is of paramount importance. In an academic context, the literature focusing on VWs is still immature. Investigation of the propositions outlined in this study will make a significant theoretical contribution in helping researchers understand diffusion of innovation within virtual worlds. Thus, insights gained from this study will be of value to researchers and practitioners alike.

The model (figure 1) is being operationalised using a mixed method approach. The first phase is underway. It involves an initial period of participant observation informing the specification of a survey questionnaire. Jorgensen (1989, p. 12) argues that participant observation is relevant where “the phenomenon is obscured from the view of outsiders”. The questionnaire is being pretested. The aim is to circulate the survey to members of Second Life’s educational community, using data collected by Jennings et al (2007). Survey data will be triangulated using qualitative data from a single case, gathered using both interviews and participant observation. The need to use a combination of methods arises from known (and significant) deviations between self-report and behavioural data in social network studies (cf. Bernard and Killworth 1977). Thus, this combination of methods is deemed appropriate to probe the above propositions and refine the model presented in figure 1.

Abstract

Electronic services delivered over the Internet are gaining importance in the business world. This area has seen an increase in scientific interest over the past years under the labels “Internet of Services” and Web-service ecosystems. The paper develops a conceptual framework of actors and their roles in an open innovation system for a networked ecosystem of Web-services. The framework illustrates how open innovation can be implemented in a Web-service ecosystem to increase innovation performance. Simultaneously this research closes a conceptual gap in current reasoning about Web-service ecosystems that neglects innovation processes. The utility of the framework is demonstrated by two case studies of Web-service ecosystems in which the framework was used to identify gaps in the implementation of open innovation processes. Our research results identify specific functions to support innovation processes.

Keywords: Open innovation, service science, service ecosystems, Internet of services, networked innovation, actors.

1 INTRODUCTION

Service innovation is a primary concern for many businesses. The importance of innovation is increasing through shorter product life cycles, increased competition, changing customer behaviour, and technological progress (Leimeister/Glauner, 2008). Consequently, the management of new service development is a prime concern for companies in the service sector. Innovation is even more important in the area of Web-based services where barriers of entry are particularly low, services can be copied easily, and technological advances are especially rapid (Menor/Tatikonda/Sampson, 2002). Moreover, through the development of service oriented architectures (SOA) and Web-services the process of new service development changes. Through the development of SOAs individual service components become more fine-grained and can be re-used which affects the way new services are developed. This becomes especially apparent when looking at the vision of Web-service ecosystems or the “Internet of Services.” These visions include repositories of services that can be re-used, recombined, and re-purposed to create new, innovative services (Janiesch/Ruggaber/Sure, 2008; Riedl et al., 2009). The emergent Internet of services promises opportunities for new service development. Notably, such an environment provides a fertile ground for open innovation in which Web-service ecosystems act as catalysts. Open innovation proposes principles for the design of innovation systems in which innovation processes are open for external collaboration with a network of customers and suppliers (Ebner/Leimeister/Krcmar, 2010; Leimeister et al., 2009). It has been shown that implementing these principles increases innovation performance (Gassmann, 2006). The inter-organisational networks that are formed by Web-service ecosystems have many links with the idea of open innovation (cf., Vanhaverbeke/Cloodt, 2006). Consequently, Web-service ecosystems provide a promising environment for the implementation of these principles and thus maximising the benefit derived from open innovation. To accomplish this it is necessary to understand the actors involved in service innovation in Web-service ecosystems and how these parties can contribute to and benefit from an open innovation system. The paper develops a conceptual framework of actors and their roles in an open innovation system for Web-service ecosystems; the framework illustrates how open innovation can be implemented in a Web-service ecosystem to increase innovation performance. The framework also shows how the current conceptual thinking about Web-service ecosystems can be evolved to incorporate findings of open innovation research. With the development of this framework it is our objective to close a conceptual gap in current thinking about Web-service ecosystems that neglects innovation processes and one-sidedly focuses on processes for service delivery. The utility of the framework is demonstrated using two case studies of Web-service ecosystems. The framework allows the identification of both white spots in open innovation networks and specific improvements in the implementation of innovation processes. The rest of the paper is structured as follows. Section 2 reviews the theoretical background of Web-service ecosystems and open innovation. Section 3 presents the collaboration framework followed by the framework’s application to two case studies in Section 4. Section 5 concludes the paper with deriving practical implications for implementing open innovation processes in Web-service ecosystems.

2 RELATED WORK

2.1 Web-Service Ecosystems

Web-services have become extremely popular in recent years and the success of Web-service-centred business models such as Amazon.com, Google, and Salesforce.com demonstrate the real commercial success of these models. Building on their wide-spread use new composite services are created that span across business boundaries in order to implement end-to-end business processes. This phenomenon of a large collection of Web services has been described as a service ecosystem and a growing interest in academic research is emerging as a consequence (Barros/Dumas/Bruza, 2005;
Barros/Dumas, 2006; Riedl et al., 2008; Riedl et al., 2009; Sawatani, 2007; Wu/Chang, 2005. Although the terms used may differ, phenomena similar to service ecosystem have been researched in other areas, for example under the label “Service Value Network”, “Business Webs” (Steiner 2006; Tapscott et al., 2000), and “Internet of Services” (e.g., Dorn et al., 2007; Zhang/Chen/Zhou, 2005; Janiesch/Ruggaber/Sure, 2008; Schrot, 2007). The composability of existing services into new and innovative value added services that implement end-to-end processes is a central attribute of these ecosystems whereby services are provided and integrated by different actors of the ecosystem which leads to a division of supply and delivery (Barros/Dumas, 2006). Although the research on Internet of services and service ecosystems is just emerging, existing theories from inter-organisational systems can be drawn on to explain these phenomena. Inter-organisational relationships of business firms are complex phenomena and as such difficult to conceptualise. However, there is a broad consensus that these systems can be best approached by factoring in economic, socio-political, structural, and technological variables (Bensaou/Venkatraman, 1996, Cunningham/Tynan, 1993). Many of these frameworks are modelled on industrial supply processes, such as in the automotive and retail industries, which have now been extended with processes for services delivered over the Internet.

This work analyses the innovation activities from the perspective of the overall ecosystem rather than from the perspective of a single organisation. Barros and Dumas (2006) and later adaptations by Riedl et al. (2008, 2009) propose that the following five actors have stakes in service ecosystems:

- **Provider** - Services are offered by service providers. These organisations provide the service implementation and offer the service by publishing a service description.
- **User/Customer** - Users request and invoke the services provided by service providers. These may be other applications (or other service providers) or the actual end-user of a service.
- **Broker** - Service brokers bring service providers and service consumers closer together. They might also integrate a service with certain delivery functions such as payment and authentication or combine other providers’ services into a new offering.
- **Mediator** - Service mediators offer translations between different service formats and other routine functions to allow service brokers to concentrate on their core competencies by eliminating the need for additional technical transformations.
- **Specialist Intermediaries** - These are providers in the more technical sense as they offer services but distinguish themselves through the nature of the service they offer. Contrary to “normal” providers they do not offer services targeted at end-users but rather offer service delivery components that are used by other providers to create marketable services. Common examples for these kinds of services are payment, authentication, or monitoring services.

Another most obvious role, though not explicitly mentioned by Barros and Dumas is that of the platform provider who builds the overall platform on which the other actors operate. The role might include providing a computing infrastructure (such as Amazon’s Elastic Compute Cloud EC2) and a set of additional services such as a service registry. The main objective of the platform provider is the overall success of the entire platform.

### 2.2 Open Innovation

Open innovation is a phenomenon that is of increasing importance to both theory and practice (Chesbrough, 2003). Three core process archetypes in open innovation have been identified: the outside-in process, the inside-out process, and the coupled process (Gassmann/Enkel, 2004). The outside-in process enriches a company’s knowledge and innovation base through the integration of external knowledge sources, particularly the knowledge sources of customers and suppliers, to increase its innovativeness. The inside-out process exploits a company’s unused inventions in different markets and a managed trade of intellectual property, e.g., through licensing. The coupled process is a

---

A combination of both the outside-in and the inside-out processes intended to maximise the benefits of both approaches.

These three archetypes are achieved through various means of perspectives on opening the innovation including: (1) globalisation of innovation, (2) outsourcing of R&D, (3) early supplier integration, (4) user innovation, and (5) external commercialisation of innovations (Gassmann, 2006). These open innovation processes lead to interfirm cooperation and development of ecosystems of networked firms sharing technology and trading intellectual property (West/Vanhaverbeke/Chesbrough, 2006; Stathel et al., 2008). The successful impact of open innovation processes has been described in several publications (see Gassmann, 2006 for an overview).

We argue that an open innovation paradigm rather than a closed innovation paradigm is necessary for successful innovation development within service ecosystems. This is due to their heavy reliance on re-use, their reliance on new business models, and knowledge leveraging as services are implemented as software (Gassmann, 2006).

The focus of open innovation, however, is a single firm that thus tries to open its own innovation process (West/Vanhaverbeke/Chesbrough, 2006). Furthermore, it says little about what other actors are involved and how they interact and collaborate regarding innovation development (West/Lakhani, 2008). Web-service ecosystems can be seen as a catalyst for open innovation and thus offer an opportunity to extend the firm-centric concept of open innovation developed by Chesbrough and others (Chesbrough, 2006; Chesbrough et al., 2006, Gassmann, 2006; Ogawa/Piller, 2006) by proposing a platform-centred interpretation.

The main aspect of service ecosystems is that of a central platform that brings all actors together. Companies try to extract ideas for service innovation from this central platform and use these ideas to create new or improve existing services. So, instead of a single organisation following the open innovation paradigm, a larger pool of companies bound together through a central platform follows the open innovation paradigm (Figure 1).

![Figure 1](image_url)  

**Figure 1**  
Platform perspective of the open innovation paradigm.

To jointly develop new products and services in an innovation network, different activities need to be performed by different type of roles. These roles characterise the types of activities involved and the type of contribution that are required. For successful innovation projects this is important to understand as the roles define the capabilities that actors need to contribute (Nambisan/Sawhney, 2008). In a general concept of “Network-centric innovation” Nambisan and Sawhney (2008) propose three types of innovation players:

- **Architect** - Architects trigger and catalyse innovation. Furthermore, they envision and direct innovation and attend to the innovation network. Architects are the central members in an innovation network; they provide the initial momentum, and define key elements of the network and the innovations to be carried out.
**Adapter** - Adapters provide specialised knowledge or support services as well as infrastructure services. Nambisan and Sawhney call them adapters because they adapt to the direction given by the architect. Adapters may possess highly specialised knowledge and expertise to solve unique problems during the innovation development.

**Agent** - Agents act as mediators by liaising interactions, mediating knowledge transfer, and mediating innovation.

In a similar approach Steiner (2005) differentiates between two roles. A shaper as an entrepreneur in a central role offering a dominant design or standard, and a multitude of other organisations, called adapters, offer complementary products to that central design.

Tapscott/Ticoll/Lowry (2000) differentiate between the following five classes of network participants:

- Customers who not only receive value but also contribute value through co-creation.
- Context providers play a leading role through facilitating the interface between customers and the other network actors and lead the choreography and value realisation in the network.
- Content providers contribute the main goods, services, or information that constitutes the intrinsic form of value.
- Commerce service providers facilitate trading processes such as financial transaction management, security and privacy, logistics and delivery.
- Infrastructure providers provide the infrastructure on which the platform operates.

While most open innovation studies have focused on the firm level (West/Vanhaverbeke/Chesbrough, 2006) the three works summarised above took a first step at analysing open innovation on an inter-organisational level. However, the resulting roles vary and need to be further conceptualised.

### 3 COLLABORATION FRAMEWORK

In order to answer the questions, who are the actors involved in such an innovation ecosystems and what are their core competencies, this section first presents a consolidated view on the network roles and second an interaction model for innovation in service ecosystems.

From the description of the network roles the considerable overlap in core competencies and contributions that are expected from each role can be identified. Table 1 consolidates the roles proposed for both service ecosystems and networked innovation and groups them under four main paradigms according to their core competencies and their contribution towards the innovation space of service ecosystems. First, the customer judges the value created for her and has requirements for new services (Berkovich et al., 2009). Second, the platform provider pushes an innovation project forward in the role of a leading player and establishes the main environment for the service innovation. Third, service providers offer various support services and specialised knowledge and follow the driver within an innovation project. Lastly, the broker engages in brokering between the providers and customers and engages in transforming ideas within the innovation space without offering services on its own.

**Table 1** Consolidation of network roles.

According to their core competencies service ecosystem actors make different contributions to the innovation space. The innovation space represents possible service designs that may be reached (c.f., Millar/Demaid/Quintas, 1997). In a setting with a central platform, such as service ecosystems described above, the platform forms a collective innovation space that defines the boundaries of trans-organisational, or networked, innovation. We argue that the contributions of the actors to the
innovation space fall into three main areas: services, ideas for new services, and feedback related to service usage. This structure relates to studies of customer roles in product development where customer contributions have been classified as a source of ideas, as a co-creator through participation in product design and development, and testing and supporting products (Nambisan, 2002). Through the heavy reliance on re-using and re-purposing existing services, the variety of existing services strongly influences future service designs. The more services are available on the platform, the larger the innovation space of potential new services becomes. Thus, contributing a new service to the ecosystem may open completely new possibilities. Concrete service ideas or requirements are the most obvious source for service innovations as they directly imply possible design options. Finally, feedback from service users about existing services is a main source for incremental service innovations (Riedl et al., 2008). In addition to contributing to the innovation space, actors may also extract from and expand on knowledge from the innovation space to create new services. Brokers play a special role as they do not necessarily contribute new ideas but transform and refine already existing ideas in the innovation space (Hargadon/Sutton, 2000).

For our collaboration model we used the consolidated roles customer, platform provider, service provider, and broker presented above. Figure 2 shows the actors and their contributions to the innovation space as described above. Table 2 shows each actor’s relationship with the innovation space.

Figure 2 Interaction model for innovation in service ecosystems.

| Customer | Contribute | Customers contribute ideas for completely new services.  
          |            | Customers contribute refinements (e.g., in the form of comments and community evaluation).  
          |            | Contribute requirements and needs (e.g., via innovation communities or lead-user studies).  
          | Co-production | Customers may become providers by developing new services on their own through end-user development (e.g., user generated mash-ups, cf. Dörner et al., 2008).  
          |            | Through providing new services, customers become service providers themselves.  
          | Feedback | Explicit - Customers provide feedback regarding existing services through rating (e.g., five-star rating) or comments left through community tools provided by the platform.  
          |            | Implicit - Through actual service usage (e.g., if a service is used frequently users value the service which allows to derive ideas for service bundling; Riedl et al. 2008). In general, actual service usage indicates user preferences and willingness to pay.  
          | Platform provider | Contribute | Overall environment (i.e., platform APIs etc.)  
          |            | Platform providers contribute ideas and comments about ideas to the innovation space.  
          | Extract | Just like a regular service provider the platform provider extracts ideas to be implemented and new services to be offered. However, the platform provider has a different evaluation function in that it is focused on overall platform success. Hence, the platform provider is likely to fund ideas that benefit the entire platform even if not economically viable on their own.  
          | Service Provider |
Contribute Services to a service repository. These services can be used as building blocks for new services thus shortening time to market and easing implementation. Service providers contribute an idea for which they seek community evaluation or refinement. They may also contribute ideas as a form of requirement communication, thus requesting a new feature and playing the role of a customer. Service providers contribute new/improved service (which might be based on ideas submitted to the platform).

Extract Service providers extract ideas from the ecosystem for implementation. Every service provider rates every idea from its own perspective and decides which idea is valuable. An idea valuable for company \( A \) might not be valuable for company \( B \). This might be due to different business models or available resources. Thus, different actors will have very different views on the same set of ideas, each evaluating ideas according to its own standards.

Brokers

| Transform | Brokers engage in transforming and refining ideas. This translates to a set of four sub-tasks: Capture good ideas, keep ideas alive, imagine new uses for old ideas, and put promising concepts to the test (Hargadon/Sutton, 2000). |

Table 2 Actor relationships with the innovation space.

4 IMPROVING ECOSYSTEM INNOVATION – EVIDENCE OF TWO CASE STUDIES

Two case studies (Yin, 2003) were conducted to explore how the application of our collaboration framework can improve ecosystem innovation. From this case application we were able to identify gaps in the implementation of open innovation processes and propose management guidelines and implications for future tool support.

Since service ecosystems are a rather new phenomenon not many manifestations can be found in business life. Our rationale was to select cases that resemble early stages of service ecosystems. We chose two cases which show early manifestations of Web-service ecosystems. The first case was selected from a state eGovernment initiative, the second from the automobile industry. Both cases involve a network of actors, are concerned with offering electronic services delivered over the Web, and provide these services in an interconnected fashion, i.e., service offerings are interconnected and involve several actors for the service delivery. The case study data was gathered through face-to-face interviews with key informants: the manager for service integration in case 1 and the director for product management in case 2. The interviews were supplemented with publicly available data gathered through extensive desktop research following the methods proposed by Yin (2003) and Miles/Huberman (1994).

4.1 Case 1: The Need for Feedback and Brokerage

The eGovernment portal consists of a central service platform operated by a central government division. This platform is the single point of entry for various agencies offering services for the general public. One of these agencies, our case study partner, offers a search service which makes internal registry data available to the public. Until the start of the eGovernment initiative, registry data was only available on paper.

The portal provider plays the role of platform provider and is used by other departments (such as our case partner) to offer their raw services. A payment service is available which can be used by other agencies to design fee-based services.

The eGovernment portal was launched with an initial set of interfaces and the Web-service-based architecture. The central division providing the eGovernment portal plays a leading role in the service ecosystem by being the main architect. Agencies interested in offering services via the portal platform independently design and develop their services in internal project teams. The project team responsible for the search service was formed after deciding to offer a free interface to their existing database through the central portal. The free search service was chosen as a starting service to gather experience
in working together with the central portal for other, more complex services. Only limited interaction between our case partner and the central division took place during the development phase and this was limited to clarifying the technical interface. In case new requirements towards the portal emerged our case study partner would engage in talks and discuss if the required features could be added to the platform. Prior to launching the new service, the central division operating the portal performed a pre-launch test which included general functionality tests as well as performance stress tests to ensure that all services offered on their platform adhered to a certain quality standard and functioned properly. The search service of our case partner provides its own feedback form for users to comment or report errors in the service. A user community or an innovation community for actual or potential service providers is not offered by the central division.

In summary this case describes the innovation process from the point of view of a service provider offering a service on a central platform.

**Actors:**
- Central government division offering a portal platform open to other agencies to offer services.
- Government agencies such as our case partner, providing services delivered through the central platform.
- End-users using the services offered by individual agencies that are delivered through the portal.

**Case Discussion**

Several observations with potential for improvement can be made in this case. First, the role of a broker could not be observed in the ecosystem. The broker role would be vital in facilitating communication between the government agencies that could potentially offer services on the platform. Thus, valuable cross-fertilising between agencies and an exchange of knowledge and experiences gained through the services already offered could be achieved. Moreover, a broker could capture good ideas from within the agencies, keep ideas alive despite employee turnover, imagine new uses for old ideas, and sponsor and test drive promising concepts.

Second, a shared innovation space or innovation community, through with users, agencies, or the platform provider can communicate and exchange ideas could be offered. Apart from the community aspect, processes could be established to systematically involve service providers in improving the platform or systematically introducing new services on the platform. A central community or other central mechanism for collecting customer feedback could be offered. This mechanism could allow users to rate their satisfaction with the services they have used. This customer feedback could be used as a valuable source for improving and redesigning existing services. The single feedback form currently in existence offers only limited help to involve users in the development of new services. Furthermore, usage information could be forwarded from the central division to the individual agencies to highlight the popularity of specific services among users.

Third, interaction between the agencies regarding the re-use of services and service components is limited although this functionality of agency interaction was considered during the design of the ecosystem. Most services that that are re-used are those provided by the platform itself, thus, potential network effects could be leveraged and potential time and resource savings could be realised.

Table 3  

| Actors’ contributions and gaps in open innovation implementation. |

4.2  Case 2: Breaking up the Strong Platform Provider

Our case study partner is a platform and service provider for the automotive industry. Their platform provides Web-based services for supply chain management in the automotive and production industries. They serve both the source side (i.e., large automotive companies) and the supply side (i.e., suppliers of automotive companies). In addition to the services directly offered by the platform provider two external service providers offer specialised services that extend the functionality of the platform. Thus, our case partner is able to offer highly sophisticated services by relying on specialised knowledge from other actors which increase customer value of the platform.

In addition to providing the general platform our case partner strongly mediates between the source and supply side. Through an established internal innovation process they continually work at improving the functionality offered by their platform through close collaboration with customers from both the source and supply side. This innovation process involves expert workshops and various expert groups with participants from both sides. After gathering and sufficiently refining service ideas a formal selection process that relies on a large set of evaluation criteria is employed and ideas promising the best outcome are selected for implementation. After implementing the new functionality on the platform our case partner closely works with their customers on integrating the new features into their processes. The case partner concentrates on its core competency as an industry insider with special knowledge and experience of understanding both large manufacturers as well as suppliers of these companies. Although they act as platform provider, most of the operation and development tasks have been outsourced and the core competency is seen in industry insight and experience and thus the ability to support and enhance client processes.

Actors:
- Central actor acting as provider of the central platform and mediator between the source and supply side.
- Customers of the central automotive supply platform, both from source and supply side, provide input regarding new features they would like to see implemented on the platform.
- Two external companies offering services that extend the functionality of the central platform.

Case Discussion

The most prominent role in this case study is that of the central platform provider acting as ecosystem leader and the very active broker role. Although all actors of our collaboration framework are present in this case study several observations in the implementation of open innovation processes can be made. Two third parties offer services on the platform: they were invited to the central platform in a strategic partner selection process and the platform is not open to other service providers. The platform provider holds a rather strict guard over their platform. Consequently, there is no shared innovation space through which service providers could interact with each other and customers to drive innovation towards new services. In particular, service ideas that have been rejected by the platform provider’s internal innovation process are not visible to others who could decide that offering a certain service might present a business opportunity. This close control of the platform may limit the potential benefits of the broker role as interaction with external service providers is restricted to selected
partners. As the amount of third party services offered on the platform is very low, the potential for designing new value-added services through the combination of existing services is also very small.

5 CONCLUSION

The framework shows the capabilities of the individual actors with regard to service innovation and how these capabilities can be exploited by the overall ecosystem to advance service innovation. This highlights the potential advantages that can arise through the constellation of various actors bound together by a single ecosystem platform. Each actor benefits from the contributions of the other participants. End-users contribute knowledge about actual market demand either in the form of ideas or through feedback provided about the services used. The platform provider contributes the overall environment of the ecosystem platform and serves as an architect to drive innovation projects by extracting and implementing ideas that are likely to benefit the whole ecosystem. Service providers contribute services that extend the innovation space and may thus allow new value added services to be composed. Conversely, they extract and implement service ideas that a provider deems valuable. Finally, brokers engage in transforming ideas already present in the innovation space.

This paper proposed a new way of thinking about an innovation ecosystem where each actor contributes to a collective innovation space rather than single companies chasing their individual innovation projects. The framework serves as an interpretative scheme to structure and analyse each actor’s contribution towards the innovation space. Therefore, we believe, this model can serve as a guide in leveraging the combined resources available in service ecosystems and can guide strategies for businesses to successfully participate in service ecosystems. Moreover, it was apparent that the different types of contributions require adequate tool support to facilitate the networked innovation. Furthermore, open innovation has severe consequences on intellectual properties and sharing thereof. Adequate mechanisms to govern the use and sharing of innovation related information are needed.

From the gaps identified in the case applications we derived several practical implications for the implementation of open innovation processes for service and platform providers:

1) Use explicit user-feedback to improve, re-design, and create new services.
2) Use implicit feedback for continuous improvement.
3) Rely on outsourcing, re-use other provider’s services to save development costs, and get to market quickly and cheaply.
4) Cleverly recombine existing services to create value added services for your customers.
5) Look for service ideas outside your current customer base by looking at how you can complement services provided by others.
6) Evaluate service ideas in the service ecosystem’s innovation space according to your competencies to find service ideas that might be profitable to you but not to others.
7) Work with brokers to get new ideas and refine ideas that are “not there yet.”
8) Provide personalized tools that support the capabilities contributed by each actor.

In order to exploit the capabilities in this network of distributed innovation it is important to “find a governance mechanism that strikes a balance between order and chaos” (Sawhney/Prandelli, 2003). Thus, it becomes apparent that across multiple innovation projects a single actor may play different roles. While driving one project as a service provider or architect, in another situation the actor may only contribute end-user feedback about the services consumed from suppliers. This leads to a certain degree of overlap in the roles across different innovation projects.

Proceedings ECIS 2009
Abstract

Dynamic Capabilities are often considered as the factor justifying the different degrees of success of organizations in turbulent environment. However Dynamic Capability development remains a difficult issue to research, with a paucity of work directly addressing this question, despite its importance. The explanation of the sources of Dynamic Capabilities would give organizations the instruments to rationally improve their chance of success and to more likely sustain their competitive advantage.

We contribute to the emerging literature on Information Technology (IT) Dynamic Capability by proposing a research framework grounded in the three sources of Dynamic Capabilities: organizational processes, firm history and firm’s assets. Our model takes into consideration also the moderating role played by environmental turbulence on Dynamic Capability and on process performance.

In this contribution we lay the theoretical and methodological groundwork and we foresee the test of the model using Data Genesis (DG) capability as the context. DG is the Dynamic Capability of (1) choosing IT to unobtrusively generate and capture data in digital form, (2) integrating the technology in the appropriate business processes, and (3) managing the digital data so captured.

Keywords: IT capability, Dynamic Capability, capability development, Data Genesis.
1 INTRODUCTION

Explaining the variation in the degree of success of business organizations is an evergreen issue in strategic management and organizational studies (Zollo & Winter, 2002). Among the different concepts developed so far, Dynamic Capabilities are one of the most recent ones, employed to justify the different degree of success, particularly in turbulent environment (Pavlou & El Sawy, 2006; Rai, Patnayakuni, & Seth, 2006; Zollo & Winter, 2002).

However Dynamic Capabilities is an unclear and troubling research construct. Dynamic Capabilities risk being a vague and tautological concept as they are the things that enable organizations to sustain competitive advantage, but they can only be inferred when looking at apparently successful organizations over sustained period of time (Priem & Butler, 2001; Zollo & Winter, 2002). Even if a certain consensus on Dynamic Capabilities is growing (Easterby-Smith & Prieto, 2008), the origin of Dynamic Capabilities over time is still a difficult issue. Testament to the difficulty associated with research on the emergence of Dynamic Capabilities is the paucity of research directly addressing this question. If Dynamic Capabilities really impact organizational success, the explanation of the sources of Dynamic Capabilities would give organizations the instruments to rationally improve their chance of success and to durably sustain their competitive advantage. As a consequence, research in this area is clearly important.

The embryonic research on this subject proposes different theories and models on the sources of Dynamic Capabilities (Montealegre, 2002; Pavlou & El Sawy, 2006; Tanriverdi, 2005; Teece, Pisano, & Shuen, 1997; Zollo & Winter, 2002), but an attempt to integrate these different propositions into a comprehensive and testable research model of the sources of Dynamic Capabilities is missing. In this article we seek to contribute to the emerging literature on the sources of Information Technology (IT) Dynamic Capability, in turbulent environments. We will attempt to integrate the different models and theories on the sources of Dynamic Capabilities into a comprehensive and testable research model of Dynamic Capability development and its antecedents: Organizational Processes, Firm history and Firm’s assets. We question the validity of this comprehensive model on a specific IT Dynamic Capability: Data Genesis.

This paper is organized as follows: §2 introduces the theoretical framework, which is based on the resource-based view theory, and formally defines the Data Genesis (DG) Dynamic Capability construct. §3 summarizes the literature on the sources of Dynamic Capability. §4 describes the research model, its variables and hypotheses. §5 presents the research methodology and §6 concludes this research in progress highlighting the future directions and achievements.

2 THEORETICAL FRAMEWORK

2.1 Resource-based view

The resource-based view has been largely introduced in Information Systems research to theoretically ground studies on competitive advantage and its sustainability at the firm level (Wade & Hulland, 2004). This perspective highlights the importance of the firm’s internal resources for the evaluation of the firm’s competitive advantage (Eisenhardt & Martin, 2000).

Resources are the “assets and capabilities that are available and useful in detecting and responding to market opportunities or threats” (Wade & Hulland, 2004). More specifically, “assets are defined as anything the firm can use in its processes for creating, producing, and/or offering its products (and/or services) to the market, whereas capabilities are repeatable patterns of actions in the use of assets to create, produce, and/or offer products (and/or services) to the market” (Sanchez, Heene, & Thomas, 1996; Wade & Hulland, 2004). We label the products and/or services offered to the market by an
organization a bundle (Kohli & Bharadway, 2007) of products/services, in line with the cross-
disciplinary service science movement (Chesbrough & Spohrer, 2006).

The resources that are valuable and rare temporary provide the competitive advantage. The extent to
which these resources are also inimitable, immobile and not substitutable between firms explains the
sustainability over time of the competitive advantage (Barney, 1991).

The attention paid by this perspective to the internal resources of the firm has the weakness of
excluding the socio-economic environment outside the firm. In fact, the environmental conditions
could change and make the firm’s resources far less valuable (Leonard-Barton, 1992). Hence the
resource-based view has been extended to better explain firm performance in turbulent environments
(Eisenhardt & Martin, 2000).

2.2 Dynamic Capabilities

In turbulent environments, organisations need to constantly match or create market changes and
Dynamic Capabilities are “the firm’s processes that use resources – specifically the processes to
integrate, reconfigure, gain and release resources – to match and even create market change”
(Eisenhardt & Martin, 2000). Hence, Dynamic Capabilities have the potential (Prieto & Easterby-
Smith, 2006) to create, to evolve and to recombine internal existing resources to adapt to turbulent
environments (Teece, Pisano, & Shuen, 1997). This adaptability is especially required in fast-paced
technological environments (Banker, Bardhan, Hsihui, & Shu, 2006; Teece, Pisano, & Shuen, 1997;
Zahra, Sapienza, & Davidsson, 2006), as it has been theorized that adaptability can lead to improved
customer value (Sambamurthy, Bharadwaj, & Grover, 2003; Wheeler, 2002).

The Resource-based View foresees a direct relationship between Dynamic Capabilities and the firm’s
process performance (Ray, Barney, & Muhanna, 2004; Ray, Muhanna, & Barney, 2005; Zahra,
Sapienza, & Davidsson, 2006). However the process outperformance by one firm in competing
environments does not automatically imply any firm’s sustained competitive advantage due to the
several mediating and moderating variables interposing between process outperformance and firm’s
sustainable competitive advantage (Ray, Muhanna, & Barney, 2005). The acknowledgement of this
interposition between single process outperformance and sustained competitive advantage stimulates
the study Dynamic Capabilities and its outputs, without employing organizational global performance
as dependent variable.

Hence, in today’s competitive environment characterized by increasing IT intensity (McAfee &
Brynjolfsson, 2008) organizations should be capable of integrating new or established IT. A number of
Dynamic Capabilities have been documented in the literature, in this study we focus on an emerging
Dynamic Capability, Data Genesis (DG) (Piccoli & Watson, 2008).

2.3 Data Genesis as a Dynamic Capability

We define Data Genesis capability as the three-fold process of:

• Choosing Information Technology (IT) (Wheeler, 2002; Williams, 2003) to unobtrusively
  generate and capture data in digital form. Such IT may be emerging IT (Wheeler, 2002): a new
  technology not commercially viable (e.g., multi-touch displays). Otherwise, such IT may be
  enabling IT (Wheeler, 2002): an established technology used in an innovative application by the
  firm (e.g., RFID in gaming chips to track table play);
• Integrating the IT in the appropriate business processes;
• Managing the digital data so produced in order to continuously deliver accessible, accurate,
  complete and current digital data.

Data Genesis is a Dynamic Capability as it is the process that uses IT resources to gain and release
data and as it has the potential to create, to evolve and to recombine internal existing IT and data to
adapt to turbulent environments. This potential is based on the degree of Reconfigurability (Pavlou &
El Sawy, 2006) of the ineffective Data Genesis process into more promising one that better match the environment, better, faster, and cheaper than the competition (Eisenhardt & Martin, 2000).

Note that the DG capability is concerned with the unobtrusively generation and capture of digital data and its management, not with its actual use in, for example, analytical processes. In other words, DG is a prerequisite to being able to compete on analytics, thanks to the provision of accessible, accurate, complete and current digital data. The outperformance in the digital data accessibility, accuracy, completeness and currency are the valuable outcomes of Data Genesis.

Exemplars of DG capability are emerging, such as Harrah’s corporation: this company systematically integrates IT, such as computerized slot machines or RFID chips, to gain unobtrusively valuable digital data on customers’ behaviour at the Harrah’s casinos and it exploits these pieces of data to profile and reward customers (DeLong & Vijayaraghavan, 2003; Piccoli & Watson, 2008). Note that the unobtrusive generation of the data in the above example pertains to DG capability while the exploitation is within the scope of other capabilities (e.g., data analysis).

3 SOURCES OF DYNAMIC CAPABILITY

The relevance of DG capability in fast-paced IT environments motivates its choice as the empirical Dynamic Capability on which we build the model of the sources of Dynamic Capability. If several studies have investigated Dynamic Capabilities and their effects on business performance, there is not an equivalent attention to the sources of Dynamic Capabilities (Montealegre, 2002; Pavlou & El Sawy, 2006; Tanriverdi, 2005; Teece, Pisano, & Shuen, 1997; Zahra, Sapienza, & Davidsson, 2006; Zollo & Winter, 2002) and an integrative model gathering all these sources is missing.

By the consequence, we propose an integrative research model of the sources of Dynamic Capability. Our starting point to understanding the sources of Data Genesis Capability are the three sources of Dynamic Capabilities in rapid technological change environments (Teece, Pisano, & Shuen, 1997):

- The organizational processes of sensing, coordination, integration, learning.
- The firm’s assets, which define the firm-specific strategic position,
- The firm history, which accounts for the path dependent nature of capabilities.

Leveraging these theoretical sources of Dynamic Capabilities, a first case study empirically highlighted the set of actions to develop capabilities (Montealegre, 2002). The organizational processes of sensing, coordination, integration and learning emerged as important in capability development. By contrast, the firm’s assets and the firm history played a marginal supporting role.

Others have theorized that the learning mechanisms would be the main independent variable influencing the development of the Dynamic Capabilities (Zollo & Winter, 2002). Hence theoretically, learning would be the main organizational process for the development of Dynamic Capabilities. The other organizational processes of sensing, coordination and integration as well as the firm’s assets and history have been neglected.

In 2005, firm’s assets and organisational processes were combined in a model of Dynamic Capability development (Tanriverdi, 2005). In particular capability development depended on the IT infrastructure and IT management processes. IT infrastructure is one kind of firm’s assets, while IT management processes are a portion of the organisational processes of sensing, coordination, integration and learning. Nevertheless, this integration in one single model of Dynamic Capability development of these two different sources of Dynamic Capability still excluded firm history as the third source of Dynamic Capability.

An additional theoretical contribution reaffirmed the role of the organizational processes and of the environmental turbulence in the dynamic capability development (Zahra, Sapienza, & Davidsson, 2006). The processes of coordination, selection and combination were proposed as the main organizational processes that enable the firm to build dynamic capabilities. The theoretical model
proposed also that the environmental turbulence decreases the relative performance of the existing capabilities and hence stimulates the development of new dynamic capabilities in replacement of the obsolescing ones. The others sources of dynamic capabilities, as such firm history and firm’s assets, had no impact on dynamic capability development.

The last work proposes and measures the impact of IT leveraging competence on the development of Dynamic Capabilities (Pavlou & El Sawy, 2006). IT leveraging competence is proposed as the only independent variable, is conceived as the ability to effectively use IT functionalities and it can be classified among the firm’s assets. The other firm’s assets and the firm history were excluded from this study. On the contrary, the organizational processes of coordination, integration and learning played the role of mediators between IT leveraging competence and Dynamic Capabilities. Finally, the environmental turbulence moderated the relationships between all these variables.

Even if at different extent, all the three sources of Dynamic Capabilities have been studied separately by different authors. The lack of a comprehensive research model including all the three kinds of sources of Dynamic Capability appears as the main research gap. Therefore, our main contribution is the design of a model which combines the three sources of Dynamic Capabilities in a comprehensive research model of the sources of Dynamic Capability.

4 RESEARCH MODEL

Our research model integrates and organizes previous literature around the three-fold classification of the sources of Dynamic Capabilities: organizational processes, firm’s assets and firm history (Teece, Pisano, & Shuen, 1997). We posit that these processes are responsible for the emergence of DG capability. The outcome variables, Digital Data Accessibility, Accuracy, Completeness and Currency, dependent on DG capability and the variable Environmental Turbulence moderates some relationships. The specification of our hypothesized relationships completes the presentation of the variables (Figure 1).

4.1 Organizational Processes

The Organizational Processes of Sensing, Learning, Coordinating, and Integrating play a pivotal role in developing Dynamic Capabilities when the opportunity or need arise (Kogut & Zander, 1996; Maritan, 2007; Pavlou & El Sawy, 2006; Zahra, Sapienza, & Davidsson, 2006). The Sensing process is related to the understanding of the environment, the identification of market needs and opportunities. The Learning process determines the building of new thinking and the generation of new knowledge to enhance existing resources. The Coordinating process is about the allocation of resources, the assignment of tasks and the synchronization of the activities. The Integrating process concerns the implementation of the new configurations of operational competencies by developing the required patterns of interaction. So:

\( H1: \) the effectiveness of the Sensing has a positive and direct impact on DG capability.

\( H2: \) the effectiveness of the Learning has a positive and direct impact on DG capability.

\( H3: \) the effectiveness of the Coordinating has a positive and direct impact on DG capability.

\( H4: \) the effectiveness of the Integrating has a positive and direct impact on DG capability.

4.2 Firm’s assets

Different kind of assets can positively influence the possibility to develop new capabilities: technological assets, complementary assets, financial assets, reputational assets, structural assets, institutional assets, market structure assets (Teece, Pisano, & Shuen, 1997). The main kind of asset influencing the development of Data Genesis capability are IT assets as on IT assets the IT
Capabilities, and specifically Data Genesis, are built (Tanriverdi, 2005). For example, TER Rhone-Alpes, a French regional railway company chose RFID cards and readers to generate and capture digital data about the passengers’ flows on its trains. Passengers load on this RFID card their train passes and they have to validate the card at a RFID card reader, before getting on any train. These digital data are then used to adapt the frequency and the capacity of the trains based on their actual use, improving, by one hand, the passenger satisfaction and, by the other hand, the optimization of the train fleet.

IT assets are a two-fold category composed of: IT Infrastructure and Information Repositories (King, Grover, & Hufnagel, 1989; Piccoli & Ives, 2005). IT Infrastructure is “the base foundation of the IT portfolio (including both technical and human assets), shared through the firm in the form of reliable services” (Broadbent, Weill, & St. Clair, 1999) or functionalities (Fink & Neumann, 2007; Pavlou & El Sawy, 2006; Zhu & Kraemer, 2005). The IT Infrastructure varies in reach, and range (Piccoli & Ives, 2005). The reach of the IT Infrastructure measures the extent of the connectivity both within and outside of the firm, while the range of the IT Infrastructure sizes the scope of services that it can support. As reach and range of the IT Infrastructure increase, the IT Infrastructure ability to support capability development increases as well. The reach and range of the existing IT Infrastructure influence the possibility and cost of IT integration for gaining unobtrusively valuable digital data hence impacting on the development of DG capability. TER Rhone-Alpes has progressively extended the reach of its IT infrastructure to deploy RFID card readers from the principal traffic railways to the secondary railways, in order to capture digital data on passenger flows.

The second category of IT assets gathers the Information Repositories. An Information Repository is “a collection of logically related data, organized in a structured form, that is accessible and usable for decision-making purposes” (Piccoli & Ives, 2005). As capabilities relying on organized data need Information Repositories to develop (Piccoli & Ives, 2005), also DG capability needs Information Repositories to develop. Given that DG capability includes the use and management of digital data, DG capability needs Information Repositories to organize and access the gained digital data. A lack of Information Repositories would restrain the organization in data availability and by consequence impeding the development of DG capability. TER Rhone-Alpes exploited its information repositories on the sales of paper-based ticket and passes to establish the first kinds of train passes to transfer on the RFID card and the first train stations to deserve with the RFID readers.

Finally, IT Infrastructure and Information Repositories are subjected to asset stock accumulation dynamics (Ingemar & Cool, 1989; Piccoli & Ives, 2005): the IT Infrastructure and the Information Repositories can be accumulated by the organization into IT asset stock over time. The reach and the range of IT Infrastructure as well as the volume of Information Repositories can increase, extending the pre-existing IT asset stock. This IT asset stock accumulation influences, in general, Dynamic Capability development as well as DG capability in particular. An extended stock of IT assets facilitates the development of DG capability. Therefore, we respectively hypothesise that:

\( H5: \) the stock of IT Infrastructure has a positive and direct impact on DG capability.

\( H6: \) the stock of Information Repositories has a positive and direct impact on DG capability.

4.3 Firm history

Firm history explains the existing firm’s position and the same time it influences the firm’s opportunities ahead, framing the path dependencies of organizations (Teece, Pisano, & Shuen, 1997). Present capabilities depend on previous ones and they constrain new ones, because learning tend to be local and related to existing processes (Teece, Pisano, & Shuen, 1997; Zahra, Sapienza, & Davidsson, 2006). By consequence, the development of DG capability depends on historically existing Dynamic Capabilities closely related to DG, as such: IT capability and Information capability.

IT capability is the multi-dimensional and enterprise-wide capability to leverage IT (Bharadwaj, Sambamurthy, & Zmud, 1999). The historical capacity to leverage IT will favours the recognition by
the firm’s IT personnel of the potential of emerging/enabling IT to generate and capture digital data and the good relationships between IT personnel and line management in integrating such IT within appropriate business processes is critical. The lack of IT capability would make unclear the choice of the IT to integrate and would cause the eventual IT integration ineffective. By consequence, digital data would not be accessible or would be of poor quality, impeding any effective use (Culnan, 1983; O’Reilly, 1982; Zimmer, Henry, & Butler, 2007).

Harrah’s IT managers and customer service managers realized very early on that a modern slot machine is a digital computer and they worked together to develop a customer relationship management information system which collect over time digital data on the customers’ behaviours at slot machines (DeLong & Vijayaraghavan, 2003; Piccoli & Watson, 2008).

The concept of Information capability is rooted in Information Theory (Shannon & Warren, 1949) and Information Capability is proposed as the capacity of disseminating (Mathews & Healy, 2007), or applying and managing (Yoon, 2005), or processing (Lin, 2005) information. The historical capacity to manage information will enable the firm to manage digital data and therefore take advantage of its ability to unobtrusively generate the data in digital form. Conversely, the inability to manage digital data would negate the value of data capture and integration.

Harrah’s corporation preferred digital data on guest preferences and transactions coming from slot machines than the unstructured information coming from customer service staff. The same firm processes the collected customer data, from slot machines, to profile gamblers and it disseminates these profiles, throughout the different casinos (DeLong & Vijayaraghavan, 2003; Piccoli & Watson, 2008).

So, we hypothesize that:

**H7: IT capability has a positive and direct impact on DG capability.**

**H8: Information capability has a positive and direct impact on DG capability.**

### 4.4 Digital Data Accessibility, Accuracy, Completeness and Currency

The performance of an organization in Data Genesis capability does not automatically imply any sustained competitive advantage due to the several mediating and moderating variables interposing between Data Genesis outperformance and organizational sustainable competitive advantage (Ray, Muhanna, & Barney, 2005). Data Genesis capability aims at outputting accessible, accurate, complete and current digital data. The use in, for example, analytical processes of the gained digital data will depend on their accessibility, accuracy, completeness and currency (Culnan, 1983; O’Reilly, 1982; Zimmer, Henry, & Butler, 2007).

Information accessibility is the extent to which an individual perceives that any particular source is available for use (Zimmer, Henry, & Butler, 2007). Information accessibility is the most important driver for information source selection for use, with people consistently choosing and using lower-quality sources that are more accessible over higher-quality sources that are less accessible (Culnan, 1983; O’Reilly, 1982; Zimmer, Henry, & Butler, 2007).

Nevertheless, information quality is important because when sources are equally accessible, individuals will consistently choose and use sources that are perceived of higher quality (Hirsch & Dinkelacker, 2004; O’Reilly, 1982). Information Accuracy, Completeness and Currency are dimensions of the quality of the information retrieved from an information system (DeLone & McLean, 1992; Nelson, Todd, & Wixom, 2005). Accuracy refers to the degree to which information is correct, unambiguous, meaningful, believable, and consistent. Completeness is about the degree to which all possible states relevant to the user population are represented in the stored information. Currency concerns the degree to which information is up-to-date and precisely reflecting the current state of the world that it represents.
Harrah’s corporation appreciates the quality and accessibility of the collected data on customers at the slot machines. Basing on the accessibility, accuracy, completeness and currency of the accumulated transactional data from past guests, Harrah’s can quickly estimate the customer’s future value within minutes of the player joining the program. This enables the casino to start treating the customer according to his or her future value rather than having to wait for observed play before starting to provide rewards (Piccoli & Watson, 2008).

Consequently, the hypothesis we propose is that:

H9: the DG capability has a positive and direct impact on Digital Data Accessibility.

H10: the DG capability has a positive and direct impact on Digital Data Accuracy.

H11: the DG capability has a positive and direct impact on Digital Data Completeness.

H12: the DG capability has a positive and direct impact on Digital Data Currency.

4.5 Environmental Turbulence

Environmental Turbulence describes the general conditions of uncertainty and/or unpredictability caused by the changes in customer preferences and technology development (Mendelson & Pillai, 1998). Customer preferences’ turbulence causes unpredictability in market demand, while, technology development’s turbulence causes uncertainty regarding new technological breakthroughs.

On one hand, Environmental Turbulence stimulates the reconfiguration of existing capabilities, increasing the possibility that the Organizational Processes of Sensing, Learning, Coordinating, and Integrating develop new valuable capabilities (Sambamurthy, Bharadwaj, & Grover, 2003; Zahra, Sapienza, & Davidsson, 2006). On the other hand, Environmental Turbulence weakens the process performances depending on the existing Dynamic Capabilities (Teece, Pisano, & Shuen, 1997). So, we propose that Environmental Turbulence reinforces the relationship between Organizational Processes and Data Genesis, while it attenuates the relationships between Data Genesis and Information Accessibility, Accuracy, Completeness and Currency:

H13: Environmental Turbulence positively moderates (i.e. reinforced) the relationship between Sensing and DG capability.

H14: Environmental Turbulence positively moderates (i.e. reinforced) the relationship between Learning and DG capability.

H15: Environmental Turbulence positively moderates (i.e. reinforced) the relationship between Integrating and DG capability.

H16: Environmental Turbulence positively moderates (i.e. reinforced) the relationship between Coordinating and DG capability.

H17: Environmental Turbulence negatively moderates (i.e. attenuates) the relationship between DG capability and Digital Data Accessibility.

H18: Environmental Turbulence negatively moderates (i.e. attenuates) the relationship between DG capability and Digital Data Accuracy.

H19: Environmental Turbulence negatively moderates (i.e. attenuates) the relationship between DG capability and Digital Data Completeness.

H20: Environmental Turbulence negatively moderates (i.e. attenuates) the relationship between DG capability and Digital Data Currency.
We are now engaged in the data collection phase of this research in order to test the model through a double Configurational-Structural approach. Firstly, we will test our theory-based structural model, through Structural Equation Modelling (SEM). As the organizational alignment on the three sources of Dynamic Capabilities facilitates the development of new capabilities (Teece, Pisano, & Shuen, 1997), we think that the internal consistency among the three sources of Data Genesis will enhance its development. Hence, we will cluster the empirical data sample, in order to identify the different organizational configurations (Meyer, Tsui, & Hinings, 1993). Finally, we will test the configuration-based structural model, through SEM.

A questionnaire-based survey will be the main source of empirical data on a sample of key informants in different organizations. The target population is hospitals, as they are data intensive organisations and DG capability could advance the medical care standards (Piccoli & Watson, 2008). 200 responses from distinct organisations are pursued to assure a convenient sample size due to the 100 measured items on the 15 constructs (with 6 items for the most complex construct).

The key informants will be IT managers and line managers in order to reduce common method bias (Straub, Boudreau, & Gefen, 2004). IT managers are likely to be the most informed about IT assets, IT capabilities in general and Data Genesis Capability specifically. Line managers are likely to be the most informed about environmental turbulence, organisational processes, Information Capability and Data Genesis output. A formal check will assess the managers’ understanding on the different topics of the questionnaire (Pavlou & El Sawy, 2006), using a cut-off point of 5 out of 7.

Figure 1 The research model

5 RESEARCH METHODOLOGY
Existing measurement scales operationalize all the constructs of the model.

- **Organizational Processes – Sensing.** The effectiveness in sensing the environment will be reflected by the adaptation of the market orientation measurement scale (Kholi & Jaworski, 1990; Pavlou & El Sawy, 2006).

- **Organizational Processes – Learning.** Effectiveness in learning will be measured by the adaptation of the absorptive capacity measurement scale (Cohen & Levinthal, 1990; Pavlou & El Sawy, 2006).

- **Organizational Processes – Coordinating.** Effectiveness in coordinating will be evaluated by the adaptation of the coordination capability measurement scale (Malone & Crowston, 1994; Pavlou & El Sawy, 2006).

- **Organizational Processes – Integrating.** Effectiveness in integrating will be estimated by the adaptation of the collective mind measurement scale (Pavlou & El Sawy, 2006; Weick & Roberts, 1993).

- **Firm history – Information capability.** The Information capability construct will be measured adapting the Information capability measurement scale (Marchand, Kettinger, & Rollins, 2002) with its two dimensions: Information management and Information behavior.

- **Firm history – IT capability.** The IT capability measurement scale will adapt the Technical Capability, Behavioral Capability and Business Capability dimensions of IT Personnel Capability construct (Fink & Neumann, 2007).

- **Firm’s Assets – IT Infrastructure.** The IT infrastructure measurement scale will adapt the IT infrastructure Capability (Fink & Neumann, 2007).

- **Firm’s Assets – Information Repository.** The Information Repository construct will be reflected by the adaptation and unification of two different Repository scales (Freeze & Kulkarni, 2005).

- **DG Capability.** The DG capability scale will adapt:
  - Choosing New Emerging/Enabling Technologies construct (Wheeler, 2002; Williams, 2003), to measure the ability to choose emerging/enabling IT to gain unobtrusively valuable digital data.
  - IT Business process integration category of the IT Capability construct (Bharadwaj, Sambamurthy, & Zmud, 1999), to measure the ability to integrate in the business processes such IT.
  - Information Management dimension of the Information capability measurement scale (Marchand, Kettinger, & Rollins, 2002), to measure the ability to manage digital data.
  - Reconfigurability. The potential to reconfigure Data Genesis integrating will be estimated by the adaptation of Reconfigurability measurement scale (Pavlou & El Sawy, 2006).

- **Digital Data Accessibility.** The Digital Data Accessibility construct will be assessed by the adaptation of the Information Accessibility measurement scale (Zimmer, Henry, & Butler, 2007).

- **Digital Data Accuracy.** The Digital Data Accuracy construct will be measured through the adaptation of the Information accuracy measurement scale (Nelson, Todd, & Wixom, 2005).

- **Digital Data Completeness.** The Digital Data Completeness construct will be measured through the adaptation of the Information completeness measurement scale (Nelson, Todd, & Wixom, 2005).

- **Digital Data Currency.** The Digital Data Currency construct will be measured through the adaptation of the Information currency measurement scale (Nelson, Todd, & Wixom, 2005).

- **Environmental Turbulence.** The measurement of Environmental Turbulence construct will be based on the Turbulent Environment scale (Pavlou & El Sawy, 2006).

A set of Control Variables complements the measurement scale of the main constructs of the model. Several factors that have been previously shown to be related to Dynamic Capability development will be measured, so that their effects on Data Genesis Capability development will be controlled:

- The functional role of the respondents: management versus non-management positions (Fink & Neumann, 2007).

- The size of the organization through the number of employees (Bhatt & Grover, 2005; Fink & Neumann, 2007).

- The size of the IT department through the number of IT personnel (van der Heijden, 2000).
• The seniority of the respondents among senior, mid-level or junior managers (Fink & Neumann, 2007).

6 CONCLUSION AND FUTURE RESEARCH

Dynamic Capabilities are often considered as the factor justifying the different degrees of success of organizations in turbulent environment. However Dynamic Capabilities development remains partially unexplained. The explanation of the development of Dynamic Capabilities would give organizations the instruments to rationally improve their processes and increase indirectly their chances of success.

We contribute to the emerging literature on IT Dynamic Capability development by proposing and testing a research model on DG: the Dynamic Capability of (1) choosing IT to unobtrusively generate and capture data in digital form, (2) integrating the technology in the appropriate business processes, and (3) managing the digital data so produced.

This research in progress foresees the test of the research model on DG capability before the conference attendance in order to present some preliminary results at that time. Finally, future research includes the validation of the model in others organisations and for other Dynamic Capabilities in order to generalize the findings.

HOW TO SELECT MEASURES FOR DECISION SUPPORT SYSTEMS – AN OPTIMIZATION APPROACH INTEGRATING INFORMATIONAL AND ECONOMIC OBJECTIVES

Röglinger, Maximilian, FIM Research Center Finance & Information Management, Department of Information Systems Engineering & Financial Management, University of Augsburg, Universitätsstraße 16, 86135 Augsburg, Germany, maximilian.roeglinger@wiwi.uni-augsburg.de

Abstract

It is still an open issue of designing and adapting (data-driven) decision support systems and data warehouses to determine relevant content and in particular (performance) measures. In fact, some classic approaches to information requirements determination such as Rockart’s critical success factors method help with structuring decision makers’ information requirements and identifying thematically appropriate measures. In many cases, however, it remains unclear which and how many measures should eventually be used. Therefore, an optimization model is presented that integrates informational and economic objectives. The model incorporates (statistic) interdependencies among measures – i.e. the information they provide about one another –, decision makers’ and reporting tools’ ability of coping with information complexity as well as negative economic effects due to measure selection and usage. We show that in general the selection policies of all-or-none or the-more-the-better are not reasonable although they are often conducted in business practice. Finally, the model’s application is illustrated by the German business-to-business sales organization of a global electronics and electrical engineering company as example.

Keywords: decision support systems, information overload, critical success factors, design research.
MOTIVATION AND OBJECT OF RESEARCH

Due to the complexity of intra- and extraorganizational structures, it is impossible for decision makers in general – and executives in particular – to continuously monitor all fields of action that possibly require intervention. With reports containing in average up to 15,000 data points based on measures, i.e. key figures or (performance) indicators, information proliferation makes it even harder to focus on decision-relevant information (Axson 2007). Some measures more or less significantly influence the complexity of reports and the amount of time needed to understand them. The number of measures also drives the costs for customizing and maintaining reports. Hence, a central problem in the design and adaptation of (data-driven) decision support systems (DSS) and data warehouses (Alter 1980, Inmon 2005) still is to determine relevant fields of action and to select appropriate measures (Eccles 1991, Watson et al. 1993). Particularly the latter requires formal research (Evans 2004).

Some classic approaches to information requirements determination (IRD), such as Rockart’s critical success factors (CSFs) method (1979), provide valuable assistance with structuring decision makers’ information requirements (IR) and identifying thematically appropriate measures. However, these measures are often too many and it is unclear which should eventually be used. In this respect, decision makers’ cognitive restrictions (Browne et al. 2002, Davis 1982), limitations of reporting tools such as management cockpits and dashboards (Sisfontes-Monge 2007), and negative monetary implications need to be considered. As for measure selection in particular, there are additional deficiencies with respect to whether the selection process is intersubjectively comprehensible, decision makers can participate systematically, and (statistic) interdependencies among measures (e.g. quantifiable by means of correlation or contingency coefficients) are considered. In business practice, these deficiencies can result in that measure selection is based on “gut instinct”, that many time-consuming interviews are conducted, and that the utility of selected measures remains doubtful. Therefore, the research question is: Which and how many measures shall be selected from a preselected set of thematically appropriate measures in order to provide decision makers with optimal information as regards informational and economic objectives?

The paper relies on a design-oriented, formal, and deductive approach (Hevner et al. 2004). Section 2 compares existing approaches with respect to general requirements and identifies the research gap. Section 3 proposes an optimization model as artifact. Section 4 evaluates the optimization model by illustrating its application in business practice and by assessing how it meets the general requirements outlined above. Section 5 summarizes the results and points out future research.

RELATED WORK

Currently, measures are often contained in performance measurement systems (PMS). In management accounting and operations management literature, there is a range of requirements on PMS (e.g. Artley et al. 2001, Caplice et al. 1995, Neely et al. 1995). Accordingly, PMS are expected to capture all relevant constituencies of a specific field of action (completeness, R.1), to encompass a manageable amount of measures (clarity, R.2), and to transfer the overall business strategy to decision makers (vertical integration, R.3). The process of measure selection should be intersubjectively comprehensible (intersubjectivity, R.4), consider (statistic) interdependencies among measures (interdependencies, R.5), and involve domain experts (participation, R.6). Although the requirements are somehow vague due to prosaic formulation, the author considers that they provide basic assistance with comparing existing approaches and with identifying the research gap (see Table 1 where completeness is omitted as it is not addressed by any approach).

In the following, selected approaches from international journals and textbooks are presented. Due to space restrictions, this is done briefly. Giorgini et al. (2008) present a goal-oriented approach to determine IR for data warehouses that considers the organizational environment and decision makers’
needs. Neely et al. (2000) advocate a selection of measures in terms of a cost-benefit-analysis. Liebetruth et al. (2006) present a linear optimization model with which a utility-optimal subset of measures can be chosen from a set of preselected and thematically appropriate measures. Rockart (1979) shows how decision makers’ IR can be structured and reduced to a few essential fields of action, the so-called CSFs, each of which is monitored by several measures (see also Leidecker et al. 1984). Axson (2007) extends CSFs analysis by incorporating additional interactive elements, distinguishing primary and supporting measures as well as vaguely postulating “minimal confusion”.

The following findings are noteworthy: Almost all approaches neglect clarity (R.2) as they do not specify how many measures are to be selected. One approach allows to set a maximum number of measures. This is arbitrary and considers neither the decision makers’ information processing capacity nor economic implications. All approaches are vertically integrated by linking measures with CSFs, business strategy, or goals (R.3). Moreover, measure selection is (at least) partially subjective (R.4). Interdependencies among measures are not considered (R.5). Most approaches involve decision makers by means of explorative elements (e.g. interviews or games) (R.6). Summing up, there is a primary research gap with respect to clarity (R.2) and interdependencies (R.5). Furthermore, there still is potential for improvement with respect to intersubjectivity (R.4) and participation (R.6).

We focus on the primary research gap. In the end, this will also ameliorate the other requirements. We adopt the ideas of optimization and preselection of thematically appropriate measures from Liebetruth et al. (2006), the structuring momentum of CSFs from Rockart (1979), and the idea of explicitly incorporating negative economic implications from Neely et al. (2000). Our contribution is that we formally address the trade-off between provided information, information complexity, and negative economic implications to determine which and how many measures should be selected optimally.

### 3. AN OPTIMIZATION MODEL FOR MEASURE SELECTION

Consider a company where the reporting has historically grown and multiple (data-driven) DSS and data warehouses are in use. In order to react on its decision makers’ demand for clear information, the company launches a project for implementing a consolidated DSS. Two essential steps in this project are: (1) structuring the decision makers’ IR into relevant fields of action and (2) (pre-)selecting thematically appropriate measures from the existing systems – assuming no new measures will be added. In most cases, it will not be reasonable to integrate all preselected measures – nor even only those desired by the decision makers (e.g. Ackoff 1967, Davis 1982). This is for several reasons: some measures may (partially) “overlap” due to (statistic) interdependencies, decision makers can only cope with restricted information complexity, and customizing as well as maintaining reporting tools is expensive. It is advisable to analyze in advance which fraction of the preselected measures the consolidated DSS should contain. Whereas above thematically appropriate measures had to be (pre-)

Table 1. Comparison of existing approaches to measure selection
selected, here measures are of interest that together provide much information about other measures. As indicated, two perspectives are important here: the economic and the informational perspective. While the former is indispensable when investing in IT, the latter is necessary as DSS primarily aim at supporting decision processes by supplying decision-relevant information (e. g. Power 2002).

In order to determine the optimal fraction of measures, we propose an optimization model. Though being inherently discrete, the problem of measure selection can be interpreted as approx. continuous for sufficiently many measures. This allows to determine algebraic solutions and to gain general insights. We maintain the affiliation with the original problem setting and make reasoning about functions more illustrative by using discrete examples. A basic model for the informational perspective is proposed in section 3.1 and extended by the economic perspective in section 3.2.

3.1 A basic model for the informational perspective

Let us first consider the informational perspective where information has no price. Selecting one of the preselected measures provides information about the measure itself – as it becomes known – and about non-selected measures – due to (statistic) interdependencies. This creates informational utility. The more strongly a measure interdepends with non-selected measures, the more informational utility it creates. This is because a stronger interdependency allows to estimate values more reliably. There are also negative informational effects of selecting measures. Due to increasing information complexity, each additional measure makes it harder to cognitively process the entire amount of information. This creates informational disutility. Thus, there is an informational trade-off. The question is: Up to which optimal fraction of measures does the utility due to more information justify the disutility due to higher information complexity? The optimization model relies on the following assumptions:

A.1: There is a given finite set of measures that have been preselected ex ante with respect to thematic appropriateness. Between some measures there are meaningfully interpretable pairwise (statistic) interdependencies, that is, selected measures provide information about (the values of) non-selected measures. All measures together satisfy the decision makers’ information requirements and provide complete information. Moreover, all measures together cause highest complexity.

A.2: The fraction of the preselected measures that will be integrated into the consolidated DSS, \( x \in [0;1] \), is infinitely divisible (see discussion above). With \( x = 0 \), no measures are selected. With \( x = 1 \), all measures are selected.

A.3: \( U_{\text{info}}(x) \) represents the informational utility due to the information that a fraction of selected measures provides about itself and non-selected measures. \( D_{\text{info}}(x) \) represents the informational disutility due to information complexity. Both are functions of \( x \) and can be forecast ex ante.

On these assumptions, the informationally optimal fraction of measures \( x^{\text{opt, info}} \) can be determined by optimizing the difference between \( U_{\text{info}}(x) \) with \( D_{\text{info}}(x) \). This difference is also called informational net utility \( U_{\text{info, net}}(x) \). The corresponding objective function is given by:

\[
U_{\text{info, net}}(x) = U_{\text{info}}(x) - D_{\text{info}}(x) = \max! \tag{1}
\]

In order to formalize the optimization model, \( U_{\text{info}}(x) \) and \( D_{\text{info}}(x) \) are examined. We start with \( U_{\text{info}}(x) \). If a (rational) decision maker were restricted to select only one measure, he would select the measure with the highest individual informational utility – say \( m_1 \) –, i. e. the measure that in sum interdepends most strongly with the non-selected measures. If the decision maker were allowed to select two measures, he would take those that create the highest joint informational utility – say \( m_2 \) and \( m_3 \). In general, this joint informational utility is higher than the individual utility of \( m_1 \). This is because either \( m_1 \) is kept (as \( m_2 \) or \( m_3 \)) and another measure is added or \( m_1 \) is discarded and two other measures with higher joint utility are chosen. The only exception is if all measures interdepend perfectly. In this case already one measure alone – no matter which – provides complete information. In general, the joint informational utility of \( m_2 \) and \( m_3 \) is smaller than the sum of both individual utility values. This is
because interdependencies cause “informational overlap”. To put it more precisely: If we only consider \( m_2 \) and \( m_3 \), the joint utility of knowing both \( m_2 \) and \( m_3 \) is smaller than the sum of the individual utility values due to knowing \( m_2 \) (or \( m_3 \)) and its interdependency with \( m_1 \) (or \( m_2 \)). If \( m_2 \) and \( m_3 \) interdepend, \( m_2 \) provides information about \( m_3 \) – and vice versa. The only exception is if \( m_2 \) and \( m_3 \) are (statistically) independent of each other. In this case, the joint utility equals the sum of both individual utility values. If we consider all non-selected measures, the joint interdependency-induced utility of \( m_2 \) and \( m_3 \) is smaller than the sum of the individual interdependency-induced utility values of \( m_2 \) and \( m_3 \). For each non-selected measure, the strongest interdependency will be used to estimate its value. The only exception is if \( m_2 \) and \( m_3 \) are independent of all non-selected measures or interdepend with disjoint subsets of non-selected measures. With many measures at hand, this is rather unlikely. Hence, the marginal utility of selecting \( m_2 \) and \( m_3 \) (two measures) compared to selecting \( m_1 \) (one measure) is smaller than (and exceptionally equal to) the marginal utility of selecting \( m_1 \) (one measure) compared to selecting zero measures. This holds for any number of measures. Hence, the more measures are selected – i.e. the higher \( x \) is –, the higher is the joint informational utility and the less is the marginal utility. In mathematical terms, \( U_{\text{info}}(x) \) increases \((\partial(U_{\text{info}}(x))/\partial x \geq 0)\) and strictly convex \((\partial^2(U_{\text{info}}(x))/\partial x^2 \leq 0)\). If we neglect the discussed exceptions and treat \( U_{\text{info}}(x) \) as strictly increasing and concave, it may be formalized in a simplifying manner as follows:

\[
U_{\text{info}}(x) = x^\alpha A \text{ with } \alpha \in [0;1] \text{ and } A \in IR^+
\] (2)

Selecting no measures provides no information \((U_{\text{info}}(0) = 0)\), whereas – according to \( A.I \) – selecting all measures provides complete information \((U_{\text{info}}(1) = A)\). The constant \( A \) represents the decision makers’ present-value monetary equivalent of complete information, that is, the amount of money they are willing to pay at the moment of measure selection for complete information during the planning horizon, i.e. as long as the selected measures are in use. Reasoning from an informational perspective, \( A \) represents the value of information by itself. It does not incorporate payments e.g. for data collection. The transformation into monetary units enables to integrate the economic perspective later. The diminishing marginal utility, which was introduced above and is caused by a higher fraction of measures, is formalized by the fact that the exponent \( \alpha \) is restricted to \([0;1]\). This also excludes the case where all measures interdepend perfectly, which would lead to a non-realistic course of \( U_{\text{info}}(x) \). A value of \( \alpha \) close to 0 is appropriate if all preselected measures interdepend rather strongly. Therefore, very few measures already create almost complete information. A value of \( \alpha \) close to 1 is appropriate if all measures are rather independent, that is, the marginal utility is rather constant. A mean value of \( \alpha \) indicates that the measures split into several groups with strong intra-group and weak inter-group interdependencies. The higher the value of \( \alpha \), the more (and the smaller) groups tend to exist.

The objective function’s second component represents the disutility created by information complexity \( D_{\text{info}}(x) \). It intuitively holds that the more measures are selected, the more complex is it to cognitively process them. Mathematically spoken, \( D_{\text{info}}(x) \) increases with \( x \). According to cognitive sciences (e.g. Duncan 1980, Miller 1956), the amount of information becomes overproportionally more complex when the fraction of measures increases. Hence, a higher fraction \( x \) is also characterized by an increasing marginal disutility with respect to \( D_{\text{info}}(x) \). In summary, \( D_{\text{info}}(x) \) is strictly increasing \((\partial(D_{\text{info}}(x))/\partial x > 0)\) and strictly convex \((\partial^2(D_{\text{info}}(x))/\partial x^2 > 0)\). This can be formalized as follows:

\[
D_{\text{info}}(x) = x^\beta B \text{ with } \beta \in [1;\infty[ \text{ and } B \in IR^+
\] (3)

Selecting no measures does not lead to complexity \((D_{\text{info}}(0) = 0)\), whereas – according to \( A.I \) – selecting all measures leads to highest complexity \((D_{\text{info}}(1) = B)\). The constant \( B \) represents the decision makers’ present-value monetary equivalent of understanding complete information during the planning horizon. The increasing marginal disutility, which was introduced above and is caused by a higher fraction of measures, is formalized by the fact that the exponent \( \beta \) is restricted to \([1;\infty[\). Its value depends on the decision makers’ and employed reporting tools’ ability of coping with
information complexity\(^1\). A value close to 1 is appropriate if the decision makers already have serious problems with processing few measures and/or the employed reporting tools are restricted to a few measures. The higher the value of \(\beta\), the less decision makers are susceptible to information complexity and/or the more powerful are the employed reporting tools. Based on (1) to (3), the optimization model is as follows:

\[
\text{Maximize } U_{\text{info,net}}(x) = U_{\text{info}}(x) - D_{\text{info}}(x) = x^\alpha A - x^\beta B \\
\text{w. r. t. } x \in [0;1]
\]

(4)

A mathematical analysis shows that \(U_{\text{info,net}}(x)\) strictly increases until \(x^*_{\text{info}} = \frac{(A \cdot \alpha)/(B \cdot \beta)}{1/(\beta - \alpha)}\). Up to that fraction, each additional measure provides more additional information than it causes additional complexity. Beyond, \(U_{\text{info,net}}(x)\) strictly decreases. Each additional measure then causes more additional complexity than it provides additional information. As \(x\) is restricted to [0;1], the optimal fraction is \(x^*_{\text{info}} = \min\{x^*_{\text{info}}, 1\}\). Due to the concave course of \(U_{\text{info,net}}(x)\), a border solution such as \(x^*_{\text{info}} = 1\) only occurs on rare occasions (see below).

Two interesting questions are: How is the decision makers’ attitude towards complete information and highest complexity reflected in \(A\) and \(B\)? How do both parameters ceteris paribus affect the course of \(U_{\text{info,net}}(x)\) and the position of \(x^*_{\text{info}}\)? The following case differentiation is also depicted in Figure 1. If \(A = B\), complete information creates as much utility as highest complexity creates disutility. Decision makers then are indifferent between making decisions based on zero measures or based on all preselected measures. The optimal fraction is \(x^*_{\text{info}} = (\alpha/\beta)^{1/(\beta - \alpha)}\) and only depends on \(\alpha\) and \(\beta\). If \(A < B\), complete information creates less utility than highest complexity creates disutility. Decision makers prefer making decisions based on zero measures to making decisions based on all measures.

The optimal fraction \(x^*_{\text{info}}\) is ceteris paribus smaller than in the first case. If \(A > B\), complete information creates more utility than highest complexity creates disutility. Decision makers prefer making decisions based on all measures to making decisions based on zero measures. The optimal fraction is \(x^*_{\text{info}}\) is ceteris paribus higher than in the first case. For certain constellations of \(\alpha\) and \(\beta\) (see Figure 1 on the right), \(U_{\text{info,net}}(x)\) could have its maximum \(x^*_{\text{info}}\) outside the interval [0;1]. With \(x\) being restricted to this interval, the optimal fraction then is \(x^*_{\text{info}} = 1\). This is the only case where it may be informationally optimal to select all measures.

### 3.2 An extended model for the informational and the economic perspective

In reality, information is not for free. Hence, it is necessary to integrate an economic perspective. In order to support decision makers, measures need to be compiled into reporting tools (e. g. management cockpits and dashboards). These need to be customized and maintained during their time in use. Abstracting from fixed costs, this leads to one-time and continuous payments. Both create economic disutility and influence measure selection. Thus, there is a joint informational and economic trade-off.

The question is: Up to which optimal fraction of measures does the additional informational net utility justify the additional economic disutility due to higher present-value payments for customization and maintenance? The extended model additionally relies on the following assumptions:

**A.4:** All preselected measures are implemented and their values can be extracted automatically from the respective application systems. The consolidated DSS will be connected to the existing application systems.

**A.5:** \(D_{\text{eco}}(x)\) is the economic disutility due to the present-value payments for customizing and maintaining reporting tools. It is a function of \(x\) and can be forecast ex ante.

---

\(^1\) To simplify matters, \(\beta\) is viewed as average value of how well decision makers/reporting tools are able to cope with information complexity. Of course, it can be further refined with respect to different groups/types or even individual decision makers/reporting tools.
Mathematically spoken, is, the higher according to Axson (2007), in average 15 to 20% of the selected measures will have to be changed. These arise e.g. from updating ETL procedures, assuring data quality, or changing selected measures.

...the reporting tool. This also applies to the present-value payments for maintaining reporting tools.

...systems integration and data collection need not be considered. The more measures are selected, the more time-consuming – and expensive – is it to initially customize reporting tools. Imagine the... customers first year, 10 to 15% in the following years. Hence, the more measures are selected – that is, the higher x is –, the higher is the economic disutility and the higher is the marginal disutility.

Mathematically spoken, $D_{\text{econ}}(x)$ is strictly increasing ($\partial(D_{\text{econ}}(x))/\partial x > 0$) and strictly convex ($\partial^2(D_{\text{econ}}(x))/\partial x^2 > 0$). This may be formalized as follows:

$$D_{\text{econ}}(x) = x^\gamma C \quad \gamma \in [1;\infty] \quad \text{and} \quad C \in IR^+$$

Selecting no measures does not lead to payments ($D_{\text{econ}}(0) = 0$), whereas selecting all measures leads to highest payments ($D_{\text{econ}}(1) = C$). The constant $C$ represents the highest amount of present-value payments due to customization and maintenance of reporting tools. The increasing marginal disutility, which was introduced above and is caused by a higher fraction of measures, is formalized by the fact that the exponent $\gamma$ is restricted to $[1;\infty]$. A value close to 1 is appropriate if a small fraction of measures already leads to high payment and each measure causes approx. the same marginal disutility. The higher $\gamma$ is, the less payments and marginal disutility causes a small fraction of measures and the higher is the marginal disutility of higher fractions. Based on (4) to (6), the extended optimization model is as follows:

Maximize $U_{\text{info+econ,net}}(x) = U_{\text{info}}(x) - D_{\text{info}}(x) - D_{\text{econ}}(x) = x^\alpha A - x^\beta B - x^\gamma C$

w. r. t. $x \in [0;1]$  

Although there is no general algebraic solution, the course of $U_{\text{info+econ,net}}(x)$ and the position of $x_{\text{info+econ}}^{\text{opt}}$ can be discussed with respect to the component functions (see Figure 2). As $U_{\text{info,net}}(x)$ is concave and $D_{\text{econ}}(x)$ is convex, $U_{\text{info+econ,net}}(x)$ is concave with one global maximum at $x_{\text{info+econ}}^{\text{opt}}$. As $U_{\text{info+econ,net}}(x)$ equals $U_{\text{info,net}}(x)$ diminished by $D_{\text{econ}}(x)$, the joint informational and economic optimum $x_{\text{info+econ}}^{\text{opt}}$ is smaller than or equal to $x_{\text{info}}^{\text{opt}}$, that is, $x_{\text{info+econ}}^{\text{opt}} \in [0;\text{x}_{\text{info}}^{\text{opt}}]$. This is reasonable because $x_{\text{info}}^{\text{opt}}$ is determined on the assumption that information has no price. If $D_{\text{econ}}(x)$ is close to zero – e.g. for large $\gamma$ and/or very small $C$ –, measures can be selected almost negligible of negative economic

Figure 1. Exemplary courses of $U_{\text{info}}(x)$, $D_{\text{info}}(x)$, and $U_{\text{info,net}}(x)$

On the assumptions $A.1$ to $A.5$, the informationally and economically optimal fraction $x_{\text{info+econ}}^{\text{opt}}$ can be determined by optimizing the difference between $U_{\text{info,net}}(x)$ and $D_{\text{econ}}(x)$. This difference is also called joint informational and economic net utility $U_{\text{info+econ,net}}(x)$. The objective function is given by:

$$U_{\text{info+econ,net}}(x) = U_{\text{info,net}}(x) - D_{\text{econ}}(x) = U_{\text{info}}(x) - D_{\text{info}}(x) - D_{\text{econ}}(x) = \max!$$

(5)

To formulate the extended optimization model, $D_{\text{econ}}(x)$ is examined. According to $A.4$, payments for systems integration and data collection need not be considered. The more measures are selected, the more time consuming – and expensive – is it to initially customize reporting tools. Imagine the selected measures had to be integrated into a dashboard. If only one measure is selected, the dashboard can be customized easily. If two measures are selected, an overall layout is more difficult (but still easy) to find. The more measures are selected, the overproportionally more time-consuming – and expensive – is it to find an adequate overall layout. This includes choosing among different visualization elements, adapting their size, trying different layouts, or – in the worst case – changing the reporting tool. This also applies to the present-value payments for maintaining reporting tools. These arise e.g. from updating ETL procedures, assuring data quality, or changing selected measures. According to Axson (2007), in average 15 to 20% of the selected measures will have to be changed during the first year, 10 to 15% in the following years. Hence, the more measures are selected – that is, the higher $x$ is –, the higher is the economic disutility and the higher is the marginal disutility.
effects. Then $x_{\text{opt info+econ}}$ and $x_{\text{opt info}}$ are approx. equal. If $D_{\text{info}}(x)$ is close to zero – e. g. for large $\beta$ and/or very small $B$ –, decision makers are hardly susceptible to information complexity and/or powerful reporting tools are employed. Then an approx. solution is $x_{\text{opt info+econ}} \approx \left( \frac{A \cdot \alpha}{C \cdot \gamma} \right)^{1/(\gamma-\alpha)}$. In this case, analogous to above, the relationship between the decision makers’ subjective attitude towards complete information and highest (present-value) payments can be analyzed with respect to $A$ and $C$.

Concluding, the optimization model allows determining the optimal fraction of measures to be chosen from a preselected set of thematically appropriate measures. Accordingly, those measures are selected that together create the highest informational utility. The model integrates an informational and an economic perspective. The former reflects the decision makers’ attitude towards information and information complexity. The latter considers present-value payments for customizing and maintaining reporting tools. It could be shown that, in general, the selection policies of all-or-none or the-more-the-better, which are often implemented in business practice, are reasonable neither from an informational nor from a joint informational and economic perspective. What makes sense instead is a differentiated and balanced selection of measures.

4 EVALUATION

4.1 Applying the optimization model in business practice

The optimization model was developed in the context of a project at the German business-to-business sales organization of a global electronics and electrical engineering company. As there were only few measures, the model could be applied in a discretized form. If there had been very much measures, we would have had to evaluate a manageable subset in order to infer the continuous functions introduced above. Due to confidentiality, all data is anonymized and modified. Yet the principal results still hold.

The project’s overall goals were to better support the sales force, to reduce IT operation costs, and to modernize sales reporting. As for the first two goals, the company decided to introduce a single CRM system and to harmonize the application landscape, which consisted of more than one hundred division-specific legacy systems. The reporting mainly consisted of financial and lagging measures such as volume of sales and price margin. It was to be modernized with respect to non-monetary and leading measures. Our task was to structure the salespeople’s IR into CSFs and to select appropriate measures. At first, candidate CSFs were identified by explorative interviews with sales managers and senior members of the CRM board. Sales managers had usually worked as sales representatives for several years and were supposed to provide valuable hints with respect to IR and sales reporting. They were selected by reputational methods (Knoke 1993). For each candidate CSF, several items were identified and compiled into a five-point Likert scale-based questionnaire. After a pretest, the questionnaire was presented to 25 sales managers (the amount was restricted by the project budget).

All in all, CSFs were identified for 3 perspectives, namely organizational structures and processes (e. g. long-term customer care, cross-divisional cooperation), salespeople’s skills and knowledge (e. g. with respect to installed base and competitors’ portfolios), and IT functionality (e. g. integration with office communication software, IT-based planning of sales calls).

Figure 2. Exemplary course of $U_{\text{info+econ,net}}(x)$ for $A = B = C$
The CSF “cross-divisional cooperation” will serve as example. Together with the sales managers, we retrieved 8 thematically appropriate measures. These were: fraction of converted leads from other divisions (\% \_leads), average overall time spent on creating leads for other divisions (\_T \_leads), average time spent on creating one lead (\_T \_lead), number of trainings on other divisions’ portfolios (\# \_trainings), number of meetings with colleagues from other divisions (\# \_meetings), number of sales calls with colleagues from other divisions (\# \_calls), number of shared customers (\# \_customers), number of bids for customers of other divisions (\# \_bids). All measures had existed for several years and were reported monthly on a sales manager’s granularity.

First, we assessed informational utility $U_{\text{info}}(x)$. The exponent $\alpha$ – which indicates how the measures interdepend – was operationalized based on Pearson’s correlation coefficient. That is, we treated the interdependencies as pairwise, symmetric, and linear. We accepted this simplification because the correlation coefficient is an intuitive, widely used, and relatively easy-to-compute measure. Moreover, linear interdependencies are often considered as sufficiently good approximations for many economic settings (Edwards 1976). This turned out to be useful because, due to missing hierarchical and logic structures, the existence and strength of interdependencies among non-monetary and leading measures often need to be assessed empirically e. g. by interviewing domain experts and analyzing historical data (Küpper 2005). Let $M = \{m_1, m_2, \ldots, m_n\}$ comprise $n$ preselected and thematically appropriate (metrically scaled) measures between some of which there are meaningfully interpretable interdependencies/correlations. We considered absolute values as the correlation coefficient’s algebraic sign only indicates direction, not strength. The values are represented as $n \times n$-matrix $CM$ where $c_{ij}$ indicates how strong $m_i$ and $m_j$ correlate and where $c_{ij} = 0$ if $m_i$ and $m_j$ are statistically independent or if their interdependency/correlation cannot be meaningfully interpreted ($0 \leq i, j \leq n$, $i \neq j$). The individual correlations of a measure $m_i$ equal the $i$-th column vector of $CM$.

$$c_i = (c_{i1}, c_{i2}, \ldots, c_{in})^T$$

The joint correlations of multiple selected measures $m_1, \ldots, m_n$ (without loss of generality) are also represented as vector $c_{1,\ldots,n}$. The elements of all selected measures are $1$ (perfect autocorrelation). The element of each non-selected measure indicates the strongest correlation with any measure selected so far. This is reasonable because if decision makers want to estimate the value of a non-selected measure $m_j$, they will reasonably revert to the selected measure that correlates most strongly with $m_j$.

$$c_{1,\ldots,n} = (\max\{c_{11}, \ldots, c_{1n}\}, \max\{c_{12}, \ldots, c_{2n}\}, \ldots, \max\{c_{1n}, \ldots, c_{nn}\})^T$$

The concept of joint correlations enables to formalize a discretized informational utility as function of $x$. We need the highest joint correlation of $x \cdot n$ measures. It is determined by calculating the highest scalar product value $\langle l, c' \rangle$ where $l$ is an $n$-vector $(1, 1, \ldots, 1)^T$ and $c'$ is the joint correlations vector of $x \cdot n$ arbitrary measures. Dividing the scalar by $n$ normalizes it to $[0;1]$. This operationalization can be interpreted as a monetized mean absolute correlation.

$$U_{\text{info}}(x) = \left[ \max \{ \langle l, c' \rangle \mid x \cdot n \text{ measures are selected} \} / n \right] \cdot A$$

After CSF analysis, some sales managers from the CRM board were asked to (subjectively) judge which interdependencies between measures are meaningfully interpretable as regards the sales domain. The strength of these interdependencies was calculated by means of absolute correlation values based on historical data. Table 2 shows the results with the light grey cells marking excluded interdependencies/correlations. Concerning the value of $A$ – which represents the sales managers’ present-value monetary equivalent of complete information – we asked each sales manager how many daily rates he would pay for having complete information on cross-divisional cooperation during the planning horizon. We obtained an average of 10 daily rates, which we multiplied with the sales

---

2 In the CRM context, a lead represents a hint with low degree of maturity from inside or outside one’s division that refers to a potential customer or project opportunity.

managers’ average daily rate of 750 € and their overall number – there were 50. We finally obtained A = 375,000 €. As for informational disutility D_{info}(x), the sales managers received sample reports. Each contained a different amount of measures, but had exactly the same layout as the reports that were planned to be finally used. The sales managers’ task was to entirely understand the reports. For each amount of measures, we logged the time. In order to determine the value of B, we used the average value for 8 measures – which was 2.0 hours. We normalized it with respect to the sales managers’ average daily working time – which was 9 hours. Then, we multiplied it with the sales managers’ average daily rate and their overall number. As the report was planned to be presented monthly and the planning horizon was 3 years, we calculated the annual payments and the corresponding present value with an interest rate of 10%. Assuming that the managers had to try to understand the report completely anew each time they received it, we obtained B = 273,554 €. We used the other time values for approximating β. The sales managers coped well with a low number of measures, but had problems with more than approx. 4–5 measures. So we obtained β = 2.8. The economic disutility D_{econ}(x) was calculated based on Boehm’s widespread cost estimation model CoCoMo (1981). Together with the company’s DSS experts, we parameterized the estimation model as PM=2.94-0.20-LOC^{1.2} where PM and LOC denote person months and thousand lines of code respectively. The present-value effort for customizing a report with one measure and maintaining it during the planning horizon was estimated equivalent to 1.250 LOCs. With the DSS experts’ average daily rate of 400 € and 20 working days per month, we obtained C = 74,553 € and γ = 1.2.

On this basis, we determined the optimal fraction of measures x_{opt \_info+econ} by computing the joint informational and economic net utility U_{info+econ}(x) (see Table 3 and Figure 3). If we had only considered the informational perspective, the highest informational net utility would have resulted from x_{opt \_info} = 0.5. We would have selected the 4 measures with the highest informational utility, i.e. %_leads, Ø_T_leads, #_meetings, and #_customers. As we also took on an economic perspective, the highest joint net utility resulted from x_{opt \_info+econ} = 0.375. We selected the 3 measures with the highest informational utility, i.e. %_leads, #_customers, and #_bids. Here, it becomes obvious that measures can be discarded if the number of selected measures changes.

We applied the same procedure to the other CSFs. Advantageously, this caused considerably less effort because D_{info}(x) and D_{econ}(x) needed not to be determined anew. U_{info}(x) could be calculated based on historical data so that the sales managers’ expertise was only required for preselecting thematically appropriate measures and identifying meaningfully interpretable interdependencies. In sum, we modernized the company’s sales reporting by identifying CSFs, by integrating non-monetary and leading measures, and by significantly reducing the overall number of measures.

4.2 Checking the optimization model against the PMS requirements

The optimization model particularly aims at closing the primary research gap with respect to clarity (R.2) and interdependencies (R.5) (see section 2). By requiring to select a manageable amount of measures, the model addresses clarity in an explicit manner. Informational disutility expresses the decision makers’ and reporting tools’ ability of coping with informational complexity and is contrasted to informational utility. Thereby, we make sure that the whole amount of information does not become too complex and remains manageable for the decision makers. Interdependencies are also addressed explicitly. This is because informational utility uses interdependencies in order to express how “much” information measures provide about one another. The example showed – albeit in a simplifying manner – how an interdependency-based informational utility can be operationalized for non-monetary and leading measures with Pearson’s correlation coefficient. Moreover, the model makes the process of measure selection more intersubjectively comprehensible (R.4). Although most parameters cannot be determined without subjective influences, just the fact that it is clear how they are formally linked increases intersubjectivity. Decision makers do not only participate by means of explorative interviews, but also in a structured manner by validating interdependencies and estimating model parameters (R.6). Concluding, the model does not only address the primary research gap, but also ameliorates the other PMS requirements.

5 SUMMARY AND FUTURE RESEARCH

An optimization model has been proposed that helps to determine which and how many measures should be selected from a set of thematically appropriate measures in order to monitor specific fields of action. Informational and economic objectives are considered. That is (statistic) interdependencies among measures, decision makers’ and reporting tools’ ability of coping with information complexity as well as payments for customizing and maintaining reporting tools influence measure selection. The model’s principle applicability was shown with a real-world example. Admittedly, business practice entails problems (e. g. estimation of costs, data collection in complex social contexts, decision makers’ partial inability of unambiguously specifying IR) that make it hard to achieve truly optimal solutions. In order to cope with some of these problems, it may be useful for companies to implement the model stepwise and to involve operating staff in data collection. Nevertheless, the proposed model is a first step towards a more well-founded measure selection. It will be subject to future research:

1. The optimization model is applied to one field of action a time. Several fields of action can only be addressed successively and isolated. The fact that measures may be thematically appropriate for more than one field of action is not considered. Hence, an integrated perspective is desirable and should be added.
2. So far, only measures from existing application systems are considered. On the one hand, this is reasonable as in many companies more measures exist than any decision maker can ever analyse. On the other hand, positive effects of innovative measures are neglected and need to be integrated.

3. (Data-driven) DSS and data warehouses do not only comprise measures, but also other master data for evaluation. In order to deal with their full scope, the model needs to be complemented e.g. by an approach which assesses relevant dimensions and dimension elements.

4. Although the model has been employed successfully with real-world data, empirical evidence is missing with respect to whether its recommendations actually improve decision quality. It would be insightful and strengthen evaluation to conduct respective empirical studies.

Abstract

Although the role of theories in design research is recognized, we show that little attention has been paid on how to use theories when designing new artifacts. We introduce design principles as a new methodological approach to address this problem. Design principles extend the notion of design rationales that document how a design decision emerged. We extend the concept of design rationales by using theoretical hypotheses to support or object to design decisions. At the example of developing a new conceptual modeling grammar we demonstrate two main benefits of using design principles. First, the link between theory and design decision enables the design researcher to reason about the resulting behavior of the IT artifact prior to instantiation. Second, design principles allow deducing empirically testable hypotheses to foster the rigorous evaluation of IT artifacts.

Keywords: design principles, design rationale, design theories, theories, design research
INTRODUCTION

Often, design research results are criticized as being subjective and anecdotal in nature. Design researchers need to argue, how the IT artifact relates to hypotheses about the nature and characteristics of the artifact and its proposed benefits. Thus, theories are the cornerstone of improving the intersubjectivity of design artifacts (Walls et al., 1992). Figure 1 shows a bilateral relation between theory and design (Nunamaker and Chen, 1991). According to relation 1 “Contribution” in Figure 1, theory may follow design. Here, design research contributes to the IS knowledge base by initiating theory-building based on existing design artifacts. Walls et al. (1992) and others introduced the concept of design theories to specify the theoretical contribution of design research to the IS knowledge base (e.g. Markus et al., 2002; Walls et al., 1992).

Figure 1: The elements of IS design theories based on Nunamaker and Chen (1991) and March and Smith (1995)

Theories can also be used to justify design decisions and subsequently anticipate the behavior of the IT artifact (relation 2 “Justification” in Figure 1). This relation is based on the insight that any design artifact cannot work if it does not comply with the laws embodied in the underlying theory (Walls et al., 1992). In addition, the artifact may be significantly improved if the underlying theory is explicit (van Aken, 2004, p. 228).

Although this second relation is widely recognized on a general level (Gregor and Jones, 2007; Venable, 2006; Walls et al., 1992), we show that little attention has been paid to the methodological guidance on how to use theories when designing artifacts. This paper aims to fill this gap by answering the following research question: How can theoretical knowledge be used in the design process? To answer this question, we argue that the iterative nature of design research requires a particular focus on the specific decisions made during the design research process and the underlying arguments which finally led to the design artifact (Hevner et al., 2004). We apply and extend the concept of design rationale to structure, justify, and document the decisions made in the iterations of the design research process.

Design rationales can be used to justify design decisions during the construction of the artifact by documenting design alternatives and the reasons for selecting or rejecting them (Regli et al., 2000). Because of the transparency of the decision making process, design rationales are valuable sources to stimulate theory-building, i.e., they facilitate design researchers in specifying the first relation between design and theory (see 1 in Figure 1). However, to support the theoretical justification of design decisions (see 2 in Figure 1), we extend the concept of design rationale by introducing theory-based arguments. In doing so, the design decision can be traced back to empirically testable hypotheses, which enable the design researcher to reason about the effects of the IT artifact as well as to reason about the artifact’s possible side-effects (Weber, 1987). We argue that such theory-based design decisions form a new type of IS design knowledge, which we call design principles. A design principle is a coherent claim of utility (Markus et al., 2002) and consists of a specific design problem, a solution to the problem and the trace path of the discussion leading from theory to the solution.
The link between theory and design decision enables design researchers to reason about the resulting behavior of the IT artifact prior to instantiation. Furthermore, design principles allow deducing empirically testable hypotheses to foster the rigorous evaluation of IT artifacts.

The remainder of the paper is organized as follows: In the next section, we review existing work on the role of theories in design research. We show that little attention has been paid on how to incorporate theories when designing new artifacts. Next, we analyze the notion of theory in IS research and the concept of design rationales as the basic elements of our approach. Then, we show how to develop design principles by applying theoretical hypotheses as justificatory knowledge in design rationales. At the example of developing a new conceptual modeling grammar we demonstrate the utility of our approach. Overall, we contribute to the methodological foundations of IS design research by explaining how theories can be used to justify design decisions. The paper closes with a discussion of the implication of this approach and an outline for further research.

This paper is of exploratory and conceptual nature. Hence, we provide argumentative support when answering our research questions. However, we base our arguments upon available empirical and conceptual research results as well as on the results of a previous paper (Gehlert et al., 2009). This paper extends the results of the previous one by introducing the notion of design principles and by an in-depth analysis of the relation between these design principles and theories.

2 THEORIZING IN DESIGN RESEARCH

In this section, we summarize the current debate on the role of theories in IS design research. The important role of theories in design research has been addressed by a number of authors (Gregor and Jones, 2007; Markus et al., 2002; Schermann et al., 2007; Verschuren and Hartog, 2005; Walls et al., 1992). Gregor and Jones (2007) distinguish two roles of theories in IS design research: First, theories can be the output of design research: “The distinguishing attribute of theories for design and action is that they focus on ‘how to do something’. They give explicit prescriptions on how to design and develop an artifact, whether it is a technological product or a managerial intervention” (Gregor and Jones, 2007, p. 313). Second, theories provide the foundation of justifying decisions during the design process and the subsequent features of the artifact: “[..] we argue that these theories are a linking mechanism for a number, or all, of the other aspects of the design theory. […] Theories might come from natural science, social science […], other design theories, practitioner-in-use theories […], or evidence-based justification such as seen in medical research and action research.” (Gregor and Jones, 2007, p. 327)

Hevner et al. (2004) propose guidelines to determine the contribution of design research results to the IS knowledge base. Their guideline 3 requires that the “[…] utility, quality, and efficacy of [the] design artifact must be rigorously demonstrated” (Hevner et al., 2004, p. 83). In the line with this argument, Walls et al. (1992) argue, that design theories should propose empirically testable hypotheses to provide means for testing the utility of the design theory. Hence, the role of theories in IS design research is to facilitate the evaluation of design research results.

Furthermore, in their guideline 6, Hevner et al. (2004) characterize the design process as a search process: “The search process for an effective artifact requires utilizing available means to reach desired ends while satisfying laws in the problem environment” (Hevner et al., 2004). Hence, during the design process, the design researcher probably tries several means to solve the problem, receives unsatisfactory results, and consequently reshapes his or her approach. Hence, the design process can be characterized as an evolutionary process which should be governed by theories from the problem environment.

In sum, the role of theories in IS design research is threefold: theories are the output for the purpose of communicating and evaluating design knowledge, theories are the input for the construction of design artifacts, and theories shape the evolution of the IT artifact along the design process. Table 1 distinguishes two groups of elements. The first group consists of goals and requirements and the
subsequent design proposals that describe a solution, which matches the requirements and fulfils the goals. Overall, this group of elements describes “how to do something” (Gregor, 2006, p. 628). The design proposal can be characterized as the claim of the design researcher to achieve utility. Hence, the second group consists of elements which provide information that substantiate this claim in an auditable way (Walls et al., 1992). The approaches presented in Table 1 provide the necessary structure to document the results of design research.

Table 1: Approaches to design theories in IS design research

From a methodological point of view, the subsequent questions are how to proceed when incorporating theories in the design process and deducing testable hypotheses from the design results. Table 1 shows that the evolutionary aspect of design research has not been recognized until recently (Gregor and Jones, 2007; Schermann et al., 2007). The search process as described by Hevner et al. (2004) requires design researchers to document and trace their decisions and the corresponding justification across several iterations. Hence, design researchers need to track their decisions and the underlying linkages between informing theories, aspects of the design proposal, and resulting hypotheses (Gregor and Jones, 2007).

Surprisingly, little attention has been paid to developing methodological guidance on the use of theories in design research (Venable, 2006). We use the design research section on isworld.org (Vaishnavi and Kuechler, 2004) as example to clarify this position. In their extensive review of design research methodology, Vaishnavi and Kuechler (2004) characterize the role of theory in design research as informative: “[…] The design process, when interrupted and forced back […] contributes valuable constraint knowledge to the understanding of the always-incomplete-theories that abductively motivated the original design” (Vaishnavi and Kuechler, 2004). However, no further advice is given on how to proceed and document the learning process. How does the researcher document which design decision was grounded on which theoretical advice? Clearly, “more detailed and clear concepts would be helpful” to describe the use of theories in design research (Venable, 2006, p.1).

Overall, the general role of theory and its importance for rigorous design research has been widely recognized. However, existing approaches do not show how to proceed when making design decisions based on theory or deducing hypotheses from design proposals. In sum, our analysis shows that the required “linking mechanism” (Gregor and Jones, 2007) between goals, requirements, design proposals, underlying theories, and deduced hypotheses is largely unspecified.

3 FOUNDATIONS OF IS THEORIES AND DESIGN RATIONALES

In the previous section, we discussed that little methodological guidance exists on how to apply theoretical knowledge in design research. We suggest extending the concept of design rationales by enabling design researchers to develop a line of arguments leading from theory to an abstract design solution. In the following, we first clarify our notion of theories based on the typology provided by Gregor (2006). Second, we review the design rationale literature and select an appropriate approach for this paper. Both results are summarized as conceptual models, which will be then integrated in the next section.
3.1 The Notion of Theory in IS Research

The word theory is currently used in IS research to denote at least five different types of theoretical knowledge (Gregor, 2006). To integrate theories with design rationale approaches, we need to clarify the structure of such theories. A theory consists of a set of hypotheses (Popper, 2002). In general, a hypothesis is a correlation relationship based on two constructs (Balzer et al., 1987; March and Smith, 1995). The independent construct of the hypothesis is called cause while the dependent construct is called effect. According to the Structural Equation Modeling (SEM) approach, each construct is either represented by a set of indicators, which is called reflexive construct or is causing these indicators, which is then called a formative construct (Freeze and Raschke, 2007). The indicators operationalize the construct by providing the necessary means to measure the construct during theory testing. This notion of theory is summarized in the right area of Figure 2.

From our definition of theory we can draw three conclusions:

C1 Based on the definition of a construct, we conclude that two constructs with different sets of indicators are different; two constructs with the same sets of indicators are equivalent.

C2 Based on our definition of a hypothesis, it follows that two hypotheses are equivalent if they share the same constructs; otherwise the hypotheses are different.

C3 Based on our notion of theories, we conclude that theories with different sets of hypotheses are different and theories with the same sets of hypotheses are equivalent.

In sum, theories provide important information on cause-effect relations. However, we have shown that existing approaches to theorizing in IS research pay only little attention to the specific steps necessary to intertwine theorizing and design activities. We argue that the iterative nature of design research requires a particular focus on the specific decisions made during the design research process and the underlying arguments which led to the design artifact (Hevner et al., 2004). However, the challenge of documenting and justifying design decisions has been faced in the domains of software engineering and systems engineering, too. Thus, in the following section, we show that the notion of design rationales provide the foundation for developing theory-based design arguments, i.e., design principles.

3.2 Design Rationale Approaches

Research on design rationales is concerned with documenting and justifying particular decisions made during the design process (Rossi et al., 2004). The main goal of design rationale management is to document the relationship between the artifact, the underlying goals, the design proposal, and potential constraints (Louridas and Loucopoulos, 2000). This relationship can then be used to justify the design decisions which have led to the artifact. In doing so, the design rationale enables the design researcher to reason on his or her decisions at any given stage in the design process (Regli et al., 2000). For an extensive overview on existing approaches to rationale management see (Regli et al., 2000) and (Louridas and Loucopoulos, 2000).

Most of the approaches to design rationale management are based on the issue-based information systems (IBIS) approach (Kunz and Rittel, 1970). An issue in IBIS defines a certain problem that has occurred during the design phase. The design researcher can now establish various positions that may address the issue adequately. Then, different arguments can be made to either reject or substantiate a certain position. Finally, a position is being chosen and subsequently implemented in the design proposal (see the left area in Figure 2).

The following example explains IBIS: Let us assume we are in the process of constructing a new conceptual modeling grammar to resolve some issues with existing grammars, e.g. the Unified Modeling Language in a special problem domain (Object Management Group, 2005). The goal of the design project results in the requirement that the modeling grammar should enable its user to
understand the resulting models easily. During the design process the design researcher has to decide how to represent the concepts of the modeling grammar. An issue in this discussion could be: “Should we assign graphical symbols to the grammatical concepts?”

The design researcher is now facing two positions: “yes” and “no”. A supporting argument for the “yes” position can be found in the experience, that graphical models are commonly easier to understand. An argument objecting the use of graphical symbols could arise from the costs of developing and introducing an appropriate graphical user interface when the modeling grammar is implemented. After the arguments for all the issue’s position have been discussed, the designer needs to select a position to resolve the issue. As the experience of the design researcher favors a graphical notation, the position “yes” is chosen. This results not only in the benefits of achieving better model comprehension by having a graphical representation (desired effect) but also in the potential constraint to the design process of implementing a costly graphical user interface (undesired side-effect).

### 4 DEVELOPING THEORY-BASED DESIGN PRINCIPLES

The goal of using theories in design research is to justify design decisions. The link between theory and design decision enables the design researcher to reason about the resulting behavior of the IT artifact prior to instantiation. Furthermore, this link allows deducing empirically testable hypotheses to foster the evaluation of the IT artifact. So far, we have discussed that design rationale approaches provide the means for establishing a traceable link between design decisions and experiences of the designer. Before that, we have analyzed the structure of theoretical arguments, i.e., cause-effect-relations. In the following we show how to develop design principles by grounding design rationales in theoretical arguments. The main idea of developing theory-based arguments is to reinterpret the cause-effect relation in a hypothesis as a goal-means relation (March and Smith, 1995; Weber, 1987).

![Figure 2: Integration of Theories into IBIS](image)

To illustrate this reinterpretation, assume the following example: Larkin and Simon (1987) show that a diagrammatic notation (cause) results in a higher comprehension (effect) than textual notations. Inverting this relation and applying it to the construction of a modeling grammar allows the design researcher to formulate a theory-based argument: If the goal of a modeling grammar is to produce easily comprehensible models, one way to achieve it is to use a diagrammatic representation. However, this reinterpretation is possible only if the design researcher can actually influence the cause construct of the hypothesis, i.e., the design researcher is able to choose graphical symbols when developing the modeling grammar. In addition, there may be other mean–based on other hypotheses–which have the same effect.

In the context of the IBIS model, the starting point for developing theory-based arguments is the construct **Argument**. It provides the reasons for supporting a position or objecting to the position. The given set of arguments provides the foundation for making a decision with regard to an issue.
However, the argument itself does not explain why supporting or objecting a position resolves the issue, as long as the argument is not grounded in theoretical knowledge. In other words, if arguments are grounded in theoretical knowledge we do not only know, which arguments lead to the decisions made but also why these arguments contribute to the requirements of a design principle (\textcircled{1} in Figure 2).

When assigning a hypothesis to an argument, we implicitly build upon two assumptions (\textcircled{2} and \textcircled{3} in Figure 2):

A1 The cause construct of the hypothesis represents the position the argument refers to.

A2 The effect construct of the hypothesis represents the requirement the argument refers to via the position and issue.

These assumptions result from the reinterpretation of a hypothesis (cause-effect relations) as goal-means relations as described above. In this sense a requirement can be interpreted as (operational) goal to achieve. A position together with an issue represents possible solutions for this requirement (means). Consequently, the reinterpretation of a hypothesis must be represented by the position and requirements construct. Based on our notion of theory we know that the hypothesis’ constructs are uniquely defined by its indicators (see Conclusions C1). In the light of A1 and A2, this means that the position and the requirement must be expressed and measured by the same indicators as the respective cause and effects constructs from the theory. Otherwise the mapping between the theoretical constructs (cause and effect) and the design constructs (requirement and position) is inconsistent.

Whenever the design researcher grounds an argument in a hypothesis, i.e., whenever the link between argument and hypothesis is established (\textcircled{4} in Figure 2), the design researcher must map the hypothesis’ cause construct (\textcircled{2} in Figure 2) to the respective position and the hypothesis’ effect construct to the requirement (\textcircled{3} in Figure 2). The links \textcircled{2} and \textcircled{3} represent how the position and the requirement is interpreted, i.e., how the requirement and the position must be measured when evaluating the design principle.

Now we can deduce whether a theory-based argument supports a given position:

D1 The argument supports a position, if the selected position implements the cause construct and the hypothesis’ correlation is positive.

D2 The argument supports a position, if this position is not based on the cause construct and the hypothesis’ correlation is negative.

D3 In any other case, the argument objects to a position.

Let us return to the example of developing a modeling grammar and assume that the design researcher identified the following two hypotheses:

H1 If a graphical representation is used, the resulting models are easier to understand.

H2 If a modeling grammar has a graphical representation, then the automatic analysis of the models is more difficult.

Clearly, H1 has a positive correlation, whereas H2 has a negative correlation. As already explained above, the initial goal and thus the requirement of the modeling grammar is to enable its users to produce comprehensible models. The issue raised was whether to implement a graphical representation of the grammar. The available positions consist of “implementing a graphical representation” and “not implementing a graphical representation”.

Both positions refer to the cause construct of H1 and H2, the graphical representation. The positive correlation between the graphical representation and comprehension of H1 supports the position of “implementing a graphical representation”, because it advises the design researcher to use a graphical representation for the modeling grammar (D1). The negative correlation between graphical
representation and automatic analysis of H2 supports the position of “not implementing a graphical representation”, because it advises against implementing a graphical representation (D2).

After all arguments were put forward the design researcher needs to select one of the positions to resolve the issue. This resulting decision manifests how the requirement should be interpreted, because the effect constructs of the hypotheses, are now related to the initial requirement (\[ \in Figure 2 \]). In our example following H1 means to refine the requirement “model comprehension” to “model comprehension by persons” while using H2 means to refine the requirement to “model comprehension by machines”.

Two important implications for the design researcher can be drawn from this analysis:

1) We discussed above that the constructs of a hypothesis are defined by a set of indicators. Consequently, selecting a position results in the decision of interpreting the requirement in the way the effect construct of the underlying hypotheses is being interpreted. By choosing the position of “implementing a graphical representation” we select to interpret and measure comprehension in accordance to hypothesis H1.

2) Selecting a position is rarely straightforward. In realistic cases more than one position is supported by theory-based arguments. Consequently, choosing a particular position means rejecting potentially important theoretical arguments. These arguments represent known side-effects of the particular design decision. In the example of the modeling grammar, the design researcher now knows that implementing a graphical representation will impede any automatic analysis.

After linking hypotheses to IBIS, we can now refine our notation of a design principle. A design principle is a set of requirements, issues, positions, selected positions, arguments and hypotheses. Grounding the design principle’s arguments in hypotheses provides not only the theoretical rationale for choosing among potentially useful positions but also explains how the requirements and the selected positions should be measured. In addition, the design principle shows possible drawbacks of the selected position as these drawbacks are represented by supporting arguments for all positions, which have not been chosen.

5 THEORY-BASED DESIGN PRINCIPLES FOR DESIGNING CONCEPTUAL MODELING GRAMMARS

To demonstrate the utility of our approach, we extend the example of constructing a new modeling grammar. The overall goal is to “construct a conceptual modeling grammar for inexperienced modelers”. In particular, the modeling grammar should not be a mere implementation of an existing framework such as the BWW model (Gehlert et al., 2005) but should be based on empirical evidence (Gehlert and Pfeiffer, 2007).

Before any issue can be raised, we need to decompose the goal into requirements. According to Wand and Weber (2003) a modeling grammar should enable users to interpret their models efficiently, i.e., to understand them easily. Consequently, our requirement discussed here is: “models should be easy to understand”. From a theoretical perspective, we seek theories that explain when and why models are easily comprehensible. To explain model comprehension we apply the work of Bodart et al. (2001). They distinguish between surface level comprehension and deep-level comprehension. Surface level comprehension is measured as proportion of the model to be recalled from memory after the model has been studied by a model user for a certain amount of time. Deep level comprehension is measured as the ability of a model user to answer questions regarding the model’s content (see the right area of Figure 3).

The authors studied the influence of optional properties on surface level comprehension and deep level comprehension where optional properties refer to attributes and relationships model elements may or may not possess. Bodart et al. (2001) found a significant positive effect between avoiding optional
properties and deep level comprehension. In addition, they found a significant negative effect between
avoiding optional properties and surface level comprehension. In sum, the authors showed that
optional properties hinder deep level comprehension (negative correlation) but support surface level
comprehension (positive correlation).

Figure 3: Discussion of Optional Properties

To describe the hypotheses used by Bodart et al. (2001) we need to know which indicators were used
to measure them. The construct “surface level comprehension” was measured by the indicators
“proportions of entities recalled correctly”, “proportion of relationships recalled correctly”,
“proportion of attributes recalled and named correctly”, “proportion of attributes recalled and typed
correctly” and “proportion of relationships recalled correctly with correct cardinalities” (Bodart et al.,
2001, pp. 391). The construct “deep level comprehension” was measured by the indicators “accuracy”,
“time” and “normalized accuracy” (Bodart et al., 2001, pp. 397). The “optional properties” construct
was measured binary – optional properties were either included in the model or were not included. It is
important to note that the comprehension constructs “surface level comprehension” and “deep level
comprehension” are different because they were measured with different sets of indicators (see Figure
3). As this theoretical setting explains the consequences of including optional properties, the central
design issue for the new modeling grammar might be: Should the modeling grammar provide optional
properties? Figure 3 summarizes the discussion about optional properties.

The issue whether to implement optional properties is related to the requirement “model
comprehension”. There are two possible positions to resolve this issue, either to allow or to prohibit
optional properties in the modeling grammar. Both positions are supported by the respective
arguments and each argument is based on a hypothesis. For instance, the position “prohibit optional
properties” is based on the hypothesis “using optional properties in models hinder deep level
comprehension” (negative correlation). Since the position “prohibit optional properties” does not
implement the hypothesis’ cause construct and the hypothesis’ correlation is negative, the hypothesis
supports this position (see D2). This hypothesis, however, can only be applied in this argumentation
process when its constructs are measured in the same way as the position and the requirement
(assumptions A1 and A2). Committing to this assumption leads to specializing the meaning of the
requirement “model comprehension” to “deep level comprehension”. In the same way, the assignment
of the hypothesis to the arguments implies that the position is interpreted as “diagrams without
optional properties”.

Proceedings ECIS 2009
The same argumentation can be formulated for the position “allow optional properties”. It is assigned to the respective argument, which in turn is based on the hypothesis “allowing optional properties supports surface level comprehension”. By applying assumption A1 and A2, the meaning of the requirement “model comprehension” is specialized as “surface level comprehension”.

To resolve the issue, the design researcher needs to decide whether to allow optional properties in the modeling grammar. Figure 3 shows that the design researcher has decided to prohibit optional properties in the modeling grammar. Consequently, the design researcher chooses to interpret model comprehension as deep level comprehension rather than surface level comprehension. Based on this decision, we can derive possible constraints from our theory-supported arguments. Because of the choice to prohibit optional properties we know from the underlying theory, that the models of the modeling grammar will hinder surface level comprehension. In our case, was have inferred a side-effect from the design rational. This side-effect is expressed as constraint “the modeling grammar hinders surface level comprehension”.

Hence, the design principle can be summarized as follows: If a design researcher’s goal of a modeling grammar is to achieve comprehension, one way to realize it, is by prohibiting optional properties in the modeling grammar. This decision particularly enables deep-level comprehension of the models. At the same time it hinders the model’s surface-level comprehension.

Applying the hypothesis relating to optional properties in the design principle results in the following four effects:

- When using the design principle, the original requirement “model comprehension” is refined to the concept of “deep level comprehension” which is represented by the indicators “accuracy”, “time” and “normalized accuracy”.

- Since the argument is based on a generally applicable hypothesis, the design researcher now knows that the design principle supports deep-level comprehension whenever it is used. This claim is based on the logic of deductive reasoning. Whenever the design rationale is applied to a more concrete design situation, the hypothesis is also deductively applied in a more specific context. Because of the truth preserving nature of deductive reasoning (Balzer et al., 1987; Popper, 2002), the hypothesis will still hold in this specific context.

- Design principles enable the design researcher to keep track of the development of IS theories more easily. Assume that due to advances in theoretical IS research, the relation between optional properties and deep-level comprehension is falsified. Since the design researcher knows the link between the design principle and theory, the design decision of avoiding optional properties in the modeling grammar may be renegotiated.

- The proposed approach has also implications for theory testing. If the design principle developed above is used in different modeling grammars and the effect of deep-level comprehension cannot be achieved by this grammar, this indicates that the underlying hypothesis “avoiding optional properties supports deep level comprehension” may not be correct. Confronting theory experts with this situation may stipulate further theory testing (Weber, 1987).

6 CONCLUSION AND OUTLOOK

In line with Walls et al. (1992), we have argued that theories should be used when designing IT-artifacts. In particular, we discussed the justificatory role of theories in design research by integrating theoretical arguments in design rationales. We have introduced the concept of design principles to denote a set of requirements, issues, positions, selected positions, arguments and hypotheses. On the example of developing a modeling grammar we demonstrated the utility of design principles to capture theory-based design knowledge, which can be reused in similar design research projects.
Besides justifying design decisions, design principles have two additional benefits with regard to cumulative research activities in IS design research:

1) When progress in developing and testing IS theories falsifies a theory, the design researcher knows which design principle needs to be modified. If the design principle was not based on theory, this theoretical knowledge was incorporated into the experience of the design researcher and could not be easily identified in the design principle.

2) If a theory-based design principle fails to be useful when implementing an IT artifact, it indicates that the hypothesis used to back up the design principle’s arguments may not be correct. This situation gives raise to extensive theory testing and may lead to a falsification of this theory.

Consequently, using design principles helps to bridge the gap between design research and theoretical research and intertwine both disciplines. However, we do not argue that every design principle should be backed up by theory. Since our approach is an extension to IBIS, it is still possible to derive design principles based on experience only. The main reason for deriving design principles based on experience is that IS theories are not yet available for every situation a design researcher may face. Furthermore, theories that are available may be not mature enough or too coarse or too fine grained to be used in design principles. For instance, the well accepted and tested Technology Acceptance Model (Davis, 1989) was too coarse grained to be usable for our example of designing a modeling grammar. Instead we needed to justify our design decision with the relatively new theory by Bodart et al. (2001), which was tested only once. The flexibility to develop design principles based on both theory and experience opens up two interesting avenues of future research to extend our concept of design principles:

1) Existing design principles may be complemented with theoretical knowledge, which explains the effects and side-effects of the design principle. Because a theory’s hypothesis is always bound to its construct’s indicators, applying the hypothesis means to explain how the positions and the requirements should be measured. Consequently, adding theoretical support to existing design principles leads to more precise understanding of the requirements and the solution of the design principle.

2) If a designed artifact proves to fulfill its requirements, its design principles based on experience may be used to initiate theory building. Hypotheses can be derived from existing design principles by interpreting the decision’s position as a cause construct and the requirement as an effect construct. Consequently, each design principle exhibits at least one hypothesis. These hypotheses can then be used to construct a theory for predicting (theory type IV in Gregor, 2006).

From a methodological perspective, our immediate subsequent research will focus on exploring the benefits of using theories of the types I, III, and V in design research and incorporate other argumentation theories, e.g. from Toulmin (1958).

Abstract

In their 2004 paper Hevner et. al proposed a set of guidelines for conducting design science research
projects in the IS discipline. While useful, these guidelines have a relatively high level of abstraction.
However, various IT artifacts such as models, methods, techniques and implementations require IS
researchers to apply differing methods in order to construct and evaluate purposeful artifacts
respectively. In this paper we discuss a particular class of IT artifacts: conceptual modeling
languages. As constituent parts of software development methods, a multitude of such languages has
been proposed and discussed. Yet, in the related literature on method design only little guidance is
provided on how to derive appropriate conceptual modeling languages from empirical data. We
believe that “good methods” need to be rigorously grounded in empirical findings. Taking a look at
the related literature on inductive theory building reveals that at there are prominent similarities
between the elements that constitute theories and those that constitute conceptual modeling
languages: whereas theories comprise of constructs and relationships between these, conceptual
modeling languages comprise of language constructs and relationships among these. We draw from
the body of literature on grounded theory building and propose a new approach to designing
conceptual modeling languages.

Method
1 INTRODUCTION

Design Science Research has emerged as a popular research area in the IS discipline. Recently, there has been an increasing number of design science studies (cf. March & Storey, 2008; Winter, 2008) and also several discursive papers report on the usage of design science research in the IS discipline (e.g. Niehaves, 2007). Hevner et al. (2004) propose a set of guidelines for conducting design science research projects in the IS discipline. These guidelines are widely accepted as being feasible and providing guidance to an area of IS research that was often accused to not be rigorous and lack evaluation. While useful, the guidelines have a relatively high level of abstraction. However, particular IT artifacts such as constructs, models, methods, and instantiations require IS researchers to apply differing methods in order to construct and evaluate purposeful IT artifacts.

One such type of artifacts subsumes conceptual modeling languages, as being part of the “methods applied on the development and use of information systems” (Hevner et al. 2004, p. 82). The construction of conceptual modeling languages mainly originates from the field of information systems development (ISD). In the last two decades, a great number of modeling languages has been developed which left software engineers facing the major problem of method evaluation and selection (Harmsen, 1997). This problem has been addressed in a two-fold manner. First, unification efforts have been made in order to merge the mutual aspects of prevalent methods (Jacobson et al., 1999). Second, much effort has been devoted to the adaptation of development methodology by assembling specific aspects of different methods in order to meet project-specific requirements. This area of research became well-known in the ISD discipline under the notion of (Situational) Method Engineering (Brinkkemper, 1996; Harmsen, 1997; Ralyté & Rolland, 2001).

However, these approaches tend to not consider the actual domains, or contexts, methods are eventually applied to. The modeling languages used in this context mostly describe formal (software) systems, i.e. their constructs are anchored with formal semantics (such as programming language, c.f. Harmsen, 1997), thus having no denotation towards concepts of a material (“real-world”) domain. Nevertheless these languages are increasingly used for describing material contexts, e.g. in business process modeling (Rosemann et al., 2008) or requirements engineering (Mylopoulos et al., 1999).

In this paper we advance the construction of conceptual modeling languages by introducing a new approach to ground the development of such methods in empirical data. The motivation for this approach rests in the awareness that existent literature to a great extent does not address inductive development of methods based on empirical data. Yet, the related literature on theory building reveals that there are prominent similarities between the elements that constitute theories and those that constitute conceptual modeling languages: whereas theories comprise of constructs and relationships between these, conceptual modeling languages comprise of language constructs and relationships among these. Thus, we draw from the body of literature on theory building and propose a new approach to designing conceptual modeling languages.

The paper is structured as follows. In the next section we introduce related work on method design, design science research and theory building. We then introduce a new approach to designing conceptual modeling languages by transferring existent knowledge on theory building to the domain of designing methods. We then discuss the proposed approach. The paper concludes with a brief discussion of contributions and limitations and provides an outlook onto our future research agenda.

2 BACKGROUND

2.1 Design Science Research

Design science research aims at solving practical and theoretical problems "by creating new and innovative artifacts.” (Hevner et al., 2004 p. 75) The basic principles of design science research (DSR) can be traced back to engineering and Simon’s (1996) sciences of the artificial. In contrast to
behavioral science, DSR does not seek to understand the world as it is and how it works. Rather, it strives to develop solutions to improve the current state of affairs. DSR intends to provide IT artifacts that are novel and useful. These IT artifacts must exceed the current state of the art and have to serve a human purpose.

There have been several attempts in the IS community to define the IT artifact (Orlikowski & Iacono, 2001; Weber, 2003; Benbasat & Zmud, 2003; Venable, 2006). March and Smith (1995) differentiate between four types of IT artifacts: constructs that provide language concepts in which problems are described, methods that explicate the process of how to solve a problem, models that utilize the constructs to represent an application domain and express the problem and solution space, and instantiations that constitute the technical realization of constructs, models, and methods. In the understanding of March and Smith (1995) design science research must ultimately lead to one of these artifacts. A design science research method seeks to systematically guide the development of an artifact.

Until now, no widely accepted research method for design science has been established in the IS community. Even more so, there exist concerns that a general design method cannot be defined (Hooker, 2004). It is argued that design is a creative process that cannot be fully formalized. Nonetheless, various procedures have been suggested to methodically support the design activities (Peffers et al., 2007; Takeda et al., 1990; Nunamaker et al., 1990; Walls et al., 1992; Cole et al., 2005). More specifically, various approaches for the design of conceptual modeling methods and languages have been proposed, the most prominent of which we discuss in the subsequent section.

2.2 Design of Conceptual Modeling Languages

As has been indicated, conceptual modeling languages are applied in order to represent the relevant knowledge of a domain (Wand et al., 1995). In this paper we focus on modeling languages that are designed in order to represent facts about material domains, meaning aspects of the physical and social world or – more precisely – perceptions thereof, for means of communication and understanding (Mylopoulos, 1992). Note that such methods are not ought to be used in order to specify formal systems.

Conceptual modeling languages comprise of fundamental modeling constructs, that is, language primitives which are called the vocabulary. For example, in the Business Process Modeling Notation (BPMN), constructs represent activities, events or sequence flows. In addition to that, conceptual modeling languages provide a collection of rules that describe how the constructs can be combined to create statements about the domain of discourse. Such rules specify what constructs may be connected to each other. For example, it can be defined that activities can be linked by a sequence flow. Usually, rules are specified in a language’s meta-model and complementing contextual conditions (Earwig, 1999).

In the existent literature, two major approaches to the design of conceptual modeling languages can be found: language design in method engineering and ontology-based language development.

The first approach views conceptual modeling languages as artifacts that are created as part of a method engineering process. Thus, it is concerned with the selection, adaptation and design of (situation-specific) conceptual modeling languages as well as their corresponding modeling procedures. A system development method is assumed as to consist of a set of reusable fragments (Brinkkemper et al., 1998; Harmsen, 1997). Ralyté et al. (2004) describe different strategies for method engineering projects that differ regarding the degree of fragment reuse. However project specifics may, require the method engineer to derive novel language constructs from the problem domain at hand. While method engineering literature provides comprehensive directions on how to prepare method fragments for tool-supported integration and assembly, little guidance is given to the challenge of approaching a problem domain in order to derive feasible modeling language constructs. Furthermore, the concept of domain has primarily been perceived as the formal target systems in
earlier ISD modeling language development, such as programming languages or paradigms. Consequently, the resulting languages are mostly anchored to formal semantics.

The second approach aims to overcome the deficiencies of those languages to describe real-world-phenomena: to anchor modeling languages to material domains, it draws on the concept of ontologies as a theoretical foundation. Wand and Weber (1993) utilized a *top-level ontology* (Bunge, 1977) to evaluate existing modeling languages with regard to precision and completeness by matching the language elements with ontological concepts. Guizzardi (2005) developed an own ontological foundation for structural conceptual modeling languages and suggested an approach to derive language constructs based on this ontology. Although ontologies represent feasible anchoring systems for modeling language constructs (Harmsen, 1997), relying on this concept merely shifts the problem of how to identify useful constructs from language design to ontology design. Although one can find the notion of *ontology engineering* (Devedžić, 2002) and examples for the construction of particular domain ontologies (e.g. Fernández-López et al., 1999), the body of research work on this approach lacks generalized guidance on how to derive a conceptualization from empirical data.

Taking off from this discussion, in this paper we suggest an empirically-based approach to designing conceptual modeling languages. It is hoped that the inductive development of such languages based on empirical data can contribute to the languages’ usability and adequateness.

### 3 ON THE APPLICABILITY OF THEORY BUILDING PROCEDURES TO DESIGN SCIENCE RESEARCH

In the IS discipline, there have been attempts to classify theories and develop a more narrow understanding of what theory is. Gregor (2006) distinguishes between theories for analysis, explanation, prediction, explanation and prediction and design and action. Theory for analysis “does not extend beyond analysis and description. No causal relationships among phenomena are specified and no predictions are made” (p. 620). Similarly, conceptual modeling languages provide an analysis and description of a problem domain. Thus, we argue that conceptual modeling languages can be compared to analytic theory: they provide clear definitions of constructs that are relevant in a certain problem domain and describe relations among these.

The most general term that describes the building blocks of a theory is called a concept (Strauss & Corbin, 1998). *Concepts* represent phenomena and can be grouped into more abstract concepts that are then referred to as *categories* (Strauss & Corbin, 1998). Categories have *properties*, which describe certain characteristics that objects of the same category share. For example, if one category was “actor” objects belonging to this category could share the property of “position”. Thus, different actors could be placed on a dimensional range describing various positions, such as producer or director.

Generally, the scientific process comprises of the stages of observation, induction, and deduction (Eisenhardt, 1989; Handfield & Melnyk, 1998; Wallace, 1971). Thus, it can be argued that the scientific process starts with the inductive development of theory that is then deductively applied to incoming data and thus validated. This process of validation may lead to new or revised theory. There are various approaches of how to inductively develop theories, for example case study research (Eisenhardt, 1989), or Grounded Theory Method (GTM) (Glaser & Strauss, 1967; Strauss & Corbin, 1998). In this paper we particularly draw on the literature on GTM. As indicated, GTM aims at inductively develop theory based on empirical data. GTM is thought to ground the emergent theory in the data. It is not preconceived or forced upon the data but rather emerges from it (Glaser & Strauss, 1967).

We argue that GTM offers the researcher a set of procedures that can be beneficial in order to inductively develop conceptual modeling languages. Our argument rests in the following observations:

- The process of building grounded theories is highly iterative. Theory and data are constantly compared (Glaser & Strauss, 1967). This process can be referred to as *comparative analysis*. Similarly, DSR processes are highly iterative and constantly compare the evolving artifact with its purpose (Hevner et al., 2004).
Glaser and Strauss (1967) further introduce the term theoretical sampling as a process of “data collection for generating theory whereby the analyst jointly collects, codes, and analyzes his data and decides what data to collect next and where to find them, in order to develop his theory as it emerges” (p. 45). When designing a modeling method, the method designer will start to identify what concepts may be relevant in a certain context. In order to advance the construction, he or she will further investigate the domain at hand by decisively choosing locations and respondents he or she talks to.

Grounded theory studies typically start with a stage called open coding (Glaser & Strauss, 1967). In open coding the researcher identifies a set of themes or categories that appear to be relevant in order to describe and explain a phenomenon under investigation. Similarly, when designing a modeling method, the method designer has to identify those language constructs that are relevant and applicable to a particular domain.

Grounded theory provides procedures that support the researcher in identifying relationships between concepts. For example, Strauss and Corbin (Strauss & Corbin, 1998) suggest to classify emergent categories by whether they represent (a) phenomena, (b) conditions, (c) actions/interactions, or (d) consequences. Thus, conditional structure is identified. Likewise, the method designer seeks to identify relationships among language constructs.

Grounded theory relies on a technique called memoing (Miles & Huberman, 1994). Memos are used to document the researcher’s conceptual thoughts that eventually lead to the generation of theories. Memos are constantly written, re-written, and integrated (Strauss & Corbin, 1998). Thus, the process of memoing is conducive to the iterative nature of DSR projects, such as the development of methods. This concept is similar to what is referred to as a method rationale (Rossi et al., 2000).

In the following section we compare the basic elements of conceptual modeling languages to the basic elements of grounded theories. We then describe how the above outlined procedures of building theory can be applied to generate conceptual modeling languages.

## 4 APPLYING GTM PROCEDURES TO INDUCTIVELY DEVELOP CONCEPTUAL MODELING LANGUAGES

### 4.1 Concepts of Conceptual modeling languages and of GTM

Table 1 provides an overview of the comparison and matches the terminology of conceptual modeling language design and grounded theory method.

*Table 1 Relationship between concepts from GTM and conceptual modeling language design*
Language construct candidates are early abstractions from phenomena that a method designer perceives as relevant. These elements are part of the individual conceptualization (Guizzardi, 2005) of the context at hand. In grounded theory development, codes represent first cognate incidents in the data, which a researcher assigns to more abstract terms or themes. In further iterations, these codes are assembled to concepts by further clarifying the context’s structure and terminology.

The language construct is the central element of modeling language design. In a semiotical sense, language constructs are types of particular signs (Genova et al., 2005), that is, they have a syntactic, a semantic and a pragmatic dimension (Morris, 1970). The syntactic dimension of modeling languages can be split into abstract and concrete syntax (Earwig, 1999). While the former describes what discriminate constructs are available and how they may be combined, the latter assigns a graphical representation to each construct, so as to create a language primitive (Guizzardi, 2005). Techniques utilized in Grounded Theory Method can contribute to outline the semantic component of language constructs. The concepts derived from codified data yield a promising starting point for the material backdrop of a domain-specific modeling language. The process of refinement and abstraction to develop early sketched concepts to structured and well-defined categories is analogous to the definition of a language’s vocabulary.

Properties are a special class of constructs that denote existential dependency on other language constructs. We distinguish between different types of properties. So-called intrinsic properties are property types of language constructs that obtain a definite value when instantiated as model elements. For instance, if we defined a language construct “task” an intrinsic property could be “duration”. Mutual properties describe property types that are shared by instances of language constructs, such as being in a relationship or being part of a composite concept (Shanks et al., 2008). In the process of theory building, properties emerge from concepts that give further explanation to particular categories and are therefore existentially dependent on them.

The language rules constrain the possible combinations of language constructs and are part of the abstract syntax of a modeling language (Guizzardi, 2005). As language constructs denote concepts grounded in the domain, these combinations denote meaningful statements that must also be grounded in the empirical world. One major component of theory building is the exposition of such basic statements by revealing the relevant relationships among the concepts.

Based on the identified analogies, we propose a process that guides the development of a special type of IT artifacts, namely domain-specific conceptual modeling languages. Modeling languages provide clear definitions of constructs and (potential) relationships between constructs. The process draws on techniques that stem from the literature on theory building and results in what can be referred to as analytic theory. The approach to building theory we consider generates substantive theory, that is, theory that is applicable to a certain domain. Similarly, any language developed according to the scheme we are presenting will depend on the context it was developed in.

4.2 Applying GTM procedures in order to inductively design conceptual modeling languages

In the following we describe how conceptual modeling language constructs and their relationships can be inductively developed based on empirical data. To illustrate the process, we have chosen examples
from a grounded theory study that was conducted based on data from the film industry in order to study business processes in creative environments (Seidel et al., 2008). Thus, the language to be designed would be a business process modeling language tailored to that specific material domain. The process comprises of the following steps (cf. Fig. 1): Data Collection, Identification of concepts, further developing concepts, relating concepts, and concluding the design process. As has been indicated, alike the generation of theory the design of conceptual modeling methods is a highly iterative and interwoven process, which becomes particularly evident through the use of constant comparative analysis and theoretical sampling.

**Figure 1: GTM-based Language Design Process**

**Stage 1: Data collection**

At the outset, the modeling language designer must decide upon the data the language development is based on. Examples are the analysis of existent documentation, interviews, or observational data. Generally, a multitude of data sources can be considered, a process that is often referred to as triangulation across methods (Orlikowski, 1993). As triangulation across methods is typical for GTM studies (Glaser & Strauss, 1967), we suggest method designers to consider different data sources so as to allow for multiple vantage points for identifying what is relevant in a particular domain of interest. The result of this stage is a clear outline on what data sources will be used according to the intended scope of the modeling language to be designed.

**Stage 2: Identifying concepts**

The method designer starts with the identification of concepts being relevant in a certain context and for a certain modeling purpose. This identification of concepts draws on the process of open coding (Glaser & Strauss, 1967). Thus, the researcher opens up the text in order to identify what may be relevant in the data. By comparing incident to incident, the method designer comes up with first concepts which share certain characteristics and comes up with various concepts. Even though much of what will be needed may be found in the interview or observational data, the method designer may want to work with other techniques than simple comparisons. One such strategy that has also been proposed by Strauss & Corbin (1998) is that of making theoretical comparisons. Thus, the method designer enhances her “theoretical sensitivity” (Glaser, 1978), e. g. by evaluating existent modeling languages for reusable conceptualizations. The result of this stage is a quantity of domain-relevant concepts that are candidate language constructs.

**Stage 3: Further developing concepts**

It is not uncommon that the researcher ends up with generating a large number of concepts (Strauss & Corbin, 1998). To further integrate concepts, they are grouped under more abstract concepts called categories. By using categories the method designer reduces the number of items she works with. This process depends on the modeling purpose as well as of the individual perspective of the method designer. The result of this stage is a reduced list of categories, which comprises the elements of the first draft on the modeling language model (the meta model).

**Stage 4: Relating Concepts**
When starting to analyze the data, the researcher will recognize first relationships between concepts. Eventually, these relationships result in the formation of hypotheses or propositions. Similarly, when designing conceptual modeling languages, the method designer identifies potential relationships between language constructs. As has been indicated, depending on the type of language that is constructed it may be possible to distinguish different types of categories. By grouping categories accordingly, relationships emerge. Thus, the result of this stage is a first model of the domain-specific modeling language (the meta model) that comprises the quantity of language constructs and the typed relationships among them. These relationships represent allowed connections between instances of the involved constructs.

Stage 5: Concluding the design process, development of the concrete syntax

The iteration between analyzing data and generating language constructs and relationships can be concluded when additional data analysis does not provide any further insight. In GTM, this stage in the process is referred to as “theoretical saturation” (Glaser & Strauss, 1967). This highly iterative process rests in the application of procedures that were discussed earlier, namely the making of comparisons and theoretical sampling. During the conclusion of the theoretical development, the meta model will reach a state where no more substantially changes to the language core will be made. At this point, the language designer will assign a visual representation to each component the abstract language model (Guizzardi et al., 2002). Conclusively, the result of this stage is a domain-specific language prototype. This prototype can be used to further evaluate the underlying conceptualization, as well as to analyze the lucidity of the chosen representation (concrete syntax).

It is vital for the claim of traceability of language design and thus for the feasibility of language evaluation to rigorously document all decisions and their basis in the empirical data. As indicated, we propose to make extensive use of memoing (Miles & Huberman, 1994). There are different types of memos that can be used in order to provide a comprehensive method rationale: Codes notes, for example, accompany the process of conceptualizing based on constant comparison and theoretical sampling, whereas operational notes help to guide the researcher in deciding on what data to collect next, etc. (Strauss & Corbin, 1998).

4.3 Example Case

In the following, we illustrate the application of the proposed approach by developing exemplary language constructs based on data collected in an exploratory study on organizational creative processes. (c.f. Seidel, 2009).

Data collection: Data has been collected in three organizations with over 30 interviewees using semi-structured interview and process modeling techniques.

Concept identification: While studying the concept of CIP, the people conducting the tasks within these processes emerged as important context concepts. Example codes identified in the data were “visual effects artist”, “editor” or “sound editor”.

Further development of concepts: The roles identified within the CIP context were further investigated and mutual properties could be identified in the data. All these individuals share a certain process expertise that is necessary to carry out creative tasks, e.g. the ability to break down a creative problem in order to find a solution strategy to it. Furthermore they share the property of creative skills, i.e. the ability to generate novel artifacts and to judge solution on aesthetic aspects. As another important property with influence to CIP, the working location has been identified. The concepts have accordingly been generalized into the category artist.

The modeling language aims to provide for means to describe the processes within the domain. The category artist is codified as an element type within the language.

Relating concepts: Artists represent a specialized type of task owner in CIPs. Thus, they can be associated to creativity-intensive (sub-)processes. The property location has significant influence to
the collaboration with supervisors and clients, thus it will be modeled as an attribute of artist (c.f. Figure 2).

<table>
<thead>
<tr>
<th>Artist</th>
<th>CIP</th>

<td>creativeSupervisor</td>
</tr>
<tr>
<td>location: Location</td>
<td>artist[]: artist</td>
</tr>
<tr>
<td>assignedTo[]: CIP</td>
<td>parent: CIP</td>
</tr>
</tbody>
</table>

Figure 2: Meta model detail

Concluding design process: In this last step, a representation of the element type has to be developed. The CIP might be described in a form-based model where assigned artists can be added in a list and implemented into a modeling tool. To conclude the DSR process, the resulting language must be evaluated with appropriate measures (e.g. Recker, 2008).

5 DISCUSSION

In order to evaluate the approach we have suggested in this paper, we consider the guidelines proposed by Hevner (2004). Table 2 provides an overview.

Table 2: Evaluation with Guidelines as proposed by Hevner (2004)

<table>
<thead>
<tr>
<th>Guideline</th>
<th>Our Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Guideline 1: Design as an artifact</td>
<td>The process we proposed in this paper aims at developing conceptual modeling languages. Thus, the process results in what is considered to be purposeful IT artifacts.</td>
</tr>
<tr>
<td>Guideline 2: Problem relevance</td>
<td>It lies in the responsibility of the method designer that the problem that is to be targeted by the conceptual modeling language is relevant.</td>
</tr>
<tr>
<td>Guideline 3: Design evaluation</td>
<td>Evaluation is an integral part of the suggested process. By applying the principles of constant comparative analysis and theoretical sampling, the researcher constantly compares concepts and relationships to incoming data.</td>
</tr>
<tr>
<td>Guideline 4: Research contributions</td>
<td>It is hoped that methods designed based on the approach described in this paper are both “clear and verifiable” as Hevner (2004) states. It is suggested to accomplish this by constantly iterating between inductively generating categories and relationships that are then deductively applied.</td>
</tr>
<tr>
<td>Guideline 5: Research rigor</td>
<td>The process we introduced aims at providing a set of procedures that can be applied in order to design conceptual modeling languages. It is hoped that by following and documenting these procedures, the method designer makes the process of method development transparent and traceable. It cannot be claimed that a particular method is complete or correct – however, it can be argued that the process of method development is plausible.</td>
</tr>
<tr>
<td>Guideline 6: Design as a search process</td>
<td>The development of conceptual modeling languages based on constant comparative analysis and theoretical sampling is a highly iterative search process that in every stage is highly dependent on the substantive area in which it is grounded.</td>
</tr>
<tr>
<td>Guideline 7: Communication of research</td>
<td>Applying rigorous procedures of documenting the research process can contribute meaningfully to successful and appropriate communication of results.</td>
</tr>
</tbody>
</table>
Note that the perspective we presented in this paper largely differs from that of those approaches to method engineering that stem from the discipline of software engineering. Whereas these streams of literature seek to technically sound developing conceptual modeling languages and focus on syntactic integrity, our approach focuses on the identification of relevant language constructs and relationships.

It is our belief that the appropriateness of modeling languages is determined by the context in which they are used. Of course, the development of software systems requires methods that enable to construct syntactically correct models. Thus, in many cases it will be necessary to combine formal procedures with empirically-based, inductive methods to identifying concepts and relationships that are relevant and applicable to a particular domain.

6 CONCLUSION

This research contributes to the IS body of knowledge by proposing a rigorous, empirically-based approach to inductively develop conceptual modeling languages methods based on well-established techniques known from the domain of theory building. It is our belief that there is need for detailed approaches supporting both researchers and practitioners in developing purposeful IT artifacts. Our argument rests in the observation that (a) there are similarities between basic elements of conceptual modeling languages and the elements that constitute theory, and (b) that the GTM offers researchers a set of procedures that can also be applicable to the development of such languages.

6.1 Limitations

Inductively developing theory or modeling methods limits the scope of the artifact to a so-called substantive area (Urquhart, 2001; Strauss & Corbin, 1998). Thus, they may be very practical but are also limited to a particular scope. Thus, the approach we have advanced in this paper is limited to developing modeling languages that are applicable to particular domains. The study so far limits the discussion on the development of the language elements as constituent parts of a modeling method. However, a functional method also has to provide for a modeling process that guides modelers on how to use the language constructed. Although we believe that an empirically grounded language will assist the efficient elicitation of information in its aspired domain, one can argue that the process of modeling is also dependent on the context of application.

Furthermore, it must be noted that the result of any method design process is highly dependent on both the method designer as well as the intended purpose of the language. A possible strategy to achieve a more independent view on the domain is triangulation (Eisenhardt, 1989). For instance a researcher might employ a colleague to develop an own conceptualization based on the same data.

Conclusively, any new guideline, theory, method, or approach must be tested in practice. Thus, we motivate researchers and method designers to applying those principles we presented in this paper.

Abstract

In this position paper we discuss the importance of Green IT as a new research field that investigates all the environmental and energy issues related to IT and information systems in general. In particular we focus on the energy consumption of software applications, which is amplified by all the above IT layers in a data center and thus is worth a greater attention. By adopting a top-down approach, we address the problem from a logical perspective and try to identify the original cause that leads to energy consumption, i.e. the elaboration of information. We propose a research roadmap to identify a set of software complexity and quality metrics that can be used to estimate energy consumption and to compare specific software applications.

Keywords: Green IT; energy efficiency.
1 INTRODUCTION

“Green IT” is an expression that indicates a new research field that investigates all the environmental and energy issues related to IT (Murugesan, 2008). More specifically, we think that Green IT may refer to three different research areas:

1. Energy efficiency of IT;
2. Eco-compatible management of the lifecycle of IT;
3. IT as an enabler of green governance.

The first research area aims at designing energy-efficient IT architectures and data centers, covering also all the effects that utilization practices have on energy consumption. As we will explain in this paper, energy consumption impact on operating cost has grown in the last years and is now very significant. The second research area proposes to study new methodologies and technologies for eco-compatible manufacturing of IT components, to optimize packaging, and to minimize the environmental impacts of the whole lifecycle of IT. This includes eco-labeling and eco-compatible management and storage of waste and dismissed IT components. Finally, the third research area aims at leveraging IT as a means for measuring and monitoring the green parameters (e.g., energy consumption, temperature, toxic waste produced) related to all business processes, not limited to the IT area. This includes the design of monitoring devices as well as decisional support systems and dashboards to store, analyze, and compare green KPIs.

In this position paper we focus on the first research area and propose a research plan to analyze software energy efficiency. We illustrate as quantum physics theory offers an overall interpretation for the energy consumption of IT: elaborating information requires a minimum energy related to the quantum nature of the world. Actual consumptions are by far higher than the minimal theoretical level because current IT systems introduce a number of inefficiencies related to many different layers, which go from logical gates level to servers architecture and data centers infrastructure level. From another standpoint, this means that there are many possibilities for increasing the energy efficiency of IT, and this is a great challenge that the scientific community needs to face.

Software plays a crucial role in this scenario. Although software does not directly consume energy, it deeply affects the consumption of hardware equipment. Software applications, ranging from operating systems and drivers for hardware devices to decision support systems and ERP suites, indicate how information should be elaborated and to some extent guide the functioning of hardware. Consequently, they are indirectly responsible of energy consumption. In this paper we propose a research plan to measure and compare energy consumption of different applications and to correlate these data with traditional software design quality metrics.

The paper is organized as follows. Section 2 describes why Green IT is gaining more and more importance due to the devastating effects of energy consumption on the environment, on operative costs, and on scalability. Section 3 describes how energy consumption is distributed in a data center and illustrates how the energy actually used for chip-level computation is amplified by all the above IT layers. Section 4 presents the theoretical hypotheses at the base of our research, and Section 5 proposes our research plan. Finally, Section 6 concludes the work.

2 WHY GREEN IT IS IMPORTANT

Green IT is attracting more and more attention both in the scientific and business communities. In the past decades research and innovation have focused on increasing clock frequency and on
miniaturization (Schaller, 1997), with only a marginal focus on power consumption, mainly associated with battery autonomy of laptop devices. This has resulted in extremely fast IT systems, but which consume a lot of energy that is very often inefficiently employed.

Energy consumption has devastating effects on:

1. Equivalent CO\(_2\) emissions;
2. Operating costs;

As consumptions rise, the attention on Green IT gains momentum.

According to recent researches (Murugesan, 2008, Brown and Lee, 2007, Kumar, 2007), IT is responsible for more than 2% of global CO\(_2\) emissions, and its environmental footprint is comparable to that of the aeronautic industry. The average amount of energy consumed by a PC in 1 year corresponds to the emission of 1 ton of CO\(_2\), and a server has roughly the same annual carbon footprint as an SUV doing 5 miles-per-gallon (Restorik, 2007). In addition to that, 70% of the landfills of lead, cadmium and mercury derives from the IT industry (Brown and Lee, 2007).

From an economical perspective, whereas the cost of hardware has only slightly grown in the last 12 years, the cost of power and cooling has grown four times. Figure 1 shows data on the global spending for servers in the last years and estimates for next years.

![Figure 1 - Global spending for server (Billion dollar, Source: Josselyin et al., 2006).](image)

Nowadays, power and cooling operating costs represent 60% of the total spending for new infrastructures, and consequently have a great impact on TCO (see Figure 2). This proportion is expected to rise even more, also because of the continuous growth of energy unit cost. As in most
companies energy costs are not charged to the IT budget, the importance of this phenomenon is not yet fully perceived, but it is likely that accounting rules will change as the impact of energy costs on overall IT costs rises more and more.

In addition to that, energy consumption is a limit to the scalability of data centers. New IT equipment requires an extremely high quantity of energy per square meter (e.g., a rack with 5 blade servers of 8 units consume more than 20KW, as much as an apartment complex) and also the energy required by personal computers rises at a rate of 8-10% per year. When data centers are located in areas with high population density, as it often happens in Europe, it may be difficult for power distributors to bring the required energy in the same building. As power infrastructure modifications are difficult and expensive, data centers that are not energy efficient cannot expand their capabilities. According to Forrester Research (Brown and Lee, 2007), in the next few years 60% of data centers will be limited by power consumption, cooling, and space issues.

![Figure 2 – Spending for energy and cooling/ spending for new servers (Percent, Source: Josselyin et al., 2006).](image)

Recent surveys show that there are growing concerns about Green IT in corporate contexts: according to Forrester Research (Forrester Research, 2007), 33% of North American and 48% of European IT procurement and operations professionals think that environmental and energy-related issues are very important in planning their company’s IT operations, whereas only 15% in North America and 6% in Europe think that Green IT is not a problem at all.

### 3 A MULTILAYER APPROACH

An average data center usually consumes at least 300 KW, whereas a large data center may consume more than 10MW. However, it is important to note that this significant quantity of energy is consumed at different layers, i.e. from different parts of the data center with different logical functions.
According to (Renzi, 2007), 40% of the energy consumed by a data center is absorbed by HVAC (cooling) and UPS (back-up batteries) systems, and another 42% is absorbed by fans, AD/DC transformers, and storage, whereas only 18% is consumed by the processors. In addition to that, as some processors stay idle for some time, the energy really used for computation may be as low as 3% of the total. Hence, researches and actions aimed at optimizing the energy consumption of data centers should address all the IT layers involved.

The reduction of power consumption should obviously focus on the optimization of the layers that consume the biggest part of energy, i.e. power and cooling and peripherals systems. This requires research also on non-IT items, such as UPS, air conditioning and other equipment. In addition to that, virtualization can greatly reduce the idle time of processors thus optimizing the energy consumptions. All these researches are specific to particular contexts and typologies of infrastructure.

In this paper we take a different and innovative perspective and we focus on the cause of energy consumption by information systems, independently from their infrastructural implementation. In the next section we illustrate how elaborating information per se requires energy, according to recent quantum physics researches. Quantum physics also quantifies the minimum theoretical amount of energy needed to commute a bit of information, which according to the current state of our knowledge could be optimally represented by the spin of an electron. Of course this minimal amount of energy is much lower than current consumptions. This gap between theoretical and actual consumptions is due to all the inefficiencies introduced by the different architectural layers of a computational system, e.g. because we use transistors rather than atoms to store and elaborate bits.

We posit that all these layers amplify the unitary amount of energy required to elaborate information, as all the hardware supporting a processor and the infrastructure in a data center are sized according to the amount of elementary computations required. This hypothesis will be verified during our research.

When a processor spends 1W to elaborate information the total energy consumed by the system may be as much as 28 times higher, due to drivers, memory, cooling, back-up batteries and all the other auxiliary components needed by the processor to work (see Figure 3). Thus, the benefits obtained by optimizing the energy consumed for computation are amplified by the above IT layers and have a great impact on the total consumption.
Accordingly, our research will focus on analyzing the energy efficiency of software algorithms, i.e. how efficiently information is elaborated, thus laying down the foundations for future optimizations.

Recent researches (Bruschi, 2007) have shown that current energy efficiency of algorithms and applications is on average 20%, whereas energy efficiency related to data quality (low quality data requires more operations) is no higher than 60% (Restorick, 2007).

4 THEORETICAL FOUNDATIONS

This section introduces the theoretical foundations of our research roadmap. We will assume both a physical and logical perspective. The former is essential to understand how energy is actually consumed by the technological infrastructure that is at the base of an information system; the latter will help us understand why energy is required to manage information.

From a physical perspective it is well known that the average power consumed by a microprocessor while running an application is $P = I \cdot V_{CC}$, where $I$ is the average current and $V_{CC}$ is the supply voltage. Since power is the rate at which energy is consumed, the energy consumption of a given application is the integral of the power consumption $P$ over time $t$, that is:

$$EC_{\text{physical}} = \int I \cdot V_{CC} \cdot dt$$

(1)
Measuring energy consumption of an application by means of Expression (1) requires to measure $I$ and $V_{CC}$ on the hardware system actually used. Consequently, this kind of measures always refer to a specific microprocessor architecture. Moreover, from Expression (1) it is impossible to analyze why energy is consumed.

In order to solve this problem, we need to link the physical domain (i.e., electric energy consumption) to the logical domain. Energy consumption can be assessed by analyzing why a given application requires a certain amount of energy to produce the desired output. The following paragraphs introduce some theoretical definitions that are required to consider the problem of energy consumption from a logical perspective.

The Margolus-Levitin theorem (Margolus and Levitin, 1998) posits that the maximum frequency for the status commutation of a physical system is directly proportional to the total energy of the system itself. As a consequence, the minimum commutation energy required by a system to operate at a given frequency can be computed as:

$$E_{\text{min}}(f) = f \cdot \frac{h}{4}$$

(2)

where $f$ is the frequency, and $h$ is the Planck’s constant. For example, if we represent a bit by means of the direction of an electron’s spin, the commutation energy required at the frequency of 1 GHz (thus comparable to that of current desktop computers, considered that, for an average particle like an electron, the maximum commutation frequency is $f_e \approx 3 \cdot 10^{13}$ Hz) is $E_e \approx 5 \cdot 10^{-21}$ J.

The thermodynamic depth (Lloyd, 2006) is a property of each physical system: it is essentially a measure of the information required to describe, and consequently build, the system itself. This metric is related to the concept of entropy. It is well known that entropy is the measure of the level of disorder in a given system (Haddad et al., 2005). Assuming that a system can always be described by a string of bits (e.g., by describing initial speed and position of all its atoms), entropy is the number of bits of the system that are disordered and unavailable to produce work. Conversely, negentropy is the measure that quantifies the number of bits that are ordered and structured. For example, a human being has an high degree of negentropy, whereas a balloon full of helium is completely lacking of negentropy. If we want to describe a table we need a certain number of negentropic bits, but we do not need to describe the positions of all the billions of atoms of the table: these bits can stay entropic without affecting our description.

Based on these definitions, the thermodynamic depth is defined as the number of negentropic bits that have been used to build the system.

The logical depth (Lloyd, 2006) of a generic string of bits, that can be interpreted as the representation of a generic system (as well as the output of a computer application), is defined as the computational complexity of the most efficient program that is able to produce that output. In other words, it is the smallest number of elementary logical operations required to perform the computation that produces the desired string of bits.

A software application executes a certain number of computations on a defined number of bits in order to obtain a result. Applying the theoretical definitions discussed above, the energy consumption of a software application can be estimated from a logical perspective as:

$$EC_{\text{logical}}(f) = E(f) \cdot C_c \cdot T_d$$

(3)

where $E(f)$ is the energy required by a single bit status commutation at frequency $f$, $C_c$ is the computational complexity of the application that is executed and $T_d$ is the thermodynamic depth of the computation that is performed onto the problem representation. In other words, Expression (3) estimates the energy consumption by considering how much energy is required by a single bit status commutation ($E(f)$) that is applied on a given number of bits ($T_d$) for a given number of operations ($C_c$). Expression (3) allows to analyze the causes that lead an application to consume energy because it is elaborating information, without focusing on the physical and electrical mechanisms of consumptions.
First of all, we note that there is an unavoidable trade-off between energy and frequency: a faster system requires more energy. The minimization of energy consumption can be achieved by optimizing each of the three terms of Expression (3).

As discussed before, the minimum energy required for the commutation of a bit status at a given frequency is given by the Margolus-Levitin theorem. This is only a theoretical lower bound, which is valid if bits are represented by electrons’ spins. As a matter of fact, several attempts of building a computing machine that uses the electron’s spin to represent a bit have been made (e.g., Isaac Chuang at MIT has factorized the number 15 with a 7 qubit computer (Vandersypen et al., 20010). It should be considered that the energy $E_{\text{min}}$ is by far lower than the actual energy that is consumed to switch a bit in current computers based on transistors (modern architectures require approximately $10^{-14}$ Joules to commute a bit, and research are being carried on to reduce this energy to $10^{-16}$ Joules1). However, this is an hardware-related research area, and goes beyond the purposes of this paper.

The remaining two terms, namely computational complexity $C_c$ and thermodynamic depth $T_d$ can instead be faced from an information system perspective.

The minimization of the computational complexity required to produce a desired output can be obtained if the generic application $A$ that is executed has the minimum possible computational complexity, that is, exactly the logical depth $L_d$ of the required output.

The thermodynamic depth can be minimized by adopting the most efficient way of representing the problem and the data required to produce the desired output, that is the minimum thermodynamic depth $T_{d\text{-min}}$.

As a consequence, the lower bound of Expression (3) at a given frequency is given by:

$$EC_{\text{min}}(f) = E_{\text{min}}(f) \cdot L_d \cdot T_{d\text{-min}}$$

Just as the minimum energy of commutation given by the Margolus-Levitin theorem, also Expression (4) is only an ideal theoretical lower bound. In particular, the problems of writing an application with the minimum computational complexity required to obtain a desired result or stating which is the most efficient representation of a given problem are not trivial problems. For example, there exist problems for which we do not know whether the algorithms used to compute their solution are the most efficient ones (e.g., sorting algorithms). Furthermore, there exist whole classes of problems for which we do not even know if an efficient solution exist (e.g., the NP-complete problem class, if $P≠NP$). On the contrary, it is possible to design a methodology that allows the comparison of different applications from the efficiency of energy consumption point of view. By considering Expressions (1) and (3), we posit that:

$$EC_{\text{physical}}(f) \sim EC_{\text{logical}}(f)$$

That is, the energy consumption described from the physical perspective can be considered as a measurement proxy of energy consumption defined from the logical perspective. Accordingly, the comprehension and the optimization of application on the logical level should directly impact on the physical level, i.e. on the actual power absorption.

The following section presents in detail the research roadmap for the definition of such methodology.

---

1 http://www.itrs.net.
5 A RESEARCH ROADMAP

Our research roadmap focuses on the definition of a methodology that allows the comparison of different applications from the efficiency of energy consumption perspective. Our research roadmap includes the following steps:

1. Comprehension of the problem and study of the state of the art.
2. Identification and operationalization of proxy metrics for computational complexity and thermodynamic depth of specific software applications.
3. Implementation of a tool that measures these metrics.
5. Analysis of data and identification of the most representative proxy metrics.
6. Integration of the results in a software tool to support IT managers in assessing software energy efficiency.
7. Evaluation of the impact of energy costs on the Total Cost of Ownership of an application.

After a first step focusing on getting a more detailed comprehension of the problem, we plan to define benchmarking methodologies to compare different applications and, finally, to propose optimization approaches.

The definition of our methodology requires a thorough analysis of the boundary conditions for the execution of the applications that should be analyzed. Therefore we will perform our analyses on a number of different configurations of hardware infrastructures.

We assume that the commutation energy $E(f)$ of Expression (2) is constant for a given hardware setup (please note that also the frequency $f$ can be made constant for current hardware setup by disabling dynamic frequency adaptation mechanisms such as Intel SpeedStep or AMD PowerNow!). As a consequence, we will focus our analyses on the assessment of energy consumption inefficiencies caused by computational complexity $C_c$ and thermodynamic depth $T_d$.

From a theoretical perspective, the minimization of the computational complexity term would require to evaluate how far the actual computational complexity $C_c$ of a given application is from its lower bound, that is from the logical depth $L_d$ of the output that the application is intended to produce. However, as noted in Section 4, such solution is really hard to achieve, if not unsolvable at all (at least, given the current state of the art). First, it would require a general methodology for defining the computational complexity of a generic problem. Second, the actual computational complexity $C_c$ of the application should be properly determined. Third, a way to identify the shortest program that solves the problem should be determined (that is, define the logical depth $L_d$ of the problem). Fourth, a comparison between the values of $C_c$ and $L_d$ should be performed in order to evaluate how far the application is from the theoretical optimum. Since phases two and three cannot be completely automated, and would require to identify the minimum logical depth for each possible problem (which is a clearly not satisfiable requirement), we decided to focus on the definition of benchmarking methodologies to compare specific applications.

One of the first issues to be faced is to find suitable proxy metrics for computational complexity and thermodynamic depth of a given application.

Lloyd (2001) suggests a list of 42 different complexity metrics that could be used to characterize the complexity of a system from three different (yet complementary) perspectives: $a$) how hard is it to describe, $b$) how hard is it to create, and $c$) what is its degree of organization. Since our focus is to characterize the complexity of a software system, we plan to operationalize and apply such measures of complexity (or a subset of them) to software systems. Along with these new metrics, we are also
going to consider classic software quality metrics as validation terms of comparison, such as the McCabe's Cyclomatic Complexity (McCabe, 1976), the Halstead's Software Science (Halstead, 1977), and the design quality metrics for object oriented systems proposed by Chidamber and Kemerer (1994) and Brito e Abreu (1995). These metrics are not direct measures of computational complexity, but of software design quality and cohesion. Although there is not yet any empirical proof that these metrics are correlated with computational complexity, an high quality software is usually well structured and its operations follow a logical flow. Software quality metrics may be proxies, or indirect measures, of computational complexity. This hypothesis will be verified during the research.

With regard to the thermodynamic depth term, we acknowledge that different representations of the same computational problem (e.g., the file structure adopted to store data) can be more or less efficient, as well as the fact that different ways of representing single bits can have different commutation energy requirements. However, these issues will be included in our future works. Given the current absence of consolidated metrics for thermodynamic depths, we will perform our analyses on software systems and data sets of comparable dimensions, so to be in a situation of comparable thermodynamic depth.

After the definition of the theoretical framework and the operationalization of variables, we will develop a tool to measure these metrics by analyzing the code of an application.

We will then assess which subset of our metrics best represent computational complexity and thermodynamic depth and thus could be used to operationalize Expression (4). This will require to compare the data gathered by our tool with measures of actual energy consumption.

The measurement of energy consumption ($EC_{physical}$) related to the execution of specific applications will be performed through the use of ammeter clamps. Such methodology is commonly adopted (e.g., Isci and Martonosi, 2003) since it does not require particularly instrumented hardware, nor the definition of instruction-level energy consumption models for the target microprocessor (as done for example by Tiwari et al., 1994). Figure 4 shows the details of the power measurement setup that will be used to measure the actual power absorbed by a microprocessor.

We will conduct our experiments on a number of different hardware configurations, and for each configuration we will analyze the relationship between actual power consumption and the set of measured metrics. Metrics will be gathered for a sample of Open Source applications similar for domain, functionalities, and language. Different classes of applications will be considered and comparative analyses will be performed within each domain and for each specific hardware setting. Application classes will be selected according to relevance, usage (optimization is convenient only if usage is high), and also availability of a minimum number of Open Source projects. For example, ERP and DBMS systems are likely to be included in the analysis as they both respect all the criteria listed above. For each class specific scripts will be implemented to automatically generate benchmark workload and compare the consumption of the different applications. For example, for DBMS different kind of queries will be considered (e.g., CREATE/ INSERT/ DELETE on a test database with 20 fields and 1.000.000) and for ERP different activities flow will be created (e.g., create a new order, receive the goods in the warehouse, etc.).

Figure 4 – Power measurement setup.
We consider the realization of a software tool that can help IT managers in assessing the power consumption efficiency of software applications the first milestone of our research roadmap.

Finally, we will evaluate the impact of energy cost on the Total Cost of Ownership of an application and, more generally, of an information system.

6 CONCLUSIONS AND FUTURE WORK

In this paper we have proposed a research roadmap to identify a set of software complexity and quality metrics that may be used to assess the energy efficiency of a specific application. We plan to validate our theoretical framework by measuring the actual power consumption on a number of different hardware systems. Our research will result in a tool able to extract a set of energy-related metrics by analyzing the code of an application. Our tool will allow to compare the energy efficiency of two or more applications with the same functionalities, thus enabling a green-aware choice. Project managers, software developers, and software buyers will greatly benefit from our research as they will be able to assess the differences in power consumption among a set of software applications. An issue that will need investigation is how energy consuming will be the code analyzer tool, as it may turn out that the energy required to analyze and optimize an application outweigh the savings obtained. However, optimization costs occur one time only, whereas savings are repeated every time the application is executed. Moreover, most of the currently available code-based metrics can be easily and quickly computed by parsers and code analyzer tools.

After the first phase of our research, we foresee that we will extensively apply our methodology to Open Source applications so that we will gather a significant quantity of data to analyze. Our research will then focus on optimizing the energy efficiency of applications by identifying development best-practices.

ENVIRONMENTAL RESPONSIBILITY AND GREEN IT: AN INSTITUTIONAL PERSPECTIVE

Abstract

A recent Gartner Research report found that environmental concerns are increasingly exercising the minds of business and IT executives. This is reflected in the growing interest in the adoption of environmentally responsible approaches to the deployment, operation and use of IT. However, for the majority of firms, issues of cost reduction and energy efficiency appear to predominate. This paper argues that whether it is an interest in Green IT or in cost reduction, the concerns of business and IT managers are modulated by regulative, normative, and cultural-cognitive influences in the institutional environment. The study therefore applies institutional theory to develop a series of theoretical propositions which specify the effect that such influences have in shaping environmental responsibility in organisations. Important as such a theoretical contribution may be, there are, however, the pressing practical imperatives of formulating Green IT strategies, achieving energy efficiencies, and reducing carbon footprints—thus, the study also contributes to a practical understanding of the complex institutional influences at play in shaping such imperatives.

Keywords: Institutional Theory, Environment, Green IT
1 INTRODUCTION

The design, manufacture, deployment, operation, use, and disposal of information technology (IT) has significant implications for the environment (Aberdeen Group 2006). For example, IT (computers, networking, data and telecommunications technologies) consume significant amounts of energy when in use and contribute in no small way to the growth in greenhouse gas (GHG) emissions. Energy issues aside, IT artefacts also contain regulated and hazardous materials. Accordingly, the influence of environmentally-oriented regulatory and social pressures are especially evident in the IT sector (Murugesan 2007), particularly in manufacturing, but also in adoption, operation and use (Murugesan, 2008). IT is increasingly viewed as a significant and growing part of the environmental problem—something that few people take seriously, particularly IT executives (CNET Networks 2007).

This paper has as its focus Green IT. In the past, IT was designed, manufactured, and applied in business enterprises without regard to its environmental impact. In recent years, the term Green IT was coined by practitioners to differentiate between IT artefacts that had been designed with environmental sustainability in mind—that is, to contain the minimum amount of hazardous materials, to be energy efficient during the use period of their lifecycle, and to be disposed or recycled with the minimum effect on the environment and human health (Murugesan 2007). The IT industry has, of late, extended the scope of Green IT to include the manner in which IT is deployed to help reduce GHG emissions, to introduce energy efficiencies, or to reduce energy consumption (Adjugo 2008a,b; Gartner 2007, 2008). Academics such as Boudreau, Watson, and Chen (2008), argue that therefore IT-enabled information systems have a role to play in making business processes environmentally sustainable—they term such information systems Green IS. This study conceptualises Green IT as including all of the above, in order to avoid the possibility of definitional confusion and to maintain congruency with practitioners’ use of the term. This paper also introduces the concepts of corporate social responsibility (CSR) and corporate environmental responsibility. The link between Green IT and CSR has been commented upon (cf. Ryan 2008b); as has the relationship between CSR and corporate environmental responsibility (cf. Eisner 2004). For example, it is now common practice for many business enterprises to describe policies or measures aimed at environmental sustainability as part of their statements on corporate social responsibility—Green IT strategies are now included under this heading (cf. Ryan 2008a on Dell and Hewlett Packard).

In its recent Green IT Survey of Belgian executives, Adjugo (2008b) reports that 57% of respondents did not view Green IT as being part of their companies’ CSR (corporate social responsibility) initiatives. Nevertheless, Gartner reports that IT needs to become greener as energy is due to become a significant component of IT budgets, rising from 10% to 50%. Add to this the costs of planned carbon taxes and compliance with future environmental regulations. Current estimates suggest that IT accounts for over 2% of global CO₂ emissions (Gartner 2007)—roughly the same amount as generated by air travel. IBM (2008) argues that datacenters account for 2% of CO₂ emissions, implying that the true figure is much higher than this. Whichever figure is most accurate, the true cost to the environment of the design, manufacture, transport, and disposal of IT is much higher than estimated (Murugesan 2008).

Presently, there is little doubt of the impact that CO₂ and other greenhouse gases are having on the climate: consequently, all sectors should be taking responsibility to lower their GHG (Johnston 2008). However, a recent study by IBM argues that a majority of organizations do not possess a green IT strategy, let alone the capabilities to build one (cf. Gartner 2008, Adjugo 2008a). The reasons for this state of affairs are found in recent research by the UK’s Corporate IT Forum. This study on 150 large member organisations reported that while 81% of IT executives indicated that Green IT was higher up the corporate agenda than in 2007, it was just in eighth place behind security, legacy software, data quality and server consolidation on their list of priorities (Cooter 2008). Thus, issues of strategy aside, the costs associated with the transition to Green IT architectures are viewed as being problematic for business and IT executives. Both problems are related, however, as Cooter reports on a statement by
Ian Campbell at the European Green IT Summit in London to the effect that “managers often struggled to present a sound business case -- that was the biggest inhibitor” to the adoption of Green IT strategies. Campbell is quoted by Cooter as stating that perhaps the biggest problem faced by organisations is in measuring the impact of green IT policies. He indicated that there was an absence of standards—national and international—with which to evaluate and benchmark green initiatives. It is no doubt, with such issues in mind, that a recent study by Gartner Research (2008) argued that environmental concerns will increasingly impact on organizational decisions to purchase, deploy, operate and dispose of information technology (IT). There is, therefore, a need for business and IT managers to be knowledgeable of, and proficient in, all issues relating to the procurement and use of IT viz, the management of energy and power issues; data centre design and operation; IT server virtualization; regulatory compliance and eco-labelling of IT artifacts (in regard to the use of hazardous substances); green metrics and audits; teleworking and so on (Murugesan 2008).

Given the broad scope of the Green IT problem, this study will focus on the operation and use of IT to achieve green objectives. However, as Green IT is now a relatively mature topic for IT manufacturers, examples of their experiences in addressing regulative, normative, and cultural-cognitive institutional influences on their activities will be employed to illustrate the challenges that may confront end-using business enterprises. The question that arises from this introductory analysis and which guides the conduct of this study is: What institutional forces act to shape the ‘environmental concerns’ of business and IT managers in making the operation and use of IT green, and how can Green IT objectives be realised?

Green IT is a new and emerging issue for IS researchers. Webster and Watson (2002, p. xiv) recommend that “authors could tackle an emerging issue that would benefit from exposure to potential theoretical foundations” through the medium of a review paper. This paper follows Webster and Watson in addressing the phenomenon of the operation and use of Green IT. The first section of this paper therefore examines the forces shaping the ‘environmental concerns’ of business and IT managers through the lens of institutional theory.

2 APPLYING INSTITUTIONAL THEORY TO GREEN IT

Richard Scott (2004) argues that institutional theory is concerned with the influences that shape social and organisational structures, schemas, rules, norms, routines and, ultimately, the behaviour of social actors. According to Scott (2001, p. 33), institutions consist of “cognitive, normative, and regulative structures and activities that provide stability and meaning to social behaviour.” Thus, Scott (2001, 2004) argues that regulative, normative and cultural-cognitive institutional forces shape organizational processes and structures—such forces prescribe what is effective performance or efficient operation in organizations (Powell 1991). Focus is brought to this broad theoretical lens by DiMaggio and Powell’s (1983, p. 143) concept of an ‘organisational field’. An organisational field is constituted by a collection of “organizations that, in the aggregate, constitute a recognized area of institutional life”; inter alia, the field consists of “key suppliers, resource and product consumers, regulatory agencies, and other organisations that produce similar services or products.” While environmental ‘concerns’ shape Green IT responses across multiple organisational fields, due to the ubiquity of IT, the concept is nevertheless useful. Thus organisational fields are characterized by regulative and legislative (coercive) influences from government departments, state-sponsored agencies, the judiciary, and so on, in addition to normative and cultural-cognitive (mimetic — DiMaggio & Powell1983) influences from related organisations (professional and standards bodies, non-government organisations (NGOs), consulting organisations, professional bodies, etc.), and society at large (NGOs and community groups, for examples).
2.1 Regulative Influences on Corporate Environmental Responsibility

It is clear from Scott (2001) that the emphasis of regulative institutional influences is on coercion, indicators of which are rules and laws, which agents such as governments and regulatory agencies legitimize using legal mechanisms or sanctions to ensure Green or environmentally responsible behaviours or initiatives. Regulative institutional carriers, on the other hand, are social structures such as governance and power systems, which institute rules and laws, the organisational response to which is to institutionalize routines such as protocols and procedures (Scott 2001). Drawing on the introduction to this paper, we may now state our first general theoretical proposition:

Proposition 1: Governance and power systems, rules, and laws, will give structure to and shape organisational responses, procedures and protocols around the institution of Green IT initiatives.

Unlike organisational and societal end-users of IT, IT manufacturers are currently confronted with diverse regulations governing the design, production and performance of computers and other IT artefacts (Aberdeen Group 2006, Kellow 2006). Briefly, such regulations include the European Union’s (EU) Waste Electrical and Electronic Equipment Directive (WEEE), the Restriction of Hazardous Substances Directive (RoHS), the Registration, Evaluation and Authorisation of Chemicals (REACH) Regulation, and the Eco-Design for Energy Using Products (EuP) Directive (Hristev 2006). All of these place onerous compliance imperatives on IT manufacturers. Indeed, the rest of the world is catching up with the EU. In the US, for example, the Environmental Protection Agency (EPA) has numerous regulations covering environmental issues and hazardous substances across the whole range of manufacturing sectors. However, individual US states such as California are following the EU’s lead in introducing exacting WEEE and RoHS-like standards. Other jurisdictions are no less stringent as is the case with Japan, which also has highly demanding laws, while over the last two years, Korea, Australia, China and Canada have introduced legislation similar to the RoHS and WEEE directives.

The total amount of electricity consumed across all sectors in Europe is estimated to be growing at an annualised rate of 2% (Salhofer, Schiffleitner, and Stachura, 2008). Significantly, research by McKinsey (2007) indicates that energy consumption by computers and IT in general is projected to increase at an annual rate of approximately 3% to 2030—much higher than the overall trend. However, that estimate is conservative compared to that of Gartner (2007), who project that the energy portion of IT departments’ budgets is due to rise from 10% to 50% in a much shorter time period, with datacentres responsible for the lions share of this. Thus, corporate datacentres are singled out for special attention, as the EPA calculates that they presently account for an unacceptable 1.5% of US energy costs. In a different context, Alain Bandle VP and GM Dell Europe argues that the IT sector is responsible for 5% of total global consumption of electricity (850 terawatt hours) 520 million tones or 1.6% of global CO2 emissions (Bandle, 2008). These projected increases in consumption needs to be balanced with pressures to reduce consumption.

According to Peter Johnston (2008 p. 19), “[i]n the European Commission, we have identified ICT-enabled improvements in energy efficiency as one of the potentially most cost-effective ways in which Member States can meet their 2020 targets.” He adds that “Energy efficiency is therefore emerging as the cornerstone of energy and climate policies.” Take, for example, the EC Directive 2005 32/EC which focuses on energy efficiency in products: this sets a challenging target for energy savings of up to 9% in the period 2008-2016. Furthermore, the EU Green Book on energy efficiency estimates that energy savings of up to 30% for businesses is possible by 2020. Clearly, much will need to happen if residential and business electricity consumers are to meet EU targets. Failure to do so will, no doubt, result in further regulation in the area as energy generation in EU member states is responsible for over 24 % of the communities greenhouse gas (GHG) emissions. Thus, as EU member states fail to meet the greenhouse gas emissions targets, business organisations will be faced with regulations governing their energy efficiency. The present approach of depending on market forces and the price mechanism to control inefficient energy use by businesses will be replaced by legislation and energy audits. Thus, the option to go ‘green’ may not be left in the hands of business organisations for much
longer (cf. Johnston, 2008). The European Union continues to build a raft of environmental regulations and directives, the outcome of which will be increased carbon taxes and the imposition of further environmental compliance imperatives on GHG emissions (cf. Salnofer, Schiffleitner, & Stachura 2008). Likewise, Stephen Harper (2008) of Intel predicts that the US will adopt similar measures. Indeed, there is evidence that the US congress is already thinking along these lines (King 2007, cf. EPA 2007). Thus, business and IT managers which Cooter (2008) found to be recalcitrant in lowering the energy consumption (and associated GHG emissions) due to the cost of upgrading and replacing IT infrastructures, may have little choice in the matter in the not-too-distant future.

Take, for example, that the Eco-Design for Energy Using Products (EuP) Directive is presently being rolled out across electrical and electronics product groupings, including IT artefacts such as computers and monitors. Although still being formalised, it is being phased in and implemented across EU member states. The EuP Directive will require IT manufacturers (among others) to make voluntary declarations (presently) on the energy used in the design, packaging, delivery, and recycling of products across supply chains, in addition to the energy consumed during use. This new directive significantly extends Energy Star-like standards in EU member states such as Blue Angel in Germany Nordic Swan in Scandinavia. However, current thinking with the European Commission indicates that member states will have to regulate to have widespread efficient use of EuP, if they are to stand any chance of meeting GHG emission targets. The ever-increasing energy consumption of IT concerns the Environmental Protection Authority (EPA), as its recent report to the US Congress indicates (EPA 2007). With electricity cost and consumption rates to increase going forward, and with power shortages already evident in certain parts of the US, the EPA’s report makes some strong recommendations involving both carrots (i.e. incentives to conserve energy) and sticks (an energy efficiency tax for inefficient organisations)—all of which has serious implications for business enterprises, if adopted by the US government.

Proposition 2: Business and IT managers are more likely to be environmentally responsible (e.g. implement Green IT) if they are coerced into doing so by rigorous and comprehensive environmental regulations (e.g. aimed at reducing GHG emissions).

Thus, it is clear that in the absence of strong self-governance in relation to energy consumption, regulators in the EU, the US and elsewhere will become increasingly active in demanding compliance with energy efficiency and GHG emissions regulations and adherence to demanding targets (cf. Campbell 2007). It is certain that such measures will favour Green IT strategies that focus on structural power consummation avoidance with its emphasis on reducing the installed power base, as opposed to temporary avoidance strategies, which focus on the optimization of energy utilisation, without reducing the installed power base. Certainly, organisations that have made substantial efforts and costs to become greener will reap the first-mover benefits in terms of compliance, as has already been seen in the electrical and electronics sector (Aberdeen Group 2006).

2.2 Normative Influences on Environmental Responsibility

Scott (2001) argues that the emphasis of normative influences is on social obligation as a basis of environmental responsibility or Green behaviours: the basis of legitimacy for normative forces is moral governance. Scott also emphasises that the institutional carriers of such influences are the values and expectations that develop in cultures and organisational fields. Other carriers include authority systems in social structures and routines that reflect conformance and performance of duty.

In Joel Bakan’s The Corporation, Peter Drucker argues that executives who are concerned about the environment should be fired “...and fast”. Likewise Bakan reports that the economist and Nobel Laureate Milton Friedman holds similar views and observes that the only time that corporate social responsibility can be acceptable is when it is insincere. What Friedman means here is that ‘going green’ can only be a means to an end—the ends being to enhance brand image and increase market share in order to maximize shareholder wealth. Obviously Friedman’s views did not change since his 1970 article in the New York Times Magazine titled “The social responsibility of business is to
increase profits.” Indeed as Bakan (2005, p. 35) states “Corporations are created by law and imbued
with purpose by law. Law dictates what their directors and managers can do, what they cannot do, and
what they must do.” Indeed, this point weakens the argument for self-regulation and supports
Proposition 2.

In the four years since Bakan penned his argument, the business environment has changed. William
Ford, Jr., Chairman of the Ford Motor Company, argues, for example, that “corporations could be and
should be a major force for resolving environmental and social concerns in the twenty-first century”
(cited in Bakan, 2005, p. 31). Klaus Schwab, Executive Chair of the World Economic Forum, argues
that corporate social responsibility (CSR) focuses on the broader financial, social and environmental
effects of all that a company does (Schwab, 2008). Thus, companies who exercise CSR minimize any
negative effects of their commercial activities by taking responsibility and being accountable for
economic externalities in all spheres of its operations (Bakan 2005). Traditionally, companies attended
only to the bottom-line—their financial results, which usually did not account for externalities. Firms
practicing CSR, on the other hand, attend to a triple bottom-line, which includes being accountable for
what they are doing in terms of environmental and social responsibilities, in addition to their financial
obligations of maximizing profits (Schwab 2008). Schwab goes on to argue that CSR encompasses the
entire value chain to include suppliers and customers. The exercise of CSR by Ford Motor Co. reflects
this, as it requires all suppliers to be IS14001 compliant, thus using the supply chain as a vehicle to
drive environmental responsibility. In regard to Green IT, it is clear from Collett (2008) that CSR and
other environment-oriented initiatives introduced by industry standards bodies such as the Institute of
Electrical and Electronics Engineers, the Global e-Sustainability Initiative (which includes Microsoft,
Sun, Ericsson, Bell, BT, Dell, HP, and many others: cf. www.smart2020.com), the US-based
Electronic Product Environmental Assessment Tool (EPEAT) organisation, and so on, that self-
regulation via normative mechanisms is possible, this pleads to the following proposition:

**Proposition 3**: Organisations are more likely to be environmentally responsible if there are well-
defined systems of self-regulation with tangible recognition for rewarding often costly Green IT
initiatives.

Normative standards on computer environmental footprints are, as indicated, the Blue Angel in
Germany and Nordic Swan in Scandinavia. However, the most influential normative initiative is
undoubtedly that of the Environmental Protection Authority in the US which has a major focus on
energy-consumption-related GHG emissions. In 1992, the EPA’s instituted its Energy Star
programme—which concentrates on the energy use of products in use. Almost all major manufacturers
now produce Energy Star compliant products. Notably, only products in the first quartile (25%) of
energy efficiency standards set by the EPA and U.S. Department of Energy are awarded an Energy
Star rating. In 2006, the Green Electronics Council, which includes the EPA, U.S. Department of
Energy, and industry standards bodies introduced the Electronic Product Environmental Assessment
Tool (EPEAT). EPEAT is based on the Institute of Electrical and Electronics Engineers (IEEE) 1680
Standard, Section 4 of which governs environmental performance criteria for desktop PCs, notebooks,
and PC monitors. In terms of IEEE 1680 Standard Section 4, EPEAT is concerned with the (a) the
reduction/elimination of environmentally sensitive materials; (b) materials selection; (c) design for end
of life; (d) product longevity/life cycle extension; (e) energy conservation (Section 4.5 covers
adherence to the Energy Star standard); (f) end of life management (take-back and recycling); (g)
corporate performance (in terms of CSR); and (h) packaging (toxics, labelling). While the US
Government did not regulate on the IEEE standard or EPEAT, an Executive Order was issued by
President Bush in 2007 requiring all US federal agencies to purchase only EPEAT-certified artefacts
(Ryan 2008a) . Significantly, in July of 2007, a year after EPEAT’s launch, Energy Star 4 came into
force, which is a much more rigorous standard than its predecessor Energy Star 3. Currently, Hewlett
Packard (HP), Dell, and Toshiba manufacture computers to reach Gold standard certification (there are
also Silver and Bronze certificates). The success of the Energy Star programme is reflected in the fact
that in 2007 devices designed to Energy Star specifications resulted in savings of 40 million metric
tons of GHG emissions; this is equivalent to taking 27 million vehicles off the road annually (Hojlo
and Jacobson 2008). Yet further evidence of the effectiveness of standards in promoting environmental responsibility is the Leadership in Energy and Environmental Design (LEED) Standard, which is a Green Building Rating System developed by the U.S. Green Building Council. Deloitte is implementing those standards in the construction of its datacentre in Dallas (Desmond, 2008).

It is clear that practitioner publications, on- and off-line, such as Computerworld, NetworkWorld, CNET, the Cutter IT Journal have been raising awareness of late on environmental issues, particularly the issue of energy efficiency as it relates to Green IT. So too have bellwethers like Gartner Group, Forrester Research, the Aberdeen Group, trade and industry conferences such as Electronics Goes Green (EGG2008+), and so on. All this, in addition to normative prescriptions from the ISO and IEEE standards bodies, NGOs like the EPEAT, and so on, influences IT practitioners’ decisions. This leads to the following proposition:

**Proposition 4**: Business and IT executives are more likely to introduce environmentally responsible programmes, if Green IT is promoted by, and institutionalised through, industry standards, business publications, consultancy bodies, and other fora in which executives participate.

2.2.1 **Normative Influences of Stakeholders on Cost Reduction Vs. Green IT**

Returning to the point made by Milton Friedman, that if the social responsibility of business is to increase profits, then it is logical to assume that business will take steps to reduce costs if this increases profits. Thus, the findings of research by Forrester (2007) indicates that 55% of business and IT executive surveyed saw cost as the chief motive for instituting sustainable IT operations, not Green IT or concerns for environment-related energy efficiencies. It must be remembered, however, that it is only relatively recently that end-user organisations not in the IT sector, e.g., in the services sectors perceived the benefits of adopting ‘Green Strategies’. For example, Collett (2008) reports that Wachovia Corp. was ranked 12th in Computerworld’s survey of Top 12 Green IT Users in 2008. Likewise Desmond (2008) reports on Deloitte’s corporate Green IT initiative. Yet, there is not a widespread recognition by business and IT executives that costs can be reduced and profits increased through Green IT strategies. Significantly, Duffy (2008) reports that “80% of companies recently surveyed by Nemertes [Research] have no corporate green policies; only 13% knew datacenter energy costs; only 3% turn off their servers when not in use; and desktops are left on 50% of the time.” Clearly given the opportunity of cost reductions, IT are not serving stakeholders needs or exercising environmental responsibility. Yet as the following examples illustrate, the cost savings can be significant for relatively simple procedures.

Consultants from Adjugo (2008a) argue that “[i]mplementing quick wins like switching off computers after business hours can reduce the energy consumption up to 75% per year.” However, such straightforward changes in the management of workstations can have significant implications for an IT function’s methods of operation viz. conducting workstation and server software upgrades, patches and backups outside of normal business hours. One might be forgiven for thinking that such simple procedures would be within the ambit of business and IT managers; yet the opposite appears to be the case if stories carried in practitioner publications are to be believed. There are, nevertheless, several powerful examples of significant cost savings.

**Proposition 5**: Business and IT executives are more likely to introduce environmentally responsible programmes, if they are aware of the costs reductions associated with the implementation of Green IT initiatives and the resulting increase in profits.

2.3 **Cultural Cognitive Influences**

Cultural-cognitive influences that emphasize environmentally responsible behaviours are ‘taken for granted’. Beliefs and attitudes toward compliance are socially constructed and transferred mimetically, while being governed by a logic of orthodoxy. Institutional carriers include, according to Scott (2001),
socially constructed cultural categories and typifications and routines that are reflected in performance programs and scripts. Of interest to the present study are social structures that result in isomorphism of social and organisational practices.

Climate change and environmental concerns has led investors and investment managers to focus on green investments (Mincer 2007). Traditionally, investors have examined risk, liquidity and rate of return as investment criteria; now, however, an increasing number of investors look toward social and environmental factors (Kahlenborn 1999). Kahlenborn (ibid., p. 65) presents two contrasting definitions of ‘green investment’: in the first, it “can be understood as any form of financial investment whereby the investor pays attention to ecological goals as well as the traditional aims of investment. On the other hand, ‘green investment’ can be understood as an investment that successfully counteracts negative influences on the environment, or serves to produce goods or offer services that have positive effects on the environment.” Over the last ten years there has been a significant increase in individual investment and mutual funds focusing on what is in 2008 an established niche market (Kahlenborn 1999, Mincer 2007). Thus, in highly competitive business environments where ‘trust’ is an issue, and investor confidence seriously damaged, business enterprises that display CSR and act on environmental concerns may shape customer preferences and investment decisions in opting for ‘green strategies’ which could tap into an additional source of investment funding (cf. Campbell, 2007). It is clear that such funding is not limitless, so firms will also have to compete on their environmental credentials.

**Proposition 6:** Business and IT executives are more likely to introduce environmentally responsible programmes such as Green IT if doing so enhances their image and attracts Green Investors.

Thus, is the environmentally responsible behaviour of William Ford out of step with his corporate colleagues as Joel Bakan’s thesis would indicate? In an industry whose products are perhaps the most polluting and environmentally unfriendly when is use, presenting an environmentally positive image can only contribute to the bottom-line. So, given the nature of Ford’s business, are he and his company genuine in exercising CSR, or is this a form of ‘greenwash’? ‘Greenwashing’ products and brands has become commonplace as companies increasingly use a product’s ‘greenness’ as a basis for competition. Complaints to the UK’s Advertising Standards Authority (ASA) regarding ‘greenwashing’ in product advertising have increased dramatically in the recent past (Charles 2007): for example, complaints to the ASA averaged over 56 per month in the last two quarters of 2007. Likewise, a signal that all is not well in the IT sector comes from James Staten, a principal analyst at Forrester Research. He recently warned IT executives about the level of ‘greenwashing’ taking place in the industry, as manufacturers imply that whole product lines are green, when in fact only a proportion of products may be. The consequences of ‘greenwashing’ are significant, as stakeholders tend to lose confidence in a firm’s ability to be honest leading not only to potential damage to market share and the bottom line, but also to the withdrawal of valuable sources of investment (Zagenczyk 2004).

Greenpeace is one NGO that is especially significant in shaping public opinion regarding corporate environmental responsibility. They use their website to publish the results of studies and analyses of green and not-so-green products. Whether accurately or not, they also rank manufacturers based on their eco-friendly products and strategies. Take for example their Apple webpage ([www.greenpeace.org/apple/itox.html](http://www.greenpeace.org/apple/itox.html)) which states “Apple products – sleek looks, amazing design, and meticulous attention to detail. So what’s with the toxic chemicals inside, short life spans and allowing their products to be dumped in Asia?”. It must be noted that Apple launched its Greener Apple initiative in 2007, much to Greenpeace’s annoyance, as it considered Apple to be greenwashing. Companies like Nokia, on the other hand, are lauded for their efforts at environmental responsibility. This is one of the reasons why the Greenpeace presentation at the Electronics Goes Green 2008 conference in Berlin was, perhaps, the best attended with standing room only in the aisles. Clearly, NGOs like Greenpeace can shape public perceptions of corporations and products, hence they can exert cultural cognitive as well as normative influences on business activities. The press also shapes public perceptions and various publications are eager to report and rank firms based on their
approaches to corporate social and environmental responsibility. Take for example, McLean’s in Canada, whose Technology and Media section reported that Hewlett Packard’s efforts at social responsibility received an A+ ranking, while Dell and IBM achieved an A, NOKIA an A-, and Nortel and B+. Thus, the watchful eye of society at large is upon producers, with the media industry being all too ready to highlight issues of concern. Given the foregoing arguments, we now present the following proposition:

**Proposition 7:** Business and IT executives are more likely to introduce environmentally responsible Green IT programmes if their activities, processes and products are being monitored and reported upon by independent non-government organisations, the press, and society at large.

It is clear from Corporate Annual Reports (e.g. Dell, Intel and HP—Cf. Ryan 2008a,b) that corporate social and environmental responsibility is viewed as being increasingly vital to promote public perceptions and to add to the bottom line (cf. Campbell 2007, Adjugo 2008 a,b, Collett 2008). Thus, institutional theory would predict that mimetic behaviours would have business and IT managers imitate each other in terms of Green IT strategies. This is certainly occurring in large global corporations. Likewise, the increasing evidence of greenwashing has business ‘appearing’ to imitate. In the event that businesses do actually imitate each other and implement Green IT initiatives, then isomorphism that will benefit society as a whole will occur across firms. We may now present our next and final proposition.

**Proposition 8:** Business and IT executives will mimic successful Green IT strategies of others leading to industry-wide isomorphism in terms of environmental responsibility practices with regard to the operation and use of IT.

### 2.4 Directions for Future Research

This paper employs institutional theory to develop applied theoretical propositions; however, these require further elaboration in process-based studies, whether positivist, post-positivist or interpretivist. Such studies might employ the propositions as a theoretical lens in, for examples, exploratory or explanatory case-based research, using analytic generalisation or replication strategies (Yin 2003). The continued use of institutional theory is recommended, of course; however, following Currie (2009), we argue that multiple levels of analysis that encompass the institutional environment, organisational field, organisation and social actors would be of greatest utility. These could, for example, identify the institutional arrangements (i.e. specific Green IT strategies) organisations deploy in response to forces in the institutional environment, or the organisational field (DiMaggio and Powell 1983). In-depth case studies could also be used to inform practice as to why and how business enterprises are adopting and applying Green IT to reduce GHG/CO$_2$ emissions and introduce energy efficiencies. Such studies might also help identify how software solutions (or Green IS, if you will) can be designed and developed to make business and IT processes more environmentally sustainable across the business (cf. Boudreau et al. 2008).

Following Wheeler (2002), positivist or variance studies could build on process-based case studies to generate hypotheses and identify empirical indicators to subject the theoretical propositions/meso-level applied theory to test in order to attempt to falsify it. Here again, however, Currie’s (2009, p. 66) cautionary observation on the use of institutional theory that “Many variance and process studies examine the cause/effect relationships between IT-related constructs, such as adoption intention, assimilation and implementation, without considering the wider environmental and inter-organisational levels. Such an oversight is problematic, both theoretically and empirically, since the mainstay of institutional theory is an emphasis on multi-level and multi-stakeholder analysis.” Thus while institutional theory can contribute to a greater understanding of Green IT, Currie’s recommendations should be observed if such an understanding and theoretical contribution is to be achieved.
3 CONCLUSIONS

This paper examines a new and emerging research topic for IS researchers. Indeed, with IT literally up there with airline travel as a contributor of greenhouse gas emissions, the greening of IT should be uppermost in the minds of practitioners, as well as being high on the IS field’s research agenda. Yet despite the threats to the environment brought on by climate change, it appears from industry-based research that IT practitioners are leading the way only in their ignorance of the impact of energy inefficient practices relating to the deployment, operation, and use of information and communication technologies (ICT). Campbell (2007) argues that corporations behave in a socially responsible way when economies perform well, and are less than interested in exercising this responsibility, or are unable to do so, during economic downturns. It would be reasonable to assume that in the buoyant economic conditions that existed for the majority of firms over the past 10 years that business and IT executives would have exercised corporate environmental responsibility by making IT use more energy efficient and thereby reducing both related costs and greenhouse gas emissions. We conclude that they did not initiate energy conservation measures due to a general ignorance of the consequences and a failure to self-regulate. To be sure, there are many notable exceptions to this, but the facts speak for themselves—the majority did nothing, despite enormous increases in energy costs since 2004. Hence, such executives failed also in their primary objective of maximising shareholder wealth through increasing profits by lowering costs, both in the short term and over the long term.

This paper’s application of institutional theory to the phenomenon of Green IT indicates that a small but growing proportion of IT practitioners are responding to normative and cultural-cognitive influences and making their IT infrastructures environmentally responsible. It must be noted that many of these firms produce IT products and services (e.g. participants in Global e-Sustainability Initiative) and have for some time now been subject to regulative influences with regard to their production activities. Hence, they have been sensitive to environmental issues. Their Green IT initiatives have not, we believe, gone unnoticed by others in their organisational fields. Thus, they have shaped the broader institutional environment through cultural-cognitive influences that have engendered environmental responsibility in and across businesses through mimetic responses. At the time of writing, there is a global recession and, with corporate budgets being trimmed, Green IT initiatives are likely to suffer if they require initial investment to obtain energy efficiencies that will reap future cost reductions. Yet, in the face of ever increasing energy costs, there is hope that companies will attempt some of the ‘quick wins’ described in the literature (cf. Ryan 2008a). Unfortunately, the majority of such ‘quick wins’ will be in the front office, as improvements in energy efficiency in back-office ICT are not so easy to attain, as reducing power consumption requires structural measures such as reduction in installed power capacity—e.g. reducing the number of servers and using virtualisation to optimise server loads. Significantly, data centres account for much of the growth in IT energy consumption and related greenhouse gas emissions. (Hence, Intel’s argument that thin-client architectures are not as energy efficient as energy efficient power managed workstations and notebooks.) Thus, significant investments are required here to reduce both consumption and emissions in the operation of server farms and data centres. At the time of this submission (Dec 1st), government officials across the globe are in Poland to attend the UN Climate Change Conference, which aims to frame a replacement for the Kyoto Agreement. Likewise, the UK government is today talking about decreasing GHG emissions by 20% before 2020. Thus, it is more than likely that, economic downturn or not, governments and regulators will look to the long term and regulate inefficient energy use by business enterprises in order to address overall greenhouse gas emission targets, which are not presently being met. Indeed, many now argue that the targets set out in international agreements such as Kyoto are to be revised upwards, as with the UK—all of this has significant implications for energy efficiency in the deployment, operation, and use of IT infrastructures.

COLLABORATIVE SOURCING – THE MOTIVATION AND DESIGN OF DEMAND SIDE COMBINATIONS

Borman, Mark, The University of Sydney, Room 422 Building H69, Sydney, NSW 2006, Australia, m.borman@econ.usyd.edu.au

Abstract

Collaborative sourcing is defined as a group of organisations combining on the demand side as part of the outsourcing process. Based upon a synthesis of the outsourcing and collaboration literatures, this paper seeks to examine both the benefits of collaborative sourcing and the options available. A series of case studies identifies that a number of alternative collaborative sourcing modes are possible with differing motivations – based on economies of scale but moderated by other influences – intensity – ranging from simply aggregating demand at the contracting stage to establishing a separate entity to actually provide the services – focus – from IT infrastructure through to business processes – and extent – the number of partners involved and activities covered.

Keywords: outsourcing, alignment, collaboration, interorganisational systems
1 INTRODUCTION

Since its genesis the outsourcing literature has developed considerably from viewing outsourcing as a singular concept (Loh and Venkatraman, 1992a) to recognising that many different types of outsourcing are possible (Marcolin and McLeLlan, 1998). Variations have been identified based upon the scope of the arrangement (Sambamurthy et al, 2001), its timeframe (Lacity and Willcocks, 1998), whether one or several suppliers are involved (Currie, 1998), the type of activity concerned – for example differentiating between information technology (IT) and business process outsourcing (Dibbern et al, 2004) – its geographical location (Bergkvist and Fredriksson, 2008) and the nature of the relationship between supplier and client (Fitzgerald and Willcocks (1994). Several classifications have been proposed. Millar (1994), for example, suggested four different types of outsourcing arrangement – differentiated by purpose, inclusion and relationship. Cullen et al (2005) classified outsourcing arrangements based on scope, supplier grouping, financial scale, pricing framework, contract duration, resource ownership and commercial relationship. Willcocks et al (2007) identified alternative outsourcing models – including traditional, netsourcing and customer-supplier joint ventures.

One area that the literature appears to have neglected however is the potential for collaborative sourcing – defined here as a group of customers combining their demand as part of the outsourcing process. Gallivan and Oh (1999) recognise a class of outsourcing where a group of organisations come together to obtain a common service from a supplier, a review of the literature suggests that little research has been conducted on the phenomenon. An exception is the work of Seddon (2001) which examined the IT outsourcing by clusters of agencies within the Australian Federal Government – however this concluded that the approach does not work. Yet the potential benefits of collaboration in other spheres are well recognised (Smith, Carroll and Ashford, 1995) and a number of collaborative sourcing ventures have been initiated. In the UK, for example, Lloyds TSB Bank, Barclays Bank and HSBC bank have formed a joint venture for cheque processing (Roberts, 2004). As such it does not seem to be appropriate for collaborative sourcing either to be ignored or summarily dismissed as unworkable.

The remainder of the paper comprises two sections. The first reviews literature relevant to collaborative sourcing to develop a framework to better understand the potential motivation and identify dimensions that define the resulting design. As with outsourcing, successful collaborative sourcing requires a clear motivation or objective (Dibbern et al, 2005). In addition, the plethora of outsourcing options that have emerged – see earlier – suggest that it is important to clearly specify the design of the resulting collaborative sourcing. The second section presents the results of an empirical study of nine collaborative sourcing arrangements in Australia conducted to assess the usefulness of that framework.

2 THE MOTIVATION AND DESIGN OF COLLABORATIVE SOURCING

Given the absence of an established literature regarding collaborative sourcing, existing research on outsourcing and collaboration formed the twin starting points for a literature review to develop a theoretical framework for understanding the motivation for, and design of, collaborative sourcing.

A wide variety of motivations have been posited for outsourcing; including a desire to focus on core competencies (Lacity and Willcocks, 2001), a response to the actions of other organisations (Loh and Venkatraman, 1992b) and the perception that external suppliers have superior capabilities (Poppo and Zenger, 1998). Perhaps the most frequently cited reason for outsourcing however is the reduction of operational costs (Lacity and Willcocks, 1998), often through economies of scale – the production and distribution efficiencies which come with
larger size (Chandler, 1990; Dibbern et al, 2005). For traditional outsourcing benefits can accrue in circumstances where in-house production does not achieve the minimum efficient scale (Venkatesan, 1992). Collaborative sourcing introduces a demand side dimension to this traditionally supply side phenomenon. As a group of organisations aggregate their demand a potential supplier should become better placed to realise economies of scale in meeting it.

While outsourcing research has examined the design of outsourcing arrangements it has often done so from a process rather than a structural outlook (see Dibbern et al, 2005) – in particular emphasising the relative role played by contracts and relationships – and from a customer–supplier(s) perspective (Willcocks et al, 2007). It has not examined in any depth the possibility of, and structures for, customers acting collaboratively (ie customer-customer). As such it is necessary to turn to research on collaboration. There is a considerable body of research examining collaboration from the perspectives of motivation, intensity and extent (Powell et al, 1996; de Rond and Bouchikhi, 2004). A wide variety of motivations for collaboration have been proposed including scale economies (Larsson et al (1990), competence development (Hamel et al, 1989), the spreading of risk (Guglar and Dunning, 1993), increased resource utilisation (Clemons and Row, 1992), access to complementary resources (Guglar and Dunning, 1993) and customer service enhancement (Lambert and Knemeyer, 2004). In terms of intensity, Moss-Kanter (1994) suggests that cooperative arrangements range along a continuum from weak and distant to strong and close, while Lambert and Knemeyer (2004) define three types of partnership based on the level of integration between partners. Kumar and van Dissel (1996) and Thompson (1967) similarly differentiate between collaborations based on the degree of interdependency. When considering the intensity of collaboration a number of authors (Pisano, 1991, Dyer and Singh, 1998) have suggested that consideration needs to be paid to the governance structure that is put in place. Yoshino and Rangan (1995) differentiated between collaborations based on whether they involved an exchange of equity or not.

While the bulk of collaboration research has focused on partnerships between two organisations (Doz, 1996; Adober, 2006) there have been some studies of multi-organisation arrangements (Kumar and van Dissell, 1996). Authors such as Oye (1986) and Coleman (1990) have argued that collaboration becomes harder as the number of partners increases – not least because of the possibility of free riding. Others however suggest the opposite arguing that risks, for example, are better able to be dispersed as the number of partners increases (Adobor, 2006). Harrigan (1988) suggested that the key influence on the appropriate number of partners is the scope of the activities concerned. Not only can there be variation with regard to the number of activities included (see for example Mariti and Smiley, 1983) but also with regard to its centrality or contribution to an organisation. Weill and Broadbent (1998) suggested that from an IT perspective a separation can be made between infrastructure and applications. It is also well recognised that beyond the IT itself are the essential business processes of an organisation (see for example Davenport, 1993).

**Figure 1: Collaborative sourcing: Motivation and design**
Synthesising the outsourcing and collaboration literatures suggests that empirical research would be useful to determine whether economies of scale – a common driver for both outsourcing and collaboration – is indeed the motivation behind collaborative sourcing and identify what form that collaboration takes – in terms of its intensity, focus and extent (see Figure 1).

3 METHODOLOGY

Given that little research has been conducted to understand the phenomenon of collaborative sourcing a qualitative approach was determined to be appropriate (Benbasat et al., 1987; Strauss and Corbin, 1990). The research was primarily outcome rather than process oriented – seeking to identify the motivation for, and design of, collaborative sourcing initiatives rather than the process of making those decisions (Patton, 2002). A multi-case design was selected with collaborative sourcing arrangements selected from both the private and public sectors in Australia\(^1\). A multi-case approach, it was felt, would provide for more robust analytical generalization with regard both to the appropriateness of the motivation and design constructs and – in the case of the latter – the specific choices to be made when constructing a collaborative sourcing arrangement (Yin, 1984). For each arrangement considered interviews were conducted with more than one participant to capture any variation in perspectives. As Table 1 illustrates the provider perspective was included where possible. Interviews were between one and two hours in duration and a semi-structured interview protocol was followed. While the underlying rationale was purposeful it was deliberately non-directive so as not to preclude the emergence of factors and influences not previously considered (Patton, 2002). As such it is in line with the methodology presented by Eisenhardt (1989).

Table 1: Interviewees per case

\(^1\) Australia is recognised as a country where outsourcing is prevalent (see for example Seddon, 2001 and Willcocks et al)
With regard to analysis, data was first reviewed and coded in terms of its relationship either to the motivation for, or design of, the collaborative sourcing initiative – an approach in accord with the recommendations of Miles and Huberman (1994).

4 RESULTS

As highlighted by Figure 2 the empirical research found that collaborative sourcing was more complex than anticipated – in that there is neither a single motivation nor a single collaborative design. Each aspect – motivation, intensity, focus and extent – will be elaborated on below.

Figure 2: Collaborative sourcing – motivations and designs

4.1 Motivation

While economies of scale was cited as a motivation in all cases it was typically moderated by other factors.

- Economies of scale
  
  “The main goal is economy of scale” GGMS-A-1

  “simply by consolidating the economies of scale, we provided, in a lot of cases, services for three agencies for the price of two. So we achieved – you know, we just spoke to software vendors and other vendors and said, look, if you want to play with us into the future, it’ll cost you a 30 per cent reduction in cost” CIO-P-9

- Access

In a number of cases a goal was to access technology used by larger organisations that could not be afforded individually.

  “we simply can not afford some of the technology on our own” MD-A-3

  “all have similar needs – about 90% fit – and can pretty much assume that if it satisfies the larger ones it will be sufficient to meet our needs” GM-C-4
• Flexibility

Flexibility was not so much a pure goal but seen as an influence on how far some organisations would go down the collaboration path.

“who you link up with limits what you can do in the future .. makes you a bit dependent”
GM-A-2

“you can only standardise in certain things and only so far” DFA-B1

• Management resources

For a number of organisations a motivation was either to free up their own management resources to focus on other activities or to allow the development of specialist management skills – such as contract or supplier management – that could not be justified individually.

“maintain skills sets that can not afford individually” DF-A-7

“don’t have the competencies .. nor did we want those competencies since it was not a critical function” GM-A-2

“time you need to manage that relationship, how much time and how much effort and how much resource do you have to manage those relationships.” DBP-B-6

• Expertise

Collaboration was see as providing access to expertise – typically developed through the past experiences of one of the partners – that would be otherwise unavailable and that could make a significant contribution to improving activities.

“The IP [intellectual property] that drives the business comes out of [supplier] – the delivery capability, the management experience, the technical expertise and so on” DF-A-7

“we saw the need for a vehicle that allowed [organisations] to work with somebody else who’s got those expertise who’s looked at these things before, can bring in the processes and common systems and common sort of programs” DBP-B-6

• Revenue

Collaboration could help generate a new revenue stream such that services could be offered for sale to additional organisations beyond the boundaries of the collaboration.

“turn it into a revenue stream rather than just trying to manage your costs and minimise your costs .. ” GMA-P-7

“.. if you’re making a couple of cents a transaction and you get a big customer and they’re doing, you know, 20 - 30 million transactions a year, that’s where you make your money”
GM-A-8

• Politics / Public relations

Collaboration is seen as more acceptable than outsourcing.

“cost savings were demanded but outsourcing was off the table”DG-A-9

“jointly owned intermediary makes it more palatable – retain control and not direct with the private sector” DBP-B-6
4.2 Intensity

The research found that there was not a single design of collaborative sourcing but various alternatives which varied with regard to the intensity of the collaboration undertaken.

- Coat-tail

Where an organisation rides along on the coat-tail of another taking whatever option or solution that organisation chooses benefiting from the economies of scale but without any input or opportunity for modification. It is questionable whether such an option truly represents collaboration though in one of the cases examined there was a requirement that the coat-tailing organisation invest in the vehicle established for the purpose.

“assumption is if it suits us – the largest – it will suit them and they can come along and get the savings but we are not going to compromise our requirements” GM-A-2

“other organisations but we have not really taken them into account in the requirements” GGMS-A-1

- Aggregate demand

Organisations aggregate their demand and requirements at the tender stage but enter into separate contracts and operations with the selected supplier.

“The host agreements are all separate … So this is just purchasing power.. What we’re trying to do is to get as much of the cost benefit without selling your soul. We negotiate together, but at the end of the day we are separate entities. We are separate businesses, with the same supplier. That works for us.” MD-A-3

- Joint management

Organisations set up a jointly owned intermediary that negotiates on their behalf with suppliers and then manages the relationship with the selected supplier who provides a common service to all of them.

“Effectively what we’ve done is we’ve put a middle man in there to look after our interests.. they manage the relationship with [the external provider]. It suits [the external provider] to deal with one entity and one contract” GM-B-4

- Joint venture

Organisations enter into a joint venture with a party from outside the industry who is perceived to have the skill sets necessary to improve the activities of interest.

“They have the skill sets, the reference sites, the experience to be able to make it happen .. we have the contacts to provide the opportunity” DBP-B-6

“They have done this before successfully .. we haven’t .. do not want to see it fall over” GMCS-B-7

- Joint operation

A group of organisations establish their own service provider to provide a common service to all of them.

“It became evident in our normal cooperative effort that we needed to be combining our computer bureaus…” MD-A-5
It should be recognised that the options described are somewhat of a *simplification*. Within each category of collaboration there were variations with respect to the structure of the collaborative vehicle – in terms of the presence, and significance, of the equity invested – and the broader governance arrangements. With the exception of one of the coat-tail arrangements all of the collaboration arrangements involved the establishment of separate legal entities, companies, in which the partners purchase equity. However the level of that investment varied from the company being nominal – more-or-less in name only – to it being significant in its own right.

“no resources attached to it .. really just a vehicle” MD-A-3

With regard to governance, the structure put in place influenced the rights and responsibilities – potentially limiting input of some participants.

“So you’ve got to think deliberately about that, how the governance is designed, who should be involved and how” DF-A-7

In addition that structure was often quite complex containing multiple, nested agreements.

“When you create a structure like that, you need a lot of things to make things pump around here .. so you’ll see these services, sub-contracts and partnership agreements, second services contracts, service agreements, resourcing agreement.” DBP-B-6

### 4.3 Focus

The cases suggested that the activities collaborative sourcing has been engaged in for vary with regard to how tightly they are tied to the specific operations of the organisations involved – with collaboration identified at the IT infrastructure, IT application and business process levels.

- **IT infrastructure**

  At perhaps the most basic level is largely generic hardware, operating software and services

  “All we do is put the architecture and infrastructure in place” MD-P-5

- **IT application**

  Here standard or industry based applications are provided and supported.

  “it is [the application] opaque, it’s chugging away, and it has no bearing on the business.”
  
  MD-A-5

- **Business process**

  At the business process level the collaborative sourcing extends to the actual operation of an activity such as payroll processing, accounts payable etc. In many cases those activities are transactional in nature – high volume, standard activities requiring limited decision making.

  “its transactional, its process-driven and we’re good on process.” GMCS-B-7

  “it’s about standardisation and it’s about being able to add value to a process. So unless you can standardise it, you can’t get cost savings.” GM-A-2

However in some cases the activities concerned extended to those that were more ad hoc, unique and requiring of analytical and decision making capabilities. The inclusion of such “expert” services was seen as a means of enabling the complete removal of functions from businesses.

“I don’t think you could have the one without the other [transaction and expert services] because the whole point .. is to take those functions away from the agencies. If you’re going
to separate them out .. you’re not going to get the savings, so you really need to group them together” FD-A-2

While there is normally thought to be a hierarchy between infrastructure, applications and processes it was not found to be the case that a higher level of collaboration required that lower levels were included – it was possible to have collaborative sourcing for business processes but not applications or infrastructure.

“they have retained ownership of the underlying ERP [Enterprise Resource Planning] platform and we essentially pay for some of the access to the technology” DBE-P-6

4.4 Extent

The research suggested that collaborative sourcing arrangements varied with regard to their extent both in terms of the number of partners involved and the number of activities covered. However there did appear to be a trade-off between the two with collaborations with a larger number of partners covering a narrower range of activities and vice versa.

• Number of partners

The number of partners varied considerably – from three to over 50.

“it’s the size of the agencies and the number of them. More than three, initially, would have been messier than it was” MD-P-9

“Because we’re a private company, I think it’s capped by you can only have 50 shareholders. So 50 shareholders. So we’ve just changed them and we’re going to be a public unlisted company, so that we can bring those other people in as shareholders.” MD-A-5

As alluded to earlier, there could also be differing levels of partner involvement – at the most basic level between those actively involved in driving and running the venture and those serving simply as customers.

“varies with regard to how involved they want to be .. I am involved a couple of days a month on the board .. others take much more of a backseat” GM-B-5

“now focused not on more partners but on more customers” FM-B-8

• Number of activities

A difficulty in comparing the number of activities provided is that it is difficult to ensure that apples are being compared with apples – names of activities and what is included vary across the cases. However it is clear that at the highest level there are considerable variations in terms of the range of activities with some arrangements being focused, for example, on a single application or process area and others having a much larger remit.

“in terms of transaction management, it doesn't matter if you're doing the payroll or paying bills or moving assets, the concept is make sure you've got low decision making .. basically, it's a formula, it's getting accuracy the first time, and so what we did is actually combined all the transaction areas and just called it transactional services” FD-A-2

“We're very niche in terms of the services that we provide. very focused .. know what we are good at and want to focus on” GM-P-4
5 DISCUSSION

While clearly collaborative sourcing is more complex than originally envisaged (there is neither a single motivation nor design), the research suggests that the framework proposed remains useful with the dimensions capturing variations and facilitating a classification of collaborations.

While in all cases economies of scale is a motivation it is not always the only one and often appears to be moderated by other factors. In terms of the focus of the collaboration there is considerable variation. Furthermore there does not seem to be a simple hierarchical progression – from infrastructure through applications to business processes. With extent however there does appear to be something of a trade-off between the number of partners and activities – or the breadth and depth of the arrangement.

Combining the different elements of the framework it is possible to discern three distinct approaches to collaborative sourcing:

1. So long as I do not have to change [Cases: 1, 2, 3]
   While such organisations join with others to realise economies of scale the emphasis remains primarily fixed at the individual level and ensuring individual requirements are not compromised. “Collaborations” are typically narrow in terms of the number of partners but may cover a variety of activities and are focused on the provision of “as is” services.

2. Better in this together [Cases: 4, 5]
   Organisations recognise the benefits of sharing management resources as well as those of economies of scale. The focus of collaborations is typically broad in terms of the number of partners but tightly focused and related to infrastructure. The emphasis remains on the provision of services “as is”.

3. Grab a new opportunity [Cases: 6, 7, 8, 9]
   Organisations see an opportunity not only for economies of scale but also to develop new revenue streams through the provision of services to others. The collaboration may relate to infrastructure, applications or processes – but is typically very specific. There is often a trade-off between the number of partners and the number of activities. The emphasis is on improving the current way of doing things – and if the organisations do not have the expertise amongst themselves to do this they will bring in an external partner.

While the different groups have been described from the perspective of making their own choices, the research suggests that this might not always be the case with politics or public relations determining the path taken. There is also some evidence of collaborations in Group 2 developing over time to also provide services to customers – but in contrast to Group 3 on a “take it or leave it” basis similar to Group 1.

It should be noted though that the framework and classification is a simplification of reality. Many of the dimensions have additional complexity embedded within them. For example regarding business processes they are not all vanilla – with interviewees making the distinction between transaction and expert types. With partners, there would also seem to be differing levels of involvement – for example there are those that take an active role, those that are more passive and those that are simply customers.

Future research would be particularly useful in three directions. Firstly to examine in more detail the variations and complexities of the collaborative sourcing arrangements. Secondly to attempt to determine which arrangements are most likely to be successful – and in what
circumstances. Third to examine the arrangements over time – do they evolve as partners gain in experience and understanding? Do organizations get locked in to particular solutions and partners with alternatives becoming closed off over time?

Abstract

Blogging has fast emerged as an unparalleled social computing phenomenon not to be ignored. This paper begins by reviewing the motivation factors for blogging identified in the extant literature. These factors can be broadly classified as either activities-based or behavioral-based. We then propose that a root motivation factor based on the theoretical underpinnings of self identity and social identity can better explain blogging motivation compared to the existing factors. Specifically, we posit that individuals could be receptive toward a migration of their real world self and social identities to the online virtual blog environment and thereby cumulates in the formation of blogger virtual identities. Blogger virtual identities is conceptualized as a second order formative construct formulated through two first-order reflective subconstructs, namely the virtual self identities and virtual social identities. Drawing on the theory of planned behavior, we propose a virtual identities model of blogging intention to investigate how the blogger virtual identities can lead to blogging intention and actual blogging behaviour. A two-stage research methodology consisting of a qualitative content analysis and followed by a survey is also proposed. We conclude with a brief discussion on the potential theoretical and practical contributions of this paper.

Keywords: Blogging, Virtual identity, Social computing, Theory Building.
1 INTRODUCTION

Many would have agreed that one of the most exciting online activities in recent years has been blogging, i.e., writing on individual’s web page with reverse chronological sequence of dated entries (Herring, Scheidt, Bonus & Wright 2004; Sifry 2007). Research on blogging has become increasingly important and popular with significant amount of effort expended on identifying various motivation factors leading to a person embraces blogging and examining the social network of blogger (Gumbrecht 2004; Li 2005; Nardi, Schiano & Gumbrecht 2004a; Nardi, Schiano, Gumbrecht & Swarth 2004b; Schiano, Nardi, Gumbrecht & Swarth 2004; Trammell, Tarkowski, Hofmokl & Sapp 2006). More recently, other researchers have also investigated the motivation factors underlying microblogging, a relatively new derivation of blogging that allows bloggers to write short entries while on the move (see Java, Song, Finin & Tseng 2007). However, we believe that the extant literature does not adequately explain the root motivation factor of blogging (Nardi et al. 2004b).

This research in progress paper attempts to use the self and social identity notions as theoretical lens to address the knowledge gap. The rationale is that personal web pages have been known to be used by individuals to create their online identities as a mean of self presentation (Schau & Gilly 2003). Indeed, information provided on personal web pages pertaining to how the author would like to be regarded by others, i.e. identity claims, can portray the author’s personality accurately (Vazire & Gosling 2004). In other words, the need to project certain impression of oneself to others in the online world could plausibly explain why an individual could be motivated to blog (Schlenker 2005). To this extent, we contrive the theoretical notion of blogger virtual identities, which encompasses the online virtual self and social identities of an individual blogger, as the root motivation factor of blogging. Drawing on the Theory of Planned Behavior (Ajzen 1985; Ajzen 1991), we further propose a preliminary research model termed as the Virtual Identities Model of Blogging Intention to explain how blogger virtual identities can affect blogging intention and actual blogging behavior.

Understanding the root motivation factor of blogging from the identity perspective is important for several reasons. In particular, when individuals present themselves to others in the online world, it could either be a deception attempt or sincere portrayal of one’s self, regardless of whether it is done intentionally or unconsciously (Schlenker 2005). Our present study has the potential to demonstrate that bloggers are generally inclined towards a sincere portrayal of themselves to others. Furthermore, blogging is not only a popular online activity but has increasingly been incorporated as a pertinent feature of online social networking sites such as Friendster, Facebook and MySpace. The identity-based motivation factor can not only explain the use of blog but also be extended to examine the use of social networking sites beyond making friends to expressing one’s identity. In addition, the identity notion provides a theoretical basis for enhancing the functional design of blog tools to increase adoption and usage.

2 THEORETICAL BACKGROUND

2.1 Motivation Factors of Blogging

There are two interrelated fields of thoughts pertaining to the underlying motivation factors for a person to blog. The first field of thoughts posits that blogging arises as a form of social activity whereby bloggers create postings with their readers in mind and readers respond to the postings with

anticipation for more correspondents (Nardi et al. 2004a). This view is consistent with the notion of having a blog as a medium of communication between a blogger and the intended audiences (Gumbrecht 2004). In addition to the purpose of communication, five other object-oriented activities identified as blogging motivations are: 1) to maintain online personal journal; 2) to convey and convince others about one’s opinions; 3) to express emotions; 4) to develop one’s thinking process through blogging; and 5) to build an online community (Nardi et al. 2004a; Nardi et al. 2004b; Schiano et al. 2004). Similarly, from the microblogging perspective, people blog to talk about daily routine, converse with other bloggers, share information and report news (Java et al. 2007). Another field of thoughts anchors on the uses and gratifications (i.e., behavioral) perspective. This field of thoughts suggests that self-documentation of key life events, cultivating good writing habit and style, articulating one’s personality, acquiring information, passing time, socializing with other people, seeking personal entertainment and achieving professional advancement are the underlying motivation factors to blog (Li 2005; Trammell et al. 2006).

In our view, the two perspectives of blogging, i.e. activities and behavioral, could well complement each other to offer a more holistic perspective on a blogger’s motivation to blog. For instances, the desire to express one’s personality or life, i.e. self documentation, could account for the use of blog as personal journal and both opinions and emotions outlets. Additionally, the socialization perspective could shed insights as to why people use blogs as a communication tool and build community. However, the uses and gratifications framework primarily focuses on the motives for media use (Papacharissi 2002). It does not provide sufficient fundamental explanation for the causes and effects of categories of motivation that are chosen a priori for empirical investigation (Li 2005; Papacharissi 2002; Trammell et al. 2006). Thus, while we know that self expression and socialization have been repeatedly identified as important motivations for blogging (Li 2005; Trammell et al. 2006), the existing knowledge gap impede a fuller understanding of why bloggers would want to tell readers about themselves or develop an affinity for part of a community. Examining the two perspectives deeper, we suggest that both perspectives share a common underlying root of motivation: identity formation. We conceive that identity, in the forms of self identity and social identity, could synergize the existing two perspectives and serve as the theoretical lens to explain for why bloggers develop a particular behavior (e.g., expressing political viewpoints) or participate in a particular blogging activity (e.g., writing journal). We reason that the notion of virtual identity presents a concise and strong theoretical underpinning governing the examination of the motivation factors to use social computing applications, such as blog. These include social networking site and virtualization world that both emphasize the user’s online identity and the associated relationship with other people.

2.2 Self Identity and Social Identity

Identity of an individual could come in two forms: self identity and social identity (Hogg, Terry & White 1995; Lee, Lee & Lee 2001; Stets and Burke 2000; Thoits & Virshup 1997). The notion of self identity builds on the role identity theory (McCall & Simmons 1978) and the identity theory (Stryker 1980) to denote that one’s identity can be perceived as the expressive behavior of an individual’s role in society (Conner & Armitage 1998; Lee et al. 2001). For instance, an individual could have the identity of a doctor, a managing director, a housewife, an undergraduate student depending on his/her role played in the society. It is important to note that self identity refers to a collection of socially accepted behaviors constructed from the role in which an individual occupies in society. For instance, a doctor (role) who is engaging in a medical treatment of a patient (behavior) would be perceived to have the identity of a medical doctor. Given that there could exist a reciprocal link between an individual (i.e., self) and the society, an individual’s identity is likely to affect his/her social behavior (Hogg et al. 1995). Consequently, an individual is very likely to adjust his/her behavior in a manner that is in accordance with one’s existing/goal identity (Gecas & Burke 1995).

Social identity refers to the characteristics of the social category in which an individual perceives to belong to. According to the social identity theory, the acquired social identity prescribes one’s
attributes as a member of that group, i.e., what one should think and feel, and how one should behave. In other words, an individual regulates his/her behavior in a manner that is in compliance with the goal or image of a whole group or category of people with which the individual belongs to (Hogg & Abrams 1988). The evaluative nature of the social identity provides a strong motivation for groups and their members to adopt strategies for achieving or maintaining in-group/out-group comparisons that favors the in-group and individuals. Two sociocognitive processes may be used to achieve this objective, namely categorization and self-enhancement (see Hogg et al. 1995). The former is concerned with producing stereotypical and normative actions and perceptions that are unique to a particular group thus differentiating it from other categories. The later suggests that people tend to view members within the same group or category more favorably along the stereotypical dimensions compared to external individuals.

The two theoretical perspectives differ in one critical aspect: the self identity perspective describes individual’s role-related behaviors; comparatively, the social identity perspective focuses on group process and intergroup relations (Hogg et al. 1995). In terms of similarities, both perspectives of identities (i.e., self identity and social identity) demonstrate that the structure and function of the self is constructed socially. In other words, individual behavior is affected by the social structure and that this relationship is mediated by a multi-faceted and dynamic self (Hogg et al. 1995). Furthermore, both perspectives predict that the resulting identity mediates the relationship between society and individual social behavior (Hogg et al. 1995). Taking a holistic view of the two identity perspectives, people are organically linked to their groups through social identities and mechanically linked within groups through their role identities (Durkheim 1983). Consequently, it is necessary to consider both self identity and social identity in tandem so as to yield a holistic view and individual’s identity. Indeed, an individual’s membership in any social group or assumed role includes two important aspects, namely one’s identification with a category and the behaviors that he/she associates with the category; both of which are emphasized by depersonalization in the social identity theory and self-verification in the identity theory respectively (Stets & Burke 2000). Hence, individual could simultaneously assume a role and be affiliated to a group to influence one’s perception, affection and behavior (Stets & Burke 2000). This concept is best summarized by Thoits and Virshup’s (1997) analogy on group behavior. The authors observed that decision making committee could differentiate activities among members. Thus, it is possible that people may be simultaneously aware of themselves occupying a particular role identity, e.g. committee members occupying different positions, and as group members working for a collective identity, i.e. the committee as a whole.

Whether behavior driven by self identity or social identity is exhibited depends on both the fit of the identity to the situation, as posited by the social identity theory, as well as the structural embeddedness or commitment of the individual, as posited by the self identity theory (Stets & Burke 2000). An individual who identifies with a group need not always behave in accordance with the social identity (Van Knippenberg 2000). The same argument could also apply to self identity. Thus, understanding the antecedent of identity salience is critical to comprehend the behavior of individual. It has been empirically verified that the salience of an individual’s self identity is positively affected by the degree of commitment (vis-à-vis the number and strength of important social relationships associated with the particular identity) and evaluation (Hoelter 1983). If an individual is strongly committed to a role and evaluates his/her performance in that role positively, then he/she is likely to exhibit the behavior associated with that role. Additionally, role contingencies and identity prominence are also predictors of identity salience (Nuttbrook & Freudiger 1991). In the case of social identity salience, a “fit” between social categorization and subjectively relevant features of reality is likely to lead to social identity salience (see Haslam, Powell & Turner 2000). This “fit” consists of both “comparative fit” and “normative fit”. In addition, social identification itself also plays a role in social identity salience through the manifestation of perceiver readiness (Haslam et al. 2000).

It is also important to note that an individual may possess multiple self identities and multiple social identities since people may have different roles in society and be affiliated with different social groups (Hogg et al. 1995). However, it is likely that people may only exhibit behavior that is consistent with a
single identity at any one time depending on which identity is more relevant. This reasoning is consistent with the identity salience notion (Haslam et al. 2000; Hoelter 1983). With an understanding of the notion of identity, we apply the theoretical underpinning of identity to the blogging context.

2.3 Blogger Virtual Identities

Researchers have found that bloggers, in particular teenagers and women, are inclined towards expressing their identity on their blogs (Van Doorn, Van Zoonen & Wyatt 2007; Huffaker & Calvert 2005). Beyond personal information such as age and location (Huffaker & Calvert 2005), bloggers also express their gender identity through: 1) the use of emoticons and language styles (e.g., males are more direct and forceful whereas females are more indirect and intimate) (Huffaker & Calvert 2005); and 2) “representational domains” (e.g., males prefer occupation domain whereas females prefer domestic interests or hobbies) (Van Doorn et al. 2007, pp. 151). Clearly, it is possible for bloggers to develop some form of virtual self identities through blogs. New communication technologies have also been observed to exercise an impact on the formation and development of online communities and the resulting virtual social identity (Cerulo 1997). Specifically, it has been suggested that social identity can be developed in both virtual and real world (Bergami & Bagozzi 2000; Dholakia, Bagozzi & Pearo 2004). Consistent with the general rationale of the social identity theory, socialized bloggers will develop virtual social identities as the commitment to their blog communities, i.e., consisting of the bloggers and readers, increases gradually (Moon, Li & Sanders 2006).

Building on the virtual identities concept, we posit that individual could be receptive toward a migration of their real world identities to the online virtual environment and thereby cumulates in the formation of blogger virtual identities. In other words, individual possesses various role and group identities in their real life and are likely to extend these identities into the online world as virtual self and social identities manifested through their blogs. For instances, a college student might blog about his/her college life from the perspective of his/her role identity as a college student as well as a social identity acquired through his/her interaction with peers and teachers in the college environment. At the same time, the same student may wish to use the blog to express his/her opinion of current affairs or political issues as emanated from his/her self identity as an avid current affairs observer. Likewise, perhaps he/she routinely watches soccer matches on television with his/her friends and may have an urge to blog about the proceedings and outcomes of the matches. In the last example, the student brings the in-group behavior online to form a virtual social network based on soccer matches discussion. Collectively, we term such identities as virtual self and social identities in which the virtual identities resemble the real world offline identities.

Similar to most types of computer mediated communication medium, blog can provide bloggers with anonymity instead of using their real names (Huffaker & Calvert 2005). To this extent, bloggers may be inclined towards expressing covert self or social identities that they do not openly exhibit in their real life; but which they seek certain outlet such as blog to express these identities. We illustrate this view with examples of covert social and self identities. For instance, a computer programmer acquires a role identity of an expert programmer by virtue of his/her structural job position in society. Building on this role identity, he/she develops a covert virtual social identity with the predisposition to help other programmers in a blog community of programmers. As an illustration of a covert self identity, the same computer programmer could also be a computer hacker who frequents hacking blog community and discusses about hacking on his/her own blog. Regardless, it should be clear that the virtual social identity of expert programmer in a community and virtual self identity of computer hacker both arise from the real world offline identities possessed by the computer programmer.

In gist, we contrive blogger virtual identities as a second order formative emergent construct with each of the two separate virtual identities, namely virtual self identities and virtual social identities, as reflective first order factors. This qualifies our blogger virtual identities construct as a Type II second-order factor in Jarvis, Mackenzie & Podsakoff (2003) specifications. Our present construct exhibits several formative indicators properties suggested by Diamantopoulos and Winklhofer (2001). For
instances, omitting either of the two formative indicators would not completely represent the virtual identities of a blogger while the magnitude of the correlations among the two constituent identities cannot be precisely predicted given that an individual may possess none, one or both and the identities may or not may be related.

With the above definition of blogger virtual identities in perspective, we proceed to discuss its salience. Briefly, we anchor on the same salience notions of the offline world and propose that the salience of virtual identities is dependent on the same set of factors (Hoelter 1983; Nuttbrock & Freudiger 1991; Haslam et al. 2000) except that they apply to the likelihood of extending their real world identities online in the manifestation of blog. For instance, a positive commitment toward extending a role identity online and its positive evaluation should result in virtual self identity salience.

In summary, our present conceptualization of the blogger virtual identities construct is different from the notions of virtual identity proposed in the extant literature. For instance, Moon et al. (2006) anchored their virtual social identity construct upon the three aspects of social identity, namely cognitive, affective and evaluative. Other researchers such as Gross and Acquisti (2005), and Stutzman (2006) have examined the virtual identity of online social network communities’ members using demographic and personal information, including images. However, our present endeavor emphasizes the expression of the blogger real world offline identities to the online blog environment as reflected in the blog contents. To this extent, the blogger virtual identities construct is a more holistic one that both extends and complements the self-identity expressiveness advocated by Thorbjørnsen, Pedersen & Nysveen (2007) as well as identity claims proposed by Vazire and Gosling (2004).

3 RESEARCH MODEL AND HYPOTHESES

We postulate that the blogger virtual identities construct could account for the various “activities-based” and “behavioral-based” blogging motivations identified by prior researchers (Gumbrecht 2004; Herring et al. 2004; Java et al. 2007; Li 2005; Nardi et al. 2004a; Nardi et al. 2004b; Schiano et al., 2004; Trammell et al. 2006) through the explication of the self and social identities. For instance, a college student’s positive attitude toward explicating his/her self identities as a college student and current affairs observer should lead to blogging behaviors such as self-documentation and self expression respectively. These behaviors should then activate blogging activities such as writing online journal and expression self-opinion. Additionally, his/her social identity as part of an expert programmers group induces socialization behavior that leads to online community building activity. To this extent, blogger virtual identity presents a plausible theoretical predictor for blogging intention.

Figure 1 The research model – virtual identities model of blogging intention.

Our research model, termed as the Virtual Identities Model of Blogging Intention, is depicted in Figure 1. In the broadest sense, it is based on the Theory of Planned Behavior (TPB), which posits that
individual behavior is driven by behavioral intentions (Ajzen 1985; Ajzen 1991). Behavioral intentions themselves are affected by the individual’s attitude toward the behaviour. Thus, we posit that behavioral intention to blog is determined by the individual’s attitude toward their blogger virtual identities. In turn, behavioral intention should lead to actual blog usage thus explaining the various “activities-based” and “behavioral-based” motivations. Although blogging may not always be a planned and rational behavior, the identity salience notion (Hoelter 1983; Nuttbrock & Freudiger 1991) does suggest that an individual regularly exhibits behavior corresponding to a particular self or social identity that is relevant to them. We reason that over a period of time, it is plausible for the blogger to consistently exhibit the same relevant virtual identities in his/her blog.

Prior researchers have examined the effects of self identity and social identity on behavioral intention using TPB as the theoretical lens. Self identity was found to be a significant predictor of behavioral intention, i.e. when the behavioral role constitutes an important part of one’s self identity, an individual could be motivated to engage in the behavior (Sparks & Shepherd 1992; Terry, Hogg & White 1999). In addition, group norm is observed to have a significant effect on behavioral intention for participants with high group identification while a strong correlation exists between self identity and group norm among participants who identified strongly with the group (Terry et al. 1999). More closely relevant to our context, an individual with high self-identity expressiveness and social identity expressiveness could express a high intention to blog (Thorbjørnsen et al. 2007). In another study conducted by Dholakia et al. (2004) to examine the social influence model of consumers in virtual communities, the authors found significant direct relationship between group norms and we-intention to engage in joint behavioral action, such as a blogger posts blog entries and readers respond. This could suggest that virtual social identity might also serve as a mediator to explain the effect on blog usage on future intention of bloggers. Specifically, as observed by Moon et al. (2006), social interaction through blog and its enjoyment could lead to the development of strong virtual social identity while the resulting identity is expected to lead to a strong intention to expand the participants’ online social network and increase satisfaction with their life. The later finding provides partial support to our conjecture of a direct relationship between blogger virtual identities and intention to blog. Overall, these findings suggest the presence of a causal link between blogger virtual identities and intention to blog. Accordingly, we hypothesize a direct causality between blogger virtual identities and behavioral intention to blog:

**H1**: The blogger virtual identities construct is positively related to behavioral intention to blog.

(a) The virtual self identities subconstruct is positively related to behavioral intention to blog.

(b) The virtual social identities subconstruct is positively related to behavioral intention to blog.

According to the Theory of Reasoned Action (TRA) (Ajzen & Fishbein 1980; Fishbein & Ajzen 1975) and TPB, attitude serves as an important antecedent of behavioral intention and has an indirect effect on actual behavior mediated by intention. In a similar vein, we posit that blogger virtual identities can also function as an attitudinal factor exercising a separate and indirect effect on intention. Prior study has found that stronger social identity leads to stronger desires to participate in virtual community (Dholakia et al. at al. 2004). In other words, the relationship between social identity and desire was found to mediate a separate significant and indirect relationship between group norms and we-intentions. To the extent that desire has been defined as the motivations to decide in favor of acting as part of a virtual community (Dholakia al. et al. 2004) and that desire functions as a mediator between attitudes, anticipated emotions and subjective norms with intention (Bagozzi & Dholakia 2002), we believe desire and attitude are similar. Support for this line of reasoning can be found in their similar operationalization in prior studies. For instances, one can compare the operationalization of desire in Dholakia et al. (2004, pp. 252, Table 2) with the operationalization of attitude in Terry et al. (1999, pp. 232). Furthermore, self-identify expressiveness has been found to have an indirect effect on intention through attitude (Thorbjørnsen et al. 2007). Accordingly, we present the second set of hypotheses between blogger virtual identities and attitude toward blogging:

**H2**: The blogger virtual identities construct is positively related to attitude toward blogging.
The virtual self identities subconstruct is positively related to attitude toward blogging.

The virtual social identities subconstruct is positively related to attitude toward blogging.

The extent literature consists of numerous empirical studies that validated the relationship between attitude and behavioral intention (Sparks & Shepherd 1992; Terry et al. 1999). Accordingly, we hypothesize that:

**H3**: Attitude toward blogging is positively related to behavioral intention to blog.

According to TPB, whether behavioral intention leads to actual behavior is conditional upon individual’s control over the behavior (Ajzen 1985; Ajzen 1991). Along this line of reasoning, we posit that an individual’s behavioral intention to blog is also conditional upon his/her perceived ability and extent to blog at will. In particular, perceived behavioral control has been found to be a significant distinctive predictor of behavioral intention (Terry et al. 1999). Thus we further hypothesize that:

**H4**: Perceived behavioral control is positively related to behavioral intention to blog.

Both TRA (Fishbein & Ajzen 1975; Ajzen & Fishbein 1980) and TPB (Ajzen 1985; Ajzen 1991) posit that behavioral intention is a key predictor of usage behavior. Within the technology acceptance literature, this has also been a well researched area with strong empirical supports (see Venkatesh, Morris, Davis & Davis 2003 for a comprehensive review). In particular, an expanded version of the Technology Acceptance Model which incorporates two crucial social factors examined in our present study, namely self identity and social identity, has presumed the relationship between intention and behavior (Lee et al. 2001). Accordingly, we hypothesize that:

**H5**: Behavioral intention to blog is positively related to actual blogging behavior.

Finally, it is important to consider the effect of actual blog usage behavior on blogger virtual identities. Prior study has established that blog usage, i.e. social interaction though the blog and enjoyment of blog, could lead to the development of a strong virtual social identity (Moon et al. 2006). In particular, virtual social identity develops from the trust of and commitment to the blog community when there are intense social interactions within the blog community (Ridings, Gefen & Arinze 2002). Moreover, as the bloggers express themselves and are viewed by others as such over an extended period of time, their blogger virtual identities could further crystallize. This is consistent with the internalization of the bloggers’ self-presentation whereby the bloggers’ behaviors to create certain impression of themselves to others could ultimately influence how they viewed themselves (Schlenker, Britt & Pennington 1996). Accordingly, we present our final hypotheses to complete our proposed research model:

**H6**: Actual blogging behavior is positively related to the blogger virtual identities construct.

**a** Actual blogging behavior is positively related to the virtual self identities subconstruct.

**b** Actual blogging behavior is positively related to the virtual social identities subconstruct.

### 4 PROPOSED RESEARCH METHODOLOGY

We propose a two-stage methodology to investigate the blogger virtual identities phenomenon. In the exploratory first stage, we propose a qualitative content analysis similar to the technique used by Van Doorn et al. (2007). The qualitative data to be collected will be subjected to an interpretive analysis to understand how and why bloggers express their real world offline identities to their online virtual identities. The details of the process are outlined as follow. We begin by selecting 500 blogs at random using local blog directories, and then codify both the bloggers’ demographic and information about the blog to establish a profile for a typical blogger. Key demographic variables to consider include age, gender, occupation and ethnic group while key blog variables include age of the blog, update frequency, update recency and language (Herring et al. 2004). We then review these 500 blogs and select 6 typical blogs and 4 atypical blogs for the actual content analysis. The later will involve
examining the blogger’s profile and all postings, both textual and non-textual contents such as images, made in the last 6 months.

The results from the first stage study should enlighten us on the viability of the blogger virtual identities construct. If the findings are consistent with our conceptualization, we may then proceed to the second stage to empirically validate our proposed research model shown in Figure 1. The findings from the second stage study will reveal insights as to whether expressing blogger virtual identities does indeed leads to blogging intention and actual blogging behaviour. A survey research methodology will be used for the second stage study. The target population will consist of two groups: 1) existing bloggers recruited through local blog directories; and 2) internet users who have yet to start a blog to be recruited through local lifestyle-related internet forums. The objective of such a design is to investigate any systematic difference in behavioral intention to blog between existing bloggers and potential new bloggers. This also allows for better generalizability within each sample. To ensure that the non-bloggers are able to understand the terms used in the survey, participants from both samples will be given a simple factsheet on blog to read prior to answering the survey.

</tr>
</tbody>
</table>

Table 1 Instrument scales used to measure constructs.

Except for the blogger virtual identities and actual blogging behavior constructs, the remaining three constructs in our research model are operationalized based on validated instrument scales from the extant literature. The instrument scales for all the constructs are listed in Table 1. Unless otherwise stated, the scale type is 7-point Likert (1 – Strongly Disagree to 7 – Strongly Agree). The instrument scales will be validated through a formal procedure as described in Moore and Benbasat (1991). Emphasis will be placed on the instrument testing phase which includes pilot and field tests.
Specifically, the pilot tests will be used to assess the construct validity of blogger virtual identities using a second-order factor analysis in LISREL.

5 CONCLUSION

A substantial amount of research efforts are required to implement the proposed two-stage methodology. However, there are several potential contributions that can be realized in addition to the noteworthy achievement of a better understanding of the blogging phenomenon. Theoretically, the blogger virtual identities construct may be extended to examine other social computing applications, tools or phenomenon that emphasize the user’s online identity and the associated relationship with other people. For instance, online social networks such as Friendster, Facebook, MySpace and virtual world such as Second Life2. Practically, this paper provides a theoretical basis for refining the current design layouts and elements of blog to explicate or facilitate the development of both self and social identity in a blog environment. Specifically, design principles or elements that improve explicating of an individual’s virtual identities should lead to greater use of blog and potentially other social computing applications.

In conclusion, this paper summarizes the activities-based and behavioral-based blogging motivation factors found in the extant literature. We further highlight the inadequacies of these factors in providing a good understanding of why people would want to blog. Accordingly, we put forth the notion of blogger virtual identities that is based on the theoretical underpinnings of self and social identity. We reason that the propensity for an individual to extend both his/her real world self and social identities to the online blog environment cumulating in the formation of blogger virtual identities can explain why a person would want to blog. More specifically, we put forth the Virtual Identities Model of Blogging Intention, which is based on TPB, for investigating the effect of blogger virtual identities on blogging intention and actual blogging behavior.

Abstract

This study reports an attempt to enhance our understanding of the reasons behind virtual world usage. By providing a mixture of utilitarian and hedonic value, virtual worlds represent an emerging class of multipurpose information systems (MPIS). Previous research seems to fall short in explaining MPIS adoption, especially since key extrinsic and intrinsic motivators are not considered. Drawing upon IT adoption research, motivation theory and the consumer behavior literature, this research extends available works and provides insight into the influence and roles of extrinsic and intrinsic motivation. Hypotheses are postulated and tested using a sample of 1627 users of the virtual world Second Life. The results confirm the majority of the hypotheses and support the comprehensive model. The findings indicate instantaneous effects of extrinsic and intrinsic motivation, and highlight reinforcing effects of intrinsic motivation. Implications for research and practice are discussed.

Keywords: virtual worlds, multipurpose information system, extrinsic motivation, intrinsic motivation, adoption behavior, escapism, visual attractiveness, entertainment value.
INTRODUCTION

With increasing usage, the value of virtual worlds has been growing at an impressive rate. Parallel to their growth and diversified usage, virtual world systems have gradually advanced into more complex systems. Initially developed to serve gaming communities, virtual worlds were primarily designed in line with the intrinsic motives of those intending to use the system, that is, to create pleasurable experiences and provide self-fulfilling value (Ryan and Deci, 2000b). As such, these virtual worlds could be classified as hedonic information systems (cf. Van der Heijden, 2004). More recently, virtual worlds have started to fulfill a more instrumental role by enabling their users to perform rather utilitarian tasks such as getting insurances, following courses, and building and leasing stores. Accordingly, virtual worlds increasingly adapt to those willing to use the system for extrinsic motives, which relates to the achievement of goals/benefits external to the system-user interaction (Van der Heijden, 2004). From this perspective, virtual worlds contain characteristics that are distinctive for utilitarian information systems (see Van der Heijden, 2004). Given the mixture of hedonic and utilitarian functions, it becomes clear that the traditional distinction between these functions no longer applies to information systems like virtual worlds and thus demands revision. Mirroring the view of Hong and Tam (2006) on IT beyond work settings, we view virtual worlds as multipurpose information systems (MPIS). MPIS are defined here as information systems that provide an integrated suit of hedonic and utilitarian functions to their users.

In this paper we embrace the MPIS perspective, and introduce and test a comprehensive model of users’ motivations to adopt virtual worlds. Given the multipurpose characteristics of virtual worlds, using an MPIS perspective encompassing both intrinsic and extrinsic motives seems crucial. The vast majority of research on IT system adoption, however, has focused on either hedonic (e.g., Van der Heijden, 2004) or utilitarian systems (e.g., Venkatesh, 2000). Consequently, these works fall short since they address only about half of a system’s nature and therefore fail to provide an overall picture of the intrinsic and extrinsic motivators behind virtual world use. Furthermore, since the interrelationships between both types of motivators are relatively unexplored, possible synergies between hedonic and utilitarian system characteristics that might guide system developers remain untainted. This research intends to further our understanding of virtual worlds by introducing an MPIS model that captures both intrinsic and extrinsic believes and as such integrates the hedonic and utilitarian system paradigms.

The paper is structured as follows. We first discuss the literature on the nature and value of information systems, and address the relationships between information system value and consumers’ IT adoption motivations. We conceptualize the key constructs in our model and formulate hypotheses. The research model is then tested in a large-scale survey within the virtual world Second Life. We will discuss the results of this empirical study, and the conclusions that can be drawn from them. Finally, we will describe the theoretical, methodological and practical implications of our findings.

THEORETICAL BACKGROUND

2.1 Information system value

Research on the adoption of IT has classified information systems according to the value they provide to users. Reflecting the user’s overall experience of interacting with the system based on both the system’s usefulness and provision of enjoyment and/or fun (adapted from Holbrook, 1986; Babin, Darden and Griffin, 1994), system value is assumed to be an important determinant of adoption behavior. A common value-based classification originated in the consumer behavior literature (e.g., Babin et al., 1994; Hirschman and Holbrook, 1982, Holbrook and Hirschman, 1982a), and is used to differentiate between utilitarian and hedonic information systems (cf. Van der Heijden, 2004).
Utilitarian information systems refer to systems that are mainly used to achieve goals that are external to system usage (Van der Heijden, 2004). As such, they provide instrumental utility to the user. Hedonic information systems on the other hand, are systems that are used for their own sake and provide feelings of enjoyment, pleasure, excitement and escapism (cf. Babin et al., 1994). The usage of hedonic systems is mainly experiential in nature, which implies that users strive for instant hedonic pleasure while the consequences of usage appear in the fun and pleasure of the experience itself (Holbrook and Hirschman, 1982a; 1982b).

While the distinction between utilitarian and hedonic information systems is widely accepted, and research has demonstrated the predictive power of this value dichotomy in explaining the relative weights of IT adoption determinants (e.g., Van der Heijden, 2004, Wakefield and Whitten, 2006), recent technological developments seem to challenge its applicability. In particular, we refer to the emerging class of systems that provide both utilitarian and hedonic value (e.g., smart phones; mobile data services; virtual worlds). These systems, alluded to in our introduction as MPIS, incorporate instrumental and experiential functions in one environment (Hong and Tam, 2006). A main challenge for developers of MIPS is how to apply an integrated suite of instrumental and experiential functions, in order to enable productive and prolonged use. Such integration demands a thorough understanding of the drivers of the adoption process and stresses the need for an integration and extension of theories concerning IT adoption and use.

2.2 Motivation theory

A significant body of research has applied motivation theory (Deci, 1975; Deci and Ryan, 1985) to predict the acceptance of information systems. Referring to “enduring predispositions that arouse and direct behavior toward certain goals (Engel, Blackwell and Miniard, 1995, p. 49), motives are seen as key determinants of IT adoption. Two types of motivation exist: extrinsic motivation and intrinsic motivation.

Extrinsic motivation is defined as “doing something because it leads to a separable outcome” (Ryan and Deci, 2000b, p. 55). Extrinsically motivated behavior is driven by the instrumental value of the performed activity (Ryan and Deci, 2000b), which is derived from the outcome of the activity instead of the activity itself (Davis, Bagozzi and Warshaw, 1992). Given the instrumental value, extrinsic motives are theorized as dominant predictors of utilitarian system usage (Van der Heijden, 2004; Wakefield and Whitten, 2006). Most theories on IT adoption (see Venkatesh, Morris, Davis and Davis, 2003 for an overview) are productivity-oriented and use extrinsic motives such as ‘perceived usefulness’ and ‘perceived ease-of-use’ as key determinants of utilitarian system use.

Intrinsic motivation refers to “doing an activity for the inherent satisfaction of the activity itself” (Ryan and Deci, 2000a, p. 71). Intrinsically motivated behavior is self-determined, volitional (Deci and Ryan, 1985) and involves people engaging in activities that they find interesting, new, and optimally challenging (Deci and Ryan, 2000, p. 235). Intrinsic motivation derives its value from the appreciation of the activity itself rather than its instrumental outcome (Davis et al., 1992; Mathwick, Malhotra and Ridgon, 2001). Intrinsic motivation is closely associated with the general need for feelings of competence and autonomy, and integrally relates to emotions such as enjoyment and excitement (Deci, 1975; Deci and Ryan, 1985). The vast majority of IT adoption studies has centered on the intrinsic belief ‘perceived enjoyment’, which has been related successfully to hedonic system usage (see Davis et al., 1992; Van der Heijden, 2004; Wakefield and Whitten, 2006).

3 RESEARCH FRAMEWORK AND HYPOTHESES

This study applies an integrated approach to put forward a model of virtual world adoption. The logic behind the model structure is predicated on three theoretical considerations. First, using the attitude towards use as key independent variable, we include the general technology beliefs perceived
usefulness and perceived ease of use, as proposed in TAM. The empirical robustness of this structure supports the assumption that both constructs explain a substantial part of the attitude variance, and thus our decision. Second, we challenge the parsimony and claim to sufficiency of TAM and expand our model by including the extrinsic belief escapism and intrinsic beliefs visual attractiveness, intrinsic enjoyment and entertainment value. In line with research suggesting direct effects of ‘external variables’ on behavior (e.g., Hong and Tam, 2006; Van der Heijden, 2004) we posit direct effects of these beliefs on attitude. Third, based on classical drive theory (see Hull, 1943), we view intrinsic motivation as a reinforcer of extrinsic motivation. In the remainder of this section we elaborate on the model structure, and detail the research constructs and their hypothesized relationships.

3.1 General technology beliefs

Since its conception in 1989, the Technology Acceptance Model (TAM) has spawned a whole research tradition into the factors affecting adoption and use of various IT applications. This model is an adaptation of the theory of reasoned action (TRA) proposed by Fishbein and Ajzen (1975) which aims to explain and predict the behaviors of people in a specific situation. The core of TAM is built on two specific beliefs explaining user acceptance of information technology (Davis, 1989), namely perceived usefulness and perceived ease of use. Both these beliefs are extrinsic motivators, focusing on the instrumental value of system use (Venkatesh, 2000).

A fundamental assumption in TAM (and one that has received much empirical support) is that both these beliefs are positively related to attitude towards system use. This leads to our first two hypotheses:

**H1.** Perceived usefulness positively influences the attitude towards using virtual worlds.

**H2.** Perceived ease of use positively influences the attitude towards using virtual worlds.

Previous TAM-based research found that both beliefs are also mutually related, in the sense that a system’s perceived usefulness increases as its ease of use gets higher (Legris, Ingham and Collerette, 2003; Moon and Kim, 2001). Therefore, we hypothesize:

**H3.** Perceived ease of use positively influences perceived usefulness.

Escapism

As conceptualized by Hirschman (1983), escapism is an extrinsic motivation. It “offers the individual an avenue to a more desirable state of being than the one presently experienced” (p. 64), which means it has a utilitarian function as an anxiety reduction mechanism. At its core, escapism refers to users’ motivation to “leave the reality in which they live in a cognitive and emotional way” (Henning and Vorderer, 2001, p. 101). Although in consumer behavior research such motivations are often directly related to hedonic values (Babin et al., 1994; Bridges and Florsheim, 2007), and escapism can also be conceptualized as related to “playfulness” and “pretending” (Mathwick et al., 2001), we feel it is primarily an extrinsic motivation. The instrumental value that is derived from technology use (“getting away from it all”) is an important driver for behavior here. This is in line with Hirschman and Holbrook’s (1982) concept of “imaginative constructs of reality”, where acts are not based on what users know to be real, but rather on what they desire reality to be. Projective fantasies or absorbing experiences (Hirschman and Holbrook, 1982) can be strong drivers for the use of environments such as virtual worlds. The social play inherent in virtual worlds can be expected to positively contribute to this value, and thus be positively appreciated by individuals with escapist motivations, leading to the following hypothesis:

**H4.** Escapism positively influences the attitude towards using virtual worlds.

In line with the above, it can be assumed that this motivation will not only directly exert a positive influence on attitude towards use, but will also be positively related to perceived usefulness, where
anxiety reduction is the benefit that can be derived from system use (Hong and Tam, 2006). Therefore, we hypothesize:

**H5.** Escapism positively influences perceived usefulness of virtual worlds.

### 3.2 Elaborating intrinsic motivations: enjoyment, entertainment and visual attractiveness

#### Intrinsic enjoyment

The TAM has received considerable empirical support over the years (Adams, Nelson and Todd, 1992; Davis and Venkatesh, 1996; Legris et al., 2003), and has seen numerous extensions in terms of new variables and relationships being added to the model. Because social play is an important element supported by virtual worlds, a relevant extension of TAM in the context of the study reported here is the inclusion of perceived enjoyment. Davis et al. (1992) first introduced perceived enjoyment as “the extent to which the activity of using the computer is perceived to be enjoyable in its own right, apart from any performance consequences that may be anticipated” (p. 1113).

The variable of enjoyment is especially relevant in relation to information systems with a hedonic function. Previous research in Web-based environments has found empirical support for the influence of enjoyment on attitude towards using, and intention to use such environments (Moon and Kim, 2001; Van der Heijden, 2003). In terms of the hedonic function of using virtual worlds, enjoyment can be expected to be an important factor:

**H6.** Intrinsic enjoyment positively influences the attitude towards using virtual worlds.

In line with the relationship between perceived ease of use and perceived usefulness, perceived ease of use can also be associated with enjoyment. Venkatesh (2000) argues that users’ perceptions of ease of use are adjusted based on actual experiences with a system. More specifically, Venkatesh argues, the more a user enjoys the interaction with a system, the more they tend to “…’underestimate’ the difficulty of the means or process of using a system because they quite simply enjoy the process and do not perceive it as being effortful…” (p. 348). This line of reasoning is also found in Venkatesh (1999) and Wakefield and Whitten (2006) and leads to the following hypothesis which shows a reinforcing effect of intrinsic on extrinsic motivators:

**H7.** Intrinsic enjoyment positively influences perceived ease of use of virtual worlds.

#### Entertainment value

Entertainment value can be defined as the perceived degree to which the use of an information system is a pleasant and likeable experience (Ducoffe, 1996) and lifts the user’s spirit (Mathwick et al., 2001). Although both intrinsic enjoyment and entertainment value are fun-related notions, they are conceptually distinct. An individual may experience an information system as entertaining, regardless of the reason why he uses it. In contrast, when this individual intrinsically enjoys using the information system, the pleasure is not just an added benefit of using the system to pursue some other goal, but rather is actively sought after and a purpose in itself (cf. Brown and Venkatesh, 2005; Mathwick et al., 2001).

As was argued in the above, based on the literature it can be expected that perceived fun, in the sense of intrinsic enjoyment, positively impacts the attitude towards using the virtual world. Given that intrinsic enjoyment and entertainment value concepts share the element of fun, the same arguments apply to entertainment value. Indeed, the literature provides a substantial body of evidence suggesting a positive effect of entertainment value on digital environment related attitudes such as the attitude towards using an information system (Dabholkar and Bagozzi, 2002), towards a website (Richard, 2005), and towards online advertising (Xu, Liao and Li, 2008). Accordingly, it can be anticipated that:
H8. Entertainment value positively influences the attitude towards using virtual worlds.

Arguably, when the use of an information system is perceived to be fun this is likely to increase the degree to which this fun is seen as an end in itself. Therefore, it is expected that:

A system that entertains the user provides this individual with a service and shows that it is capable of achieving something that the user values, regardless of why the system is used. Therefore, it stands to reason that the more the system is seen as entertaining, the more this gives the user the indication that the system will also perform adequately when it is put to use to increase the individual’s performance. This is supported by the research of D’Ambra and Rice (2001) who found a positive influence of entertainment value of websites on perceived personal performance. Consequently, we again hypothesize a reinforcing effect of an intrinsic on an extrinsic motivator:

H10. Entertainment value positively influences perceived usefulness of virtual worlds.

Visual attractiveness

The impact of the visual appeal of information systems on user perceptions and behavior has been investigated in the context of the World-Wide Web, Human Computer Interaction (HCI) and mobile commerce. For instance, visual attractiveness was found to be an important determinant of user satisfaction related to web site usage (Lindgaard and Dedek, 2003). Research performed in the field of mobile commerce revealed that design aesthetics appear to influence users’ loyalty towards mobile applications (Cyr, Head and Ivanov, 2006). This line of reasoning can be extended to virtual worlds, as virtual world technologies fully support the development of visually attractive environments aiming at creating game-like user experiences. In line with previous research (e.g., Van der Heijden, 2003) we assume that the visual attractiveness of virtual worlds will be associated with a positive attitude towards using such environments:

H11: Visual attractiveness positively influences attitude towards using virtual worlds

Visual attractiveness has also been found to be related to perceived ease of use. For example, Tractinsky, Katz and Ikar (2000) found a tight relationship between users’ perceptions of interface aesthetics and perceptions of the usability of an information system. Characteristics of the user-system interaction, such as visual appeal and usability, were found to play a role in driving perceived ease of use (Venkatesh, 2000). Van der Heijden (2003, p. 544) introduced the notion of “perceived visual attractiveness” defined as “the degree to which a person believes that the website is aesthetically pleasing to the eye” and found perceived visual attractiveness to positively influence both perceived usefulness and perceived ease-of-use. All in all, these findings lead to the following hypothesis, which again establishes a relationship between an intrinsic and an extrinsic motivator:

H12: Visual attractiveness positively influences perceived ease of use of virtual worlds.

4 METHOD

4.1 Procedure

We conducted a survey to collect empirical data. The sample consisted of Dutch registered users of the virtual world Second Life. An e-mail with an invitation to participate freely in the study was sent to a mailing list of 50,000 registered users. The invitation included a link that led to a web-based survey. As incentive, respondents were asked to fill in their e-mail address to engage in the raffle of ten book tokens of 20 euro. The online questionnaire addressed perceptions of perceived usefulness, perceived ease of use, escapism, intrinsic enjoyment, entertainment value, visual attractiveness, and attitude towards use. Moreover, socio-demographics were included.
4.2 Measures

Multi-item scales were used to measure the research constructs (see appendix). For each scale, items were collected based upon previous literature. We took care to solely select items that added to the conceptualization of the constructs as applied in our research. All items were part of reliable and validated measurement instruments. We tailored the items to the context of our study (i.e., made them target specific). All constructs were measured using 7-point Likert scales (strongly disagree-strongly agree).

4.3 Sample

The data was collected from the 29th of June to the 10th of July 2007. Eventually, 1627 respondents filled in the online questionnaire. The majority of the respondents was male (n=925; 56.9%), between 30 and 50 years old (n=862; 53%). A slight majority (52%, n=846) indicated to use Second Life once per week or more, while a minority (39.9%, n=649) reported to buy at Second Life. To investigate whether nonresponse bias posed a threat to the internal validity of the study, we compared the sample demographics with those of the population of Dutch Second Life users (cf. Armstrong, J.S., and Overton, 1977; Pavlou et al., 2007). Overall, no large differences in these demographics were found. This suggests that nonresponse bias was not a major concern in this study.

5 RESULTS

We first applied EFA to test whether the measurement items only tapped into one underlying dimension. Then, Partial Least Squares (PLS) modeling was utilized to further assess the measurement model and to estimate the structural model\(^2\). PLS was selected since our model is rather complex and our research intends to develop rather than confirm theory (see Fornell and Bookstein, 1982). Moreover, PLS has some specific advantages including minimal demands on data distribution (Chin, 1995).

5.1 Test of dimensionality

EFA was run using the principal components model with the oblique rotation technique (Direct Oblimin). The data passed the thresholds for sampling adequacy (KMO MSA 0.957, Bartlett’s test of sphericity 56554.6, p <.001). Four items were removed since they demonstrated high cross-loadings. The final factor solution was then derived. Together, the 7 factors explained 84.6% of the variance in the data. Unidimensionality of the measures was confirmed since each item loaded highest on its intended factor. Moreover, except for one intrinsic enjoyment item, all items loaded very strongly on their underlying factors. As such, preliminary evidence for convergent validity and discriminant validity was provided.

---

\(^1\) Data about the demographics of the Dutch Second Life user population was provided to us by the company responsible for Secondlife.nl.

\(^2\) We initially planned to use Structural Equation Modeling (SEM). First analyses resulted in poor fit. In such situations, PLS can be seen as feasible alternative for SEM as it places fewer demands on normality of data distributions and residual distributions (Fornell and Bookstein, 1982).
5.2 Measurement model

PLS was used to assess the reliability and validity of the measures. We utilized the software package Smart PLS (Ringle, Wende and Will, 2005) of the University of Hamburg to compute factor loadings, Cronbach’s alpha, composite reliability and Average Variance Extracted (AVE). In addition, SPSS (version 13, Mac) was used to compute minimum item-to-total correlations.

The results strongly confirmed the reliability of the measures. The alphas and composite reliability scores exceeded the value of 0.90, and all AVE’s surpassed the 0.50 guideline (see Ping, 2004). Convergent validity was assessed by factor loadings (PLS), alphas, AVE’s and minimum item-to-total correlations. All scores exceeded accepted rules of thumb (factor loadings: 0.70, see Ko, Kirsch and King, 2005; alpha: 0.80, see Ping, 2004; AVE: 0.50, see Wasko and Faraj, 2005; minimum item-to-total correlations, 0.40, see Jayanti and Burns, 1998). As such, convergent validity was established. Finally, we assessed for discriminant validity in two steps. First, we used the PLS output to study the within-construct item factor loadings and compared these loadings to across-construct item loadings (cf. Wasko and Faraj, 2005). Since all within-construct item loadings were high, and lower than the cross-loadings, discriminant validity can be assumed. Second, we studied the individual AVE’s and compared the scores with the squared correlations among the constructs (cf. Chin, 1998a).

![Table 1: Discriminant validity: AVE’s versus cross-construct squared correlations (note: the boldscores (diagonal) are the AVE’s of the individual constructs. Of the diagonal are the squared correlations between the constructs).](image)

All AVE’s exceeded the values of the squared correlations among the constructs in the corresponding rows and columns. As such, discriminant validity was demonstrated.

5.3 Structural model

We then estimated the path coefficients (β) and $R^2$ values of the structural model using the bootstrapping technique (1627 re-samples; cf. Hesterberg et al., 2003). To evaluate the significance and effect sizes of the path coefficients, we conducted two-tail t-tests with a significance level of 0.01 (see Blalock, 1979). The procedure of Chin (1998a) was applied to compute effect sizes.

Figure 1: Results structural model. Note: all path coefficients are significant at p <.001.

Overall, the results strongly confirm the predictive power of the model. The amount of variance explained is high, implying a good fit to the data. The results indicate that ten hypotheses (H1, H3, H5,
H6, H7, H8, H9, H10, H11, H12) are supported and two (H2, H4) are rejected. Six significant paths are of substantial strength (>0.19; cf. Chin, 1998b), while significant but smaller effects are reported for four paths.

6 DISCUSSION

6.1 Key Findings

Our research yields a number of key findings. First, the study reveals direct effects of the extrinsic belief perceived usefulness and the intrinsic beliefs intrinsic enjoyment, entertainment value and visual attractiveness on the attitude towards virtual world usage. Together, these concepts explained 45% of the attitude variance, which is quite impressive. Perceived usefulness and entertainment were the strongest predictors. The influences of intrinsic enjoyment and visual attractiveness were less strong. Overall, these findings confirm the proposed expansion of IT adoption drivers beyond general technology beliefs, and support the inclusion of intrinsic enjoyment, entertainment value and visual attractiveness. Second, our work provides strong support for the reinforcing role of intrinsic motivation on extrinsic motivation. We demonstrate that higher levels of enjoyment, entertainment, and visual attractiveness contribute to the perceived usefulness and perceived ease of use of virtual world systems. All proposed effects were significant and rather strong in nature. Adding to our first key finding, this finding suggests that intrinsic beliefs function as first- and second-order determinants of the attitude. Third, the results show that perceived usefulness mediates the effects of the extrinsic motives escapism and perceived ease of use on attitude. Contrasting our expectations, perceived ease of use and escapism did not directly relate to attitude. An explanation for the non-significance of perceived ease of use comes from literature claiming that ease of use solely affects behavior when a) users are inexperienced (Venkatesh, 2000) and/or b) the system is highly unusable (Van der Heijden and Verhagen, 2004). Since the vast majority of our respondents used Second Life on a regular base, these conditions are unlikely to apply to our research. Regarding the non-significance of escapism, we notice that, in line with the literature, its conceptualization reflects the instrumental value of a virtual world to achieve a particular goal (i.e., to ‘escape’). As such, this task-specific behavioral belief reflects a perceived system benefit and is most likely to be used directly to form assessments about the general behavioral belief usefulness (Venkatesh and Davis, 2000; see also Ajzen and Fishbein, 1980), and not to judge about an overall disposition towards system use (i.e., the attitude).

6.2 Theoretical implications

This research is one of the first to understand the adoption of virtual worlds. We introduced and tested a model that integrates and extends existing models on utilitarian and hedonic system use. Given the fit of our model, our results seem to suggest that existing utilitarian and hedonic models fall short in explaining virtual world use. Our findings underline that user adoption of virtual worlds depends on two belief configurations, and support that extrinsic and intrinsic motives function simultaneously in adoption decision-making (cf. Engel et al., 1995). Future theoretical efforts could incorporate this evidence and test its applicability across different contexts.

To advance our understanding of the behavioral dynamics behind virtual world use, this study suggests two patterns concerning the consequences of intrinsic motivation. First, we challenged the claim to sufficiency of previous models such as TRA and TAM (cf. Venkatesh, 1999), and demonstrated that intrinsic motivation directly affects the attitude. Second, we showed that intrinsic motivation reinforces the effect of extrinsic motivation on attitude. Although this proposed order effect is theoretically plausible, and aligns with the fact that we included intrinsic motives to an existing base of extrinsic technology beliefs (and not vice versa; see also Venkatesh, 2000), this finding contrasts with previous IT adoption works showing that extrinsic motivation precedes intrinsic motivation (e.g.,
Davis et al., 1992; Van der Heijden, 2004). Apparently, the relationships between extrinsic and intrinsic motivation are more complex than initially thought and more research is needed.

6.3 Implications for practice

Our findings have several practical implications. First, our findings highlight the roles of intrinsic and extrinsic motivation as direct determinants of virtual world adoption. To directly affect adoption behavior, developers should enhance the usefulness, entertainment, enjoyment, and visual attractiveness of a given virtual world. As such, both productive and prolonged use can be triggered in a direct manner. Second, our research draws attention to the potential of integrating instrumental and enjoyable, new, challenging functions and features. The reinforcing influence of intrinsic motivation on extrinsic motivation guides such integration. For instance, employing features like attractive designs, funny navigation (e.g., flying; using cars, boats, planes), and entertaining video and sound can enhance usefulness and ease of use. Third, to further prioritize development efforts, our findings underline the vital function of perceived usefulness and entertainment value. Both constructs have strong direct effects on the attitude. Moreover, usefulness mediates the influence of ease of use and escapism on the attitude, and entertainment value has strong second-order effects via usefulness and intrinsic enjoyment. Being key influencers of virtual world adoption, a focus on both constructs and their determinants is likely to enhance the effectiveness of system development endeavors in the broader context of IS development in general.

6.4 Limitation and additional recommendation

The potential limitations of this study concern sample bias. While no evidence of nonresponse bias was found, self-selection effects caused by the use of a self-administered questionnaire cannot be completely ruled out. In addition, the sample of Dutch Second Life users implies external validation in Western culture. Scholars in the fields of information system research (e.g., Al-Gahtani, Hubona and Wang, 2007; Straub, Loch and and Hill, 2001), however, have shown that cultural differences are likely to affect IT adoption. For example, in comparing collectivistic versus individualistic cultures Davis, Wang and Lindridge (2007) demonstrate that online consumers in collectivistic societies suppress the exploration and expression of emotions. In such settings, perceptions of pleasure can be assumed to have a relatively weak impact on online system use (Davis et al., 2007). Extrapolating this research finding to virtual world adoption, it is believable that the influence of intrinsic motivation is weaker in non-Western cultures. Future research may test this assumption by cross-validating our research across different cultures.

Abstract

Second Life is a 3-D multi-user virtual environment which has gained widespread popularity amongst academic community in the recent years. However, due to its infancy very little is known about the factors driving users’ intention to use Second Life especially in the educational context. This paper presents findings from an ongoing study about the impacts of using multi-user virtual environments in higher education. In information systems research, several models and frameworks have attempted to predict the acceptance of new technology. However some recent studies suggest that the traditional technology acceptance approaches may not work well with today’s entertainment-oriented technologies such as multi-user virtual environments. They also recommend exploring those facets of human behaviour that are likely to capture the hedonic consumption of such technologies. In this paper, we propose an extended technology acceptance model (TAM) including hedonic consumption behaviours in order to explain the usage and acceptance of Second Life in the educational context. The proposed model is empirically evaluated using survey data collected from 122 users about their perceptions of Second Life. Findings suggest that hedonic consumption behaviours are strong predictors of Second Life usage as compared to traditional motivational constructs of usefulness and ease-of-use.

Keywords: TAM, Second Life, education, hedonic consumption behaviours.
1 INTRODUCTION

Second Life is an emerging 3-D multi-user virtual environment (MUVE) which is increasingly gaining wide spread acceptance from educators and students. A large number of prominent educational institutions have established their virtual campuses in Second Life (a complete list of participating institutions is available at: http://simteach.com/wiki/index.php?title=Second_Life_Education_Wiki#Institutions_and_Organizations_in_SL/). Despite the fact that emerging Web technologies like Second Life are seen as a next-generation platform for Web users, their acceptance remains a big challenge in order to become mainstream (Shin & Kim, 2008). Also, due to its infancy, very little academic research is available on the usage and acceptance of Second Life. Therefore it is important to understand the significant predictors of Second Life usage in order to utilise it as an effective teaching and learning tool.

In information systems research, several theoretical models or frameworks attempted to explain the acceptance of new technology. Among these, technology acceptance model (TAM) is the most researched one. TAM is originally developed by Davis and his colleagues to explain or predict individuals’ acceptance of computer based systems and underlying influencing factors (Davis, 1989). TAM has been validated for a number of productivity-oriented technologies like word processors, spread sheets, Web-based learning environments and multimedia application. However, some recent studies suggest that traditional technology acceptance approaches such as TAM may not work well for today’s entertainment-oriented technologies like multi-player online games or MUVEs (Heijden, 2004; Holsapple & Wu, 2007). They also recommend to consider those facets of human behaviour that are likely to capture the hedonic consumption of such technologies (Hsu & Lu, 2004). Since Second Life also inherits a large entertainment element, it is important to capture its hedonic consumption in order to explain its usage and acceptance. In this paper, we present an extended TAM including hedonic consumption behaviours in order to explain the user acceptance of Second Life. An online survey was developed using constructs from previously published research and participants were employed through various resources within Second Life as well as externally. A total of 122 participants including students, teachers, researchers and academic managers responded to our survey. The PLS (Partial Least Squares) approach was used for data validation and hypotheses / model testing. All of the hypothesised relationships formulated at the start were confirmed by the data. Findings suggest that hedonic consumption behaviours are strong predictors of Second Life usage than traditional motivational behaviours. Our model explains 51.4% of the users’ intentions to use Second Life, which is a significant outcome when compared with similar studies of technology acceptance.

The rest of the paper is organised as follows. Section 2 presents an overview of Second Life and its applications in academia, technology acceptance model and the theory of hedonic consumption behaviours. The research hypotheses and the model are presented in Section 3. We present the research methodology in Section 4. Section 5 presents results of data validation and hypotheses / model testing. We discuss the study findings, implications and limitations in Section 6. Section 7 concludes the study and points out future work.

2 BACKGROUND

2.1 Second Life and education

Second Life is a 3-D multi-user virtual environment (MUVE) launched by Linden Labs in 2003. Second Life is a world solely created by its inhabitants, called ‘residents’. Residents have the opportunities to create their digital proxies called ‘avatars’ and design their clothing, hair colour, dresses and even appearances (Coffman & Klinger, 2007). Avatars can walk, run, or even fly in the virtual environment. They can converse with other avatars using text, images, gestures or even voice.
Residents can move or ‘teleport’ from one location to another. Second Life provides enormous opportunities to imitate real world situations in a virtual environment, to name a few: reincarnation of ancient architecture and civilisations (Harrison, 2009); advertising and selling of real life commodities (Lui, Piccoli, & Ives, 2007); experiencing complex medical procedures discounting dangerous outcomes (Thompson & Hagstrom, 2008); library services (Bell, Peters, & Pope, 2007); conducting classes and labs (Holmberg & Huvila, 2008); and many more.

3-D MUVEs like Second Life offer a variety of potential benefits for educational use including: collaboration and communication, engagement, conducting activities in a risk-free environment, alternative space for instruction and tasks, and visualisation of difficult content (Eschenbrenner, Nah, & Keng, 2009). (Richter, Anderson-Inman, & Frisbee, 2007) have identified at least five different types of learner engagement that are possible in Second Life: experiential, diagnostic, demonstrative, role-play and constructivist. Second Life has the potential to be a useful educational tool for teaching and learning by using a constructivist approach (Coffman & Klinger, 2007), which is the theory of knowledge acquisition obtained through interactions and building upon own knowledge and which produces the highest type of learning according to Bloom (Cheal, 2007). Following this approach, students can discover and create meaningful content and interactions (Stevens, 2006). Teachers in higher education have found Second Life a convenient place to conduct online classes, conferences, presentations, and meetings with students (Richter, et al., 2007). However, in order to explore the teaching and learning potential of Second Life, it is important to understand the factors that affect users’ intentions toward Second Life usage. In this paper, we aim to propose and evaluate a technology acceptance model to explain user acceptance of Second Life within educational domain.

2.2 Technology acceptance model (TAM)

TAM posits that user perceptions of usefulness and ease-of-use determine attitudes towards using a system or technology. An individual’s attitude is hypothesised to influence the behavioural intention to use a technology, which in turn leads to the actual use. In the follow-up model, TAM2 (Venkatesh & Davis, 2000), the attitude component was dropped and perceived technology characteristics directly influenced the individual’s intention to use the technology. Social influences (also referred as subjective norms) were also included in the follow-up model. Both TAM and TAM2 have established themselves as being robust and parsimonious for predicting user adoption of a variety of new technologies (Raaij & Schepers, 2008) and have been validated for a variety of productivity-oriented technologies including word processors, e-mail, spreadsheets, Web-based learning systems, and multimedia learning systems (Halawi & McCarthy, 2007; Lederer, Maupin, Sena, & Zhuang, 2000; Saade, Nebebe, & Tan, 2007). However, some previous studies suggest that traditional technology acceptance approaches like TAM may not work well with today’s entertainment-oriented technologies such as multi-player online games or MUVEs (Heijden, 2004; Hsu & Lu, 2004; Koufaris, 2002). Because these technologies enable users to fantasise, role-play and be entertained, it is important to measure their hedonic consumption along with the traditional user acceptance behaviours, in order to better understand their usage patterns. In this paper, we present an extended TAM2 including hedonic consumption behaviours to predict the user intentions towards Second Life usage.

2.3 Theory of hedonic consumption behaviours

With its roots in marketing research, hedonic consumption designates those facets of user behaviour that relate to the multi-sensory, fantasy and emotional aspects of one’s experience with products (Hirschman & Holbrook, 1982). Hedonic perspective seeks not to replace traditional theories of consumption but rather to extend and enhance their applicability. The theory asserts that emotional and imaginative responses are the main drivers of hedonic consumption, which can be explained through the constructs of emotional involvement, enjoyment and role projection (Lacher & Mizerski, 1994). Several studies have reported significant impact of these constructs in explaining the consumption of entertainment-oriented technologies or systems: including online games, virtual
learning environments, online retail shopping, music, and gambling (Childers, Carr, Peck, & Carson, 2001; Lacher & Mizerski, 1994; Lee, Cheung, & Chen, 2005; Mun & Hwang, 2003; Shin & Kim, 2008; Titz, Andrus, & Miller, 2002). The traditional economic view of products as objects would seem inappropriate for products whose usage are based upon satisfying emotional desires rather than fulfilling utilitarian functions (Kim & Forsythe, 2007). Thus for the systems that are hedonic in nature, hedonic factors could be the dominant predictors of attitude towards their usage. Similarly, for MUVEs (such as Second Life) that are largely hedonic in nature, we can expect hedonic behaviours to be a strong predictor of attitudes towards using these technologies. Therefore, in this paper, we aim to examine the impact of hedonic consumptions behaviours on user intentions toward Second Life usage.

3 RESEARCH HYPOTHESES AND MODEL

3.1 TAM2 hypotheses

Perceived usefulness and perceived ease-of-use are the basic TAM constructs. In general, perceived usefulness reflects an individual's subjective estimation of the job performance enhancement that is likely to result from the use of a new technology, whereas perceived ease-of-use refers to the degree to which he or she expects the use of the technology to be free of effort (Davis, Bagozzi, & Warshaw, 1989). Both of these constructs constitute a significant influence on an individual's intention to use a technology or system (Ma & Liu, 2004). Perceived ease-of-use is also reported a significant determinant of perceived usefulness (Davis, 1989). We follow this trend and hypothesise the following:

H1. The perceived ease-of-use (PEU) of Second Life will have a positive impact on perceived usefulness (PU) of Second Life.

H2. The perceived ease-of-use (PEU) of Second Life will have a positive impact on behavioural intention (BI) to use Second Life.

H3. The perceived usefulness (PU) of Second Life will have a positive impact on behavioural intention (BI) to use Second Life.

Subjective norms refer to the degree to which a person believes that those who are important to him or her think that he or she should perform the behaviour in question (Fishbein & Ajzen, 1975). Previous studies have shown that both peers’ and superiors’ influences can affect a person’s decision to accept a new technology (Mathieson, 1991; Taylor & Todd, 1995). Subjective norms can also influence technology acceptance via perceived usefulness, which is referred as ‘internationalisation’ mechanism (Venkatesh & Davis, 2000). On the basis of this, we hypothesise the following:

H4. The subjective norms (SN) will have a positive impact on perceived usefulness (PU) of Second Life.

H5. The subjective norms (SN) will have a positive impact on behavioural intention (BI) to use Second Life.

3.2 Influence of hedonic consumption behaviours

The hedonic consumption theory focuses on positive behavioural experience: emotional and imaginative responses, which are key human factors and are likely to capture the entertainment nature of the technology of interest (Holsapple & Wu, 2007). These responses can be explained through emotional involvement, enjoyment and role projection constructs. Emotional involvement is defined as the degree to which an individual is emotionally engaged in a behaviour; enjoyment is defined as the degree to which performing an activity is perceived as providing pleasure and joy in its own right, aside from performance consequences (Venkatesh, 2000); and role projection involves the mental
activities whereby individuals project themselves into particular roles or characters (Holsapple & Wu, 2007). Some recent studies have shown the significant effect of these constructs on user acceptance of entertainment-oriented technologies (Depradine, 2007; Shin & Kim, 2008). We thus hypothesise the following:

H6: The perceived emotional involvement (PEI) will have a positive impact on the behavioural intention (BI) to use Second Life.

H7: The perceived enjoyment (PEN) will have a positive impact on the behavioural intention (BI) to use Second Life.

H8: The perceived role projection (PRP) will have a positive impact on the behavioural intention (BI) to use Second Life.

3.3 Extended TAM2

On the basis of above hypotheses, we present an extended TAM2 including hedonic consumption behaviours (in terms of emotional involvement, enjoyment and role projection) as significant predictors of users intentions to use Second Life, as shown in Figure 1.

![Figure 1. An extended TAM2 including hedonic consumption behaviours](image)

4 METHODOLOGY

4.1 Participants and data collection

Since the aim of our study was to capture the user acceptance of Second Life in the educational context, our target subjects were academic-centric participants who either have attended, designed, conducted classes or involved in some form of educational activities in Second Life. Data for this research were collected through in-world (within Second Life) and external resources. First of all, the authors joined several educational and research groups within Second Life to get an insight of the
ongoing educational activities and to make social contacts with the community. We visited a large number of educational islands and personally invited the residents to take part in our online survey. We also sent invitations to various educational groups within Second Life. The external resources used for data collection were the two popular mailing lists; Second Life Educators mailing list (SLED) and Second Life Research Listserv (Slrl). These lists are populated by large number of geographically distributed and active academic-centric individuals and are considered a constant ground for data collection. Most of the data used in this study come from external resources. Some recent studies have adopted similar approaches in exploring this new technology (Second Life) within the education context (Alvarez, 2006; Boostrom, 2008; Richter, et al., 2007). The total number of valid responses we obtained from all above resources was 122, which sufficed to perform PLS analysis.

4.2 Measures

Multiple items were adopted from previously published scales for the constructs used in our model. All items were measured on a seven point Likert scale, ranging from 1 (strongly disagree) to 7 (strongly agree). The scales for perceived ease-of-use (PEU), perceived usefulness (PU) and subjective norms (SN) were adopted from (Davis, et al., 1989) and (Igbaria, 1990). The scales for behavioural intention (BI) were adopted from (Venkatesh, Morris, Davis, & Davis, 2003). The scales to measure the perceived emotional involvement (PEI), perceived enjoyment (PEN) and perceived role projection (PRP) were adopted from (Hirschman, 1983) and (Hirschman & Holbrook, 1982). The complete list of measurement items is presented in the Appendix. Demographic items are not included due to space limit.

5 RESULTS

The research model was tested using the PLS approach. PLS is considered as a powerful tool in analysing structural models involving multiple constructs and multiple indicators. Previous research shows that PLS approach is more suitable for prediction as compared to other approaches like LISREL and EQs, because it assumes that all the measured variance in the study will be explained (Chin, 1998; Saade & Bahli, 2005). The PLS approach has been used in several other studies of technology acceptance such as (Raaij & Schepers, 2008), (Saade & Bahli, 2005) and (Mun & Hwang, 2003), thus deemed suitable for our study. After ensuring the reliability and validity of the scales, we tested the hypothesised relationships between hedonic consumption behaviours and TAM2 constructs using bootstrap re-sampling method (Cotterman & Senn, 1992). Unlike other structural equation modelling approaches such as LISREL, the primary objective of the PLS approach is the maximisation of variance explained, not the minimisation of the difference between the observed and the reproduced covariance matrices (Hulland, 1999). Thus the quality of the PLS approach can be determined by examining the R^2 values of the dependant constructs.

5.1 Demographics

Our sample included 79 females and 43 males. The mean age of the participants was 42, ranging from 17-65 years. Teachers (27%) and students (25%) constituted the larger groups while researchers the smallest (13%) group. The majority of participants appeared well educated as 67.2% of them held postgraduate qualifications. The survey results also showed that 82.8% of participants had Internet experience of more than 9 years, 94.3% of them used the Internet several times a day and the primary access location of the Internet for 56.6% of participants was the home. In addition, the majority of participants (81.9%) had at least 6 months experience of using Second Life. About half of them admitted of accessing Second Life at least once a day and the primary access location for 72.1% of participants was the home. These results suggest that our participants were mature, well educated and geographically distributed. They had extensive experience of using Web-based applications with
adequate experience of using Second Life in the educational contexts. Thus they fit well into our target participants’ profile.

### 5.2 Data validation and reliability

Table 1 presents the summary of all construct reliability measures including factor loadings, t-values, composite reliability (CR), and average variance extracted (AVE). The factor loadings provide evidence for convergent validity as all our constructs load greater than the threshold of 0.50 as suggested by (Peterson, 2000). The t-values derived from our analysis also provide evidence for convergent validity since all values exceed the threshold of 1.96 as suggested by (Gefen & Straub, 2005). Internal consistency appears significant for all of our constructs since the composite reliability values exceed the minimum of 0.70 as suggested by (Nunnally & Bernstein, 1994).

![Table 1. Construct reliability measures.](image)

Discriminant validity was met using the Fornell and Larcker test (Fornell & Larcker, 1981). The procedure involves computing the square root of the AVE of each construct, which should exceed the correlation shared between the construct and other constructs in the model. Table 2 shows that square roots (in bold) of all AVEs (on the diagonal) are greater than the cross-correlations of all other constructs. Thus all our constructs demonstrated a good degree of validity and reliability.

![Table 2. Discriminant validity of constructs.](image)
5.3 Hypotheses and model testing

Figure 2 summarises the results of hypotheses testing. We found a direct positive impact of perceived ease-of-use (PEU) on perceived usefulness (PU) and behavioural intention (BI), thus supporting hypotheses H1 and H2 respectively. The perceived usefulness (PU) also had a direct positive impact on behavioural intention (BI), supporting hypothesis H3. Subjective norms (SN) exhibited direct positive impact on perceived usefulness (PU) and behavioural intention (BI), thus supporting hypotheses H4 and H5 respectively. The three relationships (H6, H7, and H8) between the hedonic constructs (PEI, PEN, PRP) and the behavioural intention (BI) also appeared significant, with perceived enjoyment (PEN) as the strongest predictor of users’ intentions to use Second Life. Thus all hypothesised relationships formulated at the start were confirmed by the data. Our model explained 51.4% of the variance through user’s intentions to use Second Life, which is a significant outcome when compared with similar studies of technology acceptance such as: (Mun & Hwang, 2003; Raaij & Schepers, 2008; Shin & Kim, 2008).

Figure 2.PL5 results.

6 DISCUSSION

The study broadens our understanding of technology acceptance by including emotional and imaginative responses of hedonic consumption behaviours as key determinants of Second Life usage. All eight hypotheses postulated at the start were confirmed by the data. Several insightful results could be summarised form our research model as follows: First, perceived enjoyment was the most important predictor of users’ intention to use Second Life. This is consistent with the findings of (Lee, et al., 2005), which have reported the direct and significant impact of perceived enjoyment on user intentions to use Internet-based learning medium (ILM). Similarly, (Childers, et al., 2001) have reported the strong impact of enjoyment on online retail shopping behaviour.
Second, the next strongest and direct impact on use intentions was of perceived emotional involvement followed by the perceived role projection. Thus, the hedonic consumption behaviours as a whole appeared as the strongest predictor of user intentions to use Second Life. This is consistent with the findings of (Kim & Forsythe, 2007), which have reported the stronger impact of hedonic motivations than functional motivations toward using product virtualisation technologies.

Third, TAM2 constructs of perceived ease-of-use, perceived usefulness and subjective norms also had significant impact on user intentions to use Second Life but with lesser significance than that of hedonic consumption behaviours. This is consistent with the findings of (Shin & Kim, 2008), which suggests that in case of Web 2.0 technologies users may need a clear motivations of usefulness and ease-of-use than those of traditional Web technologies. This is also in line with some recent studies which have predicted that the traditional technology acceptance approaches such as TAM may not work well with today’s multi-user and entertainment-oriented technologies like Second Life (Heijden, 2004; Holsapple & Wu, 2007; Hsu & Lu, 2004).

The implications of our results for educators and researchers are multi-fold: The educators of Second Life should include elements of enjoyment, emotional involvement and role projection while designing academic activities as the findings suggest that the more the users enjoy, get emotionally involved and be able to project themselves in the virtual environment, the more likely they will use Second Life, thus enhance their learning. Similar trends are illustrated in practice by the more popular islands in Second Life such as the Genome Island (http://connect.educause.edu/Library/EDUCAUSE+Review/GenomeIsland/47234?time=1226972674) and others (see http://sleducation.wikispaces.com/educationaluses). Here, students are presented with opportunities to role play, co-create and get involved in real time educational process. This presents students a much more rich and rewarding learning experience. For researchers, the study offers a platform to further explore hedonic consumption of today’s social and entertainment-oriented technologies like multiplayer online games, social networking Websites, Web authoring tools, and other emerging Web technologies. The study also suggests that hedonic behaviours should be given due consideration while measuring the user acceptance of entertainment-oriented technologies.

Like any other user study, our study also has limitations. First of all, our sample may be biased as our respondents were more likely to be engaged with the Second Life environment than non-respondents. Therefore, respondents could have been captured to the ‘hedonic consumption behaviours’. Secondly, the study results cannot be generalised to other MUVEs because our sample represents users of Second Life only. Another limitation of our study is the use of self-reported usage data which are often measured by log files. However, it was beyond our control to obtain such data as majority of the participants were employed through external resources and we had no means of maintaining their usage log files.

7 CONCLUSION AND FUTURE WORK

Our study provided a useful insight into the usage and acceptance of Second Life in the educational context. Instead of focusing on the traditional motivational and performance-based determinants of technology acceptance, the study focused on the hedonic consumption of technology because the targeted technology (Second Life) possessed a large entertainment element. Empirical findings provided support for our proposed model. Although hedonic consumption behaviours explained a significant amount of users’ intentions toward Second Life usage, more research would be carried out in our future studies to explore other key usage predictors such as user involvement, presence, flow, critical mass, fantasy, escapism, arousal and social pressures. We would also consider conducting similar studies with other popular MUVEs such as Haboo, There or Active Worlds to better understand user acceptance of MUVEs in education and to utilise them as effective teaching and learning tools.

| Submission Type: | Research Paper |
| Keyword: | Cross-cultural issues, Cross-national study, Human computer interaction (HCI), Interface design |
GENDER AND WEBSITE DESIGN ACROSS CULTURES

Abstract

Women and men process information differently and this phenomenon is confirmed in the context of online shopping where women are known to have diverse preferences from men related to website design and website trust. Yet despite these known differences, little research has examined gender and website design. Further, although online shoppers hail from all corners of the globe, no research has examined gender differences concerning website design in a multicultural sample. To fill this gap, the current investigation examined differences between men and women with a focus on website trust, website satisfaction, and website design in eight countries. Results demonstrate significant differences between men and women on all variables tested. Further analyses of four of the countries in the sample (China, Canada, the United States, and Germany) are compared related to socio-cultural values for masculinity-femininity. As expected, countries more alike on this dimension exhibited more similarities in terms of gender comparisons. All hypotheses in the study are supported. Suggestions are made regarding avenues for future research.

Keywords: Website Design, Website Trust, Website Satisfaction, Gender, Culture.
1 INTRODUCTION

The number of women shopping online is increasing, although relatively little is known about gender differences when buying on the Web. Prior research that does examine gender related attitudes and activities on the Internet suggests women are less interested in the Internet than men, spend less time online than men, and are less likely to purchase online (Allen 2001, Garbarino & Strahilevitz 2004, Rodgers & Harris 2003).

The design of the website is expected to impact user preferences, which in turn may produce differing reactions between men and women (Chen and Dhillon 2002). Although few studies have examined gender and website design - there are some exceptions. For instance previous research has examined gender differences related to online social presence and enjoyment (Cyr & Hassanein & Head & Ivanov 2007), website design and satisfaction (Cyr & Bonanni 2005), email usage (Gefen & Straub 1997), social norms (Venkatesh & Morris 2000), online risk (Garbarino & Strahilevitz 2004), or trust (Awad & Ragowsky 2008, Cyr & Bonanni 2005).

Building on previous research, the goal of the current investigation is to examine differences between men and women concerning their reactions to an online shopping website. The research variables considered include: website design elements (such as information design, information content, visual design, navigation design) website trust, and website satisfaction. To expand the generalizability of the findings, data was collected in eight countries (Canada, the United States, India, Germany, Japan, Mexico, Chile, and China) as well as separately for English and French Canadians within Canada. In addition, comparisons are made between four countries based on levels of masculinity-femininity (as elaborated by Hofstede 1984). Of interest is whether there is any similarity between user perceptions based on gender in countries which are similar on psychological-cultural values such as masculinity-femininity.

This paper begins with an introduction to gender and information processing, as well as cultural values related to gender with a focus on masculinity-femininity. This is followed by a review of the literature related to the various dependent variables, and with respect to prior research that examines the variables in the context of gender. The method, results, and discussion follow, with both theoretical and practical implications outlined.

2 INFORMATION PROCESSING AND GENDER

Men and women are known to process information differently, and this spills into various areas of information technology communications (Gefen & Geri & Paravastu 2007, Gefen & Ridings 2005) including online shopping. Dittmar et al. (2004, p. 440) write: “Men are more functional in their buying attitudes…whereas women stress social-experiential and identity-related concerns, and in particular, emotional involvement”. Rodgers and Harris (2003) noted that inadequately perceived emotional benefits may be an underlying reason why women are less involved in e-commerce activity.

Social explanations have been advanced with relevance for why men and women vary in their perceptions and expectations regarding online shopping. Men tend to vigorously pursue self focused goals having great personal consequences, while women are guided by communal concerns emphasizing interpersonal affiliation and harmonious relationships (Petrevu 2001). To better understand differences in information processing between men and women, two theories – selectivity interpretation and item-specific versus relational processing – are advanced. The selectivity hypothesis

---

1 It should be noted that the purpose of this paper is not to compare the research variables across countries but rather to focus on gender differences within each country or group with respect to the research variables. Separate research has been conducted by this author on website design across cultures. Please refer to Cyr (2008a).
(first proposed by Meyers-Levy 1989) asserts that men are selective processors who rely on highly available and salient cues. Women are comprehensive processors who are apt to assimilate all available information before arriving at a conclusion. Translated to an online shopping experience, men tend to pursue a minimizing approach whereby they make a selection as quickly as possible. Women, on the other hand, will spend considerably more time gathering information about products and comparing the merits of each prior to making the purchase decision.

Alternately, in item-specific information processing, attributes that are unique or distinctive to a message are important and there is a tendency to focus on a few salient attributes (more male oriented). When relational processing occurs (more female oriented), similarities, shared themes, or interrelationships among disparate pieces of information are sought (Einstein & Hunt 1980). In the context of online shopping these theories find relevance in that women require more social interaction than men in the shopping experience - and which may not be possible on the Web. Hence women perceive less emotional benefit from online shopping, and have less favorable perceptions of the experience than men (Cyr & Bonanni 2005, Simon 2001).

3 SOCIO-CULTURAL VALUES OF MASCULINITY-FEMININITY

In addition to different perceptions in online shopping related to gender, culture is known to have an effect as well (Cyr & Bonnani & Bowes & Ilsever 2005, Cyr 2008, Gefen & Heart 2006, Srite & Karahanna 2006). Differences in online communication strategies for target markets occur between Japan, Spain and the United States (Okayazaki & Rivas 2002). Over the years, researchers have often used Hofstede’s (1984) classifications to study social psychological phenomena including website design and experience (Gefen & Heart 2006, Jarvenpaa & Tractinsky & Saarinen & Vitale 1999). Simon 2001).

In this research, Hofstede’s (1984) classification for masculinity-femininity will be considered for its relatedness to psychological-social phenomena with respect to gender. Masculine values emphasize work goals such as material success and having challenging work. Feminine values are focused on quality of life, nurturing, and modesty (Hofstede & Associates 1998). As defined by Hofstede (1984) works goals include a focus on recognition, challenge, advancement, earning, and achievement defined by earnings. This set of goals, termed ego goals or ego enhancing goals, is thought to be associated with masculine cultures. Alternately, quality of life work goals emphasize a supportive and friendly work environment, cooperation, job security and achievement determined with respect to work relationships and human contacts. According to Hofstede, these social or relationship enhancing goals are associated with feminine cultures. Specific to the countries in this investigation, two countries that are ranked medium in masculinity (Canada - 52; China - 50) are compared; as are two countries that are ranked high in masculinity (the United States - 62; Germany - 62). As outlined in the introduction, it is of interest to see if in similar countries based on socio-cultural values of masculinity-femininity if there are any gender parallels for these countries.

4 WEBSITE DESIGN AND GENDER

Effective website design engages and attracts online consumers (Agarwal & Venkatesh 2002). Modes of information presented on the Internet, and the quality of graphics have a significant impact on user experience (Chau & Au & Tam 2000, Cyr & Head & Larios & Pan 2009). Others have conducted research into website design related to website trust, satisfaction and loyalty and have considered separate elements of information design, visual design, and navigation design (Cyr et al. 2005, Cyr 2008). In addition, Cyr (2008) included the additional design element of information content. Building on this earlier work, in this study the following are investigated:

Information Content - information that is complete, sufficient, and effective;
Information Design - information that is logically presented and organized;
Navigation Design - the navigational scheme or format used to help or hinder users as they access different sections of a website;

Visual Design - design elements such as balance, emotional appeal, aesthetics, and uniformity of a website’s overall graphical look; this may include colors, photographs, shapes, or font type.

Few studies have explicitly explored website design differences between men and women. Although in one investigation differences in website perceptions were examined for men and women concerning information richness, communication effectiveness, and communication interface (Simon 2001). Results from this study revealed that women had a lower perception of websites than men. In another study, Cyr and Bonanni (2005) found differences on selected items only between men and women for information design, navigation design and visual design. In total, five of 11 design items were statistically different using t-test comparisons. Based on these results as well as interview data, men felt the information on the website was better organized and presented, and they were more satisfied with navigation. With respect to visual design, women were more attracted by the colors on the website while men liked the more interactive and “flashy” design elements.

Further, based on four of the eight countries in the sample, it will be interesting to explore if there are similarities between how men and women perceive website design elements in a context that includes socio-cultural values of masculinity-femininity. More specifically, it is expected that countries that are both medium in masculinity such as Canada and China will have similar results for gender comparisons. Alternately, other countries such as the United States and Germany that are both high in masculinity will likewise be similar, and in turn different from Canada and China with respect to gender comparisons for website design.

Based on the preceding, the following hypotheses are posited:

**H1: There will be differences between men and women in their perception of information content.**

**H2: There will be differences between men and women in their perception of information design.**

**H3: There will be differences between men and women in their perception of navigation design.**

**H4: There will be differences between men and women in their perception of visual design.**

**H5: Canada and China (both medium masculinity) will be similar in gender results compared to the United States and Germany (both high masculinity), and alternately the United States and Germany will be more similar compared to Canada and China for information content, information design, navigation design, and visual design.**

5 TRUST, SATISFACTION AND GENDER

According to Jarvenpaa et al. (1999) online trust refers to consumer confidence in the website and a “willingness to rely on the seller and take actions in circumstances where such action makes the consumer vulnerable to the seller” (p. 4). Building on this definition, in the current research online trust refers to general trust of the website, and that the user can trust the transaction process as well as information presented. Consumer trust in the website is fundamental to loyalty including online purchase intentions (Flavián & Guinalíu & Gurrea 2006, Gefen 2000, McKnight & Kacmar & Choudhury 2004, Pavlou & Gefen 2005) and willingness by consumers to buy from an online vendor (Flavián et al. 2006, Laurn & Lin 2003, Pavlou 2003, Wang & Benbasat 2008). Overall, women are less likely to trust a website than men (Cyr & Bonanni 2005, Rodgers & Harris 2003).

It appears that perceptions of online trust are influenced by gender, although few studies examine this phenomenon. In this investigation, website trust was examined in terms of whether users feel they can trust the website viewed. This leads to the next hypothesis:

**H6: There will be differences between men and women for website trust.**
An effectively designed website may engage and attract online consumers resulting in satisfaction with an online vendor (Agarwal & Venkatesh 2002). Palmer (2002) validated design metrics for websites and found information content, site organization, and navigation are important to website success, including intent to return to the site. In other research, website design and the “ambience associated with the site itself and how it functions” is related to online satisfaction (Szymanski & Hise, p. 313). In the current investigation, website satisfaction refers to overall contentment with the online experience (Anderson & Srinivasan 2003, Flavián et al. 2006), and may include access to information, a positive navigation experience, and perception of a well designed website (Balasubramanian & Konana & Menon 2003). While few studies have examined online satisfaction and gender, there is evidence that women tend to be less satisfied with the online experience than men (Dittmar et al. 2004, Simon 2001). Further, men and women differ in their ‘web acceptance and usage processes’ (p. 19) with men more driven by instrumental factors with stronger perceptions of usefulness of the Web than women (Sanchez-Franco 2006).

This results in the following hypothesis:

**H7:** There will be differences between men and women for website satisfaction.

Further, to our best knowledge, there is no previous research in which perceptions of website trust and website satisfaction are tested with respect to cultural differences.

**H8:** Canada and China (both medium masculinity) will be similar in gender results compared to the United States and Germany (both high masculinity), and alternately the United States and Germany will be more similar compared to Canada and China for website trust and website satisfaction.

### 6 METHOD

#### 6.1 Participants

A total of 1156 participants located in English Canada (232: Female (F) = 124), French Canada (80: F=39), the United States (197: F=116), India (106; F=90), Germany (122; F=61), Japan (78; F=31), Mexico (71: F=41), Chile (48; F=37), and China (222; F=109) completed an experimental task and online survey. To ensure participants are “of the culture” it was determined each had lived in the country the majority of their lives and spoke the native language as their primary language. Participants were recruited from a wide range of sources including universities, institutes, and companies. Average age across countries is similar with an overall average of 27.4 years. Participants are experienced online shoppers with a mean of 3.8 years of online shopping experience. They are well educated with 273 having graduate education, 487 undergraduate education, 50 technical training, and 263 with high school completion. To determine if significant differences existed across cultures based on demographics, ANOVA tests were run for age, education, and Internet and online shopping experience. Overall, no differences occurred between cultures that would influence the constructs tested in this research.

#### 6.2 Task and Website Design

This research targets user impressions of B2C Web pages. For the research treatment participants responded to the local version of the SonyStyle website represented in their native language. The SonyStyle website was chosen after an extensive search for a well localized vendor website in which the design of the website was adapted to be appropriate to the culture of each user as determined by a design expert who rated each country website. To recruit participants, the researcher sent an email to international colleagues with a link where instructions for the research and an online survey were found. These colleagues further distributed the email to students and members of their respective organizations. Participants were requested to initially view the home page of the local website, followed by navigation of the website to choose a cell phone they would hypothetically purchase. This methodology is consistent with Cyr et al. (2005) and Cyr (2008a, 2008b). Once participants concluded
this task each completed an online questionnaire. Background information to the study, and all other written content including the questionnaire were translated and back-translated into each required language.

### 6.3 Instrument Validity and Reliability

Content validity ensures construct items are representative and drawn from a universal pool (Cronbach 1971). With the exception of Information Content, the constructs used in the investigation are based on previous research and have been previously validated from a variety of sources and exhibit content validity. More specifically: Information Design (Cyr 2008a, Egger 2001), Navigation Design, Visual Design (Cyr 2007, Cyr 2008a), Website Trust, Website Satisfaction (Cyr et al. 2005, 2007, 2008a). Items for Information Content were derived from existing literature including Garrett’s (2003) website classifications, and this construct was successfully validated in this investigation. All items were assessed on a 7-point Likert scale from strongly disagree to strongly agree. The questionnaire was pre-tested with 62 undergraduate students. Categories were evaluated for item validity and reliability and several items were revised for better fit. Table 1 shows the results of the principle component analysis with Varimax rotation.

**Table 1. Factor Analysis**

---

2 The questionnaire is not included but may be obtained from the author.
Construct reliability was assessed using Cronbach’s $\alpha$-value. In Table 1 $\alpha$-values ranged from 0.714 (for Visual Design) to 0.868 (for Navigation Design). The Cronbach $\alpha$ of a scale should be greater than 0.5 for items used together and ideally higher than 0.7 (Rivard & Huff 1988). Therefore all constructs possess construct reliability. The average variance extracted (AVE) for a construct should exceed 0.5 (Fornell & Larcker 1981). In Table 1 this criterion is satisfied for all constructs, and the constructs used in this study exhibited satisfactory convergent validity (demonstrated by the principle component factor analysis) and satisfactory discriminant validity (shown from inter-construct correlation analysis).

7 RESULTS

A goal of the investigation is to determine if gender differences exist for an international sample of participants. Comparisons were conducted using Tukey HSD testing (N=1156). Results for gender differences for the mixed country sample appear in Table 2. For all dependent variables significant differences between men and women are noted. This serves to confirm Hypotheses 1, 2, 3, 4, 6 and 7.

Table 3. Gender Differences for Mixed Country Sample [Sample N = 1156]

Comparisons for gender differences for China, English Canada, the United States and Germany appear in Table 4. As predicted, China and English Canada which both are medium for masculinity are more similar for the various dependent variables compared to the United States and Germany, which are both high for masculinity. This confirms Hypotheses 5 and 8.

Table 5. Gender Differences for China, English Canada, the United States, and Germany

It is interesting that in the medium masculinity countries where socio-psychological values would be more similar, there are few gender differences related to website design. For China, the only significant gender difference is for information content. Men score higher than women. For English Canada, the only significant difference is for satisfaction and rather surprising, women report greater satisfaction than men. The U.S. and Germany both have numerous significant differences by gender. For the U.S. 5 of 6 variables are significantly different, and in each case men score higher than women. For Germany, all variables are significantly different, and unexpectedly men score lower than women in all cases.
8 DISCUSSION

8.1 Theoretical and Practical Contributions

This study, based on a large sample of participants from eight country locations, serves to strongly reinforce the reality that men and women have a different experience of the same website. In the mixed country sample significant gender differences were found for all dependent variables. Further, the direction of the findings was as expected from previous research for website design (Cyr & Bonanni 2005, Simon 2001), trust (Cyr & Bonanni 2005), and satisfaction (Dittmar et al. 2004, Simon 2001). In all cases women score lower than men. Looking at each variable separately, mean scores are reasonably high for both men and women and range for men from 4.9 (out of 7) for satisfaction to 5.7 for visual design. Alternately, mean scores for women range from 4.5 for satisfaction to 5.1 for navigation design. While scores for women are lower, there are parallel patterns of preference for both men and women. This data provides insights into website characteristics that are most important for the user, and as such offers designers important information as to how to please online shoppers.

An interesting discovery from this research is that based on socio-cultural values associated with masculinity-femininity patterns emerge related to gender preferences between countries. This suggests that countries that are more similar on the masculinity-femininity dimension also score similarly in terms of gender differences for the dependent variables as tested in this research. It would appear that there are fewer differences between men and women in countries where masculinity is moderate (as in Canada and China) versus higher (as in the U.S. and Germany). Perhaps this can be explained by more similar socio-cultural values in those countries - regardless of gender. For Web designers this might feasibly suggest that for countries with similar cultural values, that the requirement for website localization (or adaptation) is less than for companies where cultural values are more discrepant.

8.2 Limitations of the Research

Data was collected in eight countries, including separate samples for English Canada and French Canada with a total of 1156 participants. A large and diverse sample population is a positive feature of this investigation. Participants are from a variety of sources including companies, universities, and institutes which offers generalizability of the findings. Concerning limitations to the research, a single vendor website (SonyStyle) was used. The possibility of response biasing could occur as respondents are aware of the company name and reputation, and may have previously established impressions of the company. In addition, a single task was used of searching for a cell phone for hypothetical purchase on a product-based website. No actual purchase was required. While this procedure is consistent with other e-commerce research, this may limit transferability of the findings to real e-commerce situations. In the future, similar research could be expanded to include a greater variety of tasks on both service and product websites, a larger sample of websites, or websites without specific branding.

8.3 Directions for Future Research

The findings for Germany are puzzling, with eight of nine variables significantly different between men and women and higher in each case for women. This finding merits additional investigation, perhaps using qualitative methodologies, to discover why exactly women are responding differently from their female counterparts in other countries. To date, there is no evidence to suggest why this result occurred.

Since the investigation of website preferences and the online shopping experiences between men and women is relatively new, there is much scope for future investigations in this field. Further research is suggested to more deeply probe online trust and satisfaction. In addition, differences in design preferences for men and women indicate this area offers multiple opportunities to expand understanding as to what is gender relevant when browsing or shopping online. Although website localization is usually considered in a cultural context, researchers and web designers might also want to consider the notion of gender localization – given the results of this study. With large numbers of
both men and women shopping online, vendors who create gender appropriate websites may reap
rewards from customers who are more satisfied and loyal.

Abstract

Large-scale organizations are increasingly promoting more collaborative and collective work practices across organizational boarders. A predominant way to achieve better collaboration in large-scale heterogeneous contexts is to establish an integrated and standardized technological infrastructure. Ethnographically inspired studies, on the other hand, have challenged such perspective and illustrated that generic technology does not fit in local contexts and needs to be worked-around. Similarly, this paper empirically exemplifies local workarounds and illustrates ongoing and persistently imperfect integration of a collaborative infrastructure in a global oil and gas company. More importantly, however, our analysis focuses on how integrated technology is used across contexts. We illustrate how local workarounds, as a result of tight technological integration, shape use patterns across contexts. Integrated systems establish interdependencies across contexts, thus, the use implies cross-contextual rather than local enactment. Since the trajectory of enactment is influenced by cross-contextual constrains, our study is addressing the existing overemphasis on studying/analysing the use of technology in isolated local contexts. Practically, our study suggests considering workarounds as an intrinsic part of every day work, which should be calculated as additional costs of making the generic technology to work in practice.

Keywords: workarounds, integrated systems, situated action, standardisation
1 INTRODUCTION

Abandoning earlier and overly structuralist accounts, there has been a steady increase in information systems research exploring contextual aspects of how technology is developed and used (Avgerou and Ciborra 2004). Ethnographically inspired studies have demonstrated beyond any reasonable doubt the situated nature of how information systems are appropriated (Orlikowski 1996; Robey and Sahay 1996; Walsham 2001). Theoretically, there has been an ‘agentic turn’, which has “led increasingly to the theoretical positions that privilege human agency over social structures and technological futures” (Boudreau and Robey 2005, p.3), for instance by advocating how technology is always ‘enacted’ (Orlikowski 2000). The locus of attention is local work practices and how technology is enacted in a situated context, where context is limited to individual actor’s engagement and “recurrent interaction with the technology at hand” (Orlikowski 2000, p. 47). Since, enactments more than often deviate from intended system design, a practical concern, then, relates to whether workarounds need to be eliminated (Azad and King 2008) or considered as an intrinsic part of every day work (Rolland and Monteiro 2002).

Integrated, collaborative systems (e.g. enterprise resource planning (ERP) systems, coordination technology (Lotus Notes, MS SharePoint), customer relationship management (CRM) systems) are attractive to business and public sector for their promise to promote more collaborative and collective work practices. Working more collectively across geographical, professional and organizational boundaries entails that one previously local, independent context of use gets linked with (i.e. becomes dependent on) other contexts. As opposed to largely local, independent contexts of enacted technology, use of integrated systems implies the interdependent enactment across the contexts now linked as a result of the integration.

The main purpose of this paper is to analyse the form and implications of cross-contextual enactment of integrated systems. We explore questions such as: how does one local workaround affect other contexts of use; how does local appropriation of technology ‘travel’ to other contexts mediated by the integration, possibly creating unintended consequences there?

The empirical basis of our paper is an ongoing, longitudinal (2007-2008) case study of a global oil and gas company (OGC, a pseudonym to maintain anonymity) where we also earlier (1997-1998) studied integrated, collaborative systems (Monteiro and Hepsø 2002). Operating across significant geographical, professional, business and organizational boundaries, OGC is struggling to move towards more collaborative modes of working. Integrated systems are a strategically recognised vehicle to address this challenge. Our study reports from an ongoing effort to deploy an integrated system based on Microsoft SharePoint (MSP) technologies1. We trace out local enactment (e.g. workarounds) of MSP, but more importantly demonstrate the cross-contextual nature of this enactment i.e. how workarounds in one context affect local appropriation of MSP in another context.

The structure of the remainder of this paper is organized as follows. In the next section we conceptualize the use of integrated information systems. Then, we outline our research approach and introduce historical context and intentions of changing collaborative infrastructure in OGC. Thereafter, we illustrate and discuss how local workarounds, as a result of the tight integration in MSP, shape use patterns across contexts. Finally, we provide analytical implications for studying the use of integrated IS and offer practical implications for managing generic infrastructures.

1 http://www.microsoft.com/SharePoint/default.mspx
CONCEPTUALISING THE USE OF INTEGRATED SYSTEMS

2.1 Using technology in a situated context

Mirroring a more general interest in the social sciences for practice theory (Gherardi 2000; Savigny, Knorr-Cetina et al. 2001), information systems research has for some years studied its principal ‘practice’ viz. the practices that go into the use of information systems. Analyses of how users perceive, appropriate and subsequently use information systems demonstrate the highly contextual or situated nature of the use (or practice of use, if you want) of technology.

An early and influential contribution was Gasser’s (1986) study of users’ strategies of fitting, augmenting and working around the intentions inscribed into the functionality of the system. Gasser (ibid.) empirically illustrated what people actually do when confronted with rigid and unreliable computing procedures. The author vividly illustrated that users in fact do not use information systems as they are designed, but invent various ad-hoc strategies to fit the technology for a particular task. The major conceptualization from this study was the notion of workaround, which refers to “using computing in ways for which it was not designed or avoiding its use and relying on an alternative means of accomplishing work” (ibid., p.216).

While Gasser (1986) studied the rigid inventory control system, other more flexible types of systems were studied as well. For instance Orlikowski (1996) investigated how quite small customer support department used a new system to provide a better service for customers. Orlikowski (ibid.) illustrated how users contingently appropriate technology over the time. The central characteristic of appropriation is continuous change with unpredictable trajectory (‘improvisation’) rather than stability.

Central to these studies is to understand how technology is used in a situated context. While the notion of context is certainly vague (Chalmers 2004), context, in this case, is limited to individual actor’s engagement and “recurrent interaction with the technology at hand” (Orlikowski 2000, p. 47).

2.2 Integrated systems

Several scholars have been interested in how integrated systems are used (‘enacted’). For instance, Boudreau et al. (2005) in their recent study showed how, despite inherent rigidity of an ERP system, users are working-around the system in unintended ways. They argue that users first avoid the system (due to inertia), later learn by improvising (rather than in formal training) and finally reinvent the system in not-planned ways. Thus, the authors emphasize the human agency perspective over the technological logic and argue that “technology’s consequences for organizations are enacted in use rather than embedded in technical features” (ibid. p.14). Other researchers have similarly emphasized the impossibility of large-scale systems to be universal across contexts due to local relevance or cultural fit (Joshi, Barrett et al. 2007). Some researchers have suggested that workaround is an intrinsic part of every day work rather than negative or unwanted effect (Rolland and Monteiro 2002).

In general, it was suggested that technologies would always drift from initial plans due to the improvisational capability of a human actor. In turn, the same technology can produce contrasting effects in similar organizational contexts (Robey and Sahay 1996) and these should be addressed employing the logic of opposition (Robey and Boudreau 1999).

Overall, studies on IS use tend to overemphasize local practices and do not “adequately address the longer-term co-evolution of artefacts and their social settings of use” (Pollock, Williams et al. 2007, p.257). Certainly, the relationship between contexts and spanning-effects are discussed by several scholars (Hanseth, Ciborra et al. 2001; Ellingsen and Monteiro 2006), however, there are few if any studies which conceptualize how local workaround does influence other contexts of use. For instance Boudreau et al. (2005) do identify the relationship between local appropriations: “An error occurring
at one level of the system would have a ripple effect at other levels” (ibid., p.13), however they do not elaborate on the issue, nor do the authors elaborate what is the role of local enactments in larger contexts: “one cannot categorically argue that unintended actions are good, any more than one can argue that they are bad. Like any other aspect of organizational behaviour, evaluations of effectiveness are relative, not absolute” (ibid., p.16).

To sum it up, the study of integrated information systems has been framed to date largely along the lines of practice theory in the sense that local strategies for appropriation and use have been highlighted. Our study supplements this with a more systematic attention to the interdependence of cross-contextual appropriation mediated by integrated systems.

3 METHOD

We report from an ongoing longitudinal research project started in January 2007. Our research approach can be conceptualized as an interpretive case study (Walsham 1993) as we “attempt to understand phenomena through the meanings that people assign to them” (Klein and Myers 1999, p.69).

Data collection activities started at the beginning of 2007 with the primary aim to explore the change associated with the implementation of MS SharePoint technologies. We have employed 3 modes of data gathering: informal and formal interviews, observation and document studies.

We have conducted 25 in-depth interviews, on average lasting 1-1.5 hours. First interviews were open ended and aimed to identify IT strategic visions and implementation activities related to MS SharePoint. During later interviews, we analysed specific infrastructural components, work practices or individual engagements with technology. The technological complexity and intentions behind the new infrastructure were discussed with developers, administrators and managers of the collaborative infrastructure. The use of collaborative infrastructure was explored with actors from several organizational units. Interviewed users represent such disciplines as technology managers, human resources, senior researchers and various engineers involved in oil and gas production activities.

Participatory observations and informal discussions were mainly carried out in one of the OGC research centres, where both authors were granted access since the beginning of data collection. Since January 2008, one of the authors has been granted an office space, an access badge and access to OGC IT network. Since then, the researcher has been spending 2-3 working days a week in the research centre. Significant amount of time spent on-site forms the understanding of how work is carried out in practice and what problems and frustrations users experience on a daily basis. Additionally, being on-site gives an opportunity to have informal but informative chats around a coffee machine or during lunch breaks.

The third major empirical data source is internal OGC documents. We have extensively studied strategic documents related to planning and implementation activities of MSP. Additionally, we analysed technical descriptions, formal presentations and training materials on various MSP infrastructural components. A number of policy documents, which define how particular technology should be used or how specific work has to be carried out, were studied in detail. Finally, OGC intranet portal provided extensive contextual information on diverse OGC activities.

Data analysis is ongoing and iterative. Considering changing researchers involvement and overlapping but not the same research focus, the analysis of empirical data has many trajectories. This difference gives us a unique opportunity to analyse implementation process from slightly different perspectives. It is quite often that after interviews, if conducted together, we have a discussion and analyse what new aspects we have uncovered or what needs more attention in the subsequent data collection steps. In our faculty, there are several actors (not only the authors of this paper) exploring MSP implementation activities in OGC. We meet and discuss quite often either around a coffee machine or having more formal discussion sessions. Considering that the authors of the paper are involved
researchers, significant part of data analysis and validation is actually occurring with the help of OGC actors. During informal or formal meetings, we frequently present our findings to various OGC actors. In turn, we are challenged, supported or directed to the issues that need more attention. For instance, several record’s information managers supported our early findings on the metadata use in research and development activities, but we received extensive comments and suggestions to collect more empirical data in operative environments. Adjustments to some generalizations were made and empirical data collection directions were embraced.

In general, empirical data is classified in broad themes reflecting specific organizational project, practice or technical component. Such classification is neither all encompassing nor exhaustive; it is rather overlapping and continually changing. Theory has an important role in the analysis process. It provides an analytical lens to sort out and reclassify empirical data. For instance, in relation to this paper, the concept of workaround implied to determine when is a workaround (in relation to formal policy) and classify empirical data according to why, where and how workarounds are practiced. The concept of ‘generification’ implied to analyse how local workarounds ‘travel’ across contexts and what effects they produce.

4 CASE: COLLABORATION AND INTEGRATION

4.1 Context and history

Established only in the 1970s, the global oil and gas company (OGC, a pseudonym) has grown from a small, regional operator in Northern Europe to a significant energy company, currently employing some 30,000 people with activities in about 40 countries across 4 continents. OGC has grown largely organically, but with selected, important national and international acquisitions. Facing limited growth potential in its region of origin, OGC is actively pursuing a strategy to grow globally. To boost its financial capacity and flexibility, in the 1990s OGC diversified and expanded its shareholder ownership including getting listed at the New York Stock Exchange.

Alongside its growth in size, geography and business areas, OGC has been engaged in a number of corporate-wide initiatives to improve communication and collaboration. These initiatives have relied heavily on information systems. The first comprehensive effort to establish a corporate, collaborative information systems infrastructure was in the early 1990s (Monteiro and Hepsø 2002), at a time of oil industry recession, falling oil prices and dollar rates. Centralization, standardization and market orientation of IT services was the direct outcome of several projects whose primary aim was to solve the problems of fragmented and incompatible IT solutions. The outcome of standardization activities led to the establishment of the Lotus Notes-based collaborative infrastructure.

The Lotus Notes based infrastructure has proven successful inasmuch as it has been widely used for a range of different purposes. A key vehicle for facilitating collaboration within projects in OGC has been Lotus Notes Arena (Arena for short) databases for collective storing and dissemination of documents. The challenge, however, with the Lotus Notes based infrastructure has been to promote communication across the project-defined boundaries of the Arena databases. The Arena databases had no central indexing functionality, meaning that it was impossible to retrieve a document by searching if one did not know which database to search. With Arena databases thriving apparently ‘out of control’ – there were some 5000 databases by the latest estimates – locating relevant information stored outside your immediate project scope was non-trivial. Each user had in addition access to both personal (G disc) and departmental storage (F disc) areas. In short, information was scattered and duplicated over many local storage arenas.
4.2 New collaborative strategy – higher efficiency with tighter integration

To overcome the problems with Lotus Notes and establish more effective ways of collaboration, coordination and experience transfer, OGC formulated a new strategy in 2001. According to this strategy, OGC already had a set of general collaboration tools, but “these tools are poorly integrated”, and “there is a particular need for better and more integrated coordination tools, better search functionality and improved possibilities for sharing information with external partners” (internal strategy documents). The change in the collaborative infrastructure was defined as a necessity and catalyst in order to achieve goals formulated in the strategy. The decision was made in 2003 and the rollout of a new infrastructure based on the Microsoft SharePoint (MSP) started. MSP was selected exactly for its potential to overcome the fragmentation resulting from project-specific Arena databases. Recent accounting regulation in the aftermath of Enron added pressure to ensure more systematic and consistent documentation of business decisions to inform the stock market and the public.

MSP is a core element in the new OGC collaborative infrastructure. The central element of MSP is so-called team site (TS), the virtual arena for collaboration. TS provides functionality to check-in and check-out documents, post announcements, share links and create discussion boards. Another important element of TS is a so-called workspace. A workspace is a web site connected to a TS (sometimes called baby-team site), used for production and sharing of a specific document or collection of documents. While MSP is mainly used for documents management, the technology is integrated with a corporate-wide search engine, an archive system and MS Exchange system.

While the technology itself (MSP) is customizable for specific contexts, the OGC decided to make the solution as generic as possible so that it would fit all contexts (internally it is referred as one-size-fits-all strategy). The strategic choice to rollout ‘out-of-the-box’ solution with minimum customization was highly influenced by the previous implementation experiences. In particular, the straightforward MSP implementation process was planned in contrast to recent experiences with an opposite (extensive customization) strategy when implementing a several hundred million dollars worth corporate-wide ERP solution. These experiences were translated in the standardization of both the functionality and the interface of every TS. The only element that differentiates team sites is metadata. The metadata standard provides a common and standardized classification scheme on how the information should be classified. Thus, the metadata can be seen as the main element in the collaborative infrastructure, which should fit a generic TS to a specific local situation. The metadata standard represents quite complex classification scheme with 13 different ‘elements’ and corresponding ‘sub-elements’. In total there are more than 120 sub-elements in the metadata standard. Taking into account all sub-elements, the standard describes “identity, authenticity, content, structure context and essential management requirements of information objects” (OGC internal).

5 ANALYSIS: CONTEXTUAL AND CROSS-CONTEXTUAL USE

What studies of contextual use of information systems have convincingly established is the importance, indeed, necessity, of users’ active appropriation of technology to local circumstances and concerns. In other words, local workarounds (or appropriation, tweaking, improvisation, drift etc.) are not anomalies or design shortcomings but constitutive elements of working technologies (Rolland and Monteiro 2002).

Zooming in on two extended illustrations from OGC’s implementation of MSP (the use of workspaces and classification of documents), we first reiterate this point. More importantly, however, we go on to identify how these local workarounds – as a result of the tight integration in MSP – shape use patterns in other contexts of use. Table 1 summarizes this. One way, then, to formulate the gist of our analysis is to say that the local strategies of appropriation, the prerequisite of working information systems, are
simultaneously non-local side-effects significantly influencing patterns of use in other contexts (i.e. cross-contextual).

Table 1. A summary of local (contextual) and non-local (cross-contextual) enactments of integrated information for two examples within the MSP infrastructure.

5.1 Workspaces: local appropriation as replicating existing practices

Prior to the implementation of MS SharePoint an important decision not to have folder structure in team sites was made. This decision was made due to the technical inability to create a complex folder structure in team sites (limitations of the URL length). On the other hand, users in OGC had quite long experience with folder structure in Lotus Notes infrastructure and indeed as Boudreau et al. (2005) explain did have difficulties to ‘forget’ previous practices. In the initial stages of MS SharePoint implementation users tended to avoid the new system and used file servers to share information instead. As one manager explained, the amount of documents in file servers exploded when team sites were introduced. However, after some time users got acknowledged with the system and found out that it is possible to replicate previously existed folder structure with the help of workspaces:

“From the beginning it was very clearly communicated that we are not allowed to use workspaces to replicate folder structure. That was the intention… however people have been using computers here for the last 15 years, so they actually continue to make folders with workspaces despite the fact that they are told no to do so… All our team sites have a pile of workspaces [the user navigates to one of the team sites and shows a list of approximately 30 workspaces]” (User working with operational support for offshore activities)

Overall, replicating folder structure with workspaces is quite popular workaround in OGC. In particular, the workaround is practiced in information-rich contexts. The ‘popularity’ of this workaround illustrates that users do not adhere to OGC policies but are actively engaging and experimenting with technology. The existence of such workaround is not surprising; it can be explained with the concept of ‘installed base’, used by Boudreau and Robey (2005). Such treatment of workaround requires shifting the focus from identification to explanation of the effects a workaround is producing. Precisely because the MSP infrastructure is integrated, local appropriations, outlined above, are not only local; they have cross-contextual implications.

The initial intention of using workspaces was related to the possibility for team site users to create ‘areas’ (i.e. workspaces) with custom access rights. In that sense, a workspace was considered as a temporary ‘arena’ in order to limit or expand the original access rights in a team site. However, in practice, users sometimes create folder-like workspace structures and use the functionality of limiting the access. Importantly, in its current configuration, corporate-wide search engine is only returning those documents that a user has access to. Thus, documents stored in workspaces with limited access rights will be visible and retrievable only to specified users and ‘invisible’ to others.

Cross-contextual effects are especially experienced by users working across contexts i.e. whose ability to find information depends not only on their skills, but also on how others manage information.
locally. For instance, a well engineer responsible for conducting well interventions across different fields explains:

“It is quite often that we do not have access to necessary information. When planning a well intervention we have to know a lot of technical information about a particular well and history of the well in general [this includes information about previous challenges/problems, and conducted interventions with corresponding experience reports produced after each intervention]. Sometimes you do not find information just because you do not have access… so you have to call various people and ask… it is very time consuming and I know some people do not bother spending all their time on that… however, not having important information means more uncertainty during operation, and this can increase the risk and cost of operation.” (Well engineer; emphasis added)

Oil and gas exploration, production and export activities span across many disciplines not only in the OGC, but a significant part of activities is carried out by various external contractors. For instance, while a plan to drill a new well is primarily produced by several internal disciplines, an external contractor can perform drilling. This means that for a certain period of time an external contractor needs access to information related to the new drilling activities and probably to some historical reports. It adds complexity to access management, and workarounds made some time ago tend to pop-up here:

“It is quite often that I get a call asking for help to find information or to give access. So I have to use a lot of my time on this… I would like them [contractors] to be more independent … to avoid this [access problems], for instance, after a meeting with contractors I am sending two emails, one to internal OGC employees with a link to a document and another one to external ones with attachment.” (Drilling engineer; emphasis added)

Many users are aware of cross-contextual effects of incorrect access rights management by explaining that they do not know whether a specific information is existing or not: “the worst thing is that if you don’t find information it does not necessarily mean that information is non-existing” (Engineer). Such effects lead to uncertainty and distrust the capabilities of the search engine. In general, these examples show that local workarounds change use patterns across contexts. In that sense, working in an ‘integrated environment’ means shifting the focus from how the system fits locally to how the system fits across contexts.

5.2 Classification of documents: the power of the default value

The decision to have flat document structure did not fuel too much enthusiasm for end-users and, as argued in the previous section, invoked workarounds. By removing folder structure the implementation team understood that some alternative way to classify information should be provided. In turn, it was decided to develop a common predefined classification scheme, which would form the basis for information structure and help both to sort and retrieve information.

As we have argued in the previous section that thinking ‘flat’ (no folders) introduces some problems, common classification scheme also did provide challenges for end users. The notion of ‘common’ does not imply fits-all or having the same meaning across contexts, on the contrary, as Star (1991, p.44) explains, “no networks are stabilized or standardized for everyone”. Thus, in some contexts classification is not acknowledged:

“this metadata, it is bad… very often when you will store a document none of the provided values fit. For instance for this document I can choose from 10-12 different values… but they all do not fit… for this document I can select such values as ‘none’, ‘agenda’, ‘minutes’, ‘presentation’… this document is presentation so ‘presentation’ value fits very well [the respondent starts laughing]” (Engineer working with oil and gas production; emphasis added)
While users are quite often confronted with metadata that does not fit in their contexts, the questions remain how they cope with this situation. Sometimes users just tend to ignore the existence of metadata and use such values as ‘none’ or ‘miscellaneous’. It was planned to have a controlled vocabulary (the values are predefined in advanced) and all policies state that users should use provided metadata. Interestingly enough, MSP functionality allows to delete provided metadata values and create new ones. In turn, the second enactment strategy is to develop new values that would make more sense in local context:

“We have replaced provided metadata values with the new ones, which actually represent the activities we are working on in the project. Provided values were meaningless in relation to this project, so it would make no sense to use them” (User working in R&D)

Another challenging issue related to classification in OGC is the classification of sensitive information. Users are provided with rather simple security classification scheme to identify which documents can be available to anyone (open), to all OGC employees (internal), to specific groups (restricted distribution) or to selected individuals (confidential). Security classification is managed in team site and on the workspace level, implying that confidential document should be placed in a confidential team site rather than in an open one. The security classification scheme can be described as simple and intuitive, however, in practice, the definition of what is ‘confidential’ and how it should be handled (for the sake of convenience or additional work) is not given.

In turn, local enactments diverge from formal policies. It was, up to now, quite a ‘standard’ to store personal information on the private team site, which is not classified as confidential. In some instances, due to convenience reasons, a classified report from an external company was stored in an ‘open’ projects team site, rather than in a workspace with restricted access. Perhaps the most ‘problematic’ enactment of security classification was to store, due to unawareness and additional work, human resources related information in not confidential team sites.

Overall, classification, being an inseparable part of everyday work, is not given but has to be enacted in practice (Bowker and Star 1999). The problematic aspect, as we have illustrated above, is that imposed common classification has local variations (workarounds). While the problem of global standardization and local variation has received quite some attention (Star 1991), it is much less clear how local variations ‘travel’ across contexts. Essentially, common (shared and used across contexts) classification can be characterized as inherently having cross-contextual aspects. Such aspects are captured with writing/reading metaphor: “any reading and writing artefact that accumulates inscriptions cannot but coordinate [constrain and transform] the activities which write and which read these inscriptions” (Berg 1999, p.391). Thus, working-around common classification not only erodes the common and controlled character of classification, but also automatically imposes a certain amount of additional work for actors across contexts.

Such cross-contextual effects can be nicely illustrated with an example of planning and drilling a new well. While planning activities are conducted onshore, drilling process is to a large extent managed offshore. Planning is a collective effort of various disciplines and results in producing several documents. Central documents describe the whole drilling program, detailed drilling procedures, possible risks and a checklist, just to mention some. Drilling a new well means producing at least some 200 documents, which have to be stored in team site(s). Since they are stored in a flat structure, metadata is the primary sorting and filtering mechanisms. The problem according to one engineer is that “while the metadata values are not very bad, people sometimes do not use them or use them wrong”. In turn, incorrect use of metadata in one context, produce effects in other contexts:

“sometimes I get a call in the evening from offshore people saying that they have been searching for a specific document for an hour or so with no success… to avoid this we have developed a practice [which is unofficial i.e. a workaround] that for every new drilling program, a drilling engineer [working onshore] creates an excel document containing links to documents that are most important for drilling engineers working offshore. It is additional work as we [engineers working onshore] have to update those excel documents during
drilling, but then offshore people have much better overview.” (Drilling engineer working onshore; emphasis added).

In that sense local workaround (wrong classification of documents) produce additional work in other contexts and later trigger other workarounds (engineers developing an excel sheet with links). Thus, local workarounds can produce ripple effects. More importantly, achieving working infrastructure entails collective enactment across contexts rather than local enactment.

Another, more substantial cross-contextual effect, was enacted with security classification. Documents were not always classified as intended. Incorrect classification of documents, due to the tight integration with the corporate search engine, made possible for confidential information to be available to many more than it should be. For instance, during an interview with two system administrators responsible for technical aspects of MS SharePoint infrastructure, we were shown the possibilities of the search engine. One administrator entered the name of his colleague sitting besides to demonstrate how the search engine works in practice. Among the first results, a document containing the administrator’s work evaluation appeared. It was an embarrassing moment, for administrators in particular. Such document contains personal information, and it should be available only to few persons and certainly should have not been retrieved in that situation. Similar local enactments not only propagated across contexts but accumulated as well. The situation, according to one manager “got out of control, since too much sensitive information due to incorrect classification was available for way too many users”. Since it was not impossible to apply any ‘quick fix’, the search engine was suspended. The corporate-wide search service was not available to users for 5 months, the period that was used to ‘clean-up’ incorrect classification and develop the approach that would prohibit such incorrect enactments later. Compulsory training sessions, technical usability improvements, control routines and other initiatives are currently executed to prevent such effects. However, as it is now acknowledged in some management levels, order without workarounds is out of reach: “we may hope for altered attitudes and more care taken in the future – however, all the time search has been suspended, people have been working as before (but all the errors have been “invisible” as search was not available)” (a recent presentation on information security in OGC).

6 IMPLICATIONS AND CONCLUSIONS

We draw two sets of implications from our study of the deployment of a MS SharePoint based information infrastructure in OGC: one analytic and one practical.

Analytically, our study demonstrates the rich array of strategies and improvisational acts that go into the local appropriation of technology. Existing research (see above) has vividly illustrated process of social shaping of technology, i.e. how both flexible and rigid technologies are shaped in situated contexts. In line with the ‘practice perspective’ of Orlikowski (2000), our findings confirm that local workarounds, tinkering and ‘situated improvisations’ are not anomalies or design shortcomings but constitutive elements of working technologies.

More importantly, however, our study continues to address the nature of non-local – what we in this paper have dubbed cross-contextual – effects that are embedded in the appropriation of integrated systems. For sure, the mere existence of cross-contextual effects has been acknowledged before. Boudreau and Robey (2005) for instance point out that local practices may have ‘ripple effect’ beyond the local context. Yet they fail to develop this observation into a more systematic framework or make it subject to substantial theorising (see Hanseth et al. (2006) for an exception). One implication of our study, then, is to contribute to a higher visibility of cross-contextual effects of the use of integrated information systems. Systematic attention to cross-contextual side-effects extend the way the use of integrated information systems has been conceptualized to date. As opposed to largely local independent contexts of enacted technology, the use of integrated systems implies the interdependent enactment across contexts now linked as a result of integration. This entails considering the technological, and in particular integrative technological, detail more seriously than the previously
outlined ‘practice lens’ (Orlikowski 2000) or the application of the ‘practice lens’ in integrative environments (Boudreau et al. 2005). In this way, our study is addressing the existing overemphasis on human agency and contributes to the studies on mutual shaping of information technology and its use, to approach equally important question on how technologies constrain the trajectory of enactment (Kallinikos 2004; Doherty, Coombs et al. 2006). The empirical illustration above of how the accumulation of multiple, local appropriations added up to the effect of closing down the corporate-wide search engine service for almost half a year is difficult to arrive at with attention largely focused on local, contextual or situated ‘enactment’ of technology.

Practical implications of our study relate to the (project) management of embarking on large-scale, comprehensive infrastructure like efforts of the type reported here. At the core, the insight that due to the scale and heterogeneity of work practices and existing technological interdependencies, workarounds need to be considered as constitutive elements of working infrastructures rather than anomalies, design shortcomings or unexpected effects. More importantly, working-around integrated systems cannot be any longer considered as local phenomena, which could be black-boxed and ascribed to a specific context. Prototyping early versions of integrative technology, for instance, has more limited value than for non-integrated technologies. While the attractiveness of integrated technology is based on seamless cross-contextual information exchange, such technological platform also comes (quite often as a surprise) with inherent cross-contextual effects. Simply put integrative technology is more than often evaluated from a perspective of what positive effects it can bring, while underestimating how local (small and perhaps unimportant at first) activities can produce great effects some time later across contexts. Essentially, the benefits of integrated systems can only be realized if they are fitted across contexts rather than in some local contexts.

The second practical implication relates to the evaluation of cost and benefits (Goodhue, Wybo et al. 1992) of generic, corporate-wide integrative infrastructures. We consider the term evaluation from an interpretive perspective (Walsham 1993, p.165-186) rather than an economic one. ‘Costs’, include both, the developer’s effort to establish technological platform and users adjustments of technology to his/her needs. Generic solutions are adjustable and can fit quite well in some, but most often not in all contexts. If generic technology does not fit, additional work (‘costs’) has to be carried out. Classification is an illustrative example of this. We have exemplified how locally irrelevant classification will require additional users work to make it meaningful locally. The same happens with generic technological functionality. For instance, some users in OGC, unsatisfied with MSP functionality, voluntarily and not in accordance with existing policies, invest their time in implementing, learning and using more flexible technologies (such as Groove) or social software solutions (Wiki’s). One way to evaluate then is to consider, by percentage, to how many actors the generic technology does fit. A qualitative alternative is to consider whether generic technology fits well in specific (not excluding core) business activities. In our evaluation, we are employing the latter perspective, and have illustrated throughout the paper that both development and use costs are high, and we doubt whether they outweigh the benefits. As the IS management literature suggests, the implementation of new technology should be cost-efficient. In turn, the management should take into account not only the costs of establishing integrated technical infrastructure, but the invisible (i.e. workarounds) costs as well. In that sense, it should be made explicit who, how much and when will pay the costs of having the generic integrated infrastructure.

DOES TIME MATTER?
The Role of ICT in Shaping Temporal Assumptions

Abstract.
Despite its importance to temporal issues, research into the temporal impacts of information technology in organizations is still limited. On the other hand, organizational culture research shows that the way time is perceived and collectively organized reflects assumptions that are an expression of the specific organizational setting, underscoring that cultural assumptions are an important contributory factor to the strength and direction of organizational change. In this contribution, we investigate the role ICT can play in promoting changes in the temporal dimension of organizational culture, and seek to assess whether temporal assumptions can affect the way a new system is used, thus facilitating/hindering the achievement of the expected results. This research-in-progress paper presents some preliminary results of a multiple case study, showing what types of ‘temporal performance’ management expects to see thanks to the introduction of a workflow system, and showing that managers have different levels of awareness about potential temporal performance of the system. Preliminary results also seem to confirm that, after the introduction of the workflow, some temporal dimensions of organizational culture of the departments involved present some significant changes, which confirm hypothesis 1 of the study, but also some contradictory effects that seem to confirm hypothesis 2.
Introduction
It is generally accepted that, when implemented in organizations, information technology hugely speeds up business processes, thereby enabling the adopting organizations to save a great deal of time. Despite its significance in temporal terms, research on the time impact of information technology in organizations is still limited (Lee and Whitley 2002).

Empirical studies on this topic began to appear in the last decade in the journals of both Organization and IS discipline (Sahay 1998; Lee 1999; Lee and Liebenau 2000; Orlikowski and Yates 2002; Sawyer and Southwick 2002; Scott and Wagner 2003; Sarker and Sahay 2004; Prasopolou et al. 2006). Accelerating the pace of work processes, fostering workers’ polychronicity, promoting shifts from “batch” logic to “flow” logic, and improving synchronization among organizational units are just a few examples of some key objectives that can be pursued by firms when they adopt systems like Workflow or ERP. Such objectives, which we will refer to as expected temporal performances, are related to potential changes in the temporal organization of processes and activities, but also to potential changes in people’s assumptions on time and time use in the workplace.

What do we mean by assumptions on time?
Organization studies have long acknowledged time as a fundamental dimension of organizational culture (Hofstede 1991); Schein as well, in his study on organizational culture (1988), maintains that organizational culture has groups’ dominant assumptions of time and space embedded within it and describes a variety of “assumptions on time” that characterize different organizational cultures. Schriber and Gutek (1987), in their empirical research, also described rules about time as specific “dimensions of organizational culture” and found that these cultural features varied across organizations and working groups. It has been underscored that, in addition to being a condition for the coordination of activities and the production of organizational outputs, the temporal organization of work processes constitutes a framework that plays an essential role also as a template for organizing behavior: a cognitive and cultural framework that defines the activities and routines of both people and organizational units, used by people to make sense of actions and events in the workplace (Barley, 1988). In his study on temporal patterns in the organization of activities in hospitals, Zerubavel (1979) found that various types of schedules worked as “cognitive maps” used by personnel to provide a background, a “repertoire of what is expected, likely or unlikely to occur within certain temporal boundaries” [p.125]. Temporal assumptions thus represent an expression of the specific organizational and professional culture that produces them, conveying a symbolic value for the individual and the group of workers. Finally, assumptions on time can also be an expression of the specific sub-culture of different departments and professional groups within a firm (Lawrence&Lorsch 1967; Gherardi and Strati 1988; Dubinskas 1988). Therefore, the relevance of temporal assumptions as both a cultural framework and a cognitive map can be considered a factor that contributes to their strength and permanence within a given organizational context. As a result, the introduction of technologies with the potential to bring changes to this domain also involves a challenge to many of the cognitive orders and cultural values on which organizational actors rely.

Adopting the perspective of organizational culture, this research –in-progress paper seeks to contribute to the research on the temporal impacts of information technology in organizations, presenting a multiple case study that investigates the role ICT can play in promoting changes in the temporal dimension of organizational culture, and tests the hypothesis that temporal assumptions shared by people before a system is introduced can affect the way it is used, thus facilitating or hindering the achievement of the results the system is expected to convey.

Assumptions about time: a dimension of organizational culture
Schein (1985) in his study on organizational culture, maintains that organizational culture has groups’ dominant assumptions of time and space embedded within it and describes several “assumptions on time” that characterize different organizational cultures. Schriber and Gutek (1987) describe as well “norms about time” as specific “dimensions of organizational culture”, proposing scales to measure these dimensions. Besides being a fundamental condition for the coordination of activities and the production of organizational outputs, the temporal organization of work processes, as pointed out by
Barley (1988) plays an important role also as “an interpretive framework for rendering action in the setting meaningful” [p. 125]. In other words, organizational actors evaluate and make sense of events occurring during their own activity or other people’s activity using the temporal framework as a scheme of expectations to judge whether results and behaviours are appropriate.

Temporal patterns represent thus an expression of the specific organizational and professional culture which produces them, conveying a symbolic value, for the individual worker and working groups: according to Dubinskas (1988), the socially constructed character of time is such that all “times” existing within the high technology organizations of his study could be considered as “symbolic nexes around which coalesce issues of order, power, self definition and knowledge”.

As an example, in Barley’s study (1988) the different temporal organization of work of two professional groups, radiologists and radiological technicians, was also a representation of the different hierarchical and professional status of the two groups: given the “temporally unpredictable world” (p. 145) of the radiologists, technicians never knew when radiologists would be available and had to hunt for them whenever they needed one; radiologists on the contrary, given the predictable and highly scheduled “tempo” of technicians, always knew when they could summon up one of them.

Another example: Zerubavel found that a major aspect of the socio-temporal order expressed by the “schedule” of coverage in hospitals was that it functioned “as a moral order”, an expression of some fundamental organizational values like responsibility towards the patients, fairness towards staff members. Consequently, it was also a criterion to judge the appropriateness of personnel’s behaviour: some actions were considered “legitimate”, for example, only at the end of a shift, but not at the beginning. In this view, the temporal dimension appeared central for the definition of the “boundaries of norms”. The relevance of temporal assumptions as a framework and a cognitive map can thus be considered a factor which contributes to their strength and permanence within a given organizational context, consequently the introduction of technologies which have the potential to bring changes in this domain involves also a challenge to a multiplicity of cognitive orders and cultural values on which the organizational actors rely. On the other side, like all other social structures, they have a provisional nature and change over time (Bluedorn and Denhardt 1988; Ancona et al. 2001), also in association with technological innovations.

**Study Aim and Research Questions**

The purpose of this study is to investigate the role ICT can play in promoting changes in the temporal dimension of organizational culture: does the introduction of a new system contribute to change shared assumptions about time and time use in the workplace? Can ICT help transform the way people view time and the ‘appropriate’ way to collectively organize it within a given context (at organizational/department/group level)? Can temporal assumptions affect the way a new system is used, thus facilitating/hindering the achievement of the expected ‘temporal performance’ conveyed by the system? Our investigation into these issues is based on a multiple case study including three companies where a Workflow System was introduced in several organizational departments with the aim of improving cross-department processes, and addresses two main research questions:

1) Does the introduction of the workflow system transform the temporal assumptions shared by people in organizational units, thus achieving the expected temporal performance, and, if so, to what extent?

2) Do the temporal assumptions that exist in organizational units before the introduction of the system affect the use of the system, thus facilitating/hindering the achievement of the expected temporal performance?

**Assumptions about time: a framework for the analysis**

The theoretical framework adopted in this study to describe and measure the temporal dimensions of organizational culture is based on a set of concepts which have been operationalized with Likert scales and tested in previous research into the psychology of work and organizational culture (Schriber and Gutek 1987; Bluedorn et al. 1999).

---

Page 4 of 13  17th European Conference on Information Systems

Proceedings ECIS 2009 3
The framework was then integrated with concepts drawn from the ethnographic work by Zerubavel (1979) and Barley (1988) which have been adopted in order to assess more aspects of the temporal order within organizational departments which were not included in Schriber and Gutek’s model. Schriber’s work, based on data collected from 529 respondents from 51 work groups in 23 organizations, has developed and tested 15 Likert scales measuring perceptions on norms about time that have become standard measurement tools in studies at the work group and organizational levels of analysis. Bluedorn et al.’s work, based on data collection from 2 samples of 205 and 115 respondents from 2 organizations, has developed and tested a Likert scale instrument (Inventory of Polychronic Values) in order to measure the cultural dimension of polychronicity introduced by Hall (1959).

Both Schriber’s and Bluedorn’s instruments have been adopted to study changes in the temporal dimensions of organization occasioned by the introduction of information systems (i.e. Lee 1999; Lee and Liebenau). We investigated these dimensions by submitting questionnaires to employees and managers within the departments involved by the introduction of workflow systems. We also cross-checked these dimensions with the results of the content analysis of semi-structured interviews gathered within the firms. We will now explain the meaning and the relevance to our study of the dimensions considered in the conceptual framework. From Schriber and Gutek (1987) the following dimensions were drawn: Deadlines, defined as the importance of defining and meeting deadlines, temporal start-and-stop points of activities and Scheduling defined as the importance of scheduling (an activity that “concerns location in the temporal realm and gives organizations a framework for constructing temporal boundaries”). In the case of introduction of a workflow system, we could expect these dimensions to be relevant because the system could help introducing a more definite scheduling of the process, visualizing due deadlines for the deliveries and dates of completion of different parts of the process, thus strengthening perceptions and norms about the importance of meeting deadlines.

Synchronization and coordination: this dimension is related to the perceived importance of cooperating with others and working in a coordinated way or as a team. For the specific purpose of our study, this dimension was investigated because the workflow system was linking many different organizational units, thus the importance attributed to cooperation, coordination and teamwork among different organizational units was very relevant and could show significant changes.

Sequencing: the order in which activities and tasks take place; the authors distinguish this concept from scheduling stating that “scheduling is laying out a pattern of activities anchored to points in time within a specific time-measurement system, sequencing is the ordering of activities over time within that system” A specific order/sequence in time may be “inherent in the task, or prescribed by the individual who controls the process”. In our research this variable was relevant because the introduction of a workflow system can interfere with the customary sequence workers adopt in carrying out the daily activities (if any), both interrupting the sequence with queries coming from other subjects or departments, or prescribing a new sequence, embedded in the automated process.

Autonomy of time use: the perceived amount of freedom workers have in setting schedules for completing their tasks over time; The authors state that this dimension is also related to scheduling, although it is not a direct characteristic of it. It’s a secondary effects of scheduling, and reflects a more abstract level of the temporal environment. The variable was thus included in our framework because variations in schedules and deadlines, sequencing, and work pace due to the introduction of the system could bring as a consequence workers’ perceptions of enhancement or limitation of their autonomy over the way they use their time.

Awareness of time use: people’s awareness of how they use their time on the job and expectations that they know how long they take to perform activities. The concept is referred to the degree of attention and importance people pay to how they use their time at work (i.e., if they know and plan how long it will take them to accomplish a task or an activity, how worried they are about using their time well).

As in the case of autonomy, the variable was included in our framework because variations in schedules and deadlines, sequencing, work pace, or even tighter coordination with other organizational units due to the introduction of the system could bring as a consequence more awareness over the way they use their time. Speed vs. Quality: rules that people follow on trade-offs between the quality of work and the speed of work over time.
**Work Pace**: rate at which activities can be accomplished: the speed of work and people’s expectations to work fast. It concerns the perceived speed of work and people’s expectation to following their own rhythm, take breaks and so on rather then work fast. Each culture appears to have a pace that is considered appropriate for activity. This dimension was included because strictly related to speed: the introduction of ICTs is often associated to the objective of speeding up processes, which could result in increasing the work pace or, on the contrary, to slow it down because automation of phases of the process could facilitate worker’s activity, eliminate duplications of activities and so on.

**Allocation**: the amount of time devoted to a task or activity; can be considered a measure of work overload in that it defines the degree to which schedules seem too tight for activities/jobs; As for the case of work pace, this dimension was included in the framework because strictly related to speed: the introduction of ICTs, as pointed out before, is often associated to the objective of speeding up processes, which could result in increasing the perception that time to complete activities is tight or, on the contrary, that there is more time because automation of phases of the process could facilitate worker’s activity, eliminate duplications of activities and so on.

A few dimensions included in Schriber and Gutek’s model were not adopted for this study because not related to its object. They are: “time boundaries between work and non work”, “future orientation”, which is generally connected to perceptions about how much the firm invests in the future, “routine versus variety” related to the variation of job content in general, which was not relevant in our case since the system was applied to routine activities.

We included as well in our framework the dimension of polychronicity, as defined by Bluedorn et al. (1999) the extent to which people in a culture prefer to be engaged in two or more tasks or events simultaneously; and believe their preference is the best way to do things. The cultural dimension of monochronicity and polychronicity were first introduced by Hall (1959) at the level of national cultures. At organizational level a polychronic culture would value behaviors where individuals do several things at once, with short periods of time spent on each of several activities and people dealing with a number of different problems simultaneously. (Bluedorn et al., 1999)

We could expect polychronicity to be a relevant dimension to investigate since it a workflow system allows to have access and deal with a plurality of information at a time in a constant flux; moreover it allows to be connected and react in a flexible way to the flux of information, activities and queries of people working on the same processes in other departments.

In this study we included other two dimensions drawn from the ethnographic work by Zerubavel (1979) and Barley (1988). The first is the notion of Social cycle, defined by Zerubavel (1979) as a regularly recurrent pattern of activities and events, “the time intervals during which sequences of recurring successions of social activities are completed”. Zerubavel observed that the beginnings and ends of cycles are treated as discrete segments of time surrounded by rigid boundaries.

Many organizational activities may be structured in accordance with such rhythmic patterns, and the introduction of a technology can challenge the configuration of such cycles (for example allowing to work adopting a “flow”, destructured logic rather than a “batch logic” where a cycle of activity is completed before another gets started) or potentially alter the way in which cycles of different organizational units are connected to each other. We will briefly recall that this dimension is referred to coordination between the activities of individuals or groups by Barley (1988), who, building on the notions of temporal symmetry/ complementarity/ staggered coverage by Zerubavel, introduces the notions of temporal symmetry and temporal asymmetry. According to Barley the first type of temporal coordination implies that individuals or groups share a common pattern of temporal conditions (they share the same schedules, recurrences, and their working activities are synchronized). In the case of temporal asymmetry, individuals or groups operate according to different temporal patterns. The two authors point out that a condition of temporal symmetry constitute a powerful basis of mechanical solidarity among individuals and groups, while temporal asymmetry requires the development of organic solidarity. Moreover, in Barley’s study the condition of temporal asymmetry among distinct groups led to conflictual attitudes and relationships, which was reduced when their temporal patterns became more symmetrical. Though in our study we didn’t focus on the punctual mapping of the structural aspects of temporal patterns, we adopted the concept because we have different departments...
cooperating to one same process, thus temporal symmetries/asymmetries among departments might lead to cooperative/conflictual attitudes and be modified by the introduction of the system. From a methodological point of view, the two dimensions of social cycles within departments and temporal symmetry among departments were investigated through the content analysis of semi-structured interviews gathered within the firms. Ultimately, we propose the construct of “Expected temporal performance”, which we define as the whole of the expectations expressed by managers with regard to temporal issues, such as process acceleration, changes in people’s time orientations, changes in the temporal dimensions of a departmental culture etc. This aspect was investigated through the content analysis of semi-structured interviews gathered within the firms.

**Workflow introduction and time-related assumptions at Alpha, Beta, Gamma: Research Design**

The research, currently in course, is designed as a multiple case study (Yin, 2003), coherently with the descriptive and explanatory aim of the research project. Our research is based on the study of three cases. In all the three companies, which we will call Alpha, Beta and Gamma, a workflow system was introduced or is being introduced, in order to improve processes requiring the coordination of several different organizational departments. The relevance and significance of these cases to our study is confirmed by the fact that each of them: a) introduces the same type of technology solution b) applies the same type of technology to different processes c) represents different project phases. While Alpha, Beta and Gamma are three different kinds of companies, they have several key features which make them comparable for the purpose of our study: they are medium sized companies, operating in the service sector; and each of them has at least a 7 years story, which made possible to consolidate a peculiar organizational culture.

The study develops in two phases, having two different objectives: **Phase 1** Investigation of the temporal performance expected by the managers adopting the system. **Phase 2** Investigation of the temporal dimensions of culture existing in the three departments before and after the introduction of the system.

**Data collection**

Data is collected through documental analysis, semi-structured interviews with IT and Organization managers, department managers and employees of the three organizations, and questionnaires based on Likert scales addressed to both managers and employees. We first gathered background information through the analysis of company documents concerning the project and then collected data through semi-structured interviews and questionnaires with the managerial level and with employees. We interviewed so far from three to fifteen people in two out of three companies and collected 37 questionnaires in one company (one case is complete and research is still in progress in the other two companies).

**Case I: Alpha - Research results**

The first case study was conducted in the Italian branch, employing 350 people, of a multinational manufacturing company. The Italian branch delivers commercial and distribution services to Italian customers. Here, a Workflow System (Lotus Notes) was introduced to improve Customer Service processes, in particular, the Complaint Management Service, the most prominent customer service activity, which requires the coordination of three different departments. As we will describe later, the workflow system was considered critical due to its potential to achieve results related to temporal issues. The company supported the change management process by organizing an internal workshop, held by the IT and Organization manager with the involvement of the department managers, which took place during the design phase in order to share the objectives and optimize the fit between the features of the complaint service process and the new system. The system had been introduced about eight months before the fieldwork started in July 2007, thus the implementation stage was sufficiently advanced to enable us to measure possible changes in the temporal assumptions within the departments.

**Expected temporal performance.** The analysis of managerial interviews showed that the main objectives inherent the introduction of the workflow system were widely shared and that expectations were very much related to temporal issues. Four expectations, relevant from the temporal viewpoint, turned out to be widely shared by all managers:

1. **Speeding up the Complaint Management Process**
   This meant accelerating the individual activities that make up the process, like the gathering of documentation on the customer’s order, collecting information about the specific problem encountered, monitoring the customer’s “complaint dossier”, and reducing the overall “lead time” of the process in order to provide faster answers to customers. “Lead time” was a very common expression used and the cross-analysis with the Workshop documentation confirmed it as one of the project’s key goals. It also meant reducing duplications and the time needed to produce and store physical documents: “less paper” was a common remark of all managers.

2. **Reducing temporal misalignment among different departments**
   Customer Point operators, who are subject to daily pressure from customers, were far more aware of the delays suffered in providing the customers with answers (“defining the dossier”) compared with other departments, which latter had other priorities and followed their own activity cycles. The workflow system was expected to facilitate departmental “alignments” on priorities and deadlines. This kind of objective can be better explained using Zerubavel’s concept of temporal asymmetry; these departments didn’t share the same “temporal order”, each of them having its own scheduling and activity cycles, which obstructed the complaint management process.

3. **Shifting from a “batch logic” to a “flow logic”**
The system was expected to make it easier for people to deal with issues instantly, as they arose and without waiting until they had accumulated a “pile of dossiers” on their desk. As the IT and Organization manager put it. “We want people to change their mentality, from a ‘batch logic’ to a ‘flow logic’, which means dealing with problems and requests as soon as they show up”. These remarks referred to the tendency to organize the activity in recursive “cycles”, occurring in some cases merely once a week (i.e. the storehouse operators were reported as checking the queries coming from the Customer Point only once a week) and also to a preference to do one type of activity at a time (monochronicity). Reduction/elimination of such cycles and enhancement of polychronicity were the objectives in this case.

4. Shifting from “indefinite urgency” assumptions to “definite deadline” assumptions

Managers reported that the appreciation of the level of urgency of a “dossier” was left to the individual operators, who, based on their experience and willingness, judged whether a complaint case was more or less urgent. There was no sharing of common deadlines for dossier definition and responses given to both internal and external clients: this resulted in a general feeling of uncertainty, well expressed by all managers when they stated that “everything is urgent here”, and that “in general, there has always been a rule that any complaint must be processed within 24 hours”. Managers admitted that it could take up to ten days in some cases.

Changes in temporal assumptions. Data from the employee questionnaires collected in the three departments were triangulated with data from ten in-depth interviews carried out with the four managers and six employees, enabling us to analyze the temporal dimensions of each department’s culture and assess the perceptions of change in these dimensions before and after the introduction of the system. For the purpose of this article we will focus on the analysis of the main changes in the temporal assumptions, following the introduction of Lotus Notes.

Data analysis showed a significant increase in three dimensions - deadlines and scheduling, synchronization and coordination and temporal symmetry among departments - after the introduction of the system. Deadlines were not perceived as so important before the introduction of the system. Although the respondents reported that there was a belief that “everything is urgent” and a general rule that “overall, all complaint dossiers should be opened on the day the complaint arrives”. Others reported that “we didn’t really think of deadlines, it was more indefinite”. According to the results of the questionnaires, the value of this dimension scored very high ten months after the introduction of the system. Respondents reported that what really made the difference was the introduction of a formalized classification of complaints based on the expected completion time and the visualization of dossiers flagged by a colored tag, which was visible to the operators of all departments, thus reminding them of the existence of a deadline and that it required alignment among departments.

The introduction of this system of deadlines and of the colored tag “artifact” represented a liaison between departments: using Barley’s concept of symmetry, the three units now share a common deadline system and have to meet aligned deadlines, which has increased the overlap among their different temporal orders.

The value of synchronization and cooperation among departments ranked very high in all three departments and was perceived as having increased significantly because the sense of “teamwork” with the other departments had also increased. Customer Point operators reported that, pre-Lotus Notes, the synchronization with other departments was very poor: other departments were reported as “having their own time”, “creating bottlenecks”, “being slow to give answers”. All the interviewed customer service operators shared the strong conviction that this situation had improved significantly with the introduction of the workflow system because their requests are now transmitted instantly through Notes and the date and hour of the request, as well as the other department’s response, are recorded. On the other hand, operators from other departments reported that the system made it “simpler and quicker to gather and send documents because the databases are now interconnected”.

The increase of these three dimensions confirmed also the achieving of three expected temporal performances: the lower level of misalignment among departments, the adherence to defined deadlines, and the speeding up of the customer complaint process.
This kind of evidence would seem to confirm the first hypothesis of the study, that the introduction of workflow systems has the potential to transform the temporal assumptions shared by people in organizational units. Nevertheless, it is important to note that the introduction of the workflow system was combined with an internal workshop involving the managerial level and that the results we report were associated by the respondents with both the innovations introduced by the system and the effectiveness of the workshop as a change management strategy.

To the contrary, the dimensions of polychronicity and sequencing showed no significant change, while the social cycles characterizing the departments revealed contradictory patterns of change. These dimensions were associated with the achievement of the objective whereby, in performing their activities, workers would shift from a batch logic to a one-piece flow logic.

Polychronicity scored low in the questionnaires gathered from all three departments. When triangulated with the interview data, the result was explained in this way: in all departments the workflow was recognized as fostering polychronicity because all data and documents were stored in a single database, making it “easier to open and close items related to different activities simultaneously, having links immediately available”.

On the other hand, employees pointed out that they didn’t like working this way and that there wasn’t yet a shared belief that this way of working was “better”. High scores of time allocation dimension cross-confirmed that there was a feeling of an increasing work overload. Further, when under pressure to deal with overloads, operators shifted back to batch logic: for example, Customer Point operators during phone call peaks (twice a day) interrupted their other activities to concentrate on answering the phone, admitting that “messages in Lotus were left on stand-by”. Another case was when they had a number of administrative tasks requiring high levels of concentration: they adjusted with colleagues in order to divide labor based on specialized activities and followed a monochronic logic. Interestingly enough, as far as Social Cycles are concerned, the interviews showed that, though the pressure toward a “flow logic” had increased, operators retained their previous cycles: at Customer Point, the activity is still organized around the “phone call peaks” and four main daily cycles are still in place. This influenced, as pointed out in the previous section, a use of the workflow system that is not yet thoroughly in line with the expected “flow logic”. The same happened in Storehouse and Logistics, where the importance of sequencing is a key feature of the departmental culture and where monocronicity is high. Here, operators reported that there had been an adjustment between the social cycles of their activity and the need for more polychronicity: they used to follow a five-six day cycle in complaint management activity: i.e. the “pile of paper” here was left to grow until, finally, they dedicated one entire day to this specific, time-consuming activity. The presence of this cycle expresses the “batch logic” they followed. In addition, this created a noticeable temporal asymmetry with Customer Point operators, who were left waiting for answers for up to a week. This department is characterized by another typical cycle, the Morning/Early afternoon cycle. In the morning, ordinary activity takes place; at one p.m. afternoon planning starts, while deliveries take place through to five p.m. At present, complaint management has been re-allocated according to this second cycle: Lotus Notes is checked in the morning and, accordingly, complaints start to be checked in a more “flow oriented” logic. This allocation of the complaint management activity to the morning/early afternoon cycle has enhanced the symmetry with Customer Point. In this case, the shift to a “flow logic” has been partly obtained through an adjustment to existing social cycles and to a still strong orientation to monocronicity in departments. To summarize, our findings suggest that the persistence of two temporal dimensions of organizational culture - monocronicity and sequencing - and the strength of the social cycles existing within the departments have influenced the use of the system and the achievement of one important expected temporal performance, the shift to a flow logic. This result seems to support our second hypothesis that temporal dimensions of organizational culture can affect the use of the system, thus having an impact on and even hindering the achievement of the expected temporal performance.

Case II: Beta – Preliminary results

Beta is a company created by a consortium of about twenty banks in northern Italy. It provides full outsourcing services to the banks belonging to the consortium, employing about 250 people.
Our fieldwork in this company, still in course, takes place in a mature phase of the project, where we can investigate consolidated outputs and changes.
In 2003 Beta introduced a workflow system (docflow) aimed at managing their accounting passive cycle (the whole process leading to suppliers payments), which is, in this company, the most prominent accounting activity since they have a lot of suppliers but very few customers (i.e. banks forming the consortium). This process requires the coordination of three different organizational units: two different offices within Administrative Department, and Purchasing department.

Expected temporal performance.
The analysis of interviews with the managerial level showed that in this case the objectives inherent the introduction of the workflow system were partly related to temporal issues. In this project attention and expectations were initially focused on reducing the production, duplication and storage of physical documents (“reducing paper”); another priority was to create a logical flow in order to decrease information redundancy, and finally to improve quality and reliability of data gathered by administrative department. In this case, compared to the previous one, managers showed a lower level of awareness about the potential of the system from a temporal point of view.
This lower level of awareness is expressed by a poorer articulation, compared to Alpha, of possible time-related objectives going beyond the “speeding up” issue.
Two objectives in this project were explicitly addressed to temporal issues:

1. Reducing the duration of passive administrative cycle process
This was explained as the need to reduce the overall time during which suppliers invoices moved around from one office to another before being paid.
The process required that invoices, once arrived via mail or fax to one of the two offices within Administrative department, were duplicated and sent to buyers operating at the purchasing department (who were responsible for specific contracts with suppliers) for technical check and authorization to payment. Another duplication was sent to the other administrative office for the checking of contractual conditions. During this double check and authorization process, invoice copies could either be left standing by until checks were completed, or move back to the first administration office with a request for keeping the payment suspended, or move back with authorization to payment. The duration of the whole process was described as “unpredictable” and it was often difficult to make out why an invoice hadn't come back and which office was keeping it suspended. For the same reason it was difficult to inform creditors about the state of their payments. Thus the workflow system was expected to speed up the process: partly because of new electronic format of dossiers related to invoices and the possibility to track them along the process, partly because it could facilitate departmental “alignments” on priorities and deadlines.
This kind of objective can be better explained if we refer to the concept of Awareness of time use: there was an overall unpredictability of duration of the process for many reasons: lack of awareness of how long each one would take to complete his own check, lack of awareness of reasons why there were delays and in which part of the process. Another aspect of this objective can be related to Zerubavel’s concept of temporal asymmetry: the different units, buyers in particular, didn’t share the same “temporal order”, each of them having its own scheduling and activity cycles, which obstructed and made the duration of the process unpredictable.

2. Respecting payments deadlines
Unpredictability of the duration of the process caused delays, which made it difficult for administrative operators to be punctual in meeting payment deadlines Even if deadlines were set within contracts, administrative operators had to work hard to compensate for delays; moreover, it was difficult to give creditors timely information about the state of their payments.

Changes in temporal assumptions.
We are not able to give a complete account of this case, nor to confirm our hypothesis yet because data collected in this company so far are not complete. Data analysis of the interviews collected so far with managers and employees who are still working in the company and can account for the changes occurred after the introduction of the system, allow us to present only some preliminary results.
A significant increase is perceived by interviewees in three time-related dimensions — scheduling, awareness of time use, and temporal symmetry among departments - after the introduction of the system. On the other hand, social cycles seem to have only partly changed.

As far as Scheduling is concerned, the workflow introduced and made visible a clearly structured sequence in the process. The operators reported that structured scheduling is now perceived as very important because all operators can locate at what point, in the temporal domain of the process, a single invoice is and what is its advancement state. As administrative operators put it “Now I can see where invoices are and who is in charge for it at any given moment” The increased importance attributed to a more structured schedule reduced as well the feeling of uncertainty about the ongoing of the process, expressed by sentences like: “I feel more in control” “Now the process is under control”.

Every action in the process being tracked, awareness of time use seems to have increased because everyone can check how long it takes to everyone else to complete his “to do list”. As an administrative employee put it, “information about ‘bottlenecks’ is now transparent”. Moreover, the system sends automatic warning mails when a due action is not completed, contributing to awareness of one’s own time use as well. As far as Social Cycles are concerned, it turned out that, before the introduction of the workflow, both buyers and administrative employees followed a similar rule: the so called “bunch rule” which meant that they would care of invoices payment process when the bunch of invoices was thick enough. This rule is similar to the “pile of dossiers” rule in the previous case. This rule gave rise to cycles which could last from one to two weeks for buyers, while administrative employees followed a one/two days cycle during ordinary periods of the year (when not under pressure for other important tasks, i.e. closing balance sheet). This created temporal asymmetry between buyers and the other units. Interviewees reported that these cycles have partly changed: administrative employees state that their activity is now generally driven by the “to do” proposed by the system. Buyers have partly modified their routines, due to the fact that access to electronic documents and data about invoices is much easier than before. Their activity has other priorities, thus many of them continue to take care of this process periodically. Interesting enough, both groups reported that they developed a sort of “bridge” between their different temporal orders based on the artefact of “urgent query”: when requested, buyers are much more flexible and quicker than in the past to give answers on specific and urgent issues blocking a payment. They recognized this “bridge” is now possible because they can have easier access to workflow data wherever they are.

**Preliminary conclusions**

Despite its importance to temporal issues, research into the temporal impacts of information technology in organizations is still limited. On the other hand, organizational culture research shows that the way time is perceived and collectively organized reflects cultural assumptions that are an expression of the specific organizational setting (at firm, departmental, group level), underscoring that cultural assumptions are an important contributory factor to the strength and direction of organizational change. In this contribution, we have investigated the role ICT can play in promoting changes in the temporal dimension of organizational culture, and sought to assess whether temporal assumptions can affect the way a new system is used, thus facilitating/hindering the achievement of the expected results. The preliminary results of this multiple case study show that managers have different levels of awareness about potential temporal performance of the system.

Case Alpha covered four types of ‘temporal performance’ management expected to see thanks to the introduction of a workflow system. In Case Beta managers showed a lower level of awareness about the potential of the system from a temporal point of view. This lower level of awareness was expressed by a poorer articulation, compared to Alpha, of possible time-related objectives going beyond the “speeding up” issue. Both cases showed that, after its introduction, the temporal dimensions of the organizational culture of the departments involved showed some significant changes, which seems to confirm hypothesis 1 of the study, but also some contradictory effects that seem to confirm hypothesis 2. In case Alpha, significant increases were seen in three dimensions - synchronization and coordination, temporal symmetry, deadlines and scheduling. The increase of these dimensions confirmed the achievement of the three expected temporal performances: the reduction of the misalignment among departments, the shift to definite deadlines, and the speeding up of the
process. This seems to support the first hypothesis of the study, that the introduction of workflow systems helps transform the temporal assumptions shared by people in organizational units. It is important to remember that the system was introduced in tandem with an internal workshop involving the managerial level and that the results reported here were associated by respondents with both innovations introduced by the system and the workshop. Nevertheless, the assumptions underlying the objective that workers would shift from a ‘batch logic’ to a ‘flow logic’ in performing their activities failed to show any significant change: data analysis shows that the persistence of two temporal assumptions - monochronicity and sequencing - and the power of the social cycles existing within departments influenced the expected use of the system and the achievement of one important temporal performance, the shift to a flow logic. This supports our second hypothesis that temporal dimensions of organizational culture can affect the use of the system, thus hindering the achievement of the expected temporal performance. Preliminary results from Case Beta also seem to confirm that significant changes were seen in three temporal dimensions - scheduling, time awareness and temporal symmetry. It seems remarkable that in this case these changes can’t be considered as planned results but rather as unexpected consequences of the workflow introduction.

OBJECTS AND THEIR PARTICIPATION IN THE INTERDISCIPLINARY DESIGN AND DEVELOPMENT OF COMPUTER GAMES

Abstract

This paper investigates the role of boundary objects in the interdisciplinary collaborative processes found in computer games development. It draws on data from an in-depth case study in a computer games studio that explores boundary objects in relation to the compelling, sensory and entertainment-centred game-playing practices that inform computer games design and development. Sensory user experience and aesthetic considerations – of primary importance in computer games development – are becoming increasingly significant in the design and development of many other kinds of software and information systems. For this reason developments in the design and production of computer games have wider implications for other software and information systems settings and provide valuable insights into processes of collaboration that bridge cultural and aesthetic as well as technical forms of expertise. The paper seeks to provide insights into how objects contribute to such collaboration, with attention focusing especially on how game developers devise objects that span boundaries and draw on these in their collaboration. Through its focus on the material production and practices of computer games development, the research presented also seeks to contribute to the theoretical treatment of interdisciplinary collaborative working in software design and development via a critical assessment of the concept of boundary objects in the setting being studied.

Keywords: Boundary Objects, Computer Games, Design, Development, Aesthetics, Representation, Collaboration, Interdisciplinarity, Art, Programming, Practices.
1 INTRODUCTION

Most work is conducted by diverse collectives of people and things from different backgrounds and with varying levels and types of capabilities. Shared artefacts are seen by a number of studies from a range of literatures as playing a crucial role in the bridging of boundaries of human expertise and embodied skills involved in collaborative work (Gerson and Star 1986; Callon 1991; Henderson 1991; Fujimura 1992; Bowker and Star 1999; Carlile 2002; Bechky 2003; Carlile 2004; Bruni 2005; Engestrom and Blackler 2005; Levina 2005; Levina and Vaast 2005; Miettinen and Virkkunen 2005; Suchman 2005; Ewenstein and Whyte 2007; Luck 2007; Nicolini, Mengis et al. 2008). For example, a physical prototype (Carlile 2002; Bechky 2003) might help a designer communicate his/her vision to a production engineer and at the same time help the engineer understand the implications of that vision for production of that design in order to respond accordingly. Further examples from existing studies include design drawings (Bodker 1998) and engineering sketches (Henderson 1991; Bechky 1999).

More specifically, artefacts that exhibit a capacity to help different collaborating groups share representations with each other have been conceptualised by Star and Griesemer as boundary objects (Star and Griesemer 1989). Star and Griesemer's starting point for developing the concept of boundary objects is that for the success of collaborative work, cooperation and coordination need to be achieved across domains, and shared meanings and understandings established. For this to take place, information needs to "retain its integrity across time, space, and local contingencies" (Star and Griesemer 1989). This does not necessarily mean that for cooperation to take place consensus must be achieved. Instead, those involved in collaborative work have to "translate, negotiate, debate, triangulate, and simplify in order to work together" (Star and Griesemer 1989).

"In conducting collective work, people coming together from different social worlds frequently have the experience of addressing an object that has a different meaning for each of them. Each social world has a partial jurisdiction over the resources represented by that object, and mismatches caused by the overlap become problems for negotiation. … Because more than one world or set of concerns is using and making the representation, it has to satisfy more than one set of concerns." (Star and Griesemer 1989)

According to Star and Griesemer boundary objects "both inhabit several intersecting social worlds ... and satisfy the informational requirements of each of them" (Star and Griesemer 1989). They are "both plastic enough to adapt to local needs and the constraints of the several parties employing them, yet robust enough to maintain a common identity across sites" (Star and Griesemer 1989).

"These objects may be abstract or concrete. They have different meanings in different social worlds but their structure is common enough to more than one world to make them recognizable, a means of translation. The creation and management of boundary objects is a key process in developing and maintaining coherence across intersecting social worlds."

While a number of studies have made strong cases for the role specifically of boundary objects in collaboration (Gerson and Star 1986; Henderson 1991; Bowker and Star 1999; Carlile 2002; Carlile 2004; Levina 2005; Levina and Vaast 2005), most of these have been concerned with more conventional science, technology, and business settings where the forms of collaboration involved are functionally-based. There remains, however, a significant gap in the existing research regarding the role of boundary objects in relation to collaborative efforts that depend on linking technical forms of expertise with expertise in the areas of entertainment, culture, and aesthetics.

Computer games design and development, involves a highly diverse set of participants in multiple roles (Gershenfeld and Loparco 2003). Furthermore, because computer games are designed to be compelling on a sensory and entertainment level as well as to perform functionally, their development is an arena of techno-cultural production and differs from many other collaborative settings (Baba and Tschang 2001; Swartout and Lent 2003). For this reason computer games development was seen as a
good setting through which to investigate the importance of boundary objects in a situation of collaborative production characterised by a cultural and entertainment dynamic and to explore the forms of boundary objects being drawn upon. In particular, the research has sought to investigate what the role of boundary objects in the interdisciplinary collaborative processes found in computer games development is and whether the boundary objects involved reflect game-playing practices as compelling, sensory and entertainment-centred.

The article presents key boundaries and objects that span these boundaries identified so far in computer games development and describes the role of these objects in terms of how they contribute to collaboration. Attention focuses especially on how game developers devise boundary objects and draw on them in their collaboration. It also suggests ways such devised boundary objects might relate to specific performance outcomes and what the properties of boundary objects associated with successful projects might be.

2   RESEARCH APPROACH

As outlined, the study focused on boundaries of expertise encountered in an interdisciplinary computer game development setting and the use of boundary objects in the process of realising such an innovation outcome. To this end, an interpretive case study research approach was chosen (Walsham 1993) that focused on the work practices of game developers and the boundary objects they interact with during the development of these games. In particular, the research has aimed to acquire an in-depth understanding of the way in which the developers studied create, leverage, and alter boundary objects in this work and to access the meanings they create and attach to them (Ngwenyama and Lee 1997). This will ultimately form part of “thick descriptions” of the research phenomenon through engaged field experience that capture its distinctive complexity (Geertz 1973).

2.1   Data Collection

Through a combination of in-depth interviews and observations at computer games developer studios the research project presented is seeking to investigate the way the interdisciplinary collaboration involved in the development of computer games is performed by the humans and objects involved. This paper is based on interviews and some initial observations conducted at GamesDevCo, a pseudonym for a UK-based games development company, and the first of three planned case studies investigating the design and development of computer games at different development companies.

The researchers made a number of visits to the company’s studios and headquarters between September and December 2008. During these visits a tour of the five divisions was undertaken. The various teams that comprise each division were encountered and informal and unstructured conversations with team members relating to their work, their interactions with other teams, the way they work within the team, and the importance of objects to this work took place. An in-depth formal interview with the company’s director of development was also conducted and there were also a number of more informal discussions and interactions with the company’s director of business development.

A range of artefacts involved in the design and development of past games titles also formed an important part of the evidential basis for the fieldwork. Finally, a significant amount of documentation generated from a part publicly funded joint commercial and academic international research project relating to the development of reusable multimedia objects was also accessed. This provided an in-depth view of the approaches the company was exploring in terms of re-using games ‘assets’ and how to enable those from an more creative background without expertise in computer technology and programming to interact directly with the technical components of games and input graphic elements and animations without the intervention of the technical experts.
Data collection also sought to pay attention to material entities, activities, schedules, hierarchies, routines and variations, significant events, participants’ meanings, and social rules (Altheide and Johnson 1994).

While the use of other forms of evidence such as photographs of the studio and teams at work, pictures of the artefacts and objects studied, and screenshots of tools and objects used in collaboration was considered, that was not possible in this case study due to the strict non-disclosure conditions stipulated by GamesDevCo.

Interviews were recorded and transcribed, while observations were intended as a way of appreciating in greater depth and detail understandings garnered during the interviews.

2.2 Data Analysis

The analysis of the evidence has sought to counterpose theoretical formulations relating to boundary objects with the empirical data collected in order to develop an in-depth understand of how a variety of constructed boundary objects help shape, are shaped by, and represent shared meanings or interdisciplinary intersubjectivity.

From the data collected, the analysis first sets out to identify key objects used in the design and development of computer games at GamesDevCo and that were found to span the disciplinary boundaries in the company. Attention focused in particular on how these objects identified were involved in the collaboration across disciplines and what kind of interactions among the developers they were a part of.

Drawing from the original conceptualisation of boundary objects developed by Star and Griesemer (Star and Griesemer 1989), a mapping between the objects used in collaboration across disciplines in the empirical setting and the four key categories of boundary objects (repositories, ideal types, objects with coincident boundaries, standardized forms) proposed by Star and Griesemer was undertaken. On the comparison made possible by this, an analysis of conceptual concurrence and difference was undertaken, which formed the basis of the discussion that this paper presents.

3 CASE STUDY IN PROGRESS

Since its foundation in 1990 GamesDevCo has grown into a leading independent multi-platform developer employing around 250 people and comprising of five distinct divisions: family games; mature titles; serious games; downloadable games; and games technology. The company develops games under both its own brands as well as on behalf of external publishers and intellectual property rights holders.

3.1 Formal Structures and Disciplines

Formally, the various divisions of the company and the teams that comprise them are divided along the following three main disciplinary lines: art; design; and programming. The way the teams are structured in practice, however, can vary “as project needs ultimately dictate the structure and skills of the team and teams also vary in size as what [each] client needs is often very different”.

The broad structure the company adheres to was described in the following way. A project director manages schedules and interacts with clients. Then, in most divisions there will be a manager for each of the disciplines involved, with, for example, a technical manager for the programmers, a design manager for design issues, and an art manager in charge of animators and concept artists.

This structure reflects the current company view of the key disciplines involved in the games development process. In practice, however, there appeared to be much more fluidity in the disciplinary boundaries that were likely to shift and be reconsidered. An example was given regarding the
introduction of an animations manager because the animation requirements for a project were considered so demanding and there were a large number of animators involved in the work. “It is something we are experimenting with” commented a senior development executive.

Below these discipline-specific managers each team in each discipline will have a “lead” or “senior” person “to help managers organise and lead their respective departments”. These senior figures were described as “important to communications” and “senior in terms of what they have done”, with 5-10 years of experience and having “done high-profile games, either previously at the company or at other companies”. They were described as knowing “inside-out the company’s technology, its games engine, and how to make games”. Their job titles are along the lines of “lead programmer” or “lead designer”, “lead artist”, “lead animator” and so on.

Under this level are what were described as “general programmers, artists, designers, animators, and concept artists who do [technical design] concepts and visualisations”. With bigger project teams of 50-60 people, specialisations might “go a lot further”, especially with regards to art. For example, with regards to animation for large high-profile projects they now have people who are solely involved in “rigging” characters which involves “putting the skeletons on characters, but not actually animating them”. “It is quite a big job and very critical with regard to the success of the project and the success of the animations”. Similar developments are taking place with regard to 3D artists with the company now having environment artists, character artists, and “people … just dealing with lighting”. Disciplines were described as “getting more and more specialised”, with the example given of the introduction of “special effects-only artists”.

“The bigger teams definitely have the ability to have people that are specialised in a certain skill and very much at the top of their game with regards to smaller parts of the game that make the difference. The smaller teams don’t really have such needs, but that will also often depend on what the client needs”, explained the company’s development director.

The reason given for this specialisation and fragmentation of the three main disciplines were as follows:

“The stakes are so much higher regarding the visual quality of the games, the complexity of the designs, and the technology we are using. Years ago … any decent artist could get away with doing special effects and knowing what to do, because it was very much dealing with 2D assets. These days, depending on the target hardware, what the [games] engine is capable of, and the technical requirements of the [games] engine a lot of special effects artists need to have a very good technical grasp of the technical aspects of the game in terms of coding and also for coders to have a very good understanding of how the rendering technology works with regards to that rather than just have a good knowledge of coding. You need to have extra knowledge on top.”

The director of development talked about the necessity to “marry-up two different people” in one role creating “a ‘technical artist’ who knows a lot about hardware, about software, about good visualisation techniques, but also has a very intuitive mind in terms of experimenting with new and unusual ways of doing say a fire effect or a sparkling effect that goes in a totally different way than most others would do”. Such a person would do “research stuff that instead of going down the normal route … could go in a completely opposite way” by talking with people and “figuring out that there may be a really cool alternative way of doing something”.

Individuals from all the three disciplines are involved from the early stages of the origination of a game, with the creative side and designers taking a lead, but “senior technical guys and senior art guys” following them closely. “The industry is so tied together discipline-wise”, explained the director of development, who went on to add:

“Any change within an art specification could change the technical specification and the design specification definitely does [change] in terms of how many characters you can have on screen or how big the levels are and what the designer might want to do. The technical guys must look
at that and say: ‘is that possible, how is it possible, how much would it cost if we did do it?’ We try to involve those three sides of the disciplines – design, art, and technical sides – at a very early stage along with the manager. … Ultimately the project director will look at that from a costing and … scheduling point of view and say ‘we have x amount of time to do this in and these resources we can bring, what are the major risks we need to be focusing on’ and get a good estimate really of what kind of skills will be needed, what amount of people they are going to need and so.”

In the case of GamesDevCo that works quite a lot with third party intellectual property rights holders, the GamesDevCo managers dealing with the interdisciplinary team from the client side also have to consider the specifications of a project strategically and technically in terms of what the studio wants to do with regards to its styles and “where [they] want to take the engine”. “We work with that and make sure the pitch fits with what we want to do as well as meeting the clients’ needs at the same time; we kind of marry those two up and then go in to further negotiations, explained a senior GamesDevCo executive.

As can be seen in this section, even at the level of concept origination for a game, a significant amount of interdisciplinary work is already involved. At the same time, while disciplines are recognised at the corporate and organisational level in the company, in the actual work practices of the teams developing a game the disciplinary boundaries are porous and flexible.

3.2 Concept Book

An important material nexus for this early-stage interdisciplinary work as the computer games move from conceptualisation to actualization was what was often referred to by the GameDevCo developers as the “concept book” and discussed as follows:

“In the end [of the conceptualisation phase] we get to the point where we create a high-end specification document that looks great and [is presented] with good PowerPoints and videos and all sorts of madcap stuff. One thing we really have trouble doing in the industry is selling the vision of the game. … Trying to get that across is quite tough to do and quite expensive. Years ago we used to go through word documents and write stuff out and give lists and a bit of concept art here and there; nothing too major really. Now days we are dealing with producing videos and actual 3D assets which is probably the most expensive thing we do at the studio. Even [just] producing the documents you have seen takes a huge amount of resources and time to do.”

The samples viewed were from past games. They were very professionally produced and aesthetically engaging documents, styled in accordance with the theme of the proposed game. For example, one for a very successful science fiction film series had covers made out of shiny metal that was shaped and indented in such a way as to look like one of the very characteristic spaceship doors in the film. Another for some medieval adventure had the look of an old and musty book.

The documents included text that described the game and its features to the reader, the thinking behind it as well as visual representations of the main characters of the game accompanied by what can be described as imaginary biographies for them outlining their roles in the game and what they could do. The documents often – though not always – also included outline budgets and cost projections for the proposed game. It was explained that the production of these documents was undertaken by a specialist “pre-development” team that included individuals from business development and marketing as well as individuals with skills in business analysis, project planning, desktop publishing, and writing and editing text. This core team would then draw from the expertise of the different developers involved in the project from the three formal disciplines acknowledged by the company of art, design, and programming.
3.3 Game Design Document

Once a more formal agreement to proceed with the development of a title has been reached, whether this is with an external publisher or in relation to internal approval procedures, a number of new objects that are crucial to the interdisciplinary collaboration involved are assembled, as the following passage describes:

“The aim at the beginning of each project … is to create a ‘game design document’ an ‘art design document’ and a ‘technical design document’. The game design document will contain everything that is in the game. It will classify all the characters, all their moves, all the mechanics, all the animations needed, all the pickups, all the weapons, all the locations, all the mechanics. That will grow to at least a couple of hundred pages for just that. … [The game design document] is also crucial to the relationship with the client [as well as in terms of] visibility for the collaboration. The same with the art and technology design documents and what they deal with. Everything is documented in terms of meeting notes. Everything visual is designed and we obviously design everything digitally or scan it in or drawn digitally. So we keep a record of that.”

The games design document is not only a repository of all the elements that need to be assembled during the development of a game. Because the milestones agreed for the delivery of different parts of the game are also included, much of the scheduling of the tasks for a project and included in a “milestone schedule” will also flow from it.

These milestone schedules are a central coordinating device in the development process that span all the teams and disciplines involved in the project. They reach right down to the level of each individual, with printouts of graphical representations of the schedule observed fixed either side of their computer screens on to the wall or the separator screens on to which the desks of the developers abut.

The games design document is not a static high-level brief. It evolves and grows together with the games project, with minutes, drawings, and other relevant resources and assets added throughout the development process.

3.4 Drawing and Visual Representations

Drawings, within the context of both the concept book and the games design document, but also more generally in the games development process as a whole, were found to have a crucial boundary crossing role. Drawings – but also visual representations in general – were very much linked to one of the central preoccupations for a games development company: how to capture and communicate, both internally and externally, the “vision” for a game. The importance of drawings is captured in the following passage:

“We try and draw a huge amount of stuff during the project because the cheapest way of getting any visualisations is by drawing. The [art specialists] are trained to draw extremely fast as well, so we spend a lot of time drawing out the environments, drawing out some of the character moves in regards to the animations cycles, drawing out all the characters' weapons, individually style anything else we need, sometimes just drawing with regards to diagrammatic things saying: 'I want this character to move like this', or, 'here is one of the character moves and I want it to look dynamic in this kind of way', or whatever. Some quite functional things like that. So, when we hit production we've got a huge amount of material there.”

But it is not just the drawings that are so important in terms of the circulation of the vision for the game. Within the studio there was a wide-spread use of all sorts of sizes and types of models in the development process ranging from miniature mock-ups of landscapes made from the kind of modelling materials used by model railways enthusiasts, to small sculpted figures or portraits of
characters. Throughout the studio, props and objects from various well-known film and television titles could be seen on the desks of individuals and in areas occupied by different teams, but also all around the office space, giving a visually intense feel to the place.

Even external visual resources are utilised in order to convey to the individuals involved the elusive vision for the game, as illustrated in the passage below:

"With everything we have created, even if it is ‘true to original’ there is always a movie, or a book in some cases, or another game possibly, that have done something similar or have done something diametrically opposite that we can say: ‘this is really what we don’t want, we really don’t want this vision’. Or, ‘what I am trying to get to is this’, or ‘here is a movie’. Everyone watches the movie and they then hopefully understand what you mean about the emotion of the game or the visual style of the game or whatever it might be. … Using those … references, to say, 'right we really want this', then … people come up with ideas and come up with visual styles [and] that's how [the vision] works; it kind of trickles down."

3.5 Other Objects

The development of computer games at GamesDevCo also depends on a number of tools and development methodologies that have knowledge, skills, expertise, and ways of viewing and knowing the processes involved in games development built into them.

These include computer programmes for the digital manipulation of artwork, for creating high-end 3D assets, development platforms for writing computer code, and project management applications. Of particular interest in relation to understandings of collaboration built into such tools was provided in this case study by the decision of GamesDevCo to abandon Microsoft Project in favour of a programme called Hansoft, which has been developed by a number of games developers who built a specialist project management software application.

4 ANALYSIS AND DISCUSSION

Our account of games development projects at GamesDevCo has focused on three of the objects that were found to play vital boundary crossing roles because of the important consequences for interdisciplinary collaboration they were found to have in this setting.

The concept book not only crosses the boundary between the games studio and the client, but also allows the developers from a number of areas of expertise to bring together in a common space their interpretations of the vision, concept, and ideas of the proposed game.

These interpretations are then, for the purpose of the concept book, expressed in text, textures, materials, drawings, photographs, tables, and spreadsheets that have been made combinable but also accessible by all those involved in the games development process and from different areas of expertise with different representational techniques. The co-production of shared representations is a central element in the conceptualisation of Star and Griesemer (Star and Griesemer 1989), as the following passage shows:

"Because more than one world or set of concerns is using and making the representation, it has to satisfy more than one set of concerns. When participants in the intersecting worlds create representations together, their different commitments and perceptions are resolved into representations - in the sense that a fuzzy image is resolved by a microscope." (Star and Griesemer 1989)

The game design document is also crucial in this respect. It specifies a whole set of objects and relations among these objects that must come together in a game. It will specify, for example, the number of levels the game will have, what these levels will be, the storyline of the game and how that
relates the different levels to each other, who the characters are, what their role in the game is, where they can appear, how they can encounter each other, what the mechanics of their interactions are going to be, how they are going to move, what ‘things’ they can interact with or manipulate, and so on. These are all objects that whether an individual participating in the development process is a coder, an animator, a 3D artist, or an special effects or artificial intelligence specialist, will, during the trajectory of the game from concept to actualisation, continuously cross backwards and forward between individuals and groups of individuals with a particular expertise and way of working and interacting. As was explained during the research, this way, when for example the character artists come into the team, they can see straight away what characters are needed from the concept art already done in 2D and included in the document. Or a programmer can “look at the game design document, look at the pages which relate to character movement or even read the whole document with regard to how all that is going to feed into the mechanics and other stuff and then be able to think, 'OK I have got it.'”

Furthermore, the dynamic nature of this documentation means that this a continuously expanding body of material of all kinds, both textual and visual, that tracks and accompanies the game through its development, recording but also making available back to them the interactions of all those involved in the project. It also provides an updatable representation of the game being developed itself, but in such a way that this representation is a shared representation that can be used by all the different disciplines for their own purposes.

This document also includes the crucial for every project, team, and individual team member “milestone schedule”. The milestones themselves are more that just a project management device. It is through them that the performance of individuals, teams, and ultimately the company itself are judged, evaluated and rewarded, as the following passage from an interview illustrates:

“The project director gets involved … to create a ‘milestone schedule’ with a list of deliverables for the duration of the project. [The milestones] are usually monthly and those deliverables contain certain parts of the game like an x amount of characters and an x amount of levels or whatever it might be. It is important that the teams are involved in whatever they are signing-up for as it is important that the milestones that are agreed on are met, as this is how we get paid monthly in arrears from our clients. We have to be aware that our milestones are judged by the fact that if we hit the milestone – which we luckily do mostly – then we get paid. That is how the visibility works.”

Even conceptually, however, the notion of the schedule and the key stages in the lifecycle of every games project, regardless of the relative duration of each phase or the content of the work involved, shapes to a great extent the interactions of the developers with the project and with each other. They all know that there will be a pre-development phase, a production phase, and a finishing phase in every project and within these there will be certain inputs and contributions they will have to make. In turn, these broader phases are composed by other commonly understood and to a great degree inviolable key stages, like for example alpha testing, beta testing, console standardisation and certification, and the eventual graduation of the game from the “master version” to “gold master”, which is effectively the game that is played by people “in their sitting rooms” and than one can find on the shelves of the shops.

While the concept book and game design document are much more clearly discernable as boundary objects in the way proposed by Star and Griesemer, it is the non-representational capabilities of the drawings and visual representations (models, sculptures, props, books, TV series, films, other games) that enable the circulation among the developers of the “vision and emotion” of the game being built that provide the most interesting insights from a theoretical perspective.

Although the research is still at a relatively early stage and the analysis presented here is based on a preliminary assessment of the evidence collected from only one of the three sites to be studied, some important theoretical points are raised from the first iteration in confronting the material collected with the literature relating to boundary objects and their importance in collaborative work.
The central role played by visual representations, not in terms of the representational work they do but in terms of circulating among the developers involved often intangible aspects of the game such as its “vision” and the emotional response it must produce, raises an important question for the notion of boundary objects. This is because the original conceptualisation of the boundary object as articulated by Star focused on rather narrow representational aspects of these objects and the systems of representation they are part of.

Furthermore, something that became quickly evident even during such an early phase of this research project was that while objects and artefacts clearly had very important roles to play in the collaboration involved in the design and development of the computer games, it was much more difficult to discern clear-cut boundaries between disciplines or particular social groups in the setting being investigated, despite the formal categorisation of art, design, and programming used by the company itself.

While Star acknowledges that “no representation ... is either complete or permanent”, but rather that “any description is a snapshot of historical processes in which differing viewpoints, local contingencies and multiple interests have been temporarily reconciled” (Gerson and Star 1986), her formulation of boundary objects depends on a fairly stable view of roles, identities, and social groups. The notion of boundary objects depends on boundaries to have relevance, but the boundaries encountered in this research so far are not stable and ‘given’ but constantly shifting and changing. This critique of the original conceptualisation of boundary objects is made, if in a rather oblique way, by Fujimura (Fujimura 1992), who writes in a footnote:

“I do not assume that social worlds, e.g. disciplines, are stable entities in nature or society … [and] that disciplinary boundaries are also constructed and therefore can be destabilized.”

It is important to keep in mind – as Fujimura suggests – the location of Star’s work in the field of "symbolic interactionism" and the interest of this field in how people act toward things based on the meaning those things have for them. From the way individuals interacted with these key objects identified in the case study presented we can say that social groups and disciplines are not pre-existing but formed and dynamically sustained out of the interactions of individuals and their embodied knowledge and skills through these important objects.

Finally, it is important to note that it was not just objects that were found to have an important role to play in spanning the shifting and fluid boundaries encountered in this setting. Individuals in the form of the “technical artists” mentioned by one of the interviewees when describing the experienced and senior ‘leads’ of the studio, had vital boundary spanning roles to perform. As the work on interdisciplinary collaboration in IS development by Levina (Levina 2005) suggests, participants’ diverse backgrounds constitute powerful resources which help to shape the mode of collaborative actions and design.

5 CONCLUDING REMARKS

Drawing on data from a case study in a computer games studio we explored boundary objects in relation to the compelling, sensory and entertainment-centred game-playing practices that inform computer games design and development. Our analysis of this case study – the first of three such cases – highlights three set of objects found to have important boundary crossing roles in the design and development of computer games in this setting.

Paying particular attention to the importance of sensory and experiential characteristics in computer games and the need to bring together during their development diverse skills and expertise from art, design, and computer programming, the paper assessed the relevance of the notion of boundary objects in relation to the empirical evidence collected. While the importance of objects in the kind of collaborative work involved in the development of computer games was affirmed, the centrality given to the representational aspects of boundary objects in the original conceptualisation developed by Star
was found to be limiting (Nicolini, Mengis et al. 2008). In addition, the boundaries of social groups and the worlds they delineate were found to be fuzzy and shifting and far from stable in the way that the notion of a discipline would presume, with many individuals able to be part of more than one group and participate in more than one system of representations.

User experience and sensory and aesthetic considerations are increasingly taken into account in the design and development of software, hardware, and information systems (Bertelsen, Petersen et al. 2004; Fishwick 2006; Floyd, Jones et al. 2007), so acknowledging and understanding the multiplicity of roles that objects that participate in the interactions of social groups or even of the individuals involved in such forms of collaborative work is crucial. While the original notion of boundary objects developed by Star was important in terms of highlighting the role of objects in collaborative work and how common representational spaces are achieved in such situations, there is more than representation that these objects are involved in (Thrift 2007).

In a small way the games developers studied in this research and the importance to their collaboration of “the vision and emotion” of a game and how they deal with these elusive and difficult to represent entities in practice provide a glimpse of why the kind of research programme advocated by Ciborra (Ciborra and Willcocks 2006) “in which inner life is as important as surrounding circumstances, where the pre-theoretical is preserved by giving space to the moods, emotions and dispositions not linked to thinking”, is of such relevance.

Following on from these findings from the first case study, investigative effort over the next case studies will be directed towards trying to understand the techniques through which intuitive and difficult to represent aspects of the objects being realised through such processes of design and development – such as, for example, their sensory, aesthetic, or emotional appeal – are accessed and shared by those involved in their production.

Abstract

The service-orientation paradigm has not only become prevalent in the software systems domain in
recent years, but is also increasingly applied on the business level to restructure organisational
capabilities. In this paper, we present the results of an extensive literature review of 30 approaches
related to service identification and analysis for both domains. Based on the consolidation of a
superset of comparison criteria for service-oriented methodologies found in related literature, we
compare and evaluate the different characteristics of service engineering methods with a focus on
service analysis. Although a close business and IT alignment is regarded as one of the core beneficial
promises of service-orientation, our analysis suggests that there is a lack of unified, comprehensive
methodology for service identification and analysis integrating and addressing both domains. Thus,
we discuss how our results can inform directions for future research in this area.

Keywords: business-IT alignment, service analysis, service identification, service orientation.
1 INTRODUCTION AND MOTIVATION

The emerging and accelerating trend towards business networks of collaborating business partners and the anticipation of entire service ecosystems comprising dedicated service marketplaces increase the need for enterprises to engage in service-orientated approaches to be able to gain the flexibility and agility required to succeed in this changing environment (Cherbakov et al. 2005, Sanz, Nayak and Becker 2006). It is no longer sufficient to apply the paradigm of service-orientation to the advancement of technical software architectures only. Instead, entire business architectures are about to be restructured from a services point of view in order to allow flexible and reconfigurable collaboration scenarios in business networks. While services in general can be seen as abstract resources that represent consumable capabilities (W3C 2004) offered by a service provider who performs specific actions on behalf of a service consumer at a certain point in time and place and through some channel (Dumas et al. 2001), to be more precise, we thus have to differentiate between the following two basic views of services:

- First, service-orientation on the business level enables organisations to expose and offer operations as business services to business partners in order to facilitate on-demand collaboration opportunities. A business service is the outcome of a specific “chunk of operation” that is performed by an organisation (Sanz, Nayak and Becker 2006). These services can have different levels of granularity ranging from comprehensive offerings (e.g. purchasing services) to fine granular services (e.g. address verifications) (Bieberstein et al. 2005).

- Second, to enable business services and thus support the agility of organisations, service-orientation on the technical level fosters the utilisation of software services and enables a close business and IT alignment (Cherbakov et al. 2005). Software services expose application functionalities that can be re-used and composed based on business needs. Hence, a software service supports the execution of a business service.

These two different views are both addressed by the Organization for the Advancement of Structured Information Standards (OASIS) in their definition of Service-Oriented Architecture (SOA) as a “paradigm for organising and utilising distributed capabilities that may be under the control of different ownership domains” (OASIS 2006). Since these capabilities can relate to business functions and to application functionalities as well, this definition supports a holistic SOA view.

As a consequence of the proliferation of the service idea on both the business and the software level, there is now a demand for service engineering methodologies that cover both business and software services and provide an integrated, holistic approach to ensure business and IT alignment and agility. Service engineering in general is still regarded as a research challenge in the literature about current SOA research roadmaps (e.g. Papazoglou et al. 2007, Kontogiannis 2007).

In our research, we aim at identifying an existing or developing a derived methodology for service analysis that accounts for the holistic view of service-orientation with its two domains of application, the business and the software domain. Service analysis is one of the earliest phases in a service engineering process, which covers the whole lifecycle of a service. It is of particular importance, as any errors made during this phase can flow through to and build up in the design and implementation phases, which results in increased cost due to necessary rework (Inaganti and Behara 2007). Not surprisingly, the two basic views of services introduced above are also reflected in the propositions about the scope of service analysis (see, for example, the different definitions by Marks and Bell 2006, p. 58, and Papazoglou and van den Heuvel 2006, p. 417). In this paper, we view service analysis as a comprehensive phase where the concept of service-orientation is applied to analyse the capabilities provided by an organisation and to consequently identify services that are currently supported and could be supported by IT. This notion includes the analysis of the impact of service-orientation on the
business level as well as on the technical level, which is congruent with the notion and scope of SOA introduced earlier.

As a first step towards achieving our higher research goal, the objective in this paper is to begin with a contemporary overview and comparison of existing major service analysis-related service engineering methods covering business and technical viewpoints in order to analyse their characteristics in detail and to evaluate to which extent these approaches are ready for the emerging requirements as stated above. Such a comparison and evaluation will not only point out possible gaps and necessary directions for research, it will also provide a general overview of the methods that can be chosen to start a SOA endeavour.

This paper is structured as follows. The second chapter will provide an overview of related work in the area of service-orientation methods comparison. Subsequently, we will present the criteria that have been used to compare and analyse extant approaches for service analysis and we will define the composition of our sample in the third chapter. The fourth chapter represents the actual comparison and the evaluation of the approaches regarding the selected criteria. Subsequently, we will discuss the findings and directions for further research. The final chapter will provide a conclusion.

2 RELATED WORK

The domain of service analysis is still rather young. Although the number of service-oriented methods has grown significantly, our literature review yielded only a rather narrow set of papers dedicated to the comparison of existing service analysis approaches. Moreover, these papers exclusively focus on the analysis of approaches related to software services and are very limited in regard to the number of methods compared. We essentially identified three papers on the topic (namely Klose, Knackstedt and Beverungen 2007, Kohlmann and Alt 2007 and Ramollari, Dranidis and Simons 2007) that provided sets of criteria for the comparison of service engineering methods with a focus on service analysis. For an overview of these criteria, the reader may refer to Table 1, which is presented and discussed in the next section.

Klose, Knackstedt and Beverungen (2007) not only compare nine existing approaches and, as a result, note the lack of a unified method for identifying services, but also present their own proposed method, thus adding to the set of existing methods. The objective of their comparison of different methods is limited to an overview of the width and depth of a few existing methods. Kohlmann and Alt (2007) compare six methods related to service analysis and modelling, particularly focusing on their criteria on the set of activities relevant for those methods. Finally, Ramollari, Dranidis and Simons (2007) compare ten methods, which are related to the development of SOAs in general. Thus, the analysed methodologies have typically a wider scope than just service analysis.

The authors of these publications conducted their method comparisons for different reasons, so that the employed criteria are not completely congruent. For example, Kohlmann and Alt (2007) seem to have chosen criteria that reflect the strengths of their own proposed method, while Ramollari, Dranidis and Simons (2007) provide a more general overview of service-oriented development methodologies ideally covering the complete life cycle of a service.

For this paper, we have consolidated the criteria already used in the three analysed related research publications based on a clustering process (see next section) to provide a comprehensive set of criteria for the comparison of service analysis approaches for both business and software services, thus catering to the underlying comprehensive notion of SOA and services as introduced previously.
3 SELECTION OF COMPARISON CRITERIA AND SAMPLE

3.1 Selecting the criteria

To be as neutral as possible and to increase the validity of our research by building on the existing body of knowledge, we decided to make the superset of the criteria used in the three analysed related research papers the basis for the set of criteria to be used in our more comprehensive method comparison. As there were overlaps in the original criteria, we had to consolidate the superset based on semantic similarities. This task was conducted independently by two different coders and resulted in clusters that were almost 90% identical. In a discussion process, the differences were debated and resolved, thus leading to Table 1, which not only shows all the criteria used in the three related papers, but also their grouping in the new clusters and the labels assigned to these clusters. These labels eventually represent the criteria that we use in our own comparison. In the following, we will describe our criteria, briefly explain the grouping of the criteria from the analysed papers as reflected in the rows of Table 1 and also define symbols and abbreviations used in our comparison overview in Table 2.

Table 1. Clustering of previously used criteria to compare service analysis-related methods

**SOA concept:** To analyse whether both service concepts (business and software services) are supported, we selected SOA concept as a criterion reflecting whether an approach’s primary focus is on the derivation of business services (BS), software services (SS) or both (BS/SS). Klose, Knackstedt and Beverungen (2007) have utilised a similar criterion, but as their focus is restricted on software services only and, in addition, it is not clear what the foundation and the possible values of their criterion actually are, we abstracted from these specific values and only analyse if the SOA concept rather refers to business services or software services.

**Delivery strategy for SOA:** To address organisation-specific requirements (e.g. the need to leverage existing legacy systems), different delivery strategies for a SOA are conceivable. Hence, we need to analyse whether a particular approach supports the top-down strategy (T), where services are derived based on the analysis of business requirements (Erl 2005), the bottom-up strategy (B), which focuses on the derivation of services based on an analysis of legacy systems on an as-needed basis (Sneed...
or the meet-in-the-middle strategy (M) that combines the other two strategies (Inaganti and Behara 2007). The delivery strategy criterion was included to reflect which strategy an approach recommends to implement a SOA. To provide information about the particular starting point and focus of an approach, we included a textual comment in our analysis. Klose, Knackstedt and Beverungen (2007) call their related criterion ‘Background and starting point’, Kohlmann and Alt (2007) roughly differentiate between technical and business-driven identification and Ramollari, Dranidis and Simons (2007) just distinguish the three basic SOA delivery strategies mentioned above.

**Lifecycle coverage**: While some proposed SOA development approaches aim at offering support for the full SOA lifecycle, other approaches are more focused on a subset of the activities to be performed in the life of a SOA. This criterion has been derived by combining the criteria ‘Lifecycle coverage’ used by Ramollari, Dranidis and Simons (2007) and ‘Covering of SOA design phases’ as proposed by Klose, Knackstedt and Beverungen (2007). In our analysis, we use a trivalent scale (0, +, ++) with the following semantics: 0 stands for methods that focus on service identification and analysis only, while + represents methods with a service analysis and design focus and ++ finally marks more comprehensive approaches that include phases like implementation etc.

**Degree of prescription**: A service analysis method can be rather prescriptive and define a rigid, heavy-weight process with lots of details, or it can describe a more lightweight, flexible, less structured process that is adaptable and allows for an agile approach. This criterion is based on the ‘Degree of prescription’ criterion and the ‘Process agility’ criterion both introduced by Ramollari, Dranidis and Simons (2007), as we considered the two to be highly related. In our analysis, we use a trivalent scale (0, +, ++) with the following semantics: 0 stands for methods that are very lightweight, while + represents methods with a moderate degree of prescription and ++ marks highly prescriptive approaches.

**Accessibility and validity**: To be useful, a service analysis approach should not only be well documented, but the documentation must also be accessible, and the validity of the approach should be made clear. The documentation should provide many details, examples, ideas, case studies etc. to provide useful guidance in practice. Sometimes, methodologies proposed by vendors or industry players are proprietary. Typically, detailed knowledge about these approaches cannot be easily accessed, whereas non-proprietary approaches are openly available. Moreover, this criterion captures whether an approach has been validated or illustrated by presenting real case studies, whether it uses fictitious examples only or even remains on a purely theoretical level without any examples at all. Klose, Knackstedt and Beverungen (2007) (‘Documentation of the method’) as well as Ramollari, Dranidis and Simons (2007) (‘Availability’ and ‘Industrial application’) apply corresponding criteria for their comparisons. In our analysis, we used a three-valued tuple to describe the documentation (textual comment), the availability (trivalent scale with 0 standing for a proprietary, not openly available method, + representing a method that is at least partially documented for public use, e.g. in the form of papers about single activities that constitute the method, and ++ marks a fully open method) and the validation, e.g. in form of industry case studies etc. (textual comment).

**Adoption of existing processes/approaches/techniques/notations**: The proposed service analysis methodologies might utilise already existing techniques, procedures and notations that can serve as a foundation for the approach. Klose, Knackstedt and Beverungen (2007), for example, use their ‘Application of process models for service identification’ criterion to explicitly analyse if methods consider process models as input. Moreover, they introduce the ‘Proposal of IT criteria for service identification’ criterion to examine whether existing IT criteria (e.g. design principles, such as high cohesion and loose coupling) are proposed for service identification. Under the umbrella of their ‘Adoption of existing processes/techniques/notation’ criterion, Ramollari, Dranidis and Simons (2007) similarly analyse if methods propose reusing proven existing processes, techniques and standardised notations. Also, a number of criteria used by Kohlmann and Alt (2007) can be assigned to this cluster. For example, they analyse whether an approach comprises a ‘Domain analysis’, whether there is an ‘Alignment with process models’ and whether the emerging SOA architecture is illustrated using a...
‘Visualisation with service landscapes/maps’. In our own comparison, we describe the results for this criterion in the form of a textual comment to cope with the variety of possible result values.

**Regarding stakeholders:** As service analysis methods should address the requirements of potential stakeholders regarding services, Klose, Knackstedt and Beverungen (2007) (‘Regard to stakeholders for service analysis’) as well as Ramollari, Dranidis and Simons (2007) (‘Supported roles’) include respective criteria in their analyses. This criterion particularly reflects if the perspective of the service consumer is included or if solely the perspective of the service provider is addressed. To be flexible in our analysis, we use a textual comment to describe the value of this criterion.

**Service classification and clustering:** The criterion service classification and clustering describes if the method distinguishes different kinds of services. As the approaches do not use the same terminology for service types, we will only compare the approaches based on the number of different service types as an indication of the level of detail of each approach, similar to Klose, Knackstedt and Beverungen (2007) with their ‘Service hierarchies and classification scheme’ criterion. Kohlmann and Alt (2007) address this aspect implicitly by using the criteria ‘Service specification’ and ‘Examination of service cut’. They also introduce a ‘Service clustering’ criterion, which can be seen as a grouping mechanism above the level of individual services. In our analysis, we use a simple trivalent scale (0, +, ++) to indicate if there is only one single service concept in the method (0), if the method distinguishes between different service types but does not provide details (+) or if the method includes a detailed definition of the different service types (++).

**Additional characteristics:** This criterion is a placeholder for any other important characteristics of the analysed methods that seem important enough to be pointed out. For example, Kohlmann’s and Alt’s (2007) analysis if the respective methods postulate alignment with the sourcing strategy can be an aspect that is reflected here among others. We use a textual comment again to express aspects of interest in this category in a flexible way.

Having detailed the different criteria we employed to compare the various service engineering methods with a service analysis focus, the next paragraph will explain the selection process that was used to compile the sample of methods to be analysed.

### 3.2 Selecting the service analysis-related service engineering methods

After having defined the criteria for the comparison of extant approaches, we had to identify those prominent service analysis-related methods that were the most appropriate candidates for our analysis. We did not aim at a representative sample but rather at a comprehensive mix of approaches reflecting the broad spectrum of different characteristics. To this end, we made sure to not only include academic work, but also approaches developed by the largest providers of packaged business applications such as IBM, Microsoft and SAP (Genovese 2007). We ensured that the sample included both top-down and bottom-up approaches. Another requirement was that each approach to be included explicitly referred to the concept of service-orientation. The sources of the methods are manifold as they range from journals (e.g. Papazoglou and van den Heuvel 2006) to conferences (e.g. Klose, Knackstedt and Beverungen 2007), books (e.g. Erl 2005) and white papers (e.g. SAP 2005). The final sample of analysed extant approaches can be found in the first column of Table 2, which also shows the characteristics of each approach with regard to the selected criteria. The ordering of the list of approaches in Table 2 allows the visual identification of different classes of approaches according to the underlying SOA concept (BS, BS/SS, and SS), which are separated by thicker lines in the table. For the category of approaches that are only concerned with software services (SS), subclasses can be identified depending on the delivery strategy for SOA (T, T/M, M, M/B, or B) separated by dashed lines.
4 METHOD COMPARISON AND EVALUATION

The comparison of the 30 extant service engineering methods as reflected in Table 2 was conducted independently by two coders, whereby the second coder restricted the analysis to a random control sample. The results of the coding process of the control sample were consistent with the results of the original coder. In the following, we describe our observations that resulted from the analysis of the 30 methods for each criterion used in the comparison process. The criterion “Additional characteristics” will not be elaborated on as it is assumed that the description provided in Table 2 is self-explanatory.

SOA concept: SOAs containing primarily business services are less prevalent than SOAs for IT infrastructure. Jones (2006), OASIS (2005) and Sehmi and Schwenger (2006a) propose approaches that do not directly apply to the concept of a business service. Nonetheless, the underlying concepts can be adopted for the identification of business services. Flaxer and Nigam (2004) and IBM (2005) explicitly define business services, but a detailed approach for the identification of these services is missing. Kaabi, Souveyet and Rolland (2004) identify business services based on goal-modelling, which can then be supported by software services.

Table 2. Comparison of the 30 approaches
All other approaches focus on the derivation of software services, although the term business service is used to distinguish between services that encapsulate business logic and services that encapsulate application logic.

**Delivery strategy for SOA:** The delivery strategy for SOA is partially dependent on the underlying SOA concept. Approaches, which address the analysis of business services, postulate a top-down strategy for the delivery of services. Regarding the scope and depth of these approaches, none of them provides a detailed description of how to include existing (legacy) systems into the analysis. For example, Sehmi and Schwegler (2006a) propose a pure top-down approach that describes how a business model can be implemented using software services. As their method has been incorporated in Microsoft's 'Motion Methodology' (Merrifield and Tobey 2006), all details are not openly available. The starting points for the business service analysis vary widely. Jones (2006) and OASIS (2005) postulate a method that does not necessarily rely on any models or documentations, but on the collaborative analysis of the business of an organisation. IBM (2005) addresses business services as provisions of business components, whereas Flaxer and Nigam (2004) propose to analyse business entities to identify business components and business services subsequently. A bottom-up strategy for business services could not be identified.

Approaches addressing the derivation of software services postulate one of the three described delivery strategies. The top-down approach is supposed to derive a high quality SOA that is built on well-designed services and service compositions. However, depending on the size of the company and on the scope of the SOA initiative, a top-down strategy may consume significant resources, such as money and time, without showing an immediate outcome, since the upfront analysis has to be conducted before actually deriving services (Erl 2005; Gold-Bernstein and Ruh 2004).

Contrarily, a pure bottom-up strategy to deliver software services typically comprises activities that analyse existing legacy systems in order to define fine-grained services that can be linked to business processes and business requirements (Sneed 2006). Hereby, one can distinguish between two types of bottom-up analyses. Non-invasive legacy approaches encompass methods that do not change the structure of the legacy code (Nadhan 2004; Al Belushi and Baghdai 2007). They propose to build wrappers around the functionalities and components of the legacy system, so that they can be used in a service-oriented environment. Invasive legacy approaches aim at self-contained software services that encapsulate the functionalities provided by the legacy systems by restructuring the respective legacy code (Chen et al. 2005; Sneed 2006; Zhang, Liu and Yang 2005).

An interesting point is that most approaches postulate a meet-in-the-middle strategy that takes into account business requirements as well as existing legacy systems to combine the advantages of both strategies. Thus, the advantages of a high quality SOA have to be weighed against reality constraints applied by the legacy systems. Arsanjani (2004) as well as Zimmermann, Krogdahl and Gee (2004) describe what an overarching approach could look like, but they fail to go into detail, as their approaches are proprietary.

**Lifecycle coverage:** Regarding the lifecycle coverage, it is obvious that the scopes of the methods vary widely. While certain methods specifically focus on the analysis phase (e.g. Klose, Knackstedt and Beverungen 2007), others also address the service design phase (e.g. Kohlmann and Alt 2007) or even address the complete lifecycle (e.g. Erl 2005, Papazoglou and van den Heuvel 2006). However, as a unified, standardised life cycle for services or SOA is not prevalent in literature, authors addressing the life cycle of a service propose such a life cycle in the course of their publication.

**Degree of prescription:** Some of the approaches do not provide any structured guideline or process to derive services. These approaches give general suggestions about what to do, but do not provide information on how it should be done (e.g. Arsanjani 2004). Thus, they can be used or must be used in a flexible manner, as detailed application steps are missing. Nonetheless, most of the analysed approaches provide some kind of procedural model to identify business services or software services. The steps or phases for the identification are very approach-specific. For example, Rahman et al. (2006) propose an Model Driven Architecture (MDA) approach that focuses on the derivation of three
specific models (three phases) to identify services. Jones (2006), on the other hand, proposes four steps within his identification framework that can be used to identify services.

**Availability and validity:** There is a strong correlation between the documentation of the method within the respective publication and the application in practice. Typically, if the method has been applied in practice by conducting a case study, the case study will be described within the paper. If the method has not been applied in practice, typically just basic examples are presented.

**Adoption of existing techniques/processes:** Different methods relate to already existing concepts. Zimmermann, Krogdahl and Gee (2004) compare service-orientation to component- and object-orientation, as does Chang and Kim (2007), for example. Some methods specifically relate to UML, such as Stojanovic et al. (2004) to model services, which is widely applied in industry. Other methods utilise very specific languages or techniques that are tailored to their respective needs, e.g. Zhang, Liu and Yang (2005) or Quartel, Dijkman and van Sinderen (2004).

**Regard to stakeholder:** Stakeholders are addressed differently by the analysed methods. Some do not consider stakeholders at all (e.g. Arsanjani 2004), whereas others address stakeholders during the identification of services (e.g. Jones 2006, Sehmi and Schwegler 2006a, Kaabi et al. 2004 and Klose, Knackstedt and Beverungen 2007). However, the way the stakeholders are addressed varies amongst these methods. For example, Jones (2006) analyses the way in which external stakeholders interact with the services of an organisation, whereas Klose, Knackstedt and Beverungen (2007) analyse the stakeholder involvement in the service delivery process by examining the takeover and visibility potential of different process steps.

**Service classification:** Different authors propose different classification schemes based on the scope of their proposed approaches. Some approaches only provide guidelines to derive services in general, others distinguish between basic types of services and a few provide a classification scheme with descriptions of the objectives of each service. In the case of business services, no classification scheme based on the analysed approaches could be identified. For example, Arsanjani (2004) as well as Sehmi and Schwegler (2006a) propose decomposition approaches that can be used to identify services, but no classification for services is provided. If the SOA concept of software service is addressed by the approaches, different levels of details are observable. For example, Sneed (2006) and Zhang, Liu and Yang (2005) do not provide any classification and thus propose approaches that generally identify software services. Zimmermann, Krogdahl and Gee (2004) provide a rough differentiation between services, whereas Erl (2005), Klose, Knackstedt and Beverungen (2007), Kohlmann and Alt (2007) and SAP (2005) offer more detailed classification schemes. As the naming of the different services is not standardised, a proliferation of homonyms and synonyms can be encountered.

5 DISCUSSION

The number of publications that broach the issue of service engineering including service analysis has increased in recent years, but to the best of the authors' knowledge, a comprehensive analysis of the coverage and specific characteristics has not been sufficiently conducted yet, particularly not against the background of evaluating the fitness of extant methods in regard to requirements resulting from the trend towards an integrated application of the service paradigm in organisations on both the business and the technical level.

Our research has yielded a framework of criteria that was used to describe the characteristics of a significant sample of service analysis-related methods in detail. One benefit of this framework of criteria and the method comparison is that they support the process of method selection by an organisation, as they facilitate the definition of a set of desired method properties based on individual requirements and the subsequent evaluation of the methods against these desired characteristics. The second benefit of our results is that they are suitable to suggest ways how to address identified shortcomings. For example, based on our analysis we conjecture that there is currently a lack of methods that meet the requirement of a holistic service analysis method - the requirement that
motivated our research in the first place. A consolidated method should comprise business services as well as technical services. Thus, a comprehensive method needs to provide guidelines about how to identify business services that can subsequently be supported by software services. In the following, we discuss first suggestions how the results of our analysis can inform the design of such an improved method. Investigating the overlaps and complementary aspects of the analysed methods, one can apply the concepts behind method engineering (Odell 1996) to outline what a consolidated, comprehensive method may look like.

For example, we identified several commonalities and complementary aspects of the analysed methods (e.g. common starting points, different phases supported etc.). An earlier version of the method published by Jones (2006) has been used to serve as the foundation for OASIS (2005). These approaches can be complemented with the method proposed by Sehmi and Schwegler (2006a) and IBM (2005), thereby creating the foundation for the identification and analysis of business services. As processes are one of the underlying elements of a business service as defined by Sanz, Nayak and Becker (2006), methods proposing to use process models as a starting point for service analysis can be utilised. As our analysis pointed out, the majority of methods actually utilise process models for the analysis of services. For example, the methods proposed by Klose, Knackstedt and Beverungen (2007), Kim and Doh (2007) and Kohlmann and Alt (2007) could extent a detailed comprehensive method as the one developed by Erl (2005), as the different steps to derive services are complementary. Other methods use compatible starting points that could potentially be converted to be complementary to the process-driven approaches. For example, a use case corresponds to the activities and goals of an elementary business process and hence, the concepts behind the identification of services of use case-oriented approaches can be consolidated with the approaches focussing on process decomposition. Zimmermann, Krogdahl and Gee (2004) point out, however, that successful service analysis and design requires a focus on processes first, as it is necessary to analyse more than one system at a time to derive adequate services. The approach by Gold-Bernstein and Ruh (2004) can be adapted to business process models, as they propose that a table with events occurring during the operations of an organisation be used as the foundation for deriving services. These events can also be represented within a business process if they are brought in a sequential and logical order. Other approaches build upon one another and thus overlap to a certain extend.

Once the software services are identified, one needs to consider the actual application landscape that provides the needed functionality, as proposed by Erl (2005) and Inaganti and Behara (2007). The actual implementation might utilise methods for invasive or non-invasive code restructuring (Zhang, Liu and Yang 2005 and Nadhan 2004, respectively). Further research will need to show how a detailed consolidated method can be developed and how applicable such a method will be in practice.

6 CONCLUSION

In this paper, we have compiled a framework of comparison criteria that was used to provide an overview and analysis of 30 extant service analysis-related service engineering methods that can be used as a starting point for the journey into service-orientation. The comparison presented is the first step towards filling research gaps as proposed in recent research road maps of SOA and motivated in the introduction of this paper. The analysis supports the conjecture that there is currently a lack of a comprehensive service analysis method that comprises the identification and analysis of services on both the business and the technical level, thus ensuring a high level of business and IT alignment and agility. Our research has pointed out initial considerations for the consolidation of existing methods to achieve this goal through further research.

MEASUREMENTS, FEEDBACK AND EMPOWERMENT: CRITICAL SYSTEMS THINKING AS A BASIS FOR SOFTWARE PROCESS IMPROVEMENT

Øgland, Petter, Department of Informatics, University of Oslo, P.O. Box 1080 Blindern, 0316 Oslo, Norway, petterog@ifi.uio.no

Abstract

While organizations in software industry want to portray themselves as professional in terms of following standards and methods, they may also have needs for improvising and short-cutting when necessary. Such dilemmas of dual logics are sometimes internally resolved by evolving a false belief of what is done (practice) being in correspondence to what is said (standards), regardless of what an empirical investigation might show, something that can have poor business implications and also poor social implications. Particularly focusing on this latter point, the meta-methodology of total systems interventions (TSI) has been used for integrating critical systems theory with total quality management, improving social conditions in parallel with improving business processes. Although TSI is not designed for liberating organizations where nobody see themselves in need of liberation, the hypothesis of this paper is that it is possible to design quality management systems as “conflict machines”, causing sufficient social tension for more or less automatically changing “fake quality” into “real quality”. The hypothesis is investigated by applying design research in a Scandinavian public sector organization. The findings consist of statistical and interpretative evidence for the success of the approach, making a contribution to how TSI can be applied in the software industry.

Keywords: Software process improvement, total systems interventions, design research
1 INTRODUCTION

Selecting an effective strategy for designing software process improvement (SPI) systems can be a difficult problem, depending both on technical issues related to the complexity of production processes, software products, chosen set of SPI standards and practical engineering of the control system, and on social and cultural issues.

According to Brunsson et al (2000, p. 130), extensive research since the mid-1960s has shown that “there may be substantial differences between presentation and practice, between formal structures and actual operations, and between what people say and what they do. […] Actors have dual systems which are decoupled from each other; they may argue that they follow a standard while not doing so in practice. This is a phenomenon which standardizers seldom appear to notice, or at least seldom discuss seriously in public”.

Indeed, in many of the classic references on total quality management (TQM) and software process improvement (SPI) (e.g. Crosby, 1979; Deming, 1986; Juran, 1993; Humphrey, 1989), the main issue is on issues like explaining the importance of aligning quality control with business strategies, measuring customer satisfaction, implementing the methods in a technically sound manner, and getting sufficient management commitment for making sure that the system will be developed and sustained. The issue of organizations pretending to follow standardized principles of TQM or SPI just to win contracts or attract customers, and how this influences culture, is seldom addressed.

Primarily focusing on the internal politics of organizations along the vertical axis of management and labour, Flood (1993) has developed an approach to TQM based on systems thinking and critical theory. The idea is that TQM should be understood in a holistic perspective and it should be used for improving social conditions along with business processes. The idea of implementing TQM in this way was developed as an application of a more general framework called Total Systems Intervention (TSI) (Flood & Jackson, 1991; Jackson, 2000). TSI has been a topic for discussions in academic journals for systemic research (e.g. Tsoukas, 1993; Flood, 1994), has been used as a framework for doing action research (Green, 1992; Flood, 2006), and it remains an interesting topic among both researchers and practitioners in the area of TQM (Taiwo, 2001; Beckford, 2002; 2009).

However, as Beckford (2002, p. 301) points out, “the process of [critical thinking in TSI] is, of course, only useful where all parties are willing to contribute to the process and to make adaptations based upon the findings”. This does not present TSI as a promising approach when we deal with organizational dualism, implying primarily external motivation for implementing SPI. On the other hand, a well-known challenge in knowledge management systems design is that knowledge is political, meaning that changing the flow and distribution of knowledge may have consequences for explicitly and implicitly existing organizational power structures (Davenport & Prusak, 1998).

The hypothesis in this research is that (1) a political SPI system, exploiting political tensions induced by creation and distribution of knowledge, can be designed to fit with the ideas and framework of TSI, and (2) this type of political knowledge management approach can create a stable SPI process (improvement process) in an environment where there is otherwise little support for making SPI work.

In section two, a more detailed theoretical presentation of the revised TSI model will follow. This is followed by a section three concerned with the design of empirical research for exploring and evaluating the model in an empirical context of looking at how SPI is practiced among software engineers, managers and administrative staff in a Scandinavian public sector organization. The results of this investigation are reported in section four, pointing out aspects of the SPI project that were successful and aspects that failed. Finally, in section five, the empirical findings are used for evaluating the model, summarising the research in terms of pointing out how the political analysis leads to political guidelines all aimed at creating tension along the vertical and horizontal axes of the organization and making sure that the critical approach can be maintained.
2 PROCESS IMPROVEMENT BY SYSTEMS INTERVENTIONS

As SPI can be seen as TQM applied in the area of software engineering (Humphrey, 1989), generic quality management standards, such as the ISO 9000 standards and guidelines, can be used as framework for SPI. In the ISO 9000 series, there is a difference between control and improvement (Hoyle, 2006), that corresponds with what Argyris & Schön (1978) refer to as single loop learning and double loop learning. Quality control is the task of making sure that processes are carried out in compliance with standards and regulations (single loop learning). Quality improvement deals with challenging and improving such standards and regulations (double loop learning).

The diagram below illustrates the single loop learning of auditing a quality management system (QMS) used for defining a SPI system. The QMS contains all procedures and standards that describe how software engineering shall be carried out in a given organization, and this set of documents is used as a reference point \( r(t) \) when doing audits \( y(t) \). If there is a mismatch \( e(t) \) between practice \( y(t) \) and procedure \( r(t) \), that should function as a point of action \( u(t) \) for management.

![Diagram](image)

Figure 1. The basic configuration of a simple closed-loop control system (DiStefano et al, 1990, p. 16)

Mathematical theory of control systems started in electrical engineering, but has later been used both metaphorically and technically for studying both technical and social systems (Berlinski, 1976). In order to study the audit control system in figure 1 from a mathematical perspective, one would typically need a description of the relationship between \( u(t) \) and \( y(t) \) in terms of differential equations, and areas to be looked into would typically be observability, controllability and stability of the system (DiStefano et al, 1990).

2.1 Total Systems Intervention (TSI)

TSI evolved as a method for solving two problems; how to apply critical social theory in management problems based on a systems approach, and how to select the best systems methodology depending on the nature of the management problem to be solved (Jackson, 2000).

Doing TSI consists of going through three phases. First there is a phase labelled “creativity” that consists of using metaphors for trying to see to which extent various metaphors may give insights on problems and perspectives of the organizations (Morgan, 1980). Secondly, there is a phase labelled “choice” that deals with choosing an appropriate systems-based intervention methodology to suit particular characteristics found through metaphor analysis. As the makers of TSI experienced some difficulty in getting managers to understand Morgan’s way of linking metaphors and sociological paradigms, Jackson (2000) develop a simplified method called the “system of systems method”. Thirdly there is the phase of “implementation” which means that the conventional implementation strategies of Viable Systems Methodology (Beer, 1972), Soft Systems Methodology (SSM: Checkland, 1981), Critical System Heuristics (CSH: Ulrich, 1983), or whatever systems approach
chosen is implemented, given that the implementation of a chosen methodology or mix of methodologies is employed according to the logic of TSI (Jackson, 2000, pp. 368-370).

Although practitioners working with TSI as an approach for implementing TQM reported successful results, theoretical criticism came from academia, questioning the use of metaphors for framing problems, the way metaphors linked with methodologies, whether TSI practitioners could be expected to have the enormous amount of systems theory knowledge that seems to be needed, whether each of the methodologies catalogued by TSI are as different as the framework assumes etc. (Jackson, 2000, pp. 371-374). As a consequence of such questions, TSI theory keeps developing (e.g. Flood, 2006).

What TSI still seems to lack in its analysis, however, is that the people responsible for designing organizational interventions may neither represent the workers nor the managers, but could be considered a separate group. In his comments on the early days of Operational Research (OR), Beer (1968) points out that there were ongoing tensions between managers and scientists. The scientists developed an understanding of the organizational problems from a mathematical point of view, although with little practical understanding. The managers had a practical understanding developed through experience, but little conceptual understanding in terms of mathematical models. This resulted in mutual distrust.

Rather than trying to provoke labour and management through the kind of critical questions suggested by CSH, for an organization that is only pretending to be committed to SPI, it is an underlying assumption in the hypothesis stated in this paper that it may be better to design the SPI system as a conflict machine, a system that is not primarily designed for making people think less in order to work more efficiently but rather as system that contributes to the production and distribution of knowledge in ways that are likely to challenge current power structures. The idea is to build tension along the management/scientist and labour/scientist axes and use debate that results from this for making the organization focus on the management/labour axis.

In 1996, Flood and Romm redesigning TSI in the language of triple loop learning. Figure 2 illustrates the principle of how the nested loops are represented with different types of logic. The innermost loop of the system tries to answer the question of how to improve efficiency, how to reduce error rates, how to increase customer satisfaction etc. If a SPI problem is formulated in a clear and well-defined way, there is a large body of literature from OR that could and should be used. However, if the problem is neither clear nor well-defined, there is a body of literature on Problem Structuring Methods (PSM: e.g. Rosenhead & Mingers, 2001) that include various methods for organizations to reach mutual understanding of problems. SSM is one of the most used methodologies of this category. The aim of PSM is to address the question of what the problem is. Finally, there is a third loop that aims as questioning why are given problems focused in the first place. Whose interest are people serving by solving the given set of problems? Who is gaining power? Who is losing power?

![Figure 2. Triple loop learning as a way of describing TSI (Flood & Romm, 1996)](image)

The control loop in figure 1 gives a more detailed description of the first loop in figure 2, suggesting mathematical notation and logic that fits with the rationality of OR. The single loop learning aspect of quality management can be a highly difficult problem from a technical point of view, but from a social
point of view it is banal in the way that it simply consists of measuring whatever people are doing against the organizational standards of how it should be done.

Second loop learning in TQM is socially more challenging, as this loop consists of getting people in authority to interpret what is going on, try to make sense out of these interpretations and then choose targets for technical investigation and improvement. As Checkland (1981) argues, problem structuring methods such as SSM contain elements of critical thinking in the way that they challenge the views encoded in the single loop learning. Perhaps the problem being solved by the current OR loop is not the right problem to solve? An SSM analysis can bring in the perspectives of different people in the organization, producing a collective understanding of the organization and business, and cause radical changes in the understanding of what should be studied and improved.

For a SPI system to comply with the ISO 9001:2000 standard, the system must have elements of double loop learning. Not only do the ISO 9001 clauses require that process should fit with procedure, but procedures and all aspects of the QMS are to be audited and challenged on a regular basis (e.g. ISO 9001 clause no. 4.1; see: Hoyle, 2006). But, as argued by Brunsson et al (2000), the fact that an organization is required to practice double loop learning does not necessarily mean that it does, even if they are certified against ISO 9001 and being regularly checked.

The third loop in figure 2 is something that does not read naturally as a part of ISO 9001:2000, and something one would not expect to find in management consultant literature (Legge, 2002). From a business point of view, the aim of the organization may be issues like making a profit, or delivering services at high quality with low cost. On the other hand, there may be other agendas. The purpose of the third loop is to identify such agendas, help people to discover that they may be imprisoned by agendas they don’t know, don’t understand or may be unhealthy, and then to help in the process of liberation (Critical Systems Thinking, CST: Flood and Jackson, 1991), the socially critical aspect of TSI.

2.2 Adding the idea of a “SPI conflict machine” to TSI theory

As observed by Bénézech et al. (2001), the fact that the ISO 9001:2000 model can be interpreted as a double loop learning model means that a management system (or a SPI system) compliant with ISO 9001:2000 can be seen as a knowledge management system.

Although not explicitly stated by Flood (1993), one way of interpreting his use of critical theory as a foundation for TQM could be to say that quality management systems are not tools for managers to exercise command and control (e.g. Braverman, 1974), but they are rather tools for workers to gain knowledge and power over their own work situation, become experts and be able to challenge oppressive power structures.

In order to give people freedom, it is necessary that knowledge becomes visible and available. It is necessary that the implementation of TQM follows a strategy that is based on how knowledge about quality of processes and products affects the power structures of the organization. As pointed out by Davenport and Prusak (1998, p. 177), one of the main challenges in the implementation of knowledge management systems is that current power structures may be based on keeping people unaware, only letting an inner circle of people have knowledge that matters.

Reyniers and Tapiero (1995) discuss the design of contracts and the control of quality in a conflictual environment through the use of game theory. They model the situation between the supplier and producer as players in a nonzero-sum game, where the supplier can control the effort invested in the delivery of quality and the producer may or may not inspect incoming materials. In their paper, they state (p. 373) that the traditional approach to statistical quality control does not recognize that quality management often takes place in a conflictual environment.

The game design suggested in this paper, in order to make SPI work as a “conflict machine”, is to regard the QMS as the rules of the game, use quality indexes (measurements of compliance with QMS
standards) as payoff functions (“score”), turn the game from into a “perfect information game” (like chess, unlike the “imperfect information game” of bridge) by distributing the scores vertically and horizontally across the organization, aligning knowledge distribution strategies with power strategies as they may be identified through experience and analysis.

The most important design aspect of this SPI game design, however, is to make sure that the game is kept alive, in other words make sure that it does not challenge those who are capable of destroying the SPI system (“the owners of the system”; Checkland, 1981, p. 318).

3  METHODOLOGY

In order to investigate the effect of the revised version of TSI, the TSI method has been implemented and tested in an organizational setting, and a design research framework has been implemented (Simon, 1996; Hevner et al., 2004; Iivari, 2007). The design research approach is illustrated in figure 3, where the emphasis is on showing how the engineering cycle and the research cycle run in parallel through iterations of four stages, the engineering cycle applying theory while the research cycle aims at contributing theory. The ellipse marked “model” in the middle of the figure corresponds with the models discussed in the context of the theory in section 2 above with section 2.2 containing specifications for the design/artefact to be evaluated in the context of a TSI implementation.

In practical terms, the way the engineering cycle is used as a framework for research is by using the assumption of a successful design and statistically stable design process as hypothesis, considering the design process as an experiment, and look at the design evaluation as a test of hypothesis. This idea was originally formulated by Shewhart (1939) as a way of thinking about quality control in the field of mass production as a framework for scientific investigations, where he suggests the use of statistical process control (SPC) as a way of testing the hypothesis that the design process is statistically stable (“assignable causes have been eliminated”; Shewhart, 1939, p. 150).

As the experiment is based on a short number of life cycle iterations, the X-MR chart will be used as SPC-design (Clark, 1999, pp. 86-90). In addition, as there are controversies among statisticians as to how SPC links with statistical hypothesis testing (e.g. Woodall, 2000), the testing of whether the SPI process is stable or not will be done by visual judgements (Interocular Traumatic Test, ITT) as suggested by Roberts and Sergesketter (1993, p. 64).

If the test should indicate that the SPI process is perfectly stable during TSI, this should indicate that similar designs should be carried out under other conditions, such as other units within the same
organization or, preferably, other organizations. Otherwise, if the test should indicate problems, exploratory research needs to be carried out.

3.1 Population, research procedures, data collection and analysis

The setting for investigating the changed version of TSI is a software engineering unit within the IT department of a Scandinavian public sector organization. The unit to be discussed consisted of about 20 people, more or less equally distributed between males and females. The average age was about 40. Half of the people were systems designers who were also responsible for testing the system on large scale, while the other half were programmers that implemented the design in COBOL software and did detailed tests. The system followed an annual life cycle model, and all people were involved in writing and updating system documentation.

The initial version of the system was implemented in 1998, and the first few years consisted of making the solution fit with the original systems requirements. During the time of investigation, the system had reached a level of maturity where the life cycle work mostly consisted of making adjustments and improvements as requested by the ministry. Although the TSI implementation was carried out through annual cycles between 2003 and 2005, aligned with the lifecycle model, earlier project documentation was also used. Three evaluation reports were produced during the TSI experiment, as decision support for management at the time of the annual life cycle when the system went into production. The reports were written by the author of this paper, then functioning in the role of quality manager being assisted by quality coordinators for doing audits and tests. The final analysis has been conducted after the TSI projected was completed, depending to a certain degree on retrospective reflection.

4 CASE STUDY

4.1 Evolution of the SPI system from a technical perspective

As a part of the design research approach, the tools for evaluating the design evolved as a part of the evolution of the software process improvement (SPI) system. In the context of this narrative, the SPI system consisted of the strategies, policies and standards that made up to documented part of the quality management system (QMS) and the QMS practices that were carried out in terms of checking whether the documented system was being followed, recording problems, and taking corrective and preventive action.

Prior to taking contact with the unit in question, some interviews were first carried out with IT top management and representatives of the internal audit. In both these cases, it was pointed out that the QMS for this particular unit was one of the better systems of the organization. People were following the rules, as they should, and there was organizational learning in terms of continuous improvement.

Reading the reports from internal audit and generating a general overview of the documented part of the QMS, it quickly became obvious that there were no independent quality audits, at least not in the way required by the general QMS. Perhaps the QMS worked perfectly within the unit, people following standards as they should, but there was no way of knowing this without establishing a practice of doing quality audits.

A quality audit system was easy to implement as the procedure V10 for doing audits was written and just waiting for being put into use. Separate audits should be done along the software development life cycle, including the phases (1) threat and risk assessment, (2) quality planning, (3) requirements analysis, (4) analysis, (5) implementation, and (6) test. As a final checkpoint on procedure V10, the audits should be summarized and presented to management as input for the acceptance procedure N7.
As there were detailed standards for how to document and carry out work within each of the phases above, it was easy to develop simple checklists that was then used for ticking off and producing quality indexes for measuring compliance on a scale from 0 to 100 percent, defining $e(t)$ in figure 1.

The diagrams in figure 4 show the final results of plotting the average of all quality indexes year by year. Indexes for the years 2000 to 2002 were constructed by performing quality control of old documents and old software, while the more recent indexes were computed along with the design process and used as immediate feedback. Control limits for X-MR are based on values 2001-2003.

![Figure 4. Total quality index and improvement rate (annual increase in total quality index)](image)

As the X-MR diagram on the right hand side in figure 4 goes slightly above upper bounds in 2004, the null hypothesis of instability due to assignable causes cannot be rejected. The assignable cause for the anomaly is that the QMS consists of procedures and practice, and much of the practice was carried out by the quality department through their SPI design research rather than by the people in the unit themselves, indicating that increase in improvement rates may be a direct cause of the TSI approach.

Using a t-test with four degrees of freedom for comparing improvement rates before and during TSI made it possible to reject the null hypothesis of no difference in sample average at a significance level of 0.022. Recalculating control parameters for separating the process prior to intervention and during intervention, the average improvement rates would first be 0.6 before TSI and 3.6 during TSI. A SPC design based on X-MR only for the TSI period showed no indication of instability.

![Figure 5. Total quality index and improvement rate (annual increase in total quality index)](image)
When decomposing the total quality index into what was measured (the final year) for each of the six phases of the software cycle, the left hand side of figure 5 shows how the compliance between different phases differ. The right hand side of the figure shows the development of the column marked “assessment and risk analysis” on the left hand side of the figure, showing how the practice in this part of the life cycle got less and less compliant with the standard. Another indicator systematically evolving in the wrong direction (not included in the diagrams here) was a process capability indicator for measuring the ability of the production indicator to be within required limits.

4.2 Evolution of the SPI system from a social perspective

During the interview with the IT top manager prior to investigating this particular SPI system, the quality manager (author) was specifically being told to think about the organization and the systems development processes through the metaphor of a machine. The IT manager made some drawings in the air, indicating that he was thinking in terms of a hydraulic machine pumping information through the organization and out to the users and owners (ministry).

The systems approach used for structuring the problem of investigating the SPI was partly based on SSM-like principles like discussing with various people while drawing “rich pictures” in order to figure out how they differed in their understanding of the system. When doing audits of software engineering practice against the software engineering standards, this feedback was useful for understanding the gaps while not preventing gaps from being documented.

This approach, mixing conversations with measurements, became the implementation method that was followed consistently during the three years of the experiment.

**First year:** Reporting the findings upwards in the system caused emotional stir. People felt they were doing as best as they could, performing and documenting much better than what was required by the standards, and felt humiliated and demotivated by quality audits giving them scores in terms of numbers (“quality index”) and so on. They wrote a letter to the general director (head of the larger organization) and complained about the situation. The quality manager never got a copy of the letter, but was told by the IT manager that there were some misunderstandings and that quality audits should continue as planned.

**Second year:** Based on previous year’s unfortunate circumstances, it was important to be gentle yet sufficiently specific in order to help the software unit to improve. However, as new versions of documents were audited, the same errors and lack of compliance with standards remained. Little improvement. The people said they did not have time to improve, just to do what was absolutely necessary. Besides, they felt quality audits focused too much on process and forgot about the product. They said they took pride in producing products of high quality, and methods (means) for achieving such excellent results were of less importance as long as the results were good.

**Third year:** Trying to respond seriously to what people were saying, the same audits from the previous year were repeated but now expanded in order to include product quality indicators. Using statistical analysis, the quality management people found that the main production indicator for the system was rapidly declining, as could be seen from updates of the annual Cpk capability index (Deming, 1994). When presenting this finding to the systems and software people, they said this had to be the result of socio-geographical dynamics, not a phenomenon they could control. When asked about whether it would be a good idea to improve the prediction algorithm that caused the problems, they said they had no time for dealing with such issues. It was too difficult. They had been told to follow a given formula, and it was not their task to analyse whether this formula was optimal or not.

In 2005, after the study was completed, the people in this particular unit took part in rewriting software engineering standards to be used for further SPI. When the software engineering standards were updated, many of the changes in the methods and standards were of a kind that would give higher score according to the quality audit system but would make the method itself significantly worse. For instance, the process of updating requirement documents was eliminated.
5 DISCUSSION AND CONCLUSION

The development of the SPI system followed the three stages of TSI. **Creativity:** The quality manager was explicitly told to think about the organization as a machine. **Choice and implementation:** According to Flood (1993, p. 81), typical systems methodologies fitting with the machine metaphor are the classical management frameworks described by Taylor and Fayol. In order to carry out the technical part of quality audits, this was done according to the professional guidelines of quality engineering, i.e. in a machine-like manner.

However, this rigid design proved useful in making people respond and reflect upon the standards they had defined for their own work. When presenting the results of audits, a “soft systems approach” was used, in order to figure out what people were thinking, how one could solve the situation together, asking people what they would do if they were responsible for doing quality audits etc.

Unlike Flood’s attempts to ask critical questions for making people reflect, the method of trying to force people to follow their own standards by first “measuring the facts” and then doing SSM-like discussion, worked well for creating debate. Particularly the way audits and quality reports were widely distributed made the QMS into a “conflict machine”.

5.1 The illusion of excellence as a mental prison

It is not too difficult to see how the organization was imprisoned in a belief of high quality and continuous improvement, while the measurement of practice against standard indicated low degree of compliance with internal quality standards and continuous spiralling in the wrong direction. Similar to the cases reported by Brunsson et al (2000), the organization had locked itself in a situation where there was no measurable feedback on whether they were doing the right thing or not, only good intensions, hard work, and occasional verbal feedback if production went well.

It did not improve matters that the internal audit had investigated the unit, been impressed by standards, written procedures and system documentation without going into depth when analysing how this was used. The result of this may have been twofold; firstly adding to the beliefs of the organizational unit that they were doing things as expected, and secondly enrolling the internal audit into the same “fake quality” belief system, as it would be easier to accept the happy belief that the unit was doing fine rather than to question the quality of their own audit methods.

Although not specifically mentioned in the case study, as it happened prior to the time when the TSI experiment was carried out, the national audit had done a similar overview audit to what the internal audit later did, also contributing to the general belief that everything was fine. In other words, it would almost come as a surprise if these people were not trapped in an illusion of excellence and internal bliss, like Adorno’s interpretation of Odysseus and the lotus eaters (Sherratt, 2000).

5.2 The liberation process

As explained in the story, the “fake quality” was easily revealed through quality audits as what people were saying did not fit the results of the audits. When confronted with the facts, the response was a mixture of surprise, irritation and what they described as “unfair game” of being measured and having the measurements distributed upwards and sideways in the organization. The crash between their self-perception of what they were doing and the measurements caused emotional outbursts and intense debate.

In other words, liberation through quality management was in this case a process of agony and frustration, and it remained a difficult process during all three years of the experiment. While there were no dramatic changes during the period of experimentation, there were signs of improvement in
terms of discussion and awareness of quality management issues that seemed to have been more or less totally ignored after the QMS had been documented and made into “shelfware”.

Although some of this liberation resulted in attempts to fight the quality department and attempts to change the software engineering standards for producing better score without resulting in higher quality, the main reason for applying critical theory as a foundation for SPI should not be to force people follow standards or force them do what the quality department wants them to do, but it should be to generate debate about standards and make people take responsibility for their own software engineering processes.

The fact that the software engineers got the methodology group to remove the maintenance of the requirements documents from the software engineering methodology (end of section 4.2), despite the fact that the organization was required to keep a ten year record of requirements, was an interesting example of how SPI can be a political game of accepting and distributing responsibility. Although a strategy like this would be helpful for improving the score for the software engineers, the overall impact on the organization would be a step backwards down the maturity ladder if assessments had been done through CMM or similar SPI models (Zahran, 1998).

5.3 Theoretical implications for the TSI model in software process improvement

Although the SPC diagram and statistical reasoning in section 4.1 do not contain sufficient data for making judgements that would convince a properly trained quality engineer, the results are consistent with the interpretative narrative.

The interpretative part of the study provide the key insights on what happened, although a rich case like this contains actors and actions responding and reacting in different ways. By thinking about SPI as knowledge management rather than control, the design idea of using (1) horizontal benchmarking, (2) vertical jump-reporting and (3) improvisation for preventing those in power to destroy the TSI implementation, made the SPI system work successfully as a “conflict machine”.

Although three years was a rather short period for a case like this, and the fact that the design was particularly made to fit with the internal power struggles in a hierarchical public sector organization, the design idea (section 2.2) worked well, making a theoretical contribution on how TSI can be applied in the software industry.

The overall interpretation of the case study is that the use of critical thinking as a foundation for SPI was a fruitful idea that should lead to more empirical research.

MOBILE INFORMATION SYSTEMS AND ORGANIZATIONAL CONTROL: A FOUCAULDIAN APPROACH

Leclercq-Vandelannoitte, Aurélie, IESEG School of Management, 3 rue de la Digue, 59000 Lille, France, a.leclercq@ieseg.fr

Abstract

The latest advances in the field of communication tools and networks have led to the development of ‘mobile’ technologies. Mobile technologies provide workers with almost permanent access to their company’s Information System (IS) and continual availability of information in time and space, thereby contributing to the development of “mobile IS.” Mobile IS generate a reconstruction of the relationship between time and space, and act as catalysts of deeper social and human changes, leading to ambivalent effects in the field of management. More particularly, a paradox emerges with respect to mobile IS as they can be considered in turn as instruments of autonomy and freedom or control of distance activities. To what extent are the interactions between mobile IS and organizational actors liable to change the company’s control systems? In this paper, we argue that a Foucauldian approach can enrich our understanding of the evolution of organizational control linked to mobile IS. We present the results of four case studies (based on 85 semi-structured interviews and 10 days of observation). This research shows the relevance of Foucault’s conceptual framework (linking discourses, discipline and ethics) to explore the interactions between IS, the organization and individual actors, in a political perspective.

Keywords: Mobile information systems, management control, organizational change, surveillance, case study, IS philosophy (Michel Foucault)
1 INTRODUCTION

The latest advances in the field of communication networks and data processing tools have led to the development of ‘mobile’ technologies. Mobile Information Technologies (IT) cover a wide range of terminals, such as mobile phones, laptops, personal digital assistants (PDA) and tablet PCs, linked to networks comprising numerous information resources. Lyytinen & Yoo (2002) define mobile technologies as a “network of interconnected technological, social and organizational elements”, enabling mobility which is both “physical and social” for the players concerned. Mobile ITs transcend company boundaries and are frequently used in contexts outside business, reflecting the emergence of a form of ‘multicontextuality’ (Henfridsson & Lindgren 2005). They provide us with almost permanent access to a company’s Information System (IS) and continual availability of information in time and space, thereby contributing to the development of “mobile IS.” Mobile technologies generate a reconstruction of the relationship between time and space, and act as catalysts of deeper changes that go hand in hand with the use of these tools. Both the concept of work and management and the way companies operate are directly affected by the development of this culture of mobility and the technologies that are its reflection. As they revolutionize the traditional time-space aspect of organizations, they are likely to give rise to new forms of work organization. Today, work is no longer understood as a place, but rather as an activity that can be performed outside traditional spatial and temporal frameworks.

A global discourse, conveyed by the media, IT constructors, and companies, links mobile IS to new types of flexible, responsive, dynamic and non-bureaucratic organization systems. The advent of mobile IS thus accompanies managerial and organizational discourse linked to employees’ empowerment, emancipation, autonomy, delegation and flexibility. Nevertheless, the characteristics, uses and challenges mobile IS throw up for the organization and management also engender new issues with respect to control. These technologies enable a control of distance activities (Wiredu and Sorensen 2006). In consequence, a paradox emerges with respect to mobile IS as they can be considered in turn as instruments of autonomy or control. Our aim in this paper is to analyse the ambivalent effects of mobile IS in relation to hierarchical relations and control. In addition, if the advantages companies reap from the integration of mobile IS appear undeniable, it is important to keep in mind that the systems are adopted by organizational players who must familiarize themselves with these tools before using them. Mobile IS thus raise the issue of the acceptance of a new form of work organization and re-engineering the relations with the company, reflecting a process of technological, social and human change. It is therefore also important to consider how individuals use these mobile IS, how they perceive the new working conditions that combine autonomy and control, and how they may influence the evolution of systems of control. To what extent is the use of mobile IS in an organization liable to change the company’s control systems and what are the ensuing grounds for appropriation? In this paper, we argue that a Foucauldian approach can enrich our understanding of the links between organizational control and mobile IT. This paper is structured as follows. In the second section we present a literature review about the potential links between mobile IS and organizational control. The third section explores Michel Foucault’s conceptual framework. The fourth section provides a description of our research method. In the fifth section, we present the successive results of four case studies. These results are then interpreted and discussed in a sixth section. In the final section, we present the contributions and limitations of our research and give some suggestions for future research.

2 MOBILE IS AND ORGANIZATIONAL CONTROL

2.1 Mobile Information Systems and paradoxical effects

It is now widely acknowledged that mobile IS provide an innovative answer to the challenges generated by a competitive, changing and global environment that is shaped by hyper-competitiveness, where companies are subject to cost constraints and an ever greater need for reactivity with respect to their clients and partners. As Varshney (2003) points out, mobile technologies are a way of
introducing a new form of “flexibility, in terms of time and place” into organizations, and in this sense, they offer businesses promising opportunities. Employees can log onto their company’s IS and be in contact at anytime and in any place (Robey et al. 2004). The benefits are numerous, the first being an increase in individual productivity through a decrease in work constraints, greater flexibility, and reduced coordination costs. With enhanced communication and knowledge exchange, these technologies also allow information to be accessed immediately, provide improved decision-making performance and consequently greater reactivity (Davis 2002). More and more companies now provide their employees with mobile ITs, primarily field workers such as sales representatives, consultants and technicians, but also more sedentary workers.

However, the advent of mobile IS and their use within companies can lead to negative side effects which recent studies have brought to light (Robey et al. 2004, Cousins and Robey 2005, Besseyre des Horts and Isaac 2007). Demands for almost permanent availability and responsiveness appear to have developed alongside the use of mobile IS by organizations. When employees use mobile technologies, companies have access to a potential form of “digital traceability” (Robey et al. 2004), which can give rise to a certain degree of stress. Information and cognitive overload is also linked to the use of mobile technologies within business organizations. Often encompassing a notion of continual availability, the utilization of these technologies raises a number of issues with respect to infringement of private life and the breakdown of borders between private and professional life (Cousins and Robey 2005). It also leads to issues of fragmentation and interruptions at work (Davis, 2002), fostering distraction rather than time for reflection. Similarly, employees may feel oppressed by the emergence of a culture of speed and instantaneousness and a sense of permanent urgency, which obliges them to make over-hasty decisions or decisions in contexts unsuited to decision-making. In addition, as Lytinen and Yoo (2002) pointed out, several levels of analysis are affected by what they term “nomadic computing,” not only at individual level, but also at the level of the team, and, more widely, the organization. Consequently, it is likely that evolutions in employees’ space-time norms, and the lack of face-to-face interaction will impact on cooperation, cohesion, trust between colleagues, group decision-making and, more generally, interpersonal relations.

Notwithstanding, mobile technologies may be considered as particularly equivocal tools, whose effects cannot be predicted in advance, either in terms of social interaction or of company management (Arnold 2003, Jarveenpa and Lang 2005). To this effect, Cousins and Robey (2005) highlight the contrast between the expected benefits and the unexpected social impact resulting from mobile system environments. At a time when management practices are being reinvented around mobility via the porous nature of time and space, it is important to consider the issues involved in mobile IS and the renewed management style they engender.

2.2 The evolution of control systems associated with mobile IS

More particularly mobile IS raise a challenge concerning the evolution of control systems. Control can be defined as “the effort exercised by managers, not just to collect and share information, but also to use information for directive purposes with their units: the aim is to encourage or provoke a general reaction from the people who report to them” (Mintzberg 1994). A focus on the informational dimension of organizational control indicates that the latter is enabled by data processing and storing. In consequence, given their capacity to save, store and analyse information flows, information technologies are far from being neutral elements with respect to control. Furthermore mobile technologies offer both continuity and discontinuity in comparison with other generations of technologies. They perpetuate certain practices and management methods, such as task allocation, process standardization and activity control (Zuboff 1988), but the liaison opportunities they offer also pave the way for new means of communicating, exchanging information and working outside the traditional corporate space-time framework. Mobile IT revolutionize the traditional time-space aspect of organizations. For instance management today is no longer confined to the company premises but may potentially be practiced anywhere, at anytime and in unexpected contexts. Management is no longer limited to the traditional idea of time-space and no longer necessarily occurs in a context of shared action.

A paradox emerges with respect to mobile IS as they can be considered in turn as instruments of autonomy or control, freedom or servitude. While mobile IS represent a means to promote flexible, responsive, dynamic and non bureaucratic organization systems, they may also be perceived as
instruments that reinforce control and demands in terms of availability and responsiveness, as well as employee traceability, acting as a sort of “electronic lead”, that goes way beyond organizational boundaries (Sorensen and Gibson 2005, Jarvenpa and Lang 2005). Mobile IS appear as tools to enhance the independence and mobility of the workforce, but they are also symbolic of the preservation of the “hierarchical line,” even beyond the company boundaries. More specifically, mobile technologies reflect a dichotomy through the autonomy they offer and their potential as instruments of control (Zuboff 1988). The same technology can thus be considered in two different ways that are entirely contradictory. Jarvenpa and Lang (2005) highlight the different paradoxes that result from the use of mobile IS, some of which are directly linked to control and autonomy, the individual’s decision-making freedom and the constraints that influence their activities (Besseyre des Horts and Isaac 2007). The paradoxes between freedom and servitude, independence and dependency, improvisation or planning, engagement or disengagement, are all conflicting consequences that arise from the use of mobile IS, which reflect both autonomy and control (Besseyre des Horts and Isaac 2007). According to Wiredu and Sorensen (2006), mobile IS raise the question of organizational control, insofar as they play a major role in the control of distance activities.

2.3 Important issues at stake

Mobile IS are far from being neutral tools of communication and information transmission. On the contrary, they may influence systems of control and take place in political contexts, constituted of hierarchical relationships, interactions between organizational actors, power games, negotiations, and conflicts (Markus 1983). Given that mobile IS influence the very foundations of collective action, the space-time dimension of human experience and interpersonal relations, it seems necessary to analyse the political dimension, the power balance and the issues at stake during mobile IS implementation. Different stakes arise, such as the political dimension of these interactions and also attitudes when confronted with control and the technologies that sometimes support it. Given the control potential of mobile IS, it is important indeed to hone in on the attitudes and practices that individuals adopt, and the different interactions possible between individuals and mobile IS. Mobile IS implementation not only represents a technological change but also social and human ones. It is therefore also important to consider how individuals perceive the new working conditions that combine autonomy and control. Even if the individual cannot always choose to accept or reject the technology in an organisational context, he can still choose the manner in which he appropriates it, via varying levels of engagement or involvement. Individual attitudes thus have a necessary influence on systems of control linked to mobile IS implantation. Despite the fact that IS are directly involved in control issues, their effects are in no way predetermined. We should therefore avoid any “determinist perspective”, adopting instead an “emergent perspective”, which dwells on the interactions of system and context of use and offers a means of identifying the political dimension of dialectics between control and IS (Markus 1983). An emergent perspective highlights the interactions between the technological, individual and organizational choices, together with their integration in a political context involving the interactions between players and their relation to power (Markus and Robey 1988). This analysis highlights the importance of placing our research in an overarching framework that enables us to analyse the ambivalent effects and the paradoxes of mobile IS in terms of control, with a focus on the interactions between the players, the organisation and IS. It seems necessary to develop a conceptual framework to explore the relationships between individuals, the organisation and technology in the light of control issues, at the same time taking the political dimension of these interactions into consideration. As shown in the following section, our attention was drawn to the thinking developed by a particular theorist, Michel Foucault. We believe that his work provides tremendous potential for developing a new approach to technological and organizational change.

3 CONCEPTUAL FRAMEWORK: THE RELEVANCE OF A FOUCALDIAN PERSPECTIVE

This section provides an analytical framework based on Michel Foucault’s work, whose main concepts can provide in-depth insights when applied to research in management and IS.
3.1 Three conceptual entities: discourse, discipline and ethics

Foucault’s genealogical method, which focuses on three conceptual entities - “discourses”, “discipline” and “ethics” - appears highly relevant in analyzing some emerging forms of organization, closely linked to the effects of information control promoted by IS.

3.1.1 Discourse:

Foucault (1971) examined the social effects of the knowledge produced by discourses. According to Foucault, discourses both create and control the objects they claim to know. The social world is organized and normalised in specific ways through discursive practices. The Foucauldian perspective shows that discourses are far from neutral, and constitute the “crucial way” to the exercise of power. For example, in his early writings, Foucault shows how madness, prisons, the body, life, death, and above all human beings, progressively became the objects of observation and new scientific discourses, which offer “an insidious form of social control.” In this way, organizations can be seen as political arenas where discourses are manipulated to influence individuals. Several studies in organization theory focus on the discursive practices that constitute organizations as regimes of truth and discipline, and act as a powerful constraint on the organizational members (Sewell and Wilkinson 1992, Barker 1993, Knights 1997). Organizations are considered as political spaces where discourses are constituted (Barker 1993) to better control organizational members. Foucault emphasizes the deeply relational nature of power and its incarnation in discursive practices which convey representations of the organization and technology.

3.1.2 Control mechanisms and discipline:

This focus on discourse, truth and knowledge enables Foucault to develop the image of a disciplinary-based modern society. In this disciplinary society, various means, technologies and practices - such as “hierarchical observation”, “normalizing judgment”, and “dressage” - are used to govern men. Hierarchical observation, combined with division and classification practices, enable to closely supervise organizational members. Moreover, a deep process of normalization enables to establish goals, to compare individuals and to make distinctions between modern subjects. Finally, “dressage” practices render bodies and minds obedient, docile and useful. Foucault (1975) explains how the soul, conscience and thought progressively became the primary objects for punishment and rehabilitation. These practices enable to discipline and to correct abnormal behaviours. Every aspect of human life is controlled through the construction of a “micropower.” Foucault uses the metaphor of the “panopticon” developed by Bentham (1791) to represent this disciplinary power. In panoptic architecture, observers can observe all prisoners without the prisoners being aware that they are being watched. The panopticon is characterized by invisible surveillance, a depersonalization of power, an embedding of controls, and subtle coercive mechanisms. In this way, technologies can be seen as object of disciplinary power, while the development of specific discourse legitimizes its adoption and use. Many authors relied on this panopticon metaphor to show the role of IT in surveillance, though the concepts of “electronic panopticon” or “electronic eye” (Willcocks 2004; Lyon 1994).

3.1.3 Ethics and resistance:

Because of his developments regarding disciplinary power, Foucault was accused of developing his own “iron cage,” where the human subject appears passive and subject to an entire disciplinary society. This led Foucault to develop his consideration of “ethic” for and “care of the self”. Foucault (1976-1984) describes a responsible individual actor who is able to resist disciplinary practices. “Here Foucault focuses on a more active, individual subjectivity, less imprisoned in and less constructed through scientific discourse and power relations, more geared to self-knowledge supporting work of self on the self, to constitute a self-stylization able to separate from subjectification practices” (Willcocks 2004:248). Foucault considers that individuals are able to find satisfaction in constraining situations through ethics. Foucault identifies different kinds of “technologies of the self” which allow individuals to work on themselves by regulating their bodies and thought and by constructing their identity (McKinlay and Starkey 1997). Modern subjects can subvert the conditions of their own subjectivity and constitute themselves as moral agents through ethics (Willcocks 2004).
3.2 The Foucauldian perspective: toward a renewed overarching theoretical framework

The ideas developed by Foucault provide us with a conceptual framework with powerful heuristic possibilities. At the centre of Foucault’s thinking, the concept of “power-knowledge” provides us with a tool to grasp the links between his conceptual entities (discourses; power and control; and human agency). Power produces knowledge, and discourse and knowledge have power and truth effects. “Power and knowledge directly imply one another…there is no power relation without the correlative constitution of a field of knowledge, nor any knowledge that does not presuppose and constitute power relations” (Foucault 1975). This concept implies that disciplinary power permeates the social body through power-knowledge relationships. But it also reveals that power relations are not merely negative but productive as well. “Power must be analyzed as something that circulates…Power is exercised through networks, and individuals do not simply circulate in those networks: they are in a position to both submit to and exercise this power. They are never the inert or consenting targets of power; they are always its relays” (Foucault 1975). In consequence, there are no relations of power without resistance. Foucault identifies the existence of norms that condition behaviours, but meanwhile recognizes that individuals are able to resist such norms.

Foucault’s main concepts can be usefully harnessed to management research, particularly in IS research. Foucault’s ideas encompass the issues of discourse with respect to a phenomenon, control and resistance within a single conceptual framework, at the same time placing the individual at the heart of the question. Foucault endeavoured to bring out the relative character of “discourse” and truths by identifying “power/knowledge” games that both engender and drive them. ‘Man’ is not simply an object of knowledge, but is also an object of power, which is expressed in micro-physics and disciplinary technologies. Beyond these disciplinary mechanisms, however, ‘Man’ also appears as a moral agent, subject to a certain form of behaviour and motivated by a deep “care of self” ethic.

The Foucauldian approach moreover provides a novel definition of technology, allowing us to consider IT as an “electronic panopticon,” and also as technologies embedded in the micro-physics of life, power relations, discourse, and resistance moves. Willcocks, for example, develops an analysis of “behavioural and social technologies encoded in material technologies” (Willcocks 2004, p.289), while Knights and Murray (1994), developing a Foucauldian perspective, consider IS as “a set of human and non human artefacts, processes and practices, ordinarily directed toward modifying or transforming natural and social phenomena in pursuit of human purposes.” Technology mirrors a vision of the organization and the intentions of decision-makers, but its effects can never be predicted in advance. Developing a Foucauldian approach, Bloomfield suggested: “Technology does not impact on organizations or society: a change in social relations, tasks, skills and knowledge is already prefigured in the way that the technology is conceived and constructed. Machines do not control social relations: they presuppose, mediate and reinforce them” (Bloomfield 1995, p.497).

As regards our research question, the introduction of mobile IS into the workplace has given rise to certain arguments concerning the transparency provided by these technologies, the increase in autonomy and the potential for new forms of work organization to emerge. A Foucauldian perspective enables us to see beyond these discourses and understand how such technologies are employed in systems of control. The Foucauldian approach thus provides a means to analyze how certain technological resources may be used in a hierarchical relationship and what changes arise as a result of these tools in terms of organizational control and autonomy. Moreover this approach enables us to explore individual reactions and attitudes towards technology and underlying effects on systems of control. Thus, at a time when management is built around discourse, a Foucauldian perspective provides an interpretative framework that helps us understand how certain technological resources may be used in a hierarchical relationship via power-knowledge relations, and how control systems can be influenced by individual interactions. This approach informs the development of a political model of technological and organizational changes in organizations, that we will confront to reality in a qualitative empirical study (Figure 1).
4 RESEARCH METHOD

Our study has adopted a “dialogical perspective” (Leidner and Schultze 2002), which allows us to study the nature of a constructed reality as well as the impacts of power-knowledge and discipline. We developed a qualitative study of four cases, representing high diversity, to explore the empirical contributions of a Foucauldian approach to the analysis of interactions between mobile IS, individuals and organizations from the perspective of organizational control systems. This empirical research study includes different kinds of data: primary data consist of semi-directive interviews and direct field observations. Secondary data include internal documentation, meetings, and press reviews. We interviewed different levels of respondents: managers and top managers (CEO, CIO, human resource managers, operational managers, middle managers, area managers) and field workers (equipped with mobile IT). Our qualitative analysis was developed from both a deductive and an inductive perspective: on the one hand and in accordance with the deductive principle, we identified a priori the main topics (based on Foucault’s conceptual entities which informed the interview guide) related to organizational discourses linked with mobile IT deployment, impacts on the ways of governing employees (control systems, discipline, authority versus empowerment, flexibility, autonomy, decentralization, and delegation), and individual reactions (acceptance of change, resistance moves, adoption and appropriation of mobile technologies). At the same time, in accordance with the inductive perspective, other themes, as expected, emerged from the corpus of transcriptions. Different interview guides were prepared beforehand based on our literature review and in accordance with the different functions performed by respondents. Every interview began with general questions about the respondent (his or her role and responsibilities) and then covered wide-ranging, open topics linked to mobile IS implementation, impacts on systems of control and individual reactions.

A total of 85 semi-structured interviews of approximately 90 minutes were conducted in four French companies between January 2006 and November 2006. Ten days of direct in the field observation were also carried out in order to enrich our analysis. These interviews were tape-recorded and fully transcribed. We first conducted an infra-case analysis, in other words, an in-depth analyses of cases, followed by inter-case analyses, that is to say pure comparative analyses, which enabled us to identify consistencies between the cases, and to isolate recurring elements that are common to several cases and identify disparities. The interviews were subjected to a qualitative thematic analysis, using Nvivo software to reduce and codify the data. We applied a mixed and rich thematic coding system and performed textual and Boolean searches. We also employed double-coding as a means to check the reliability of our analysis.
5 RESULTS

The first case, Technoplus, involves a French family company with 160 employees specialized in retail of industrial products. In 2004, suffering from fierce competition in its sector, the company decided to improve its customer responsiveness by equipping its technical-sales staff with mobile technologies. Every sales representative was given a Blackberry, directly connected to the company’s commercial IS. This technology was presented by management as a means of increasing the employees’ responsiveness and productivity, while reinforcing their autonomy and responsibility, as all necessary information was now at their disposal from a distance. The sales manager thus expected the technical-sales representatives to become “autonomous entrepreneurs” in their respective area. The introduction of mobile IT was justified by a climate of urgency and a demand for greater customer-centred involvement. According to the CEO, the technical-sales representatives were largely involved in the development of this technological project. Nevertheless, we should stress that the technical-staff representatives were only allowed to give their opinion on minor aspects of the technological development. Furthermore, the fact that representatives were associated with the technological deployment was used by the CEO as an argument to prevent any resistance from employees. As they had been party to improving the device, they were no longer in a position to resist or express deviant opinions. In fact, mobile IT deployment was unilaterally and rapidly introduced, characterized by a highly directive style of use. Furthermore, initially legitimized by an imperative of responsiveness, mobile IT use progressively turned into an obligation, a duty of efficiency and performance for these representatives. The CEO explained that they had no other choice than to be responsive, available, efficient, and high-performing. Moreover, the introduction of mobile technologies led to some changes in the control methods. Before the development of mobile IT, control methods relied on management by objectives and commission, and was essentially based on trust. The introduction of mobile IT reinforces surveillance over technical-sales representatives, with increased visibility and follow-up, and a normalization and homogenization of behaviours. The discourse deconstruction we carried out for example reveals a metaphor of visibility in the management interviews. Representatives must fill in a sales report in real time, just after their visits. These reports directly inform the sales manager, who knows exactly how many visits have been made by representatives during a certain period of time. The sales manager thus has the possibility to compare the representatives’ performances, to identify anomalies and gaps, and to correct abnormal behaviours. This first case thus demonstrates the panoptic evolution of control systems. Mobile IT give the management control over the behaviour of their mobile staff that the company could not manage physically. The technical-sales representatives nonetheless adopt different attitudes to mobile technology, depending on their profile and experience, and have various representations of the underlying changes in control methods. Some uses are in line with senior management expectations, while others are more or less deviant. For example, some sales representatives take advantage of mobile IT to structure and organize their activities; others use mobile IT as instruments to demonstrate to their managers their involvement in the company; on the other hand, the more experienced representatives claim they don’t need such tools and deliberately neglect their sales report. In these specific cases, the company management accepts such practices as these representatives are generally good professionals. These disparate uses may reflect adherence to objectives, hostility to organizational goals, or recourse to habits. The case finally shows the capacity of representatives to resist and the identification of sources of satisfaction in a set of social relations that are constrictive by nature.

The second case, ABConstruction, involves a very large French building company (38,500 employees), where a mobile IT project entitled “Sesame” has been developed to improve data management and optimize processes. Site foremen have been equipped with Tablet PCs, directly connected to the company’s IS, in order to enter the data relative to the building site directly into the system. The Sesame project enables more reliable and rapid data tracking and is supposed to avoid double entries. The project generates other effects linked to the equipping of site foremen with new mobile IT, such as enhancing their role and repositioning them at the heart of company. Top management moreover relies on these induced effects to promote the project to site foremen who are unfamiliar with new IT. Major discourses around the site foremen’s empowerment and role enhancement are developed to promote their acceptance of the technology. A satisfaction survey
carried out among a few site foremen was widely disseminated within the company, for example, to gain the support of other site foremen, and even to generate a sense of shame among those who were on the verge of rejecting the project. This project led to major changes in processes, practices, and control systems. Before the Sesame project, site foremen had to fill in a paper report, which was then transmitted to the accounting services for control and validation. Because they knew there were multiple checks, site foremen didn’t usually pay a lot of attention to these reports. Moreover, they were directly supervised by their operators, who regularly visited building sites to check that procedures were respected. Many site foremen would therefore offload their report onto their operators. The company’s top management team progressively considered these controls and checks by administrative services and operators as a waste of time and efficiency. As the site foremen’s position in closer to the building site, they hold crucial operational information for their company, so management decided to give them the means to enter their data and report directly in the IS. The site foremen’s responsibilities and relationships with their operators consequently evolved, as they now had to manage the building site expenses. The technologies at their disposal became “disciplinary” technologies, in the sense that they introduced rigour to the practices and provided a form of distance surveillance. This technological deployment led to a transition from controlling execution to controlling objectives/results (project profitability). The control systems changed from close, direct supervision to self-control procedures for site foremen who were firmly invited to check the data they entered in the system themselves, including the amounts for expenses. The empowerment and greater autonomy of the site foremen thus engenders new obligations and constraints for them that represent an evolution which is at times difficult to accept. As a consequence, the site foremen adopt different attitudes. Some of them seem to appreciate their management team’s initiative and feel valued and recognized by the hierarchy. Others tend to resist this organizational change which they consider as a top management initiative that goes against their own identity. They resist through deviant uses of the technology, by making voluntary mistakes in their report for example. Although they are in a subordinate position, they know they hold power (linked to operational information relative to the building site and to their position on the site foremen recruitment market). Such information constitutes resources which make them less disposed to obey. They therefore develop a strategic use of the technology at their disposal and finally manage to overturn managerial intents.

The third case, GammaCom, involves a large French telecommunications company (7400 employees), which decided to install a system to optimize interventions on its telecommunication network sites. Every day, different teams of technicians have to maintain or repair network sites. The new technological system is composed of a smartphone, connected to software which plans the interventions of technicians every day, depending on the needs of the network sites and the localization of the technicians. Every technician is equipped with a smartphone which dictates the list of jobs he has to do every morning and the approximate time he should spend on each site. The software is based on a geo-localization system, which enables the management to know exactly and in real time where the technicians are. Top management argues that this technological deployment should improve the technicians’ profitability and security. Nevertheless, the technicians immediately considered this system as a means of controlling their activities. It is true that some problems occurred in certain teams in the past, when technicians were accused of putting their own interests first when planning their interventions, instead of optimizing their round. To solve such problems, the new system makes the technicians follow a given round. This system thus leads to changes in the control systems, which rely on structuring behaviours. Mobile IT appear in this case as direct supervision tools. It’s all the more important to note that the management stresses the discipline potential, and uses the notion of surveillance as an argument to structure technicians’ behaviours. The upshot of this discourse around potential surveillance is that most of the technicians expressed strong reticence linked to concerns about loss of freedom. They therefore try to take advantage of the technology by adopting different attitudes. Some of them, for example, circumvent the system by switching off the geo-localization device in their car when they want to cut themselves off (at lunch or in the evening for example). Moreover, most of them reinvent the sense of technology and use it as an instrument of proof for their hierarchy, arguing that the technology is a means for them to demonstrate their involvement to their managers, for example. They thus develop a defensive use of mobile devices.
Finally, we should note that such actions lead the technicians to legitimize the technology and underlying control system.

The fourth case, Eurobank Consulting, involves a consulting firm composed of 12 consultants. These professionals work in a context characterized by fierce competition from leading consultancy agencies. A general ambient discourse conveys the idea of urgency and hyper-reactivity in this specific sector, where time appears to be a key resource. In order to increase efficiency and optimize time, the company has moved towards an agile and flexible organizational form. Consultants are increasingly allowed to work at distance, from home, for example, and to limit their movements to visits to customers. Surprisingly, no mobile technologies have been deployed in this company, except in the case of associates who are equipped with modern and sophisticated devices (in a statutory logic). On the contrary, the consultants are generally left to find their own equipment for professional purposes. They are fully aware of the need to be available and reactive. According to the managers, no particular control system exists within Eurobank Consulting. They claim that the company is characterized by an extremely flat management system, absence of control, and a relationship of trust with the consultants. They apply a management by objectives system, so that control is focused on “deliverables” (services provided to customers). In fact, the consultants create their own rules and use a form of self-control. The consultants consider that working outside traditional hours is a moral obligation and they remain available through mobile IT use. Following a long socialization process, they associate specific values with their job of consultant (involvement, responsiveness, discipline linked to time pressures). They finish by accepting implicit organizational rules as their own rules, and believe that they respect values they have developed on their own. In the end, their flexibility and freedom appear to be a disguised form of “coercive autonomy.” This case indicates the emergence of a subtle, invisible form of control via the mobile technologies used and the emergence of a permanent availability. As they consider involvement to be their duty, the consultants construct their own control system via mobile technology which is reinforced by temporal pressure.

6 DISCUSSION

6.1 Unanimous discourse regarding efficiency to recognition of diverse concepts of control

A summary of the cases studied shows the existence of unanimous discourses concerning efficiency and reactivity, which legitimize and justify the introduction of mobile IS in organizations. This discourse gives a dominant place to the notions of liberty, emancipation, autonomy and empowerment of mobile populations, together with a democratization of access to information (especially in the cases of Technoplus, ABConstruction and Eurobank Consulting). There is a counterpart to this culture of transparency, however, as it applies to the individual’s behaviour with efficiency consequently becoming a duty. A Foucauldian perspective provides a counterview to the idea of individual empowerment by showing that the delegation of responsibility generated by these technologies gives rise to new obligations which are just as constricting. Nonetheless, these constraints and, to a larger extent, the issue of control, are often neglected in the discourses. To be more precise, they are exploited in different ways by the senior management teams in the companies we studied. Our cases show the existence of discourse manipulation tactics, illustrating different visions of control and trust, depending on the populations in question. Discourse is thus manipulated to orient individual behaviours (for example, threat of surveillance is upheld to structure the technicians’ behaviours in the case of Gammacom while, on the contrary, the panoptic evolution of control systems at Technoplus is completely hidden behind the official discourses, so as to promote acceptance by the sales representatives, who are used to having a certain amount of power in their commercial area).

6.2 Changes to control systems

One of the main changes to control systems in the cases studied is the emergence of a time-related discipline system, enabling people who are by definition mobile in space and visually ungovernable to be controlled. Through the use of mobile IS, time effectively becomes an instrument for locating people, an organizational norm, and a governance technique. The organization thus uses time to
control individuals who cannot be compartmentalized in space. This shift may be likened to the move towards “control societies,” characterized by continuous control and instant communication (Deleuze 1990). The structuring of mobile populations in space-time leads to different and flexible forms of control, as they adapt to the populations in question through surveillance and bureaucratic control, target-based management and control via the shared values (concerted control). Let’s highlight that the different forms of control enabled by mobile IT, observed in our case studies (bureaucratic control, target-based management, and control via the shared values), correspond to the various disciplinary technologies identified by Foucault himself (hierarchical supervision, normalization, and dressage). The case studies also show a shift in the location of exercise of authority, as individuals take on an increasingly active role in the control process. (Some actors are led to legitimize the technology and underlying control system, while others directly participate to the construction of their own control). Lastly, this analysis enables us to highlight the subjective dimension of control, which depends on the vision that individuals have of their autonomy and control, as well as the use that is made of the technology by the manager. Control depends on the information needs of the activity, and the perceptions developed with respect to the mobile populations in question. These findings explain the emergence of different kinds of control. At the end of the day, technology does not necessarily imply ‘de-bureaucratised’ forms of control, as more subtle forms of control are involved via technology.

6.3 Individual reactions or the importance of power-knowledge relations

The cases studied highlight different reactions and forms of appropriation, identified by applying a Foucauldian perspective. In some cases, individuals develop highly proactive and positive attitudes with respect to technology, whether they are aware of their control potential or not. Self-discipline, the search for a certain degree of satisfaction and equilibrium in the professional and private sphere, and the emergence of personal reflexivity, are all reflections of the trend towards the adoption of technology. Other cases provide us with insights into the resistance of some individuals, with some forms of resistance motivated by the notion of identity and the vision of job function and autonomy. A Foucauldian approach also provides insights into the interactions between the individual, technology and the organization in the framework of a power-knowledge relationship that is highly evolutive, and that should be repositioned in a wider institutional and societal context.

7 CONCLUSION

As mobility becomes a central feature of society, exploring the evolution of control systems in relation to mobile IS is a key issue in the field of management and IS research. It is also a key issue for practitioners in the field of human resource and IS management since it has a direct bearing on change management and the adoption of technologies. Our research shows the relevance of Michel Foucault’s conceptual framework (linking discourses, discipline and ethics) to explore the interactions between IS, the organization and individual actors, particularly from the viewpoint of hierarchical relations and control systems. we need to take a critical look at our research approach given its anchoring in the Foucauldian perspective: this research itself contributes to a regime of truth. We therefore need to emphasize the very relative aspect of the validity of knowledge produced in this study, as well as the highly structuring aspect of its framework discipline. We nevertheless encourage other researchers to broaden the frame of our model and to develop a Foucauldian model applied to IS, which provides a political analysis of technological and organizational change.

Abstract

Today’s growth of the service sector as a whole has created demand for more efficient service production. Many services require interaction between customers and service personnel, whereas some can be automated into self-services. In this study, we focus on services, that are neither purely human facilitated, nor purely automated, and contain uncertainty in the production process. Based on resource centric theories of strategy and research on uncertainties in service production, we introduce a research framework to evaluate efficient solutions for service production. Our research framework looks at environmental and informational uncertainties, and how an organization can adapt to these by utilizing technology or skilled labour. Illustrated with a case company, we show how mobile information systems can be used to manage service production related uncertainties, which are also typically barriers to standardization. The case study demonstrates how informational uncertainty could be more easily controlled using the new system. The job satisfaction of the workers was increased and their turnover and training time was decreased. Additionally, customer complaints were reduced and invoicing became more efficient. These enabled the company to enhance the efficiency of the service production processes further, moving closer to standardizing and automating the service production process within an uncertain environment.

INTRODUCTION

Service has been characterized as something that is perishable, immediate, subjective, intangible, and inherently variable (Chen & Chien, 2008); services are consumed but not possessed (Berry, 1980). Today, the service sector comprises roughly 75 percent of the gross domestic product of developed nations and employs more people worldwide than either agriculture or manufacturing (Maglio et al, 2008). The stream of activity in western economies flows from manufacturing of goods towards service production (see e.g. Penttinen 2007). Yet, there is also an undercurrent of conceptual change in the opposite direction: service production is increasingly turning into “service manufacturing”, or standardized service production, and information and telecommunication technologies (ICT) have a salient role in this development.

Not all services will be affected alike, though. Standardized service production requires automation and current technologies apply differently to different categories of services. Many services close to the conventional services marketing paradigm, such as hairdressing, require interaction between the customer and the service personnel, and hence are ill suited for automation at the current level of technological development. At the opposite end of the continuum are those services, such as personal banking, that can be – and in many cases have been - automated into self-services. In between these two opposites lies a host of services, for example environmental management or health care services, production of which requires combining the best parts of both technology and service personnel: efficiency and predictability of technology with human skills and flexibility. The focus of our study is on these services, that are neither purely human facilitated (like hairdressing), nor purely automated and digitized (like e-banking).

Furthermore, our specific interest lies in the possibilities of mobile technologies in supporting efficient delivery of these services. These mobile business-to-employee solutions, such as wireless field force automation are used by mobile employees, remote from their base of operations, utilizing wireless technologies to perform their specific business tasks in, for example, services such as facilities maintenance and insurance claims appraisal (Barnes et al, 2006). Mobile technologies are expected to enhance business efficiency by distributing information to the workforce, as well as by offering new communication channels with customers (Leung & Antypas, 2001). For example, in an action research study on mobile technology in field customer service, Rossi et al. (2007) claimed that with a mobile information system, the case company was able to realize efficiency gains through simplified processes and at the same time the company could serve the customers better through more transparent stock and sales information.

Managing services is different from managing goods, because of uncertainties related to the characteristics of services. Intangibility implies that service cannot be inventoried or easily displayed; heterogeneity arises because service often depends on labour, which is inherently more unreliable than machines; simultaneity of production and consumption (inseparability) means that the customer participates in the transaction, and therefore service is not easily centralized, and; perishability means that for many services, once the time of potential service passes, the opportunity to sell that service perishes (Roland & Chung, 2006).

In this study, we look at how mobile information systems can be used to manage uncertainties in service production. Based on resource centric theories of strategy and research on uncertainties in service production, we introduce a research framework to evaluate efficient solutions to service production, in terms of environmental and informational uncertainties. Furthermore, we are interested at how the uncertainties affect the levels of standardization or flexibility in the process of producing services. To illustrate the usefulness of the framework, we present a case study in a major Finnish waste management company. Even if the industry under study may be lacking in glamour, it is one of the future growth industries in the service sector and serves as a good example of an industry where companies operate in distributed
production environments. It is also a good example for describing the opportunities mobile technology offers for services standardization.

2 THEORETICAL BACKGROUND

Our study builds on resource centric theories of strategy, namely the resource based view (RBV) (Wernerfelt 1984; Barney 1986), the resource dependency theory (RDT) (Pfeffer 1981), and transaction cost economics (TCE) (Williamson 1975, 1992, 1996), focusing particularly on the treatment of uncertainty. Our perspective follows the tenets of service-dominant logic: we conceptualize service as a process, rather than a unit of output; we focus on dynamic resources, such as knowledge and skills, rather than static resources, such as natural resources; and we view value of service as a collaborative process between providers and customers, rather than what producers create and subsequently deliver to customers (Lusch et al, 2008).

Resource based view, resource dependency theory, and transaction cost economics as streams of strategic thinking, differ in their motivation: transaction cost theory has been conceived to explain the existence of different organizational structures (i.e, markets vs. hierarchies) in exchange systems. The resource dependency theory builds on research on the bases of power within organizations (Weber 1947) and seeks to explain organizational survival. The resource based view is motivated by the heterogeneity of organizations even when discounting the differences across industries.

What is common to these streams of strategic thinking is their focus on resources and, emphasis on uncertainty as the most important target of management function. Uncertainty, defined as “the degree to which future states of the world cannot be anticipated and accurately predicted “ (Pfeffer & Salancik, 1978, p. 67), is a central concept in management literature for it is the ultimate source of both opportunities and risks.

RBV (Wernerfelt 1984) emphasizes uncertainty related to intra firm factors of production. Barney (1986) suggests that internal resources and the related uncertainty are more firm specific than environmental uncertainty and hold higher promise for unique, sustainable advantage. TCE is motivated by environmental uncertainty which, combined with bounded rationality (Simon 1991) of decision makers, subject the firm to opportunistic behaviour of its transaction partners. The position TCE holds on uncertainty is close to that of the RDT, which posits that organization’s success is tied to managing environmental uncertainty related to supply of strategic factors of production (Pfeffer 1981). Thus, while RBV focuses on resources and related uncertainties internal to an organization, both TCE and RDT focus on external dependencies on strategically important factors of production.

The RBV suggests that firms should examine internal resources related uncertainty in an attempt to learn how to extract unique, sustainable competitive advantage. The other two schools of strategic thinking concentrate on inter-organizational relationships in resource acquisition and, as a result, emphasize environmental uncertainties. TCE suggests that organizations are born out of desire to optimize over production and transaction costs (Williamson 1975; 1992; 1996). RDT posits that the central management function is minimization of organization’s dependence on external resources and maximization of others’ dependence on resources of its own (Pfeffer 1981).

3 MANAGING SERVICE PRODUCTION

The Unified Service Theory defines a service production process as one that relies on customer inputs; customers act as suppliers for all service processes. Non-services (such as make-to-stock manufacturing) rely on customer selection of outputs, payment for outputs, and occasional feedback, but production is not dependent upon inputs from individual customers. (Sampson & Froehle, 2006) The increased service production requires more efficient ways to cope with the
variance that customers bring into service production process. From the service provider’s perspective, a major element of service production is human capital. When customers introduce a high degree of variability (in other words, uncertainty) into the service production process, service organizations may be able to address this variability and successfully satisfy customer needs, when their employees are proficient at diagnosing problems, thinking creatively, developing novel solutions, and so on; that is, when they possess high levels of skill, knowledge, and expertise (i.e., human capital) (Skaggs & Youn, 2004). Although, employees’ personal skills as well as the service production environment vary every time the service is produced. Standardizing the service production process or making it more flexible can be solutions to improve the service. Nowadays technology plays an increased role in the process. Next, we will define environmental and informational uncertainties, discuss the standardization and flexibility in service production, and introduce the role of mobile technologies in this context.

3.1 Uncertainties in service production

Environmental and informational uncertainties have an effect on the possibilities to standardize a given service or a service process. Environmental uncertainties are related to complexity and variability of the environment where the service is produced. Environmental situations and conditions cannot be fully controlled by the organization, and thus increase the uncertainty that the service provider faces. Environmental uncertainties are considerably lower for services produced and delivered at the service organization’s premises than for those produced and delivered outside. Furthermore, the environmental uncertainties are lower for services produced and delivered in a single or permanent location, than services produced in multiple or varying locations.

Informational uncertainty is an internal uncertainty within the organization. In producing non-standardized services, the experience and information held by personnel plays an important role. When a customer demands customized service, the employee needs to hold enough information to be able to produce the service in the best possible way. This involves informational uncertainty for the whole organization as the information might not be distributed within the organization, while it may also flow outside of it.

3.2 Technology-enabled standardization or labour-enabled flexibility in service production

To adapt to the environmental and informational uncertainties presented above, the organization has two options: either to standardize the service production process or to enable more flexible process. Levitt (1972) suggests that the standardization of a service can take three forms: (1) substitution of technology for personal contact and human effort; (2) improvement in work methods; and (3) combinations of these two methods. Standardized services do not, however, necessarily mean mechanical services, although many service tasks are routine, allowing specific rules and standards to be easily established (Järvinen et al., 2003). If the environmental and informational uncertainties are high, standardized service production process might be unrealistic, as it would require the organization to be able to control the uncertainties. Clearly an organization cannot fully control its environment. Standardization works best on routine type of services that are produced in a fixed location.

Increased flexibility in the service production process, regardless of high uncertainties, requires highly skilled labour, who can creatively adapt to changing needs. This is a solution with high environmental uncertainties. Still, the knowledge is rather personal and leaves the organization with a risk of losing some of the information along its labour.
3.3 Role of mobile technologies in service production

Mobile technology offers new possibilities to overcome service production related uncertainties. The crux of employing mobile technology is that it enables companies to collect and maintain real time information about the variable production environment and to share this information on the on-demand basis to the employees going about in the distributed production environment. The environmental uncertainties can be brought under control through more complete real time information. Changes in the environment can be instantly, and often automatically, fed into the system, and they are immediately available to others in need of this information. From the resource planning point of view accumulation of production related information in the company databases diminishes the informational uncertainties caused by the stickiness or leakiness of information. Information necessary to efficient resource planning will not remain the property of individual employees, rather, it is instantly available to all employees and the mobile systems can be used to automatically feed this information to those needing it to diminish the informational delays. This information will also remain in the company even after the employee who discovered it leaves, decreasing the dependency on particular individuals’ attributes.

The more dynamic the environment, the more important is timely flow of information. The more complex and idiosyncratic the service production process is, the more information is needed to properly automate or standardize the process. Especially those services produced and delivered outside of the company premises are likely to benefit from the opportunities provided by mobile technology to standardize the work flow and the service production process.

4 RESEARCH FRAMEWORK

Our research framework builds on the environmental and informational uncertainties, and two extremes for an organization to adapt to the situation: standardization with technology and flexibility with highly-skilled labour (see Figure 1). As explained, typically low uncertainties in service production enable standardization as technology can easily be utilized but increased uncertainties require flexibility in the process and highly-skilled labour that can cope with varying requirements that the uncertainty creates.

The upper left corner in our framework demonstrates a situation with both low environmental uncertainty and low informational uncertainty (L,L). Both the service environment and the information related to service production are stable, making it relatively easy to standardize the service production using technology instead of labour. In fact, not standardizing it would increase service production costs since, skillful workforce would be used for tasks that do not require workers to assess each situation separately and make situational decisions. An example of this type of service could be a retail store cashier. Standardizing service production in low uncertainty situations decreases the significance of particular workers’ personal learning abilities and importance of having long term loyal workers that have learned from practice and stay within the same organization to use and share the knowledge. If and when these workers leave the organization their knowledge leaves with them. However, as both uncertainties are low the necessary knowledge can be stored within the organization and share it as it is needed. This is particularly easy in routine services but also possible in some more complicated type of service, if the knowledge is such that it can be saved in a database. Then other workers can be provided with access, so they will be able to produce the service according to general guidelines without needing to assess each situation separately. This leads to increased homogenization of organizational roles at the same organizational level and tasks, but heterogeneity of the roles at the different organizational levels.
Figure 1. Service production and related uncertainties

The lower right corner shows the combination of high environmental uncertainty and high informational uncertainty (H,H). High environmental uncertainty demands high flexibility in the service production. As the service production environment and the required information varies, workers need to be flexible and skilled to assess the service production situations separately using their knowledge and decision making rights. An example of a service producer in an uncertain environment could be a travel guide. Greater flexibility that is achieved through highly trained service personnel would mean encouraging learning. Simon (1991) offers that organizational learning is profoundly influenced by the organizational roles. Distribution of decision making rights and the related expectations decree the organizational role structure. The mandate of the role is largely dependent on the variety of situations facing the employee. Clearly, if the service production process is characterized by high environmental uncertainty, the service varies highly depending on its environment, the customer, and the service producers. Thus, the workers need to be able to make quick decisions in each case. The role within an organization requires ability to learn, assess the particular situation and make a decision. As people vary on their ability to learn, wider mandates typically lead to increased heterogeneity in de facto organizational roles and produced services.

The lower left corner, on the other hand, suggests low environmental uncertainties but high informational uncertainties (L,H). In this, having highly-skilled and flexible labour handling tasks that have low environmental uncertainties basically means high costs and thus inefficient service production process. Based on the stable service production environment, the service could be automated or standardized utilizing technology, but now skilled-labour is occupied in producing this service. If the information held by the labour would be stored within an organization and the service would be automated, the production process would shift to the upper left corner making it much more efficient. The upper right corner demonstrates high environmental uncertainty but low informational uncertainty (H,L). This is not an efficient solution for service production, as high environmental uncertainty requires skillful and flexible employees. If the internal informational uncertainty would be low, it suggests that employees do not possess critical knowledge and are therefore not able to respond the need set by the uncertain environment. Thus this means that the company has high opportunity costs as it cannot produce the service in a way that would meet the demands set by highly uncertain service production environment. Having high environmental uncertainty and need to operate efficiently, an organization must move to lower right corner and invest in skilled labour.
Utilizing technology to automate or standardize service production process in a situation of both low environmental uncertainty and low informational uncertainty or investing in highly-skilled and flexible labour in high environmental uncertainty and high informational uncertainty are thus both applicable and sustainable solutions for an organization. This area is demonstrated with white colour in our framework. However, having a situation where environmental uncertainty is low but informational uncertainty is high, as in the lower left corner of the framework, means high service production costs: if the service production environment is stable, investments made on flexibility and ability to adapt to environmental uncertainty are needles. On the other hand, if environmental uncertainty is high but informational uncertainty is low, as in the upper right corner of the framework, the changing environment requires flexibility and adaptation to new situations but the organization does not meet these requirements lacking the required information and flexibility.

Thus, when facing a situation of high environmental and informational uncertainty, the service production requires flexibility created and information produced by skilled labour. To adapt to this situation an organization might gain greater control over the informational uncertainty if technology can be utilized to maintain more up-to-date information about the service production environment and other service production related issues, and distribute it on a need-to-know basis. As mentioned having highly trained service production personnel increases organizations dependency on them which increases informational uncertainty. The solution is to have more up-to-date information stored within the organization databases that is shared in service production. The stored information makes it possible to decrease the impact of environmental and informational uncertainties that the service producer is facing and move the production process closer to automation also within an uncertain environment. In terms of our framework, this would mean that moving from lower right corner closer to upper right corner is still efficient, as the required information or environment has not objectively changed. This requires an extensive use of mobile technologies to be able to share the information to service producer living within an uncertain service production environment.

5 EMPIRICAL STUDY

In the empirical part of our study, we look at the presented ways to manage service production related uncertainties in a company specializing in environmental management. In particular, we focus on a new mobile system introduced to facilitate the field work of the service personnel in waste management, and the ways the system has helped to adapt to both environmental and informational uncertainties. Furthermore, in order to illustrate the usefulness of our framework, we discuss the case company solution in terms of informational and environmental uncertainties.

5.1 Research methodology

We chose to look into one case to be able to acquire more in-depth understanding of the phenomenon. The empirical material was collected through in-depth, semi-structured interviews with four employees of the case company. In order to get as multifaceted view of the phenomenon as possible, the interviewees were at different levels and different positions in the company: the development director, the Auvo system developer, the project manager, and finally a field worker. All of them have been closely involved in the development and introduction of the mobile logistics system. The interviewed field worker uses the system on a daily basis, and he has been with the company long enough to know both the earlier system as well as the new mobile system.

Each semi-structured interview, lasting from half an hour to one hour, was conducted by two researchers. All the discussions were recorded and transcribed for analyzes. The topics covered the old service process, the new system, and its implications. Of particular interest was how the new system has changed the work process, what kinds of benefits had been created by it, and
the impacts the new system has had on the processes and the company. In addition to the interviews, publicly available information related to the organization and its services was collected and analyzed.

5.2 The Case Company: Lassila & Tikanoja

The case company, Lassila & Tikanoja (L&T) specializes in environmental management and support services for properties and plants. L&T has business operations in Finland, Sweden, Latvia, Russia and Norway. L&T’s net sales in 2006 amounted to EUR 436.0 million and it employed 8,328 people at the end of the year. The company’s shares are quoted on the Helsinki Stock Exchange. L&T’s services are split into three divisions: Environmental Services, Property and Office Support Services, and Industrial Services.

L&T employs a vast number of maintenance personnel and similar, whose work consist of a collection of maintenance and support tasks in customers’ premises. Previously each worker received a list of work tasks and their planned schedule as they arrived to the office. They got all the needed information, tasks, schedules, and maps on paper format, with which they started their work day. After accomplishing the tasks, they returned to the office to report the finished work tasks and to receive a new set of instructions. Changes to the schedule were possible only as the workers physically visited the office. This process involved a lot of driving, causing high fuel as well as car maintenance costs. Salaries and fuel and car maintenance costs account for the top three costs for the company. Furthermore, in the old paper based system, the field workers had to learn the routes and tasks, which took a considerable amount of time for new workers.

5.3 The Mobile System: Auvo

L&T launched the mobile logistics control system, named Auvo, to improve its efficiency. Auvo collects information related to service production and distributes it on demand see Figure 2.). For waste management field workers, whose job includes a lot of driving, the information related to the locations and the routes is crucial.

![Diagram](image)

**Figure 2. The new mobile system: Auvo**

Each maintenance worker has a mobile device with him, providing the work tasks, schedules, as well as maps that were all previously delivered on paper format. Workers do not need to return to the office to sign for new tasks, but the updates and changes are delivered automatically on their mobile devices. As the maps and routes are provided directly to the devices, the routes do not need to be learned. As a task is completed, the worker signs it by pressing Enter on the device, possibly adding some other information, if needed. The process moves from the
customer order to the service production and finally to billing without manual paper handling. The field workers have their mobile devices with which they operate, and office workers and customers can access the systems using a web browser.

5.4 Benefits of the new system

According to the development director and the developer of Auvo, the new mobile system has had a significant effect for the company in form of reduction of production costs, consisting of salaries, fuel costs, and the maintenance of special vehicles. Fuel consumption has decreased, since there is less unnecessary driving back and forth to the office, and the field workers know exactly where the target customer sites are. Maintenance of the vehicles is now cheaper because the control system lowers driving speed, causing less damage to the vehicles. Also the shortening of the entire production process from order to invoice from earlier 30 days to only 3 days with Auvo is seen as a significant advantage.

</tbody>
</table>

Table1. The benefits of AUVO system according to the interviewees (+ denotes a mention by an interviewee)

For the project manager, the biggest benefits of Auvo are created by GPS positioning, shorter production life cycle, and automation of invoicing and customer orders. Waste management production life cycle has shortened from 1.5 days to 1 day, because now the management can reschedule orders and change the order of customer sites to be visited, if needed. The field workers can serve more customers in the same time, and there is no more waiting for the next assignment at the office. New customer orders are relayed directly to the field workers’ task lists and to the electronic maps, reducing the number of mistakes made. GPS positioning in vehicles makes it possible for the supervisors to know in real time where each vehicle is driving. Automation of invoicing has decreased manual work from 100 to 4 invoices, as there are no
more paper orders to handle. Furthermore, invoicing has increased for 10 %, because there are fewer orders and invoices forgotten. The decreased number of mistakes has also increased the level of customer satisfaction. Also the number of customers has risen lately.

In the point of view of the field workers, the biggest advantage is that the work is, in general, easier than before, and there are less risks of making mistakes. GPS maps and work lists in cars allow the field workers to know exactly where the next customer site is and how to drive there. The field worker we interviewed also valued the fact that acknowledgement of orders and customer sites target is easy and swift. The job satisfaction of field workers has increased, and worker turnover has decreased dramatically from 60% to 4,5 %. A significant advantage is also that it is quick and easy to train new field workers. Our interviewee has already trained 100 workers to use the new Auvo system.

Summary of all the benefits mentioned by the interviewees is presented in Table 1.

5.5 Discussion

Service production that requires high flexibility has conventionally been labour-intensive and more costly than standardized service production. Being able to standardize the production process enables the company to decrease production costs, in our case through simultaneous management of environmental and informational uncertainties.

The service production environment involves uncertainties as the service is produced in customer premises. The routes can change and it is crucial for new employees to learn the environment related information. Conventionally, the employees have been the data depositories possessing the idiosyncratic information needed to efficiently navigate the distributed production environment. This makes the informational uncertainty also relevant for the service production. Ownership of production related information commands increased influence. The knowledgeable employees have been a valuable asset to the company and, hence, enjoyed considerable negotiating power over the terms of employment. Information uncertainty is most clearly reflected in the inability of the employer to prevent information from leaking outside the company as employees change their employment. The mobile logistics control system enabled the collection of service production related information and its distribution on demand decreasing informational uncertainties that the company is facing in its service production process.

Figure 3. Service production and related uncertainties in L&T
With the old paper-based system, the company was situated in the lower right hand corner of our research framework, having high environmental and informational uncertainties. Before the emergence of mobile location-aware information systems, environmental uncertainty could only be combated with specialized labor, as technology fell short of meeting the requirements of the work and its employment would have led to high opportunity costs in the guise of low service quality. The mobile production system allowed simultaneous combatting of both environmental and informational uncertainty. Even if the environment cannot be changed, its idiosyncrasies can be tracked in real-time. This information ends up being stored in the company instead of being in the possession of employees only, which decreases informational uncertainty. This decrease in informational uncertainty is depicted in our framework (see Figure 3) as a move closer to the upper right corner. The mobile system thus has changed the preferred organization for efficient service production: the upper right corner had previously been an inefficient solution but utilization of mobile technology has pushed back the frontier of efficient service production, increasing the ability to automate service production within an uncertain environment.

The mobile logistics control system also adds value for the workers. All the necessary information is stored in a database and accessible on demand. Especially the electronic maps and routing makes the work easier and less stressful. Previously having all the information on paper was risky in the sense that losing some of the papers, or ordering the papers enabled more mistakes from the workers. Now, it is easier and quicker to train new workers, and the work in general is easier. Initially, when the system was introduced, change resistance occurred, as the workers could not see the added value. However, after its launch, the system has been constantly updated and improved, the workers have been encouraged to put forward any wishes concerning its improvement. After the adoption, job satisfaction has clearly increased and consequently, the turnover of workers has fallen considerably.

The impact of the system in an organizational level is easy to recognize. Customer service quality has been improved as the number of mistakes has fallen. This can be seen from the radically decreased amount of customer complaints. The invoicing is more accurate as the system does not loose orders or forget to send invoices. Previously the financial department used to go through approximately 100 orders, in comparison to 4 nowadays, as 96 are invoiced automatically. This improvement is dramatic. Also, unnecessary driving back and forth is minimized which decreases fuel consumption. Overall, the lifecycle of the production process has fallen from 1.5 days to one day.

6 SUMMARY AND CONCLUSIONS

In this study, we looked at how a mobile information system can be used to manage uncertainties in service production process. We introduced a research framework based on resource-centric theories of strategy and literature on uncertainties in service production. The research framework looks at environmental and informational uncertainties, and the efficient ways of service production within the framework. The framework was illustrated with a case company in the field of waste management. The case company had previously used a paper-based system in distributing work tasks, which has now been replaced with a mobile information system to improve and rationalize the information flow within the service production process.

The efficiencies gained with the new mobile system are clear, as the length of the service production life cycle as well as the invoicing life cycle have fallen together with the number of customer complaints and lost orders. The improved information handling and its on-demand delivery were not possible before the launch of the new mobile system. This efficient information processing and sharing are required to enable production of standardized services. Thus, with soundly implemented mobile system service production can be standardized to an activity reminiscent of goods manufacturing. Standardization of service production process
improves cost efficiency, as the company does not have to train and support highly diverse and skilled workforce, and some parts of the process can be automated.

This case study also demonstrates how ICT changes the composition of the efficient solutions. Utilizing ICT applications companies can change their service production processes from highly flexible to standardization, which would not be possible with the traditional paper based systems. The next step in our research is to further evaluate the framework with other companies in different industries and environments, with different informational and environmental uncertainties.

Abstract

This paper proposes the use of laddering technique to determine the decision making process to adoption. Means end theory reveals the human values that are fulfilled for the individual by using various m-technology and services. Preliminary findings of a bigger study are presented. IT shows that mobile technology and services often fulfil such basic needs as self-esteem, achievement, individuality, belonging and well-being. Exploring the realization of values as a theoretical framework offers researchers a way forward in environments characterised by individual technology decisions.

Keywords: Technology Adoption, Means-End Analysis, Mobile Communication, Mobility
1. Introduction

Mobile phones are one of the fastest adopted technologies in history. In 2002 the number of mobile phones worldwide surpassed the number of landlines, with 4 billion mobile phones forecasted for 2010 (Nystedt, 2006; Srivastava, 2005).

The mobile phenomenon goes beyond its unprecedented speed of adoption. Many factors that have contributed to this adoption include the technology’s ability to be used at any time in any place, its simple operation and compatibility and the fact that it connects to any phone system (Rogers, 2003). Also, mobile technology is continuously being upgraded and reinvented (Anckar, 2002; Rogers, 2003). Mobile phones have evolved from being a tool for business people always on the move to becoming an integral part of people’s personal communication. Mobile devices and services keep continuously presenting new features and application that are leaving its core function behind. Mobile phones importance is such that there are. Sociological studies turn to mobile phone as an integral tool to understand social behaviour in the 21st century (Srivastava, 2005).

The aim of this paper is to present the preliminary findings of a study of m-technology and services adoption and usage. Using means end chain and laddering framework and methodology. It will begin by explaining the growth and significance of mobile-communication. It will then assess the applicability of means ends chain for researching m-technology and services adoption and use. The paper explains the benefits of using laddering to identify the reasons underpinning different consumer value choice perceptions. Finally, the significance of values to explain the decision making process with be discussed.

2. Theoretical Framework for examining Mobile adoption and Use

Many scholars and industry professionals are attempting to understand what influence individuals’ to adopt and use mobile services. A number of theories have been used to study consumers’ decision making process and to determine the “how” and “why” of adoption of technologies. People adoption of new technologies depends on several of factors, for example, how useful they perceive the technology to be, the product availability and price, how user friendly it is, social-economical motivation (benefits), culture, demographics and psychographics, and past experience.

A number of theories relating to the adoption of new technologies by consumers exist in the literature:

Some authors such as Barnes and Huff (2003) have used Roger’s (1962, 2003) innovation and diffusion theory to examine the diffusion of Internet access via mobile phones (iMode). Roger’s developed a number of characteristics that explain innovation diffusion: 1) Relative advantage: The degree to which the technology provides an advantage over other methods, 2) Compatibility: The degree to which the technology is compatible with how people work or behave, 3) Complexity: Whether people perceive the technology as easy to understand and use, 4) Trialability: The degree to which a technology can be trialled before being adopted, 5) Observability: The level of visibility of the product to the other members of the adopter’s social group.

Studies related to advertising and marketing are closely associated with consumer attitudes and built around the Theory of Reasoned Action (TRA) (Ajzen & Fishbein, 1980; Fishbein & Ajzen, 1975)and its applications to IT settings. The theory provides a framework to understand why people behave as they do when they are making decisions. TRA proposes that the use of technology can be predicted by a person’s behavioural intention and that this is determined by a person’s attitude towards using the technology. A person’s attitude is shaped by their positive or negative feelings towards performing a specific behaviour (or using a technology) and whether people who are important to that person, typically in the workplace, think that the person should or should not perform the behaviour.
Using a form of TRA (Tsang, Ho, & Liang, 2004) examine the link between attitude, intention and behaviour in relation to m-marketing. In their model entertainment, informativeness, irritation and credibility are seen to shape attitudes in addition to permission which has a major impact. The availability of incentives, such as free calls, impacts on intention to receive m-marketing for certain attitudes. Intention is directly related to behaviour in relation to m-marketing. Their study findings indicate that consumers have a negative attitude towards mobile advertising unless they have consented to it. All four attributes of mobile advertising impact significantly on attitude towards mobile advertising. Attitude was significantly correlated to intention with incentives also positively impacting on intention. There is a strong correlation between intention and behaviour. This study was conducted in Taiwan with a large percentage of respondents regularly using SMS, although it is unclear from the results presented the extent to which respondents had received mobile advertising.

The Technology Acceptance Model (TAM)(Davis, 1989) is tailored to information systems contexts and is designed to predict IT acceptance and usage in the workplace. It focuses on perceived usefulness of the technology and perceived ease of use. The consumer behaviour literature shows that utilitarian, in the sense of instrumental value, or hedonic benefits determine the intention to consume. In some m-commerce studies hedonistic factors including entertainment value have been considered as significant (Bauer, Barnes, Reichardt, & Newman, 2005; Bouwman, Carlsson, Pirkko, & Francisco, 2008).

As there are a number of adoption models available to researchers, (Venkatesh, Morris, & Davis, 2003) synthesized the main models in order to provide a unified view of user acceptance. The unified model identifies determinants and moderators related to intention and suggest intention is a predictor of use behaviour. Four factors impact on intention and usage: performance expectancy, effort expectancy, social influence and facilitating conditions. The key moderators are gender, age, experience and voluntariness of use. Interestingly, attitude was considered to be in overlap with performance and effort expectancies. The non-significance of attitude in the presence of these two other constructs has been supported in a number of other studies (Standing, Benson, & Karjaluoto, 2005). The unified model was found in empirical studies to be a substantial improvement on any of the other earlier models. Work on technology acceptance is still evolving with for example studies that integrate user satisfaction constructs with technology acceptance constructs (Venkatesh & Brown, 2001).

Standing, Benson and Karjaluoto (2005) used a version of the Unified Theory to determine significant factors in the decision to participate in m-marketing schemes and found that granting permission, financial savings and highly relevant information were significant factors in the decision to participate but the time and effort involved in processing m-marketing messages were not considered important.

Consumer adoption related factors can be summarized as including the consumer’s general attitude toward the technology, level of involvement, innovativeness, response to stimuli, trust and perceptions of utility, choice, control and risk. Demographic factors (age, gender, income, education) have also been found to be important control variables to consider when looking at consumer acceptance of m-services (Barnes & Scornavacca Jr., 2003; Bauer et al., 2005; Davis, 1989; Gebauer, Tang, & Baimai, 2008; Jonathan, 2008; Se-Joon, James, Jae-Yun, & Kar-Yan, 2008).

Although it is widely recognized that younger consumers have embraced mobile technology it is being increasingly recognized that factors beyond age or gender may be important. It can be argued that segmenting people on the basis of their acceptance and use of technology as well as their lifestyle motivations is more representative of their actual behaviour (Sultan & Rohm, 2005). One study by Forrester Research (Forrester, 2001) looked at factors such as technology attitude, income, career, family and entertainment. One older group identified in the study characterized by high income, interests in
entertainment and a positive attitude toward technology may be high mobile device users. Cultural factors can also impact the type and nature of service used. For example, in high power distance cultures such as Korea, text messaging to supervisors would be seen as a serious offence (Sarker & Wells, 2003).

Consumers’ adoption of new technologies/services depends on a number of factors, for example, the type of service to be offered, how comfortable people feel using the technology, how user friendly the service interface is, socio-economic factors, motivations (benefits), culture, demographics and psychographics, time that the customer expects to use the service and past experience (Daghfous, Petrof, & Pons, 1999; Sultan & Henrichs, 2000). Sarker and Wells (2003) provide a framework for understanding the adoption and use of mobile devices that includes most of these factors. Their model considers not only the decision made in the initial adoption but also how users appropriate the technology and services through exploration and experimentation. They argue that users assess their experiences on at three dimensions: functional (e.g. time savings), psychosocial (e.g. safety, elevated self-worth, sense of freedom) and relational (building relationships). We argue that the benefits are consequences of using the technology but the real psychosocial implications are the drivers – in other words all three are not on the same lane but part of a hierarchy.

3. Means-End Chains

The means-end chain concept concentrates on the relationship between product/service attributes, consequences and values (Gutman, 1982; Judica & Perkins, 1992; Leao & Mello, 2001, 2002; Reynolds & Gutman, 1988; Woodruff & Gardial, 1996). Attributes relate to product characteristics. Consequences are defined as the physiological or psychological results acquired directly or indirectly by the consumer from his/her behaviour (product or service use). This model represents how the consumption of a product enables the individual’s realization of his/hers ends desires. The central aspect of this theory is that “...consumers choose actions that produce desired consequences and minimize undesirable consequences” (Reynolds & Gutman, 1988).

It is implicit to the means end chain model different levels of abstraction to demonstrate their depth, the levels of abstraction are a way to identify different subcategories of attributes, consequences and values (Gutman & Reynolds, 1979). Attributes are described to be the physical aspects of the product or its abstract properties. For example mobile phone size is a physical, tangible attribute. However more subjective properties like cute or flash are abstract attributes (Fouskas, Pateli, Spinellis, & Virolo, 2002; Reynolds & Gutman, 2001). For consequences the levels of abstraction are functional and psychological. Functional consequences relate to direct results of using the product. For example SMS saves money. Psychological consequences are those instrumental to the achievement of psychosocial results. (Reynolds & Gutman, 2001) For example make an impression, have fun, feel powerful etc. Finally Values, they represent end states of existence. The value construct in this model is drawn from the concept used in psychology and sociology and relates to Rokeach, (1973) classification of human values. (Rokeach, 1973) identified two types of values: instrumental and terminal. Instrumental values relate to those values that act like tools in achieving end-state behaviours (values like courage, honesty, ethics, etc.). Terminal values, also used by (Gutman, 1982) refer to “Preferred end-states of existence” (Gutman, 1982 p 61) for example: accomplishment, happiness and satisfaction. Gutman’s, (1982) model (1982) has two basic underlying assumptions: 1) Values are connected to consequences as long as the consequences have positive or negative connotations and 2) Consequences have a direct relationship with product attributes as long as, consumers obtain the product which may cause the desired benefits. It is not uncommon for researchers to have some level of difficulty distinguishing between psychological consequences and instrumental values.
4. Methodology

The ladder technique is the method used to reveal the means-end hierarchy (Leao & Mello, 2002; T. J.; Reynolds & J. Gutman, 1988; (Zanoli & Naspetti, 2002). The term ladder refers to the relationship between attributes, consequences and values. It is a representation of the connection between the actual product and the consumer’s cognitive process that leads to a direct and useful understanding of his/hers perceptual orientation in relation to the product or service. The ladder technique is an in-depth individual interview seeking the understanding of consumers’ decisions. It translates product attributes into associations relevant to consumer’s “self”. (T. Reynolds & J. Gutman, 1988)

The data analysis using ladder has four steps. The first one is to specify the elements of the means end chain (MEC) by separating into chunks of meaning. Then a content analysis of the interviews and coding is done in order to combine and generalise the meaning across subjects. The third step is development of the implication matrix by quantifying the relations between the content codes. Finally the there is the creation of hierarchical value map to illustrate the connections between the different levels of abstraction (Gengler & Reynolds, 1995)

For this research 60 people were interviewed but only 57 used. Due to the exploratory aspect of the research the only factor that was fundamental in terms of sampling was that the subject used a mobile phone. Gender distribution was random but the total sample has resulted in 23 males and 34 females. We used a convenience sample and ages varying from 16 to 59. During the analysis the respondents were divided for demographic purpose in gender and age group. The age groups identified were: 16-25; 26-40; 41-54 and over 55. Although due paper size constrains, in this paper we will only discuss the findings in the general hierarchical value map (HMV) and a gender segmented map. The results of the HMV segmented by age will be presented in further publications.

The study aimed at identifying the underlying reasons for mobile phone usage. The ladder interview began with a question to allow respondents to elicit the distinctions they perceive as different features/services offered on their mobile phones. One of the most used question to elicit distinction was “Why did you get a mobile phone”. This has elicited direct services associate with the mobile phones as well as extended services. The interviewees did not seem capable to differentiate between “core” and extended product. Neither the literature seems to be looking at this particularity. What is a core service and what is an embedded object. However this does not seem to impact and in the end the most relevant attributes were voice and text

For this research the software Mecanalyst, (specifically for Laddering) was used. The software was particularly useful in the generation of the implication matrixes and the HMVs. Macanalyst is commercial software. There is an open source ladder software called LadderMAP developed by Chuck Gengler. However this software is MS DOS based and there is very little or inexistent technical support. Mecanalyst was designed by two Italian professors and is commercialise by an Italian SME called Skymax-dg. This software is windows based and is quite useful in the way it generates the tables and the maps. However the first step is the content analysis is still a manual effort. The second step in the data input is the grouping of the many different terms used by respondents to refer to the different levels of abstraction, where Mecanalyst was quite useful. It also generates a final list of codes. This research had 45 terms (code and synonyms) distributed in the following way: 07 concrete attributes, 03 abstract attributes, 13 functional consequences, 15 psychological consequences, 03 instrumental values and 02 terminal values. The codes table used in this study are depicted on table 1. As explained before the table is the starting point of the ladder, it is the probing method to distinguish differences between products in this case, mobile phone characteristics.
5. Findings

The attributes identified here refer mostly to handset features instead of services offered by carriers for example news alerts. This indicates that those services are not yet a major determinant to the use of mobile services. Reinforcing that voice and text are what consumers are really interested in. Three abstract attributes were identified then asynchronous nature of text message, MMS and the alternative of consumer having only one device to take pictures.

</table>

Observing the frequencies on the table above it becomes quite noticeable males’ preference for voice calls and females’ preference to SMS. However further details and relationship within the ladders is better represented in the hierarchical value map.

The hierarchical value map or HMV enable researchers to have a better understanding of the results from the laddering study without having study each ladder separately (Grunert, Beckmann, & Sorensen, 2001). “HMV is an estimate of cognitive structure for that group” (Grunert et al., 2001). When drawing a HMV a cut off level is determined to generate maps that will include only the most significant links (Grunert et al., 2001). In the HMVs illustrated in this paper the different levels of abstraction have been colour coded for easier identification. Concrete attributes are in orange; abstract attributes are yellow; functional consequences are in green, psychological consequences are in white, instrumental values are represented in salmon and terminal values purple. The arrows indicate the direction and strength of the relationships. The thicker the arrow the stronger is the connection.

The strongest relations in the ladder voice call/convenience/ get things done quicker/feel good /self esteem. However there is only a marginal difference to the ladder: SMS/convenience/ get things done quicker/feel good /self esteem Overall the preliminary findings from the general map (cut off 7) seem to confirm what is known about the key services consumers use on their mobile phones. Looking at isolated relationships, besides those already pointed, the other significative relationships are between conveniences and get things done quicker is expected. The relationship between convenience and considerate of others leading has considerable strength and seem to lead to belonging and self esteem.

Figure 2 is the HMV of males (cut off 5) and figure3 HMV (cut off 6) females. When confronting those two maps interesting results and relations are identified. The male’s map has six out of the seven concrete attributes identified indicating a more evenly use of the features and services. This can be related to the fact that most males use of their phones primarily for businesses purpose. In general, whenever talking about their personal usage of their mobiles the cost factor was raised. Another interesting finding relates to the ladder: design /looks (aA) – image (pC) - self-esteem (tV). Many would expect this chain to be stronger within the female group. However the attribute Design/looks is not represented at all in the female map contrasting with the strong relationship between designs, image and self-esteem ladder on the men’s map. Also by contrasting both maps it is noticeable that men have stronger ladders from voice. This indicates that they tend to talk on their mobiles more than women. This is visible but the strong relation voice calls/convenience- leads to achievement; self –esteem and belonging generating 3 ladders of similar strength. SMS is a strong attribute did not generate any real significant relationship between consequences and values in the males HMV. However the female HMV (cut off 6) has in SMS / convenience/ its strongest relation. The only attributes presented in the female’s map are SMS, voice call and camera. Incomplete ladders indicate a very weak relation. This is the case between camera and capture memories. The key ladder in the female map is SMS/convenience/get things done quickly / belonging. However the SMS / convenience relation lead to a series of ladders. This finding seems to contradict some popular belief that man uses more text message than woman.
Figure 1. HMV general cut off 7. This map was generated with no demographic filter. Concrete attributes are in orange; abstract attributes are yellow; functional consequences are in green, psychological consequences are in white, instrumental values are represented in salmon and terminal values purple. The arrows indicate the direction and strength of the relationships. The thicker the arrow the stronger is the connection.
Figure 2. HMV cut-off 5 filtering by male gender

Figure 3. HMV cut off 06filtering by female gender
6. Discussion and conclusion
This paper presented a summary of the preliminary findings to study mobile service adoption using means end chain and laddering. Many carriers and content creators are forecasting the change in mobile phone users expanding their services usage beyond calls and text messages. The initial findings of this study do not indicate that the existing scenario will change soon. Voice and text (SMS) are the key attribute consumers used because of its utmost convenience. This finding seems to be supported by the literature. For example (Bouwman et al., 2008) found that the usage patterns in Finland were reasonable stable in terms of preferences. The authors have indentified flexibility as a contributor factor between present and future usage.

The cognitive association maps presented may not be a definitive group for the m-services area. Rather we propose them as an illustration on the value of this approach. Nor are the maps mutually exclusive. Mobile services have a functional value as they are convenient but the decision to adopt may often be combined with the desire to feel part of a group or community of use. Indeed, the erosion of boundaries between work, home, leisure, learning and education, partly brought about by mobile technology, means that people may have multiple reasons for adopting or using services. Mobile technology can serve multiple needs including, family, friends, work and curiosity or learning.

7. Study limitations and further research
The results presented here are preliminary and partial. For a better indication of the patterns of mobile services use additional maps need to be studied. Also due to the qualitative nature of this research the aim only to gain deeper insights and understanding of consumer use of mobile services.

Abstract

We investigate the impact of Information Technology (IT) outsourcing on firm performance from several dimensions, including changes in labor productivity, improvements in financial and operational performance variables, and stock market valuation of IT outsourcing initiatives as measured by Tobin’s q. While our main objective is to better understand the economics of IT outsourcing, we also aim to contribute to the literature on the business value of IT in general. Our research contributes to the relevant literature from the following perspectives: (i) the change in the performance levels of firms due to IT outsourcing is measured against that of firms not outsourcing at all, (ii) panel data regression model is utilized in order to capture both cross-sectional and time-series differences among firms, (iii) the diversity of IT outsourcing initiatives is explicitly considered in the model, and (iv) a comprehensive data set covering the period between 1984 and 2007 is used.

Keywords: IT outsourcing, business value of IT, performance, panel data regression.
1 INTRODUCTION

Proliferation of the Internet and advancements in the Information Technology (IT) brought new opportunities to companies to conduct their businesses more efficiently than the past. The use of the Internet and IT not only changed the way firms do business, but also improved their existing processes. Today, firms can do business either by using their own resources and expertise, or by outsourcing some of the internal functions to outside contracting firms that specialize in certain functions.

Outsourcing, in its most succinct form, can be defined as the delegation to another party of the authority for the provision of services under a business contract that incorporates service-level agreements related to cost, quality, and the timeliness of deliverables. Given a diverse nature of business processes a firm has to manage today, it is nearly impossible for a firm to manage all of its processes by solely depending on its own expertise. Even if it is feasible, the firm may lose its focus and efficiency. Outsourcing some or all of non-core business processes can enable a firm to focus on core competencies, rather than services that fall outside of expertise. It will not only improve function effectiveness and flexibility by accessing a support network with highly qualified and specialized workforce, but also help firms control their costs and business risk by transforming high fixed costs to predictable expenditures.

Firms have been outsourcing various functions for years, ranging from assembly lines to Research & Development (R&D), from office documenting services to litigation. Although the very definition of outsourcing has not changed, its nature has evolved over time, expanding both the range and depth of services being outsourced. Firms today prefer outsourcing their business processes to firms that are highly specialized in using IT for business purposes. IT outsourcing, in this sense, is defined as “involving a significant use of resources (either technological or human resources) external to the organizational hierarchy in the management of IT infrastructure” (Loh & Venkatraman 1992a).

Despite its potential benefits, IT outsourcing may not be a straightforward decision for a firm because of potential risks involved, such as loss of control on outsourced activities, sharing critical company data with third-parties that may be used without consent of the firm, dependence on a firm whose internal operations may not be transparent generally due to autonomous nature of outsourcers, lack of knowledge on outsourcing process if the firm has not outsourced before, and existing firm culture that may resist to change.

Given the scale and popularity of IT outsourcing among firms today, the major organizational changes they entail, and the risk of failure, it is reasonable to expect that IT outsourcing has a significant and measurable effect on firm performance. Quantifying the impact of IT outsourcing on firm performance will not only help corporate managers make effective decisions on IT outsourcing, but also shed light on the prevailing debate over the outsourcing of U.S jobs to other countries (White House Joint Economic Committee Study 2001).

In this research, we investigate the impact of IT outsourcing on key firm performance variables by using a comprehensive data set compiled from primary and secondary sources. While our main objective is to better understand the economics of IT outsourcing, we also aim to contribute to the literature on the business value of IT in general. Our research contributes to the relevant literature from the following perspectives: (i) the change in the performance levels of firms due to IT outsourcing is measured against that of firms not outsourcing at all, (ii) panel data regression model is utilized in order to capture cross-sectional and time-series differences among firms, (iii) the diversity of IT outsourcing initiatives is explicitly considered in the model, and (iv) a newer data set covering the period between 1984 and 2007 is used.
2 LITERATURE REVIEW

Our research is strongly related to two streams of previous literature: the work on the business value of IT, and the more specialized and limited literature on IT outsourcing. In this section, we briefly survey previous studies in each of these areas that are most relevant to our research.

2.1 Business value of information technology

There is an extensive body of literature examining the business value of IT investments at the firm level. The roots of the debate can be traced back to 1990s when available data from 1980s and 1990s failed to show evidence of improved firm productivity due to investments in IT in the manufacturing sector (Morrison & Berndt 1990). This result, later called the “Productivity Paradox of IT,” was found to be even more pronounced in the service sector that had used over 80 percent of IT products during 1980s (Roach 1991). Researchers attempted to resolve the paradox by pointing out that the inability to show significant returns may be because of (i) measurement errors of outputs and inputs due to rapid price and quality changes in IT equipment, (ii) the time necessary for learning and adjustment, and (iii) mismanagement of IT resources by firms due to insufficient expertise to take advantage of the potential of using IT in traditional business environments (Brynjolfsson 1993). Other researchers rejected this paradox by providing empirical evidence to show a positive relationship between IT investments and firm performance (Brynjolfsson & Hitt 1995, Brynjolfsson & Hitt 1996, Lichtenberg 1995, Dewan & Min 1997, Bharadwaj et al. 1999, Kudyba & Diwan 2002, Anderson et al. 2003).

Not all studies, however, were able to show a clear payoff from IT investments. For example, Barua et al. (1991, 1995) both find that even though IT spending improves intermediate variables of organizational performance, such as capacity utilization, inventory turnover, or relative price, it does not necessarily lead to improvements in higher-level performance variables, such as Return on Assets (ROA) or market share.

Researchers also proposed innovative methods for measuring the business value of IT investments. For example, Brynjolfsson et al. (1994) show that effects of IT on firm productivity variables are substantially larger when measured over long time periods, since long-term returns represent the combined effects of related investments in organizational change. Devaraj and Kohli (2003) emphasize the importance of actual usage in driving the impact of IT on firm performance. In order to correctly measure the business value of IT, Kohli and Devaraj (2003) recommend that future studies explicitly report which complementary changes in business practices, such as Business Process Reengineering (BPR) and Enterprise Resource Planning (ERP), accompanied the IT investments. Barua and Mukhopadhyay (2000) emphasize that such analyses will help isolate and identify the effectiveness of complementary changes that lead to IT payoffs.

2.2 Information technology outsourcing

The main motivation for IT outsourcing is found to be cost reduction (Altinkemer et al. 1994, Gilley & Rasheed 2000). This is because paying for outsourcing generally costs less than maintaining equivalent services in-house. According to Malhotra (1995), factors that affect IT outsourcing decisions are reduction in operating costs, cost predictability due to fixed contract, sharing risk on technology investments, access to specialized expertise, political reasons that hinder internal IS efficiencies, and perception of efficiency of internal IS function. Clark et al. (1995) identify the changes in information technology, business trends, and technology management as the major factors that favour outsourcing. Outsourcing decisions may also be due to internal influence or imitative behaviour (Loh & Venkatraman 1992b).

The degree of IT outsourcing is found to be positively correlated to business and IT cost structure, and negatively related to the performance of the existing IT infrastructure (Loh & Venkatraman 1992a).
On the other hand, Wang et al. (2008) find that the level of business value created by IT outsourcing is contingent on firms’ core IT capability. That is, firms with superior core IT capability have an advantage in leveraging their outsourcing initiatives to enhance firm value. Jiang et al. (2006) find empirical evidence for improved cost efficiency as a result of IT outsourcing, but no change in the productivity and profitability of the outsourcing firms.

Researchers also investigated the effects of IT outsourcing versus insourcing on firm productivity. For example, Lacity and Hirschheim (1995) argue that most cost reductions achievable through outsourcing can equally well be achieved by the in-house IT function if it is given freedom to reorganize. They present eleven generic cost reduction strategies that internal IT departments can implement to reduce costs.

3 HYPOTHESES

Many potential benefits of outsourcing have been identified in the literature. Outsourcing firms often achieve immediate cost advantages (Jiang et al. 2006, Lei & Hitt 1995). Thus, outsourcing may be an attractive method of improving a firm’s financial performance, especially in the short run. Outsourcing firms may also achieve long run advantages compared to firms relying on internal production. In-house production increases organizational commitment to a specific type of technology and may constrain flexibility in the long run (Harrigan 1985). On the other hand, outsourcing firms can switch suppliers as new and more efficient technologies become available. In addition, outsourcing allows for quick response to changes in the environment (Dess et al. 1995). As a result, we expect firms engaging in IT outsourcing to experience an improvement in their performance variables during the period that starts when the initial outsourcing contract was signed. Thus, our first hypothesis is stated as follows:

Hypothesis 1. Firm performance improves as a result of IT outsourcing.

IT outsourcing initiatives vary considerably across firms; while some firms focus only on a single process, others may find it more profitable to outsource several business functions over the years. Diversification of outsourcing activities in this sense provides a measure of outsourcing intensity, and can affect the level of impact on firm performance (Gilley and Rasheed 2000). Besides, utilizing a diversity variable in our model provides the necessary linkage between IT outsourcing, which is implemented at the business unit level, with our performance variables, which are measured at the organizational level. Our second hypothesis is thus:

Hypothesis 2. The effect of IT outsourcing on firm performance increases with the diversity of outsourcing.

4 DESCRIPTION OF DATA RESOURCES

We used two leading online news sources, ABI/INFORM and Lexis/Nexis, to search and compile all press releases and news about firms announcing their IT outsourcing projects. We recorded the name of the outsourcing firm, the year of the initial outsourcing contract, and the type of the outsourcing projects conducted by each firm. We should note that our observations are unavoidably limited to those IT outsourcing projects that have been publicly announced. We may therefore have missed some of the projects that have not been announced, and consequently miscoded some companies as non-implementers when, in fact, they have undertaken an outsourcing project.

We observed that most of the projects announced were undertaken by large U.S. firms. Arguably, some of these firms may realize a higher level of performance benefits from IT outsourcing than others can do, which may affect the decision to undertake such a project. Therefore, in order to better understand the gains from IT outsourcing, we included in our data all of the firms in the Fortune 1000 list, regardless of whether they adopted IT outsourcing or not. Since firms frequently enter and exit the Fortune 1000 list every year, we took 1998 as the baseline year and included every firm that was listed...
in that year in our analysis. We used the Standard and Poor’s COMPUSTAT database to collect most of our data, which covers the period between 1984 and 2007. We also utilized the Information Week magazine’s Top 500 lists that publish total annual IT budgets of large companies.

5  ECONOMETRIC MODEL

Since our data has both cross-sectional and time-series components, we utilize a panel data regression analysis in order to test our hypotheses. We use the STATA statistical software package to run our regressions. By indexing firms by $i$ and years by $t$, we can express our panel data regression model as follows:

$$y_{it} = \mu_i + \sum_{k=1}^{m} \beta_k x_{itk} + \epsilon_{it} \quad i = 1, ..., N \quad and \quad t = 1984, ..., 2007.$$  

where $y_{it}$ is the dependent variable, $\mu_i$ is a separate constant term for each firm, $x_{itk}$ are independent variables, $m$ is the number of independent variables, $\beta_k$ are regression coefficients, $N$ is the number of firms, and $\epsilon_{it}$ is a classical disturbance term with $E[\epsilon_{it}] = 0$ and $\text{Var}[\epsilon_{it}] = \sigma^2 \epsilon$. The general form of our econometric model is as follows:

$$\log(\text{performance measure numerator})_{it} = \text{intercept}_i + \log(\text{performance measure denominator})_{it} + \text{implementation dummies}_i + \text{diversification dummies}_i + \text{firm controls}_i + \text{industry controls}_i + \text{year dummies}_i + \epsilon_{it}$$

We will perform the following regression diagnostics to avoid obtaining biased estimators. In order to see the level of possible multicollinearity in the regression model, we will create the correlation matrix among our independent variables, and visually examine its entries. As another check for multicollinearity, we will obtain the Variance Inflation Factors (VIF) for all of our independent variables, and check whether their values are less than the threshold level of 10. We will run our regressions by using robust covariance matrix for heteroskedasticity according to White’s (1980) procedure to prevent inconsistent covariance matrix estimates. Finally, we will utilize the Hausmann Test in order to decide whether to use the Fixed Effects or Random Effects panel data model to run our regressions. In what follows, we describe our regression variables and explain the rationale for including them in our model by providing support from the literature.

5.1  Dependent and independent variables

We construct various measures to calculate labor productivity, financial and operational firm performance, and stock market valuation (all serve as dependent variables) using standard approaches found in literature (Brynjolfsson & Hitt 1996, Bharadwaj et al. 1999, Brynjolfsson & Hitt 2000, Hitt et al. 2002).

Labor productivity is calculated by dividing total sales by the number of employees. Financial firm performance is measured via three well-known variables: Return on Assets (ROA), Return on Equity (ROE), and Return on Sales (ROS). Operational performance is measured through two variables: asset utilization that is calculated by dividing sales by total assets, and inventory turnover that is the cost of goods sold divided by inventory. Finally, the stock market valuation of IT outsourcing initiatives is measured by using Tobin’s $q$.

Tobin’s $q$ was first introduced as a predictor of a firm’s future investments (Tobin 1969, 1978). Since then, it has been extensively used as a measure of a firm’s intangible value, which is based on the assumption that the long-run equilibrium market value of a firm must be equal to the value of its
assets, giving a \( q \) value close to unity. Thus, a value of \( q \) greater than one implies an unmeasured source of intangible value generated by the firm.

Regression analyses featuring labor productivity or financial performance ratios have the advantage that they can capture different aspects of firm performance, and are commonly used in the literature. Their primary disadvantage is that they cannot adequately incorporate future gains from IT outsourcing, which could substantially exceed current or past gains. The use of Tobin’s \( q \) analysis mitigates these concerns because it is based on the expectations of future benefits that the firm may receive. For our purposes, we use the Tobin’s \( q \) specification adopted by Hitt et al. (2002), which relates market value of a firm to its total assets. The derivations of our performance measures are outlined in Table 1 below.

Table 1. Construction of Performance Measures.

Following Hitt et al. (2002), we use the logarithm of the numerator of each performance measure as a dependent variable, and the logarithm of its denominator as a control variable. This specification provides flexibility in the relationship between numerator and denominator, while retaining the interpretation as a performance measure.

Our key independent variable is the implementation dummy that indicates whether a firm conducts an IT outsourcing project during year \( t \). For each firm, it takes a value of one during and after the years an outsourcing project takes place, and zero otherwise. In order to examine possible lagged effects of outsourcing, we lag the implementation dummy up to three years. For example, if a firm started its outsourcing project in the year 2000, its implementation dummy with a 1-year lag will take a value of one for the year 2001 and beyond, and zero otherwise. Similarly, its implementation dummy with a 2-year lag will take a value of one for the year 2002 and beyond, and zero elsewhere. In order to test the second hypothesis, we use another dummy variable that indicates whether a firm diversifies its IT outsourcing activities over the years. This dummy variable takes a value of 1 for firms that are engaged in several IT outsourcing activities, and zero otherwise.

### 5.2 Firm-level control variables

Our firm-level control variables are firm size, IT budget, advertising expenditure, and market share. First, we use the natural logarithm of the number of employees as a proxy for firm size, as is traditional in the literature. Second, in order to observe the effect of IT outsourcing on firm performance across firms with varying degrees of IT investments, we utilize IT budget as another firm-level control variable. Third, there is ample evidence in the economics, marketing, and strategy literature supporting a positive relationship between advertising expenditure and firm performance (Comanor & Wilson 1974, Nelson 1974, Schmalensee 1978, Aaker 1991, Megna & Mueller 1991). Finally, market share is included as a control variable given that efficiency theory (Day & Montgomery 1983, Buzzell & Gale 1987), market power theory (Smirlock et al. 1984, Martin 1988), and studies on product quality assessment (Smallwood & Conlisk 1979) provide evidence for a
relationship between market share and firm performance. Jacobson and Aaker (1985) and Jacobson (1990) emphasize further that market share can serve as a proxy for other firm-specific assets (such as managerial skill) not specifically captured in this study. Based on the results of previous research, we expect a positive relationship between market share and firm performance.

5.3 Industry-level control variables

The literature on industrial organization economics supports the view that the structure of an industry impacts the performance of firms within the industry (Porter 1980). We, therefore, utilize three variables frequently used in previous research to account for variation in firm performance due to idiosyncratic characteristics of different industries at the 2-digit Standard Industrial Classification (SIC) level: industry concentration, industry capital intensity, and industry average Tobin’s q.

Consistent with the literature, industry concentration in our research is proxied by the four-firm concentration ratio, which is the total market share of the four largest firms in an industry. Industry capital intensity is calculated as the sum of all capital expenditures divided by the sum of all sales in an industry. It is included in our model to capture potential effects of entry barriers on firm performance. Since capital intensive industries are likely to face fewer competitors, incumbent firms could earn higher profits (Capon et al. 1990). This implies a positive relationship between industry capital intensity and firm performance. On the other hand, the relationship could be negative because high capital intensity requirements could take away resources from intangible investments, thereby reducing firm performance (Bharadwaj et al. 1999). Finally, the industry average Tobin’s q is utilized in our regressions regarding the stock market valuation of IT outsourcing projects. Inclusion of this variable enables us to justify pooling of data from multiple industries, as well as to control for idiosyncratic industry characteristics not adequately captured by the other industry control variables (Dess et al. 1990, Bharadwaj et al. 1999).

5.4 Time control variables

Following Hitt et al. (2002), we use separate dummy variables for each year to capture transitory, economy-wide shocks that may affect firm performance in our data set.

6 RESEARCH STATUS

We have finished compiling our primary data from the ABI/INFORM and Lexis/Nexis, where we have recorded the following information: (i) the names and stock tickers of all firms that publicly announced their IT outsourcing projects, (ii) the year of their initial outsourcing contracts, and (iii) the scope of their outsourcing projects. We have also finished collecting our secondary data from the COMPUSTAT database and the Information Week magazine. Currently, we are in the process of analyzing the data, and we expect to obtain our initial regression results by the time of the ECIS 2009.

ANTECEDENTS OF SUCCESS IN IS OFFSHORING PROJECTS – PROPOSAL FOR AN EMPIRICAL RESEARCH STUDY

Westner, Markus, Dresden University of Technology, 01062 Dresden, Germany, markus.westner@tu-dresden.de

Abstract

The paper presents a research model and a measurement instrument for a research-in-progress study on the antecedents of success in IS offshoring projects. In this empirical-confirmatory study, we intend to analyse the impact of the constructs “offshoring expertise”, “trust in offshore service provider”, “project suitability”, “knowledge transfer”, and “liaison quality” on offshore project success. Constructs and indicators are derived from an extensive literature review. We plan to formulate a structural equation model and to test it using partial least squares (PLS) as an analysis technique. Our research model addresses the paucity of research that quantitatively examines offshoring success.

Keywords: offshoring, outsourcing, project success, partial least squares.

1 INTRODUCTION

Information systems (IS) offshoring describes the transfer of IS services to an offshoring service provider (OSP) in a near or far away country. This OSP can be an internal subsidiary (so-called “captive offshoring”), a partially-owned unit, or an external service provider (so-called “offshore outsourcing”). The services themselves are partially or totally transferred. (Carmel and Agarwal 2002, Hirschheim et al. 2005, Jahns, Hartmann and Bals 2006/7, Mirani 2006, Niederman, Kundu and Salas 2006, Rajkumar and Mani 2001, Srivastava, Teo and Mohapatra 2008)

High labour cost differentials in comparison to western countries and the resulting cost savings are the main reasons why companies engage in IS offshoring. Accordingly, the market volume for offshoring of IT services has been growing fast in the last years, with India being the most popular offshoring destination (Knapp, Sharma and King 2007, Metters and Verma 2008, Poornima 2008). Application development and maintenance activities, where labour constitutes a significant share of total costs, are especially likely to be performed offshore (Bitkom 2005, Boes, Schwemmle and Becker 2004, William, Mayadas and Vardi 2006). However, recent studies among companies worldwide indicate that a large number of companies that engaged in IS offshoring are not fully satisfied with their engagements’ performances (Bright 2008, Computerwoche 2008).

The situation is especially noticeable in Germany. There, offshoring levels are rather low: only 6% of all companies source IS services from abroad in contrast to 64% that already use domestic IS outsourcing (SchAAF and Weber 2005, ZEW 2007). Additionally, German companies also experience difficulties in performing IS offshoring successfully (Prehl 2008). This seems to be due to language and cultural barriers (Dibbern, Winkler and Heinzl 2006, Mertens 2005, Wiener 2006).

IS offshoring is worth being researched as a domain of its own because it has specific characteristics that distinguish it from the well-researched field of IS outsourcing. In IS offshoring, service delivery occurs under the additional condition of “distance” between service provider and consumer in terms of physical distance, time zone differences, or cultural differences. Additionally, complexity increases due to the higher degree of geographical dispersion among team members. Finally, IS offshoring arrangements often create additional organisational challenges because offshore staff partially replaces domestic onshore staff. This increases the importance of knowledge transfer, knowledge absorption, project management, and HR management to ensure successful service delivery. (Chua and Pan 2008,

Research in IS offshoring has been growing in the last years and journals such as the “MIS Quarterly” (vol. 32, issue 2) or “Information Systems Frontier” (vol. 10, issue 2) have published issues addressing the phenomenon. IS offshoring research, in contrast to IS outsourcing research, is primarily case study based and qualitative, which shows that it is still in its initial, theory-building stage (Dibbern et al. 2004, King and Torkzadeh 2008). The research situation is furthermore characterised by studies that employ a project or organizational level of analysis, focus on India as an offshoring destination, and investigate “success/outcome factors” or “economic value” as research topics (King and Torkzadeh 2008).

Derived from the special characteristics of IS offshoring, we investigate how “project suitability”, “knowledge transfer”, and “liaison quality” as well as how the constructs “trust in OSP” and “offshoring expertise” impact offshoring project success at German companies. We employ a confirmatory-quantitative research approach to address this objective. In this sense we follow the current state in IS offshoring research to focus on “success/outcome factors” with “projects” being the level of analysis. However, we add original content through our research model that partially builds upon recent research results but also incorporates new aspects. We ensure methodological originality by gathering a broad empirical dataset and by analysing our research model with structural equation modelling as a tool for analysis. Finally, we address the paucity of research that quantitatively investigates offshoring in the context of German businesses.

We focus our research along four dimensions: (1) our regional focus is Germany, (2) we focus on the offshore consuming client’s perspective, (3) our unit of analysis is offshoring projects, i.e., not the arrangement or relationship between service consumer and provider in total, and (4) we focus on application development or maintenance projects.

2 THEORETICAL FOUNDATION AND RESEARCH MODEL

2.1 Research model overview

Our proposed research model argues that offshoring expertise has a direct positive effect on offshore project success. Additionally, it is positively associated with project suitability, knowledge transfer, and liaison quality which act as mediators for offshore project success. Trust in the OSP is positively associated with knowledge transfer, liaison quality, and offshore project success. Figure 1 illustrates the model. The subsequent sections develop and describe its constructs and their relationships.

![Figure 1. Research model on antecedents of offshore project success. A plus (+) symbol denotes a positive relation between constructs.](image-url)
2.2 Measuring offshore project success

Offshore project success is the dependent variable in our research model. As Erickson and Ranganathan (2006) show, success can be understood and measured in multiple ways, including “the organization’s satisfaction with the results of outsourcing (Grover, Cheon and Teng 1996), an expectations fulfillment view (Lacity and Willcocks 1998), a cost/benefit approach (Wang 2002), a psychological contract perspective on fulfilled obligations (Koh, Soon Ang and Straub 2004), and a strategic fit view of success (Lee, Miranda and Kim 2004)” (Erickson and Ranganathan 2006).

Several studies measure success as the satisfaction of outcomes, sometimes calibrated by initial expectations (Balaji and Ahuja 2005, Grover et al. 1996, Dahlberg and Nyrhinen 2006, Wüllenweber et al. 2008). In their extensive review of IS outsourcing success definitions and measures, Dahlberg and Nyrhinen (2006) find that satisfaction with outcomes can be evaluated along four categories which are “strategic factors”, “economic factors”, “technological factors”, and “social factors”. Additionally, overall satisfaction forms a part of their success definition.

Strategic, economic, technological and social outcome factors may also apply to projects but they are not applicable in all cases. For example one might think of projects that completely lack a specific strategic proposition. Since a project is by definition an effort bound by “schedule”, “budget”, “functionality”, and “quality” (Erickson and Ranganathan 2006), it rather makes sense to use these dimensional factors together with overall satisfaction as an operationalization of offshore project success.

Therefore, our paper interprets the dependent variable offshore project success as the perceived satisfaction with the outcome of the offshore project in total, and with the dimensions of schedule, budget, functionality, and quality.

2.3 The role of project suitability for project success

We define project suitability for offshoring as the sense that a project’s attributes and its task characteristics make it more amenable for delivery in a dispersed, inter-cultural environment, i.e., in an offshoring setting.

The identification of suitable project candidates for offshoring is one of the first activities before engaging in an IS offshoring arrangement. Once identified, these offshoring candidates then represent the core objects in the subsequent implementation of IS offshoring. Therefore, research and practice indicate that the identification of suitable project candidates is a main step in pursuing an IS offshoring endeavour. (Aron and Singh 2005, Chua and Pan 2006, Kumar and Palvia 2002)

Research in IT outsourcing has shown that there is a link between the function being outsourced and arrangement success (Fisher, Hirschheim and Jacobs 2008). They suggest focusing on routinely performed and non-core functions. Applying the lens of transaction cost theory and operations management models, Stratman (2008) finds that well understood, standardized service processes that are non-core are best candidates for successful offshoring. Stringfellow, Teagarden and Nie (2008) show that it is more challenging to offshore complex, loosely defined and non-standardized tasks that require complex judgments and implicit knowledge. If projects or tasks show these characteristics, offshore delivery incurs additional costs which might threaten project success. King (2008) suggests a framework for determining whether an IS activity should be considered for offshoring. He posits that activities should be kept in-house if they require proximity and the risk of offshoring is too great, or if the activity is too business-critical. Schaffer (2006) develops a similar framework that suggests refraining from offshoring projects which are very short, require a tremendous amount of personal interaction, are of high security and extreme criticality for the business. Mirani (2006) states that small applications or components of low complexity, for which specifications can be communicated completely, and whose development process is highly structured, are more likely to be successfully delivered in an offshore arrangement.
Since most of these studies are conceptual in nature or rely on a small set of empirical data, we carried out a qualitative pre-study with 47 German offshoring experts from different companies to find out whether project suitability is actually important for project success and what the respective evaluation criteria could be (Westner and Strahringer 2008). In the interviews, these experts confirmed that a project’s characteristics and its suitability for offshoring have a strong impact on later project success. Criteria such as project size, project duration, operating language, degree of codification, and business specificity were most frequently mentioned as determining a project’s suitability for offshoring with regard to successful delivery. If projects have a certain size and duration, the project language is English, the degree of codification is high, and business specificity or required domain knowledge is low, it takes less time and effort to make OSP staff fully productive. Therefore we hypothesize:

\[ H1: \text{Project suitability is positively associated with offshore project success.} \]

### 2.4 The role of knowledge transfer for project success

Following Davenport and Prusak (1998) and Lee, Huynh and Hirschheim (2008), we define knowledge as “a fluid mix of experience, values, contextual information and expert insight that provides a framework for evaluating and incorporating new experiences and information” (Davenport and Prusak 1998). Knowledge transfer as an outcome is the result of (1) the exchange of knowledge as a systematic activity between individuals and organizations (Chua and Pan 2008, Wang, Tong and Koh 2004) and (2) the ability to absorb the knowledge, to apply it and to use it in project delivery (Orlikowski 2002, Oshri, Kotlarsky and Willcocks 2007). Common terms to describe these two aspects are “knowledge transition” for (1) and “knowledge integration” for (2).

Application development and maintenance represent knowledge-intensive work. Knowledge pertinent to applications can either be explicit, such as software documentation, technical specification, or standardized development processes, but it can also be tacit, such as practices like norms of communication or non-specified processes and activities. (Chua and Pan 2006, Nicholson and Sahay 2004)

To profit from the economic benefits of offshoring, offshore staff must actually replace more expensive onshore staff (Chua and Pan 2008). Accordingly, all project-relevant explicit and implicit knowledge needs to be transferred to offshore staff. This knowledge transfer happens at the beginning of an offshoring project but is also a continuous activity during the whole project. Correspondingly, offshoring process models used in the industry and proposed by research recognize knowledge transfer as a specific activity (Bugajska 2007, Oshri et al. 2007, Voigt, Novak and Schwabe 2007).

Applying this perspective, the importance of knowledge transfer becomes obvious and has also been addressed in research. A case study by Chua and Pan (2008) examines how a financial institution transferred knowledge within a captive offshoring arrangement, and highlights knowledge transfer’s importance for successful service delivery. Another case study, by Oshri et al. (2007) from the OSP perspective, investigates best practices for managing dispersed knowledge among on- and offshore sites and acknowledges that knowledge transfer is a key part of successful offshoring. Previously, Ganesh and Moitra (2004) identified knowledge transition and the absorptive capacity of the OSP as one of the critical success factors for successful service transition in the context of business process outsourcing and offshoring. Rottman and Lacity (2008) develop best practices to ensure success in IS offshoring. Most of these best practices are fundamentally linked to facilitate and ensure successful knowledge transfer. Finally, in one of the few recent empirical-confirmatory studies, Lee et al. (2008) examine IS outsourcing arrangements between Korean firms and find significant support for the hypothesis that knowledge sharing is positively related to the success of outsourcing.

Thus, we can conclude that if knowledge transfer is successful, (1) offshore staff is more productive because it has the required know-how to perform project tasks and (2) onshore staff can be replaced as initially planned because it does not hold exclusive knowledge anymore. Based on this understanding we hypothesize that:
H2: Knowledge transfer is positively associated with offshore project success.

2.5 The role of liaison quality for project success

We define liaison quality as the degree of connectedness between onshore and OSP staff in the aim to achieve specified goals, i.e. in our case, a project’s objectives (Winkler et al. 2008). Liaison between staff should incorporate reciprocity and closeness (Xu and Yao 2006).

The environmental circumstances of IS offshoring delivery have negative impacts on liaison quality. Due to distance, communication frequency between team members decreases, collaboration is aggravated, and individuals tend to feel themselves not as equal parts of a team (Herbsleb and Mockus 2003, Xu and Yao 2006).

Therefore, research in IS offshoring emphasizes the importance of liaison quality on offshoring success. Erickson and Ranganathan (2006) highlight the need for clear roles, responsibilities, communication mechanisms, and conflict resolution in the management of global virtual teams. Rottman (2008) recognizes liaison quality’s impact on success and suggests building personal connections between OSP staff and client staff, for example by regular site visits and face-to-face meetings. Furthermore, he proposes to integrate offshore staff into onshore staff and synchronize training of offshore employees with internal training efforts. Similarly, Heeks et al. (2001) find that a high degree of congruence between provider and client improves chances for project success regarding schedule and budget. They recommend building bridging relationships between involved team members and using “straddlers”, i.e., dedicated individuals who are responsible for facilitating and moderating the interaction between on- and offshore staff. Levina and Vaast (2008) mention that liaison quality lessens negative effects of distance and thereby improves performance. They mention good onshore middle managers, frequent communication, constructive communication, and the efficient usage of technology as practices to improve liaison quality. Other research shows congruent findings and mentions the positive effect of liaison quality on performance achieved by liaison engineers and personal relationships (Kobitzsch, Rombach and Feldmann 2001), facilitation of informal communication (Herbsleb and Mockus 2003), the presence of expert intermediaries, and supplier presence on-site (Carmel and Nicholson 2005).

Achieving satisfactory levels of liaison in an offshore project setting seems to be challenging due to the negative effects of cultural and physical distance. However, liaison between on- and offshore staff is vital for collaboration, working efficiency, and productivity. Thus liaison quality directly impacts offshore project success and we hypothesize:

H9: Liaison quality is positively associated with offshore project success.

2.6 The impact of offshoring expertise on project suitability, knowledge transfer, liaison quality, and offshore project success

We define expertise as a certain degree of individual or organizational experience in managing or conducting offshoring in a more efficient and thus successful manner. In organizational research this is commonly referred to as “learning curve effects” or “experience curve effects” (Day and Montgomery 1983, Ghemawat 1985).

As mentioned in the introduction, delivery in an offshoring context raises multiple challenges for all involved parties. Individuals as well as organizations can benefit from best practices and experiences they have had in past engagements. Thus they can cope better with offshoring-specific challenges.

The positive impact of expertise on diverse activities of the offshore process and directly on offshore project success has already been addressed in research. Carmel and Agarwal (2002) develop a maturity model for companies engaging in offshoring and give recommendations how to move along this maturity curve. In a study of an eight-year offshore outsourcing alliance, Kaiser and Hawk (2004)
describe how the alliance evolved towards a more beneficial co-sourcing model, for both the consumer and the supplier. Similarly, Mirani (2006) shows how increasing expertise leads to a change in the offshoring relationship from rather simple to more sophisticated arrangements. Rottman and Lacity (2006), in their study of offshoring practices at 21 U.S. companies, also find positive effects of expertise on offshoring success.

Higher levels of organizational and individual expertise help to cope with the potential challenges of offshoring and thus increase the probability of project success. Thus, expertise has a positive impact on all three mediating constructs because based on past experiences it is rather likely a company selects projects which are most suitable for offshoring. Additionally, the organization and the individuals know how to manage knowledge transfer and improve liaison quality based on their expertise. Thus, we hypothesize:

H4: IS offshoring expertise is positively and directly associated with offshore project success.
H5: IS offshoring expertise is positively associated with project suitability.
H6: IS offshoring expertise is positively associated with knowledge transfer.
H7: IS offshoring expertise is positively associated with liaison quality.

2.7 The impact of trust in the OSP staff on knowledge transfer, liaison quality, and offshore project success

We define trust as the “expectation that an actor (1) can be relied on to fulfil obligations […], (2) will behave in a predictable manner, and (3) will act and negotiate fairly when the possibility for opportunism is present” (Zaheer, McEvily and Perrone 1998). Trust can thereby take the form of interpersonal or inter-organizational trust. Inter-personal trust is trust placed by the individuals in their individual opposite member. Inter-organizational trust is trust placed in the partner organization by the members of a focal organization (Lee et al. 2008, Zaheer et al. 1998).

Trust is important within an IS offshoring context because it is a facilitator and precondition for activities such as knowledge transfer, but also for collaboration among team members in general. Trust thereby increases the room to manoeuvre within an arrangement beyond the specifications of a contract. If individuals or organizations trust their counterparts, they are more willing to cooperate and to put in extra effort if needed. (Lee et al. 2008)

In IS outsourcing research, the role of trust as an important arrangement attribute has been widely recognized. Higher levels of trust seem to positively influence the relationship between client and vendor (Grover et al. 1996, Lee and Kim 1999, Winkler et al. 2008). Recent empirical-confirmatory studies show that trust is positively related to the extent of knowledge sharing (Lee et al. 2008) and that trust, mediated by cooperative learning, has a significant positive influence on knowledge transfer (Park and Im 2007). With respect to IS offshoring research, trust is mentioned as a critical success factor regarding the interface between offshore consumer and supplier (Jennex and Adelakun 2003). Kaiser and Hawk (2004) confirm this in a case study and perceive the creation of trust as a best practice for successful offshoring because it facilitates collaboration between on- and offshore staff. Thus, offshore staff becomes productive in a short time and projects progress faster. Winkler et al. (2008) show that trust positively influences the degree of connectedness between an offshore consumer and a service provider in their aim to achieve specified goals. Rottman (2008) illustrates how trust facilitates the knowledge transfer within an offshoring arrangement because it increases the willingness to share knowledge and collaborate.

Apparently, trust seems to influence knowledge transfer because individuals are more likely to share knowledge if they trust each other. This is especially important when it comes to implicit and thus sticky knowledge. Additionally, trust fosters and facilitates collaboration, communication, and – more generally – increases liaison quality among team members. Thus we hypothesize:
H8: Trust in OSP is positively associated with liaison quality.

H9: Trust in OSP is positively associated with knowledge transfer.

Similar to our hypotheses concerning the construct “offshoring expertise”, we could hypothesize a direct effect of trust on offshore project success. However, the studies mentioned above and other non-IS research (c.f. literature overview by Lee et al. 2008) do not support such an association. They do not link levels of trust directly to success or outcome but rather examine the impact of trust on constructs such as relationship or partnership quality, thus assuming a fully mediated effect. We nevertheless include a potential direct impact of trust on offshore project success in our model. However, because the theoretical backing is weak, we treat it with the necessary prudence regarding its direct impact in the model on success and later interpretation of results:

H10: Trust in OSP is positively and directly associated with offshore project success.

3 ANALYSIS

We follow an empirical-confirmatory research approach. Our units of analysis are offshore application development or maintenance projects at German corporations. Section 3.1 explains our measurement instrument. Section 3.2 outlines the intended analysis method using Partial Least Squares (PLS) as a measurement technique.

3.1 Measurement instrument

We measure each construct by an indicator set, with each indicator being assessed on a 7-point Likert scale from “1 – strongly disagree” to “7 – strongly agree”. As far as possible we used indicators that were developed and applied in previous research and adapted them if necessary. Only for project suitability we had to define indicators ourselves since there is no known existing instrument from previous studies. We constructed these indicators on the basis of a previous qualitative study that examined factors determining a project’s suitability for offshoring (Westner and Strahringer 2008).

All constructs are measured reflectively, with the exception of project suitability which is operationalized by means of a formative multi-item scale. The reason for using a formative measurement model is that the indicators to measure project suitability are causing the construct instead of being caused by or reflecting it. Thus, the construct needs to be measured by a formative approach. (Diamantopoulos and Winklhofer 2001)

At this stage, we are still in the progress of conducting pre-tests of the instrument with academic staff at different universities and with industry experts and practitioners. The pre-test intends to ensure validity, quality, and comprehensibility of the questions and its presentation. Table 1 illustrates our preliminary measurement instrument. Column 1 contains the research model’s constructs, Column 2 the respective label, Column 3 the corresponding indicators, and Column 4 respective references to literature, if applicable.

*Table 1.* Measurement instrument for research model.

Proceedings ECIS 2009
Together with these indicators we will also gather data regarding whether it was a recent or old project, the offshoring country, the language in which the project was carried out, whether it was a captive or outsourcing offshoring project, project duration in months, project volume in man months and currency, respondents’ personal years of offshoring expertise, career position now, role on the project at the time it was conducted, whether the respondent resided on- or offshore, and to what industry the company belongs. This additional data will be used for better understanding and will serve as control variables.

3.2 Analysis method

We will transform our research model into a structural equation model and test it using PLS analysis. PLS is especially suitable in research areas where theory-building is still in its early stage. Additionally, it works with non-normal distributed data as well as with small sample sizes and it allows for incorporating formative and reflective construct measurement. (Gefen, Straub and Boudreau 2000, Herrmann, Huber and Kressmann 2006)

4 NEXT STEPS

After data collection, we will analyse the returned data and test our research model. In doing so, we will follow the generally accepted analysis principles when using PLS. The quality of our reflective indicators will be evaluated regarding content validity, convergent validity, and discriminant validity (e.g., Gefen et al. 2000, Huber et al. 2007). The specification quality, which is important for formative indicators, is ensured by a pre-study where we conducted interviews with 47 German offshore experts at different companies. Further tests for quality of the formative indicators will focus on its predictive quality, reliability, discriminant validity, and occurrence of multi-collinearity (e.g., Diamantopoulos and Winklhofer 2001, Huber et al. 2007). We will test for non-response bias by comparing the data of early returned questionnaires with later returned ones. Finally, we will actually test our structural model and its hypotheses and analyse for the effect of control variables. The final result’s interpretation will also reflect on the generalizability of findings to other countries.

Abstract

Mergers, acquisitions and divestments, including the carve-outs of business units or parts of them, are standard strategies used by multi-divisional organizations to adjust their business portfolios. Carve-out projects are critically dependent on their management of IT. Systems, which have been integrated in order to deliver seamless and efficient IT operations, must now be pulled apart under demanding time and compliance constraints. In 2007, Delta IT Consulting (DIC), one of France’s biggest IT-service provider, sold one of its three service provider divisions, IT Product Services (IPS). This division employed about 3,500 employees in 20 countries and previously generated 0.7 billion of DIC’s 3.8 billion euro revenues. DIC itself is a division of Delta Corporation - a French high-tech company and leading player in a wide array of businesses, industries and countries around the world. This teaching case challenges the reader to analyse and manage the IT carve-out as a critical component within the divestment project. The case includes insights into strategic and organizational challenges of planning and managing an IT carve-out project.

Keywords: teaching case, IT carve-out, IT project management, IT management.

[The names, dates and numbers have been changed for business in confidence reasons.]
1. INTRODUCTION

On December 4th, 2007, Delta IT Consulting (DIC) entered into a contract to sell its IT Product Services (IPS) division as part of “Organize4Profit”, its corporate organization-wide restructuring program. This strategic business unit (SBU), which represented 0.7 billion of the IT services unit’s 3.8 billion euro revenues, was one of three SBUs in DIC. A new CEO, Thomas Hutton, had been appointed in October with a mandate from Jean Claude, the Chairman of Delta Corporation, to restructure DIC, consolidating its sites in France from 48 to 21. The media coverage was intense.

IT was one of ten work streams in the carve-out project. All members of the IT carve-out team (IT-cut) were appointed at short notice. Nobody in the team had any experience of working on a carve-out project. However, everyone agreed that the following months would be extremely hard and time-consuming. Team members had to sign non-disclosure agreements, which were not part of their regular contracts. These were not only to guarantee confidentiality for the negotiations but also to ensure compliance with anti-trust regulations. Some team members wondered if they would have a job when the carve-out was signed off.

“We have to hurry,” said Alain Croix, Chief Information Officer at Delta IT Consulting (DIC) in his first communication with IT-cut, “Time is short. The sale closes on April 1 next year. It is only three and a half months to the hand-over.”

This case study examines the strategic and organizational challenges of planning and managing an IT carve-out project. Acquisitions and divestments are critical strategic decisions in global organizations such as Delta Group, with major political and reputation consequences, and significant impacts on their bottom lines. For example, the cost of an IT carve-out is frequently significant relative to the other sale costs. More importantly, IT carve-outs must meet deadlines and functionality imposed by the sale contract or incur substantial penalties. Therefore, the success of a divestment, such as the one made here by DIC, was critically dependent on IT-cut’s performance.

1.1 Business background/ context

Delta Group is a major global organization, operating in 160 countries. In 2007, it employed 372,000 people worldwide, generating revenues of more than 71 billion euro, with a net income of over 2.4 billion euro.

DIC was part of the Digital Processing and Transmitting business area, offering a broad portfolio of multi-vendor IT solutions and services for the private and public sector. With 10,000 customers, DIC was one of the world’s leading providers of IT services, generating revenues in 2007 of 3.8 billion euro. Its portfolio contained a range of services from consulting and system integration to the management and operation of IT infrastructure and entire business processes.

DIC was divided into three business divisions. The IT Solution Services division covered the first phase in the IT lifecycle. This included consulting services and the definition of customer solutions, including SAP, system integration, and IT and process consulting. The IT Operations Services division covered the second phase in the IT lifecycle. This included both the outsourcing of IT intensive business processes, including HR and financial services, and the management of data centres, desktop environments, LAN/WAN and call centres. The IT Product Services division (IPS) covered the third phase in the IT lifecycle, specifically maintenance and infrastructure services. IPS delivered platform-

2 In April 2007, Delta embarked on a major restructuring project Organise4Profit.
independent IT infrastructure services and solutions that addressed customers’ high availability, consolidation, migration and lifecycle management requirements, supporting a range of third-party platforms.

![ DIC Business Portfolio](image)

**Figure 1: DIC Business Portfolio**

In 2007, DIC was expecting to lose 109m euro, down from a profit the previous year of 40m euro. In April 2007 Delta Group had embarked on a major restructuring project, Organise4Profit. As part of that initiative, Delta Group was looking for a solution for this challenged SBU.

2. **THE CARVE-OUT**

Starting in September 2007, there had been rumors in the media about major changes at Delta, including Delta IT Consulting (DIC), to help the Chairman achieve his target of 5%-6% profit for all SBUs by mid-2009.

Off the record, Delta managers had admitted that DIC had too many contracts that were not profitable. This had led to major write-downs. The French business press reported early in October that all of DIC would be sold.

In November, the press speculated that Siemens had made an offer but this was denied. There was further speculation about negotiations with other companies from the USA and Germany, including Gedas, the IT service provider at Volkswagen, and International Computer Services (ICS), a 50-50 joint venture between Delta and International Computer Industries.\(^3\)

Finally, on December 4, it was announced that Delta was selling the IPS business to ICS. IPS by itself was one of the largest IT service company worldwide, employing 2,300 people in 17 countries and with a global network of 60,000 service partners and system integrators delivering services in 140 countries. Selling to ICS was logical because IPS’s customers were also customers of ICS. Selling IPS to a competitor would have been a serious threat to ICS, with the new owner acquiring both major service contracts and access to valuable insights into ICS technology.

The importance of the IPS acquisition was highlighted in the ICS Annual Report 2008, page 77:

> “The Services Division of ICS commenced business under ICS management on April 1, 2008. IPS and ICS are a perfect match. This is clearly reflected in the smooth integration. Ninety four percent of all customer contracts and 86 percent of former IPS employees transferred to the new Services Division on April 1. This is a major strategic

\(^3\) ICS delivers innovative, high quality IT products, infrastructure solutions and services to corporations, SMEs, and private users in all key markets across Europe, the Middle East and Africa. ICS’s offerings range from the smallest handhelds, through personal computing systems, to fully integrated enterprise-class infrastructure solutions. ICS complements this offering with the expertise of leading technology, software and service partners.
acquisition for us, building on our vision of a full-service, customer-driven organisation. The extended service portfolio enables us to compete more effectively against the other major players in this sector. The Services Division will operate as a separate subsidiary.”

On December 20, 2007, Delta and ICS signed a contract for ICS to buy IPS.

3. THE IT CHALLENGE

Confidential negotiations between Delta and ICS had begun in early October 2007, covering strategic aspects, including customer transfer, market expansion and business portfolio development. The Project Manager of the carve-out project was not part of the negotiation. Indeed, nobody from the carve-out team, let alone any member of IT-cut, had attended any of those negotiations. As a consequence, the contract covered very few aspects of the IT handover.

The overall carve-out project structure consisted of 10 work streams, of which IT was one. For example, the Human Resources work stream was responsible for all personnel issues, including negotiations about which employees would move to ICS. The legal work stream was responsible for conforming to the relevant regulations in the affected countries. Another work stream was responsible for the transfer of real estate. With many unique and unfamiliar tasks, the project team also hired a large number of consultants to support the work streams.

The IT work stream’s tasks were divided into IT infrastructure and IT applications. IT infrastructure covered all network issues, including rules for ICS to access the DIC’s IT systems during the transition phase. Telephone, fax, email, file services, print, desktop environments, back office systems and security were also part of the IT infrastructure domain. In addition, Internet and intranet systems had to move to ICS. Finally, all services that supported the data centers were migrated.

Within Delta, some local IT applications were under the control of regional business units, while core systems were centralized. Central applications were mandated for all countries, while local applications were approved only for a business unit from a specific country. The IT system for corporate group control, reporting and financials was an example of a central application. While these centrally controlled applications were immediately salient and visible to IT-cut, local applications were not well documented and were hard to track.

Because of the difficulty in identifying the relevant local applications, ensuring their timely migration to ICS was a major challenge. Each IT application had to be classified as a Delta-wide, DIC-wide or IPS-specific application. A pre-requisite for the classification project was an agreed process for the assessment of each application.

For example, consider the spare parts ordering system and the maintenance management system. While the former was used for the order and delivery of spare parts, it also triggered the billing process. The latter scheduled maintenance calls. Both systems were IPS specific. One advantage of IPS applications was their independence from IT Operations Services and IT Solution Services, the two other divisions in DIC. The datasets for these systems belonged specifically to IPS and there was no need to identify, separate and carve-out the relevant data. In contrast, the separation of shared DIC or Delta-wide applications was challenging.
Table 1: Six types of IT applications at Delta

The scheduling and billing systems for mobile technicians was an example of a DIC-wide application. This system was used by all DIC mobile technicians regardless of whether they worked for IPS or another SBU in DIC. In this case, IPS-relevant data had to be identified and carved out. Unlike the simple, direct transfer of an IPS-wide application to ICS, the transfer of a DIC-wide application was complex. The first decision to be made was whether to transfer the applications and data to ICS, or to separate the data and integrate it into an existing, similar system at ICS. A secondary decision was whether the historical data was important to ICS or whether ICS could be given access to the data by Delta via a Transition Service Agreement (TSA) for a specified period.

Delta-wide applications included, for example, mailing, groupware systems, and business warehouse and business intelligence solutions. Mailing and groupware systems were based on Microsoft technology, while financial and controlling systems, and the business warehouse and intelligence solutions were based on SAP technology. Mailing data for the affected IPS employees could have been carved out easily because each employee had an encapsulated mailbox. However, any employee in IPS was able to store documents and post comments to the Delta groupware platform. Therefore, it was difficult to identify and separate all relevant IPS employee documents and comments in order to both transfer them to ICS’s groupware system and delete them from Delta’ groupware system.

This was also the case for other Delta systems, including business warehouse and business intelligence solutions. Delta had invested heavily to harmonize the reporting structure across all business areas and regional business units. To do that, Delta had developed a standardized architecture for the business warehouse landscape in all regional business units. With integrated templates for the regional business units, Delta was able to consolidate quickly and easily across its warehouses around the world. Not surprisingly, these templates were not useful to ICS because it had implemented a different reporting system. The contract partners had to develop solutions to break such Delta-wide applications apart and to transfer them to ICS’s existing IT landscape.

Fortunately, both Delta and ICS used Microsoft technology for mailing, office and collaboration, and SAP for their financial and administrative backbones. This meant that there was a relatively high degree of compatibility between IPS and ICS systems. Unfortunately, that was the exception, and major differences between the IT systems of IPS and ICS were found everywhere. The problems were always in the detail. For example, there were differences in the desktop standard client. Although both partners used Microsoft Windows, the installed desktop standard client of IPS could not be used in the ICS environment. As a consequence, all desktop PCs transferred from IPS to ICS had to have the ICS desktop standard client installed.

IT-cut had to decide how to handle each application separately, with particular attention to the shared DIC-wide and Delta-wide applications.
Marcel Dupuis, leader of IT-cut, identified three critical IT challenges for IT-cut.

“The first is that some IT systems at IPS are hosted on the Delta IT platform and are highly integrated with other Delta IT systems. So, we have to work out how to identify the relevant IT systems and how to cut them out of our overall IT platform. But remember, while some IT systems are IPS-specific and are managed by IPS, they may also be used by other divisions.”

The second was:

“The complexity of the carve-out project itself. IT is only one work stream, although an important one, of this carve-out project. As one of the first steps, we will define the interfaces between our IT work stream and the other work streams (including Human Resources, Customer Contracts and Legal Issues) to ensure a good information flow.”

The third was the global coverage:

“I also anticipate changes in the number of countries to be affected by the carve-out, due to legal or strategic issues. IT is not organized centrally. Regional departments have certain authorities and power over IT decisions. This existence of local infrastructure and applications significantly increases the complexity of the IT carve-out project”

4. CARVE-OUT PROCESS

Figure 1 documents the steps to be followed in a typical IT carve-out project. The overall process is divided into four phases. These are separated by specific milestones. The first phase, “Pre-Signing”, clarifies and agrees all aspects concerning the contract. This includes the dates for the Closing milestone, the Transition phase and the Cutting milestone. In addition, the contract partners agree upon the distribution of costs for the overall carve-out project. This phase ends with the milestone “Signing” of the contract between the buyer and seller, finalizing the legal framework for the carve-out.

In France, without specific approval from the anti-trust agency, the seller’s project integration teams are not allowed to talk to the buyer about the carve-out. In this case, that approval was not expected to be given before the end of January 2008. Therefore, IT-cut had to plan and begin the project without communicating with ICS.

As part of the contract, it was agreed that ICS would have access to the IPS’s IT systems for six more months after Signing. Delta/DIC would provide the IT support and access for ICS during that period.

The second phase, “Pre-Closing”, establishes a working project management structure and creates the project management office. The IT carve-out team began its work stream with the analysis of networks and IT basic services. The relevant IT applications were identified, evaluated and prioritized for the IT carve-out.

The second phase ends with the “Closing” milestone. By then, all relevant IT systems had to be separated from DIC’s IT systems and exclusively under the control of ICS, guaranteeing its independence from DIC. This included separating the IT infrastructure, including email accounts, networks and telecommunication services.
The third phase, “Transition”, commences the day after Closing. On “Day One”, ICS required access to historical financial data and to have the capacity to manage its business within its own IT systems. Recognizing time constraints, and the time needed to carve out and integrate all relevant IT systems into the ICS’s IT infrastructure, DIC created a copy of the relevant IT systems, deleting all the data that was not included in the contract. During the remainder of the transition phase, DIC gave ICS access to DIC’s IT systems. This required the development of strict rules covering the access to the DIC’s network by ICS. This is terminated at the “Cutting” milestone. After the “Cutting” milestone, – fourth phase named “Post-cutting” – while ICS still has access to DIC’s network, ICS had established its own network and the network connection at DIC was physically decommissioned.

5. GETTING GOING

With no experience of an IT carve-out, the members of IT-cut have many questions for Marcel Dupuis. One of the team members asks: “Why do we have to do the IT carve-out in two steps? Why must we first duplicate all systems to fulfill the contract in time and then carve out all affected systems of our IT landscape afterwards in order to transfer them to ICS? Can’t we carve out the relevant IT systems until Closing?” Marcel stops him there and replies: “No, the task is too complex. At this time, we have no idea how many local IT systems are running in the affected countries. And the regional companies in those countries have strong power bases at Delta Head Office. It will not be easy to get all the relevant information quickly. We have to ensure that the regional companies are working with and not against us.”

Paul Alexander, a specialist in IT contracting, asks: “And how can we warrant this for ICS?” “With the help of Transition Services Agreements (TSA),” replies Alain. “TSAs govern access by business partners to our network. Therefore, we need strict rules to manage the carve-out firewall.”

“But, we have corporate guidelines for approving IT systems. According to those guidelines, we should be able to make a good guess about the affected IT systems in each country,” comments Carol Williams, who is specialist from organizational affairs. “You are right,” says Alain. “But guidelines are guidelines and not laws. Unfortunately, we are not able to monitor and control all regional business units and their IT portfolio. A certain freedom of choice is necessary to run effective regional business units. In addition, the guidelines are frequently only applied to Delta-wide global applications, for example, the e-mail and groupware standards. In the best case, a regional business unit has its own documentation system, but many of the regional business units have no documentation. Therefore, the identification of all affected local applications is one of our biggest challenges. We need to appoint a dedicated person to coordinate across the regional business units. This will synchronize our carve-out activities and approaches.”
“When we have identified all affected IT applications, would it be possible for us to simply separate those systems out of the existing IPS IT landscape?” asked Paul. “That is difficult, because the IT systems are tightly integrated with and connected to each other. But we could try this approach for IPS-wide applications,” answers Alain.

Carol offers another solution: “Could we copy and duplicate all affected systems and give them to ICS?” All the IT-cut members pause for a moment and think over this suggestion. Finally, Ernesto, a specialist on IT infrastructure, answers: “That approach sounds interesting. Unfortunately, it would be extremely expensive for us. And, in the end, it is likely that ICS would not want to have all of our IT systems, but only want to integrate the data into their existing systems.” Alain comments: “Additionally, almost every IT system is connected to another one. This means, that data is distributed all over the IT landscape and interlinked. In the worst case, we would have to duplicate our whole IT landscape, which is not realistic“.

“Ok, but then we could go another way. We could build up all relevant IT systems for IPS from scratch and only give over the datasets,” Paul suggests. Ernesto counters: “Then, what would we do with the existing contracts and depreciation schedules? What will happen to the old IPS systems that we do not need anymore?”

A lot of work is waiting for Alain Dupuis and his team in the next few months. It is clear, that this is not a simple task. The IT carve-out will end on April 1, which is only three and a half months away. The members of IT-cut are beginning to realize that an IT carve-out is more than just carve out IT. It is time to start.

6. **CASE QUESTIONS AND ISSUES**

1. Position the IT workstream within the overall project organization of the carve-out. What are the critical roles and competences required within the IT workstream?
2. Identify the main tasks for the IT carve-out and combine them within a project plan. Use milestones to structure the plan. Begin with the basic carve-out process model and extend as needed.
3. How can IT-cut establish transparency for the existing infrastructure and applications? Develop a data collection template.
4. How should IT-cut prioritize applications/systems for transfer? Develop a prioritization logic based on your data collection template developed in response to issue 3.
5. Develop a basic reporting tool and a management dashboard for the work stream project managers.

Abstract

Business process management (BPM) is a key issue for organisations, particularly in a global
business environment. In this paper we synthesise a framework for BPM governance and then report
two case studies that explore the influence of national culture on BPM governance in India. One case
study involves a global outsourcing services company with Indian origins and the other an Indian
manufacturing company that has recently established an overseas presence. The two case studies
provide a deep understanding of how culture influences BPM governance differently within each
organization and how BPM governance practices can be established to mitigate any negative
influences of national culture in a global context.

Keywords: Business Process Management, BPM Governance, Culture, India.

Acknowledgement

This study is supported by a grant from the Australian Research Council with SAP Research Australia
as the industry partner and is part of a project that compares business process management in
Australia and India.
1 INTRODUCTION

Business Process Management (BPM) is a priority for organisations around the globe as it enables sustained competitive advantage (Hung 2006). Recent studies indicate a growing awareness of and interest in process improvement and management among organisations (Harmon and Wolf 2008, Gartner 2007). It is felt that this trend together with the enabling role of information technology in BPM renders this phenomenon of particular interest to researchers of the Information Systems (IS) discipline. BPM is defined as a “holistic organisational management practice, which requires top management understanding and involvement, process-aware information systems, well-defined accountability and a culture receptive to business processes. It is based on a process architecture, which captures the interrelationships between the key business processes and the enabling support processes and their alignment with the strategies, goals and policies of an organisation” (Rosemann and de Bruin 2005). Business Process Re-engineering (BPR) can be considered as one of the foundations of BPM and in the context of process improvement, the primary difference between BPM and BPR is that the former emphasises ongoing improvement while the latter has become synonymous with radical one-off change (Armistead and Machin 1997).

Governance is a critical success factor for any BPM initiative (de Bruin 2007) as it is concerned with delineating accountability within an organisation (Weill and Ross 2004), managing the level and distribution of risk (Zingales 1997) and providing direction for the achievement of competitive advantage (Patel 2002). For purposes of this study, BPM governance is defined as the establishment of process-related responsibility and accountability mechanisms for the purpose of encouraging desirable behaviour in BPM. The majority of existing studies tend to be fragmented with focus on specific mechanisms of BPM governance such as process ownership (Booz Allen Hamilton 2003), process modelling (Bandara et al 2006) and performance measurement (Aberdeen 2006). There are only a limited number of studies (e.g. de Bruin 2007) which explore the interactions between these various mechanisms as a whole. Furthermore, contextual factors such as national culture which could potentially exercise an influence on BPM practice have also been relatively unexplored. Reports on the influence of culture on BPR (Agarwal and Haleem 2003, Martinsons and Hempel 1998) and on corporate governance (Buck and Shahrim 2005, Haniffa and Cooke 2002, Turnbull 1997) lead us to postulate that culture could have an impact on BPM governance.

India has emerged as a major player in the global economy in recent years due to its rapidly increasing share of the IT offshoring market. Liberalisation of its fiscal and trade policies in recent times has also led to increased presence of multinational organisations in the country and a furore of activity in many of its export sectors. Investment in IT solutions to manage and support business activity is also on the rise (Tarafdar and Vaidya 2006). In the context of implementation of one such IT solution in Indian organisations, viz. Enterprise Resource Planning (ERP) systems, process-related issues have been identified (Tarafdar and Roy 2003). Therefore it is felt that India provides an ideal setting for the study of national culture influences on BPM.

This paper explores the influence of national culture on BPM governance in India. The study builds on existing theory in both culture and BPM and includes in-depth case studies of BPM in two organisations in India. The remainder of this paper is organised as follows. Following the introductory section in which the motivation for the study has been outlined, an extensive review of literature concerning national culture and BPM governance is presented. Then the case study research method is explained. The fourth section of the paper provides a description of the two case study organisations and an overview of their BPM practice. This is followed by an in-depth analysis of BPM practices in the case-studies through the lens of national culture. The discussion section then presents the main findings and implications for research and practice, and the paper is concluded with limitations of the study and directions for future work.
2 LITERATURE REVIEW

This section presents the theoretical underpinnings of the study. The concepts of BPM governance and culture are defined and operationalised.

2.1 BPM Governance

The term governance is synonymous with the exercise of authority, direction and control (Zingales 1997) and is intended to ensure an organisation’s efficiency and effectiveness (Zingales 1997, Simonsson et al 2008). BPM governance has been identified as one of the factors for measuring BPM maturity in organisations and has been defined as the establishment of relevant and transparent accountability, decision making and reward processes to guide actions (Rosemann et al 2007). While this definition emphasises the exercise of authority and control, it does not adequately explain the intent or direction of these activities. A widely-employed definition of I.T. governance is that it specifies the decision rights and accountability framework to encourage desirable behaviour in using I.T. (Weill and Ross 2004). A common feature of this perspective with that of Korac-Kakabadse and Kakabadse (2001) is the emphasis on the focus or objective of the governance activity. Therefore, for purposes of this study, BPM governance is defined as the establishment of process-related responsibility and accountability mechanisms with the objective of encouraging desirable behaviour in BPM.

The governance component of the BPM maturity model includes five capability areas which include process management decision making, process roles and responsibilities, process metrics and performance linkage, process management standards and process management controls (Rosemann et al 2007). However it is felt that some of these capability areas could be considered collectively as there they are closely related and there is some overlap in definition. Therefore, for purposes of this study, a high-level BPM governance framework consisting of four distinct components has been synthesised. This framework differs from the governance component of the BPM maturity model in several ways. Firstly, process roles and responsibilities is perceived to include roles and responsibilities in process management decision-making as well and therefore a component titled “process-related responsibilities and accountability” which incorporates both aspects has been used. Similarly process metrics, performance linkage and process management controls have been collectively considered as BPM Quality Assurance. Furthermore, while the the BPM Maturity model includes process architecture as a capability area within strategic alignment, it does not include considerations to process definition as part of BPM governance. However, it is felt that the clear and consistent definitions of process and prioritisation of these in terms of criticality to operations should be considered as part of BPM governance as it is intrinsically linked to definition of process roles, standards and quality assurance. Therefore process definition has been included as a component of BPM governance in this framework. The components of the BPM governance framework as used in this study are described as follows:

- **Process-related Responsibilities and Accountability** (Ewusi-Mensah 1997, Fitzgerald and Carroll 2005, Kirchner 2005, Rosemann et al 2007, Weill and Ross 2004) – Process owners and committees for key processes with duties and responsibilities need to be clearly specified. This includes specification of authority for providing inputs to and making process-related decisions and the specification of precise reporting structures. It also includes the rules for enforcement of accountability, definition of the corresponding penalty and reward systems as well as provision of guidelines for escalation of issues.
- **Process Definition** (Rosemann et al 2007) – Processes need to be prioritised in terms of criticality to operations. At the very least highly critical processes need to clearly defined, documented and made accessible for use.

Proceedings ECIS 2009
• **Process Standards** (Fitzgerald and Carroll 2005, Rosemann *et al* 2007) – Guidelines for conducting all BPM activity such as process modelling, communication, issue resolution and monitoring need to be established.

• **BPM Quality Assurance** (Broadbent 2002, Fitzgerald and Carroll 2005, Rosemann *et al* 2007) – Periodic reviews to manage the quality and currency of processes as well as the efficacy of the organisation’s BPM practice need to be established. Metrics, which are in keeping with the organisation’s strategic goals, must be established for each process. These may be either quantitative or qualitative in nature but need be defined in such a manner as to enable ease of measurement. Performance must be monitored on a regular basis to ensure alignment with the overall BPM and organisational goals.

2.2 Culture

Culture is defined as the collective programming of the mind that separates the members of one group or category of people from another (Hofstede 1980). At the core of culture are values which are defined as broad tendencies to prefer certain states of affairs over others (Hofstede 1980). These tendencies are manifested in rituals, heroes and symbols which are collectively represented by practices or behaviours. Although these are visible to outsiders, their cultural meaning is not necessarily so and is determined by the way in which the practices are interpreted by other members of the same group. While behaviours can be modified with the introduction of incentives, values are relatively more stable over time. There are various levels of collective mental programming such as national, regional/ethnic, gender, generation, social class, industry/professional, organisational and departmental. This focus of this study on BPM governance in Indian organisations is at the national level and henceforth the term “culture” refers to national culture unless otherwise stated. The study of national cultural differences and resultant implications for management has been dominated by the characterisation of culture along a variety of preordained attitudinal dimensions or predispositions to action. For the purposes of this study, the three most influential theories of national culture are synthesised and the resultant five dimensions deemed to be most appropriate for the study of BPM governance are presented in Table 1. These include the works of Hall (1976), Hofstede (1980) and the GLOBE project (House *et al*. 2004).

*Table 1 Dimensions of Culture*

Hofstede (1980) administered a questionnaire to and analysed the responses of 72,215 employees of IBM across 40 countries. From this analysis he developed four dimensions of culture viz. power distance, individualism, masculinity and uncertainty avoidance. Later, a fifth dimension, long term orientation, was added. Each observed country was scored relatively on an index ranging from 0 to 100 for each dimension. This work has dominated cultural studies in the information systems discipline (Myers and Tan 2002).

The Global Leadership and Organisational Behaviour Effectiveness (GLOBE) research project (House *et al*. 2004) focuses on the relationships between national/societal culture, organisational culture and leadership. It involved 150 co-investigators who collected data from approximately 9000 managers in 500 different organizations in 3 different industry sectors in 61 countries. Nine dimensions have been identified and responses to questions based on these dimensions were sought from employees in three industry sectors across sixty two nations. The dimensions identified by the GLOBE project include...
uncertainty avoidance, power distance, societal collectivism, in-group collectivism, gender egalitarianism, assertiveness, future orientation, performance orientation, humane orientation.

Hall (1976) differentiated between cultures on the basis of context for communication. His contention is that the elements which combine to produce a given meaning – events and context – are in different proportions depending on culture. Therefore he compared cultures on a scale from high to low context. High context cultures rely on extensive social networks in the everyday lives and therefore do not require as much explicit background information for communication as low context cultures.

The five dimensions of culture which have been deemed as appropriate for use as a lens to examine BPM governance are explained as follows:

- **Power Distance** is the extent to which members of institutions and organizations within a country expect and accept that power is distributed unequally.
- **Individualism** refers to loose ties between individuals as opposed to strong ties with a given social network.
- **Uncertainty Avoidance** is the extent to which the members of a culture perceive ambiguous or unknown situations as threats as opposed to opportunities.
- **Performance Orientation** refers to the extent to which a society rewards innovation, quality and performance improvement.
- **Context** refers to the degree of explicit background information that is required for effective communication.

3 RESEARCH METHOD

The primary objective of this exploratory study is to understand how and why culture might influence BPM governance in Indian organisations. Therefore case study was selected for conducting the research as it been identified as an appropriate method for conducting “how and why” enquiries into real world phenomena (Yin 2003). As a first step, an extensive literature review was conducted to derive comprehensive definitions for both culture and BPM governance. Following this an interview protocol was developed to enable a systematic enquiry. The protocol consisted of both closed and open-ended questions – the former to ensure that responses are appropriately equivalent for purposes of cross-case comparison and the latter to provoke thought and dialogue in keeping with the exploratory nature of this study.

Two case studies were undertaken, one in a global outsourcing services company with Indian origins (Case Study A) and the other an Indian manufacturing company that has recently established an overseas presence (Case study B). The case study sites were selected on the basis of matched dimensions (including turnover, number of employees, position in industry etc.) which enable cross-case analysis. The unit of analysis in each case study was the BPM initiative including people, activities and documentation. Data collection included seven interviews at the first case study site and nine at the second. Interviewees included representatives from senior and middle management as well as staff at the operational level for purposes of completeness in understanding the BPM governance practice at each organisation as well as triangulation. The duration of each interview was between sixty and ninety minutes. This was further supplemented by a greater number of shorter interviews to follow-up on particular aspects of earlier interviews as well as observation of activity over several days. Extensive notes were kept of each interaction and interviews were audio-recorded wherever permission was granted. Appropriate documents, if any, were also scrutinised.

Following the data gathering phase, the audio recordings and notes were transcribed. Initial analysis of the text was done using constructs from the BPM framework described in section 2.1. The findings are presented in section 4.2 and 4.4. Further analysis within each of these was carried out through coding based on the dimensions of culture identified in section 2.2 and is presented in section 5.
4 CASE STUDY DESCRIPTIONS

In this section a description of the two case-study organisations is presented together with an explanation of the motivations for their BPM initiatives as well as a description of their BPM governance using the framework described in section 2.1.

4.1 Case Study A

This organization provides software and business process outsourcing services. Established in the early 1980s, it trades as a public limited company and is placed in a leadership position within its industry. From its very inception the organization has focused on developing its primary client base outside India and over the years offices have been established in several countries for purposes of front-end operations such as marketing and client liaison. As a result the organization has been a key player in the phenomenal growth of the I.T. offshoring market in India. Apart from its meteoric growth, the organization is also renowned for its relentless emphasis on quality. It has adopted a number of popular methodologies for this purpose such as Six Sigma and Balanced Scorecard and has been benchmarked to a number of global quality standards such as Carnegie Mellon University Software Engineering Institute’s Capability Maturity Model, People Capability Maturity Model, Malcolm Baldridge framework, ISO9001 and EFQM to name a few. Apart from ensuring the enforcement of highest quality standards from an internal management perspective, these initiatives also serve as a powerful signal of the organisation’s competency to the external market.

The organization is structured into business units which are defined along the parameters of domain specific knowledge and skill development. The organization has a matrix structure as there is movement of personnel, information and knowledge between the business units. There is also considerable exchange of personnel, information and knowledge across the company’s global operations. In the early 2000s the lack of integration between the systems being used was identified as the primary cause for the absence of insight into initiatives across the organization, particularly in the deployment of resources that enabled/supported them. Various tactical and operational bottlenecks were also ascribed to the same cause. The senior management of the organization recognized the limitations of the existing way of working and its repercussions on the business and an enterprise-wide BPM project for integrating the rich knowledge base of the organization was initiated. A multi-disciplinary team dedicated to the capture of process-related information and its management was established. A process repository was created and made available to employees via the intranet portal.

4.2 BPM Governance at Case Study A

Process-related Responsibilities and Accountability - As soon as senior management took the decision to implement BPM as part of the overall business strategy, a dedicated BPM team was established as the preliminary step. The team consists of 6 members with clearly specified areas of responsibility which included the initial setting up of the BPM project and its ongoing management. The first task for this team was the appointment of a process owner for every critical process. The process owner was responsible for defining the process, monitoring its ongoing performance and ensuring its alignment with strategy. The main challenge was to identify appropriate process owners. In many cases, this was straight-forward and was guided by the operational role of the person concerned. However for processes which span across business units, there were no volunteers and consequently the BPM team exercised their authority to nominate a person for each role as they deemed fit. Each process owner was then advised of the scope and nature of their responsibility including their role in the decision-making process. The reporting structures within each process area and issue resolution hierarchy was clearly outlined and communicated to all the concerned persons. Extensive documentation relating to process ownership definition and organisational reporting structures was prepared by the BPM team.
Process Definition - Each process in the organisation was documented and stored in a repository. The process documentation (PD) contains comprehensive information about the process including the description and sequence of tasks, the personnel involved and the data requirements. It also contains process maps that were drawn up jointly by the process owner and BPM team. In some situations there was a need to work backwards from the operating IT systems/solutions to identify the underlying business processes. Any change to a process is documented by the process owner on an ongoing basis. All of this information is available to employees from a BPM system via the organisation’s intranet portal. Access is automatically restricted to the area of business for each employee to prevent misuse of information. Every employee is expected to use the BPM system to record everyday activity. The system has built in validation checks and authorisation requests are automatically raised. The industry in which this organisation operates exhibits high attrition rates and therefore, having detailed documentation of all processes ensures that vital knowledge is not lost with departing personnel and new employees can settle into their roles quickly.

Process Standards - Standards were established for all necessary aspects of BPM activity. This included standards for process modelling and definition to ensure common understanding and co-ordination of BPM activities throughout the organisation. All employees received the necessary training to ensure that the standards are understood and enforced. All information related to standards, including any changes, is made available to employees via the online BPM system.

BPM Quality Assurance – The establishment of standards paved the way for quality assurance activity. Appropriate metrics were defined for each process as well as standard reward and penalty structures for process-related performance. Regular review cycles were established to ensure efficiency and effectiveness of the organisation’s activities. Furthermore the BPM activity itself comes under periodic review to ensure continuing efficacy of the practice and to identify ongoing opportunities for improvement. Following the review, adherence to desirable behaviour is rewarded while non-compliance is penalised.

Case Study B

This organization operates in the manufacturing industry and is a market leader in a diverse range of consumer durables. It commenced manufacturing operations in the 1955 and prides itself on a range of innovative products with a number of patent and design registrations. The organisation has 7 manufacturing units suited for scalable operations. These are supported by 20 branch offices and an extensive distribution network to reach 400,000 retail outlets across the country. The company also operates 25 exclusive branded retail outlets. The company has achieved its leadership position in the domestic market primarily due to its ability to provide high quality products at affordable prices. All products meet global standards such as ISO9001 for both design and quality. The management believes that the company owes its survival to a fundamentally progressive philosophy which, while emphasising the organisation’s essentially Indian identity, is also receptive to flexibility and change in the way of working to keep pace with changing times.

In the early 2000s the organisation underwent a shift in focus. Having established itself as the significant player in the domestic market, the company started to explore export opportunities and after due consideration a subsidiary was established in the USA. At the same time the hitherto underlying value discipline of product innovation was perceived to be insufficient for the strategic plans outlined for the future. An emphasis on operational excellence was introduced to complement brand and design capabilities. An ERP system was identified as the appropriate I.T. solution to support operational efficiency. The introduction of the ERP system resulted in the erosion of functional silos and the organisation was restructured as a process-centric enterprise.

4.3  BPM Governance at Case Study B

Process-related Responsibilities and Accountability – Process-related decisions in this organisation tend to focus on IT rather than on business. Process-related roles were not explicitly established. This
is because, unlike at Case Study A, an explicit BPM strategy was never clearly established at Case Study B by senior management. Process management was assumed to be a part of the ERP system implementation project and fell under the overall responsibility of the IT department. Consequently, persons with operational responsibility for the various functions assumed charge of the related processes. This has resulted in considerable overlap in the case of cross-functional processes resulting in collective rather than individual responsibility and accountability. Wherever consensus is not achieved, familiarity with the ERP technology tends to dictate which person has the last word in decision-making. Reporting and issue resolution structures tend to follow a similar pattern.

Process Definition – The average duration of employment of middle managers at this organisation is twelve years and attrition does not appear to be common enough for concern. During much of the past decade the organisation experienced phenomenal growth in the domestic market and for a period of three years in the late 1990s and early 2000s, an average rate of growth of 30% was achieved. This has been attributed firstly, to the expertise of the various functional managers and secondly, to the flexibility and responsiveness of the organisation’s business processes. While these characteristics have served the organisation well during the growth phase, it has also encouraged a tendency to rely on individual expertise rather than on well-defined processes. This is also accompanied by a tendency to abstain from locking-in process definitions for fear of making them rigid and less-responsive to change. The quality assurance (QA) process and the payroll process were the only two areas within the organisation that had any kind of process-related documentation. The QA process documents were developed as part of the regulatory requirements for certification of product and design quality. The payroll process documents were prepared by the payroll manager on the basis of his own initiative rather than a directive from the organisation and rarely used to guide day-to-day operations.

Process Standards – There is also a marked absence of explicitly defined standards. In terms of process documentation, those relating to the QA process are comprehensive and meet regulatory requirements. Graphical representations of the design and manufacturing process are detailed. However, the lack of clearly established standards for documentation is evident in the payroll process documents. The process descriptions are textual rather than graphical and minimalistic in nature. Many of the terms used are ambiguous and comprehensible only to the person who created them. However, the investigation revealed that absence of explicit standards and documentation in the organisation has not hampered internal operations and dealings with local clients. Instead these interactions are guided by consciously established social relationships and networks.

BPM Quality Assurance – A structured quality assurance activity is not discernable and metrics to judge process performance are not explicitly defined. In the case of the payroll process documentation, which lists 8 core processes, the performance measure for every one has been expressed as “timely action”. There is no accompanying explanation as to what constitutes timely action. However this does not mean that activities are not monitored. Once again, the organisation relies on the expertise of its managers to track process performance and to identify shortcomings. Reviews are conducted on an ad hoc basis and in an informal manner. Furthermore, a fierce loyalty to the organisation and its leadership is evident and verbal recognition of achievement is considered sufficient reward for adherence to desirable behaviour. Non-compliance is not punished outright but gently discouraged.

5 CASE STUDY ANALYSIS

The BPM governance practices of the two organisations which were described in the previous section are now examined using the dimensions of culture as a lens.

Power Distance is described as the extent to which members of institutions and organizations within a country expect and accept that power is distributed unequally. India exhibits a tendency for high power distance and the associated behaviours include emotional relationships between subordinates and superiors and the perception of the boss as a benevolent autocrat or parent (Hofstede 1980, House et al 2004). At Case Study A, processes are adhered to mainly because of the strict enforcement of
rules and the accompanying rewards and penalties. This reflects a somewhat impersonal style of management. However at Case Study B, a strong emotional relation with one’s superiors and the respect for authority and expertise is reflected in the accompanying desire to stand favourably in their opinion which in turn motivates compliance to organisational processes. Rather than enforcing penalties for acts of non-compliance, offenders are reprimanded by their supervisors and gently shepparded back into line much like in a parent-child relationship. It was also perceived that communication between superiors and sub-ordinates sometimes suffers due to the high power distance. At Case Study A, supervisors can look up the BPM system to obtain an accurate picture of the state of operations. However, at Case Study B, supervisors request face-to-face meetings with subordinates in order to obtain an understanding of the current situation. This communication mechanism is highly dependant upon the established relationship between the people involved and effective communication is at times overshadowed by respectful reticence and fear of loss of face.

**Individualism** refers to the strength of ties within a given social network. India exhibits a tendency towards low individualism or, in other words, collectivism (Hofstede 1980, House et al 2004). At the workplace the primary visible behaviour of collectivist societies is that personal relationships prevail over task rather than the other way around and occupational mobility is lower. At Case Study A, while relationships within teams are nurtured, such structures are short-lived as employees are frequently moved across projects. Furthermore an employee’s relationship with the organisation as a whole is largely impersonal and, as mentioned earlier in this paper, attrition rates are high. At Case Study B, on the other hand, employees identify themselves strongly with the organisation and perceive the fate of the organisation as being parallel to their own. This acts as a compelling motivator for performance. Stronger bonds are forged with members of the same functional unit and this provides the foundation for all work-related activity. Most employees tend to remain in the organisation once employed and the length of period of relationship further enhances its stickiness.

**Uncertainty Avoidance** refers to the extent to which the members of a culture perceive ambiguous or unknown situations as threats as opposed to opportunities. Members of low uncertainty avoidance cultures such as India exhibit a tendency for tolerance of ambiguity and chaos and are generally better at invention than at implementation (Hofstede 1980, House et al 2004). At the first case study site, a marked intolerance for ambiguity is noticed. Roles, standards, metrics etc. are clearly specified and systematically enforced. However at Case Study B, ambiguity prevails over nearly every aspect of BPM and management of related activities is through individual expertise on an ad hoc basis.

**Performance Orientation** refers to the extent to which a society rewards innovation, quality and performance improvement (House et al 2004). India exhibits a tendency towards low performance orientation and associated behaviours include high value placed on relationships and loyalty and less emphasis on training and development, results and rewards. At first glance, these characteristics appear to correspond with the features of Case Study B and not with those of Case Study A. However, a closer study reveals that results are valued at Case Study B and this is, in fact, a reason for emphasising outcomes rather than processes. Furthermore rewards are also valued, albeit the nature of the reward is not promotion or a financial incentive (as at Case Study A) but recognition and a sense of achievement. Therefore it is concluded that the influence of performance orientation on BPM governance has not been established in either case study.

**Context** refers to the degree of explicit background information that is required for effective communication (Hall 1976). India exhibits high context tendencies which mean that members of this society rely on subtly implicit and highly contextual information to enable communication. To a person who is unfamiliar with the associated contextual details, the communication may seem ambiguous and ineffective. At Case Study A, all process-related communication is explicit and for the most part, occurs via the online BPM system. At Case Study B context rich verbal communication occurs between the peer-groups of employees constantly. Therefore the absence of explicit mechanisms does not appear to affect the quality of communication between employees.
6 DISCUSSION

A number of broad trends have emerged through the analysis of the two case studies. Firstly, this study provides empirical evidence for and insights into the influence of culture on BPM governance. The analysis of Case Study B indicates that the Indian cultural characteristics of high power distance, collectivism, low uncertainty avoidance and high context have resulted in highly informal BPM governance practices which might appear ambiguous and chaotic to persons who are unfamiliar with the cultural context. The findings related to power distance and collectivism corroborate those of a cross-cultural study on the influence of culture on BPR projects in India and the USA (Agarwal and Haleem 2004). This study established that individualism and low power distance, which are characteristics of American culture, facilitate the implementation of BPR projects whereas collectivism and high power distance exert a negative influence in the Indian context. However, the same study also established that low uncertainty avoidance facilitates BPR. This is in contrast to the empirical evidence of this study which establishes that, in fact, low uncertainty avoidance results in a more casual approach to BPM governance with less emphasis on establishment of process roles, definition and standards.

On the other hand, the analysis of Case Study A demonstrates that an organisation which operates in the same national context as CASE Study A and therefore susceptible to the same cultural influences can successfully use a highly formal and rigorous BPM governance practice to mitigate the negative impact of such influences. Furthermore, the experience of this company suggests that there is a relationship between an organisation’s motivation for BPM and its susceptibility to cultural influence. According to the definition employed in this study, the primary objective of BPM governance is to encourage desirable behaviour. At Case Study A, we find that from its very inception the emphasis has been on establishing and maintaining a client base outside India. In other words, the desirable behaviour can be described as adopting work practices that enable and support business dealings with international clients. The BPM governance practice has been consciously designed to support interactions with non-Indian persons. Therefore an examination of the various aspects of BPM governance revealed an absence of Indian cultural influence. This has proved to be a success factor for the organisation in establishing itself in the I.T. offshoring market. In contrast, until recently, the desirable behaviour at Case Study B has been the adoption of work practices that enable and support business dealings with Indian clients. The rather ambiguous and informal BPM governance that has been practiced hitherto appears to have supported this objective. This corroborates findings from a study which demonstrates that exposure to global markets has driven software firms in India to have adopt western-style corporate governance practices (Khanna and Palepu 2004).

The contributions of this study for research are two-fold. Firstly, the development of a BPM governance framework based on literature review has proven useful for the study of such practices in organisations. As mentioned earlier in the paper, existing research on BPM governance has tended to be fragmented and focussed on specific mechanisms such as process ownership (Booz Allen Hamilton 2003), process modelling (Bandara et al 2006) and performance measurement (Aberdeen 2006). The BPM governance framework employed in this study provides a holistic perspective of the topic. It has also facilitated systematic and thorough data collection and analysis. Secondly, the majority of cultural studies in IS rely on the cultural dimensions of Hofstede (1980) alone. By including dimensions from other two other sources, this study has demonstrated a richer means of analysing the impact of culture on organisational practice. Although the impact of performance orientation on BPM governance has not been established in this study, the inclusion of this dimension from the GLOBE project (House et al 2004) has enabled the investigation into the case study organisations’ approach to outcomes and rewards. The inclusion of communication context (Hall 1976) as a cultural dimension has provided a clear explanation for Case Study A’s enthusiastic adoption of an impersonal technology-based BPM system for process-related communication while Case Study B employs communication methods which appear to be highly context-dependant and therefore chaotic and ambiguous to outsiders.
For practitioners, the emphasis of the study on the relationship between motivation for BPM and susceptibility to cultural influence is enlightening. The focus on offshoring business at Case Study A has resulted in a systematic and well-designed BPM governance practice while the largely informal practice at Case Study B has proven to be sufficient for its focus on the domestic market. However, as mentioned earlier in the paper, the desirable behaviour for the latter organisation is undergoing change as it is now actively seeking to expand its export capabilities. As the example of Case Study A has demonstrated it is possible that interactions with international clients would require more explicit communication and more formalised process management thus rendering the existing informal ways of working a bottleneck rather than an enabler. Therefore one may conclude that Indian organisations seeking to establish international business should consider adopting formal BPM governance practice in a similar fashion to Case Study A in order to reduce/eliminate the negative influence of Indian culture on their operations and to facilitate open and unambiguous communication between all parties.

7 CONCLUSION

This paper makes several key contributions to the understanding of cultural influence on BPM governance. It builds on existing research on BPM governance and culture and also serves as an exemplar for conducting culture-focused case studies on BPM governance. The findings of the study will be of use to organisations in India which are en route to expanding export capabilities by alerting them to the importance of designing their BPM governance to mitigate the possible negative impact of cultural influences.

A limitation of this study is that it focuses on a single cultural context. It is felt that the influence of culture on BPM governance can be better understood by comparing practices in two or more culture contexts. This limitation of the current study helps to set the agenda for future research. An in-depth study of several organisations in India and Australia is currently underway and it is anticipated that the cross-national comparisons will explain the impact of culture on BPM governance in a comprehensive manner. Furthermore the differences between a domestic-market focussed organisation and a global one also motivates the inclusion of both locally owned/operated organisations as well as subsidiaries of multinational companies in both countries.

Abstract

As today’s Information Technology (IT) penetrates the business of almost any company, the IT integration of two companies is regarded as one of the most challenging tasks in mergers and acquisitions (M&A). This integration mainly takes place during the post-merger integration (PMI) phase of an M&A endeavor. In this phase, well-defined IT governance is critical to success since it specifies the decision rights and an accountability framework to encourage a desirable course of the IT integration. It harmonizes IT-related integration issues with desired behaviors and business objectives.

In this paper, we provide a framework for IT Governance in the PMI phase (ITGoPMI). The ITGoPMI framework can serve as a blueprint for the specification of organizational units and their decision fields when the IT functions of two companies become one. We are developing the framework according to the principles of design science research in an iterative manner. Preliminary versions of the framework were evaluated through expert interviews. They approved that the here presented version of our ITGoPMI framework already has the potential to serve as a beneficial guideline for post-merger IT integration in practice. Nevertheless, we will continue our research process with further evaluation and improvement of the framework.

Keywords: Mergers and Acquisitions, IT Governance, Design Science, Organizational Change
1 MOTIVATION

Over the last few decades, mergers and acquisitions (M&A) have established themselves as important options for companies striving for growth or increasing profitability (Alaranta & Henningsson 2008). As today’s Information Technology (IT) penetrates the core business of almost any company, the IT integration is regarded as one of the most challenging tasks in these M&A endeavors (Schewe & Lohre & Böhmer 2007, Carr 2003). Surveys underline that this integration aspect is often seen as a cause for problems or unfulfilled expectations (PwC 2004, ComputerWeekly 2001, Deloitte Consulting 2008).

Consequently, IT governance can be considered as critical to the combination of IT functions that mainly takes place during the post-merger integration (PMI) phase of an M&A endeavor. Not only in the PMI context, IT governance specifies the decision rights and an accountability framework to encourage a desirable course of the IT integration (Weill & Ross 2004). It harmonizes IT-related integration issues with desired behaviors and business objectives. Appropriate structures and procedures need to be established in order to achieve success of the overall M&A endeavor.

Although the importance of this topic is striking, the issue of IT integration in M&A has only received little consideration in academic literature (Henningsson & Svensson & Vallén 2007, Mehta & Hirschheim 2004, Alaranta & Henningsson 2008). From our point of view, especially the role of IT governance in the PMI phase of M&A has been regarded insufficiently.

Addressing this insufficiency, the objective of this paper is to provide a framework for defining IT governance for the course of the PMI phase. It can serve as a guideline to cope with the issues linked to the post-merger IT integration by suggesting IT-related organizational units and adequate allocation of decision rights.

Having provided the motivation for the development of a framework, the next section will present foundations about IT governance and M&A that lay out the basis for our work. Thereafter, we will argue that the development of such a framework can be approached according to design science which aims at designing innovative artifacts that are built and evaluated in an iterative manner (Hevner & March & Park & Ram 2004). We will present our research method by illustrating the iteration steps that have been completed so far. Subsequently, we will explain the current version of our Framework for IT governance in the PMI phase (ITGoPMI) which is the result of the third iteration of our research process. Finally, we will briefly discuss implications for further research.

2 THEORETICAL BACKGROUND

2.1 IT Governance

Beyond doubt, the term IT governance refers to the steering of the use of information technology of all kinds within a company. However, as several authors have pointed out, there is no consistent understanding of the term neither in research nor in practice (Johannsen & Goeken 2007, Rüter & Göldner & Schröder 2006, Simonsson & Johnson 2006). For instance, Weill and Ross (2004) define IT governance as “specifying the decision rights and accountability framework to encourage desirable behavior in using IT”. Desirable is the behavior that is aligned with the general targets, strategy, values and norms of a company. Therefore, the design of IT governance is always specific to a given company. The scope of IT governance are not single decisions themselves but the determination which decisions need to be made, who can contribute to the decision-making processes and who is eventually eligible to make the decision. In this sense, every company has an IT governance, but only an explicitly designed one is able to align IT effectively and efficiently to the goals of the company. In order to achieve this, IT governance needs to be in line and linked with the general corporate governance. Information and information technology are seen next to employees, finance, physical
Not only in the previous definition, but also according to Luftman (2003), Van Grembergen (2002) and the IT Governance Institute (2003) IT governance refers to the leadership of the use of IT. Furthermore, there is consensus that the ultimate goal of IT governance is IT business alignment (Gentle 2004). Steering and monitoring of structures form the key tasks of IT governance.

From our point of view, a strict differentiation between two possible conceptions of IT governance is necessary. On the one hand, IT governance can be regarded as the definition of structures and procedures of decision-making, and the allocation of decision rights to people and units. On the other hand, some definitions also include the actual decision-making. Adopting the definition of IT governance by Ross and Weill in this paper, we agree with the first conception.

2.2 Post-Merger Integration of IT

Mergers and acquisitions can be classified entirely different based on either legal terms or practical power differences between the two fusing companies (Alaranta & Henningsson 2007, Henningsson & Carlsson 2007). A discussion of these differences is beyond the scope of this paper. In fact, both mergers and acquisitions typically require the IT of two companies to be combined to a certain degree.

Integrating former independent IT functions is one of the major challenges of an M&A process, even seen more critical than resistance of employees in general. Nevertheless, this challenge is not always considered as it should be in respect to its importance (McKiernan & Merali 1995, Wirtz & Wecker 2006, Deloitte Consulting 2008). For the series of actions, which need to be proceeded to form the combined IT, the term *IT integration process* has been established. However, it is not necessarily an integration in the truest sense of the words. As a matter of fact, the IT integration process covers all decision areas of IT governance, not just the technical core parts but also its soft aspects like organization and strategy. Therefore, we assume that the integration of IT also covers the integration of information systems (IS). In this sense, we see IT as the broader term that encompasses not only technical facilities but people, organizational structures, procedures, tasks and processes as well.

The IT integration process can be regarded as a transformation caused by the overall M&A process (Farhoomand 2005, Schewe & Lohre & Genius 2007) and takes place during the *post-merger integration* (PMI) phase (see Figure 1). Together with the two phases ‘preparation’ and ‘transaction’ PMI forms the M&A process as a whole (Meckl 2006, Henningsson & Carlsson 2007).

![Diagram of IT integration process](image)

**Figure 1. Transformation of IT during the post-merger integration**

According to Wijnhoven & Spil & Stegwee & Fa (2006), there are four prototypic strategies which refer to different levels of integration. For instance, a superior player usually assimilates the inferior one, whereas there are also mergers of coequal organizations that have to proceed differently. The
The most rigorous strategy is to replace any existing IT (see outer left box in Figure 2). The second strategy is the adoption of existing IT instead of creating an entirely new one. Standardization as the third option can be described as taking parts out of both present ones and recombine them into the new IT. This is often done in a “best-of-breed” fashion. Synchronization finally describes a strategy in which the new IT is basically a consolidated interface for the still existing pre-merger ones which can stay unchanged. Independent from the chosen strategy, the PMI of IT requires in any case adequately defined structures for decision-making and monitoring as well as accountability to enable and encourage an efficient management of the desired changes (Stolzenberg & Heberle 2006, Ringlstetter & Kaiser & Schuster 2006).

Figure 2. Transformation of IT during the post-merger integration (see Wijnhoven et al. 2006)

Because of the explicit or implicit existence of IT governance in the two merging firms, IT governance during the PMI cannot be entirely detached from the existing IT governance. In fact, their structures need to be investigated during the initial stage of the PMI. Existing boards, committees and levels of management need to be carefully integrated (Wijnhoven et al. 2006). Although the situation is different for every single M&A process, it is not unlikely that the existing IT governance incorporates elements of standardized frameworks, especially ITIL or CoBIT (Fink & Ploder 2008, IT Governance Institute 2008).

2.3 Facilitating the Definition of IT Governance in the PMI Phase by a Framework

A framework is a conceptual model that describes the structures of the organization in scope on an abstract level by a selected organizational paradigm (Meise 2001). The purpose of a framework is to provide an overview of relevant elements and their interdependencies. As the arrangement of elements in a framework can be chosen freely, the visualization of the overall has priority over the detailed depiction of single elements. Every element itself can be represented by a model of its own again and thereby a hierarchy of models within a framework can be formed (vom Brocke 2003, Meise 2001).

The development of a framework often aims at creating a reference model that includes abstract solutions and generic schemes for the design of organizations and information systems (Meise 2001). Those can be based on either theoretical considerations or practical experiences. The resulting framework then describes either an ideal and theoretically sound status (“best practice”) or a systematic compressed image of the perceived reality of the modeler (“common practice”). Both types hold recommendations to help the practitioners and scientists alike in their work (vom Brocke 2003).

Whilst the main characteristic of a framework is the provision of an overview over a certain field, we especially aim at creating a model with a normative character. It is expected to give a guideline for the IT integration within the M&A process. As Weill and Ross (2004) emphasized, IT governance means to define which decisions about IT should be made by whom and in what manner in order to provide accountability and control. Finally, as discussed in the previous section, existing IT governance approaches need to be respected when designing a new one for the post-merger company. A general vision of the change process needs to be determined which eventually has to be put into practice. Altogether, these assumptions form the basic requirements for our framework for IT governance during the post-merger integration phase (see Table 1).
Framework

- Provide an overview about organizational units and decision fields
- Provide reference for IT integration endeavors

IT governance

- Define decisions to be made
- Clarify who is allowed to make these decisions
- Specify the way decision-making is done as well as accountability and control

Post-merger integration phase

- Respect that elements of existing IT governance are the starting basis for the new one
- Help to decide about the vision for the IT transformation
- Support steering and monitoring of the IT integration

Table 1. Requirements for a framework for the IT governance during the PMI phase

3 RESEARCH METHOD

3.1 Developing the Framework According to Design Science Research

We regard the development of a framework as being subject to design science research which is motivated by the desire to improve the environment by means of innovative artifacts in terms of constructs, models, methods, and instantiations (Hevner et al. 2004). However, contrary to design science research as depicted by Hevner et al. (2004) that focuses the IT artifact per se, we also include the non-technological context, i.e. people and organization. We aim at developing a framework that provides practical knowledge that is applicable for the management of IT during M&A endeavors (Carlsson & Henningsson & Hratinski & Keller 2008). This practical knowledge can also be referred to as being a design theory (Carlsson et al. 2008, Gregor 2006, Hevner et al. 2004).

![Figure 3. Framework Development Process](image)

According to Hevner et al. (2004) and March & Smith (1995), design science research proceeds as a cycle of the two phases ‘build’ and ‘evaluate’. Similarly, literature on design theory development gives ‘propose/refine design theory’ and ‘test design theory’ as two key research activities (Carlsson et al. 2008). Thus, first within an iteration loop, artifacts or design theories are built addressing problems in an innovative way. Then, they are evaluated or tested against the utility they provide in solving these problems, and they are examined whether requirements and restrictions are met (Hevner et al. 2004). If an artifact fails this evaluation, the heuristic process is resumed beginning again with the next build phase aiming at refinement of the previous result. Our research process, which is currently in its third iteration, reflects these basic principles (see figure 3) and is described in detail in the following sections.

Proceedings ECIS 2009
3.2 First Draft of the Framework

Initially, we designed a first and – in retrospect – comparatively simple and incomplete draft of the ITGoPMI framework. We selected the shape of a house according to Meise (2001) as the basic design of our framework. This reference design allocates the core processes in the center of the framework which are surrounded by steering and support processes.

The first draft was evaluated by discussing it with an academic expert in the field of PMI and innovation management. He approved the systematic design of the framework. However, he questioned the explicit consideration of an integration of IT cultures due to concerns (especially German) workers’ representatives possibly have. We answered to these concerns by abandoning the accentuation on IT cultures from our framework. Henceforth, we regarded this rather as one of the human resources topics in M&A (Picot 2005). Our overall objective was sharpened, namely to design a framework that provides a guideline for the specification of decision rights as well as an accountability framework to enforce desirable outcomes during the PMI phase.

3.3 Extending the Knowledge Base

Design science research refers to a broad knowledge base of theories, models or methods that provide the basis for the design process (Hevner 2007). Similarly, design theories are expected to ground in previous research which has to be reviewed systematically (Carlsson et al. 2008). Due to the identified shortcomings of our first draft, we recognized the need to extend our knowledge base with further existing artifacts, experiences, and expertise that define the state-of-the art.

First, we analyzed frameworks like COBIT and ITIL since organizations frequently adopt those when explicitly designing their IT governance (IT Governance Institute 2008, Rüter & Göldner & Schröder 2006, Fink & Ploder 2008). For instance, decisions regarding the ‘Service Strategy’ aspect of ITIL V3 (Cartlidge & Hanna & Rudd & Macfarlane & Windebank & Rance 2007) largely cover the IT decision fields presented by Weill and Ross (2004).

Second, we conducted a literature review in order to identify possibly existing theories and artifacts regarding IT governance in the PMI phase. To analyze the state-of-the-art of research in this field, we examined high quality publications listed as ‘A’ or ‘B’ in the well-established rankings VHB JOURQUAL 2 (Hennig-Thurau & Schrader 2008) and WKWI (2008). We searched the online databases of these journals and conferences for the terms „post-merger“, „PMI“, „information technology“, „governance“ and „IT integration“. To guarantee up-to-date results, we limited our literature review to papers published from July 2005 to June 2008.

This literature review reinforced our proposition that currently there is no comprehensive framework for our scope, since almost any of the 25 publications we identified referred to a quite specific sub-aspect. Nevertheless, most of these aspects were relevant to at least some degree and thus had to be considered in the further development of our framework. For instance, Vaast and Levina (2006) advise against over-codification of procedures, and as already presented in section 2.2, Wijnhoven et al. (2006) provide an excellent overview about possible integration strategies.

3.4 Enhancing the Framework

We refined the ITGoPMI framework driven by the identified shortcomings of the first draft and our extended knowledge base. We kept the basic design of the framework, but added certain organizational units that address key subprograms and decision fields relevant during the PMI phase. Referring to the structuring found in the frameworks ITIL (Cartlidge et al. 2007) and COBIT (IT Governance Institute 2007) as well as in further publications (Rüter et al. 2006, Weill & Ross 2004, Deloitte Netherlands 2008), we derived seven sub-aspects of governing IT in the PMI phase. These comprise: IT Strategy, IT Governance, IT Organization, IT Processes and Services, Information
Systems, IT Personnel and Change Management. Each subprogram is managed by an integration team that is lead by a team leader who is responsible for his/her particular aspect.

The subprograms are steered by superior organizational units: the IT Integration Strategy Committee which holds the overall responsibility for the IT integration in the M&A process and makes fundamental decisions, and the IT Integration Steering Committee that is responsible for the coordination with the departments of the demand organization. The IT Integration Office serves as an interface between steering level and the integration teams. Located below the subprograms, the units IT Governance Assurance Team and IT Integration Assessment Team monitor the compliance with the defined IT governance and the progress of the integration endeavor. Additionally, the Demand Organization (in the organizational view) with its levels represents those parts of both companies outside the actual IT organization that demand and consume IT services of any kind (see Figure 4). It should be noted that these organizational units are also affected by the M&A transformation and therefore may be constantly changing.

Figure 4. Enhanced Version of the Framework

3.5 Expert Interviews

Proceeding with the next evaluation phase in our design process, the ITGoPMI framework was evaluated through five (semi-structured) expert interviews. Four of these experts were professional IT consultants; the fifth person was the academic expert we had already interviewed in the previous evaluation phase. All interviewees were experienced with M&A endeavors (see Table 2). We especially asked IT consultants for their view because they are typically involved in M&A endeavors in order to facilitate the IT integration with their expert knowledge and tools (e.g. a normative framework). Furthermore, we argue that consultants, as being not directly affected by the outcomes of the M&A process itself, are less biased in their view on how the IT governance should be shaped during the PMI.
Table 2. Sample of Experts

The practical value of the framework as well as theoretical premises and the relevance of included elements were discussed. Parts of our interview outline were inspired by a past PMI survey conducted by Bauch (2004). Again, the interviewees appreciated the structuring of the framework and they honored its level of detail (the experts received a description of the framework that was of considerably more detail than the previous section 3.4). However, the heterogeneity of their perceptions – even of basic terms like ‘IT governance’, ‘change management’ and ‘framework’ – became apparent through the interviews. This also left some degree of uncertainty of how a framework for IT governance in the PMI phase precisely should look like. Nevertheless, some common criticisms led the further development of the framework. For instance, a distinct IT Integration Strategy Committee was regarded as superfluous which we consequently dropped in the next build phase. The result of this phase represents the current version of the framework being subject to the next chapter.

4 FRAMEWORK FOR IT GOVERNANCE IN THE PMI PHASE

As a result of the suggestions made by the experts during the interviews we developed the ITGoPMI framework further to its subsequently presented form. The house as the basic design of the framework has proven to be sufficient to structure the matter in a consistent and comprehensive way and thus has been kept throughout the development process. The structure is still steering as the roof, subprograms to structure the integration work itself as the body and monitoring as the basement of the framework. However, the organizational units in each part have been revised to reflect insights gained through the feedback and suggestions of the interviewed experts.

The steering level at the roof of the ITGoPMI framework has been consolidated to two units: The IT Post-Merger Integration Office and the IT Post-Merger Integration Steering Board. The first one acts as a project management office by coordinating the work of all integration teams and keeping them on track from the operational perspective. The IT Post-Merger Integration Steering Board is responsible for making strategic and far reaching decisions about the transformation of IT in general. It decides especially about the desired outcome of the overall transformation process and which strategic integration approach should be followed (see section 2.2). As this has profound impact on the way IT can support the demand organization, the demand-sided senior management level needs to be represented in the IT Post-Merger Integration Steering Board. As an M&A process is usually about more than IT, both organizational units in the framework’s roof (see Figure 5) have to keep close ties with the steering committee and project office of the entire post-merger integration process.

The steering level is supported by IT Post-Merger Integration Steering Committees for specific IT PMI decisions which require the involvement of the department level of the demand organization. For instance, these can refer to the consolidation of CRM systems, which the marketing departments heavily rely on. Nevertheless, the exact number and topics of those committees needs to be individually determined for any M&A process with its specific requirements and situation. Hereby also the likely transformation of the demand organization needs to be taken into account.

On the operational level, Business Liaison Managers form the interface between the subprogram integration teams and the departments of the demand organization. Hence, these positions possess a political dimension as especially cooperation and communication needs to be facilitated between the
different stakeholders. In this context, according to our interviewed experts, it is advisable to involve external professionals as neutral instances for this role. At least one Business Liaison Manager is needed for each subprogram. A larger number seems to be appropriate for situations with highly complex work in the subprograms or many departments involved.

**Figure 5. ITGoPMI Framework**

As shown in Figure 5, a dedicated Integration Team is responsible for each subprogram. Each team should comprise members from the two merging companies in order to avoid political disputes and facilitate knowledge sharing. All integration teams must report at least to the steering level. Out of the wide range of thinkable subprograms for the post-merger integration of IT itself, seven subprograms have been identified as being repeatedly used and/or suggested by the interviewed experts. These seven are the following: IT Strategy, IT Organization & IT Governance, IT Processes, IT Services, IT Applications, IT Systems and IT Facilities & Networks.

The subprogram **IT Strategy** aims at developing an integrated and sustainable IT strategy for the newly-merged company. Hence, the general parameters for the future developments of IT are defined in this subprogram. Moreover, this must also include the definition of an exact strategy for the transformation of IT during the PMI phase as this is highly related with the to-be future IT strategy as well as the general logic behind the M&A process.

To make the new IT strategy come alive after the merger, appropriate organizational structure and governance are needed. Due to the highly interrelated nature of IT organization and IT governance both are jointly worked on in the subprogram **IT Organization & IT Governance**. One of the key tasks in this subprogram is to determine which mechanisms and structures exist already in both companies and how they can be used or integrated into the structures during the PMI as well as afterwards.

Whilst the subprogram **IT Processes** defines – as the internal perspective of structuring – how IT operates, IT services describe what the outcomes of IT use are. These outcomes can be either delivered to the – from the point of view of the IT function – external demand organization or being used...
internally as inputs of another service. Therefore the subprogram IT Services determines what the IT is supposed to deliver to whom after the completion of the PMI.

The remaining three subprograms address the technical transformation itself during the PMI phase. The subprogram IT Applications is about the software layer that runs the business-relevant programs and their interfaces within and across the newly-formed company. The subprogram IT Systems deals with desktop hardware and system software that enables the applications to run. Last but not least, the subprogram IT Facilities & Networks is covering the topological aspect of IT by determining for example where data centers should be located and how the networks should be operated.

In the basement of the ITGoPMI framework, two teams are monitoring the IT integration. First, the IT Integration Assessment Team is concerned with tracking the progress of the transformation. Second, the IT Governance Assurance Team checks the compliance with the governance structures valid for the course of the IT integration. In order to cope with conflicting interests, both teams should consist not only of members of the involved firms but of external professionals as well. Especially from a corporate governance point of view, it is important that steering and monitoring do not influence each other. Consequently, it can make sense to involve external consultants in these two teams.

To breathe life into the organizational units, especially in steering and monitoring, we developed a set of typical processes they need to execute. Maybe the foremost obvious is that the integration office of the general M&A process needs to make sure that the IT Post-Merger Integration Steering Board is formed. Then, this board appoints the IT Post-Merger Integration Office, the integration teams at the core and all other needed organizational units. These are the most responsible actions as the choice of people with their talents, skills and motivations determines the performance that can be achieved for the whole transformation. Moreover, as the IT Post-Merger Integration Steering Board is responsible for the outcome, it needs to receive reports of the subprogram integration teams and the monitoring teams. These disclose the achieved progress of the integration and the compliance to the PMI-specific IT governance structures. Finally, the IT Post-Merger Integration Office manages the day-to-day coordination between the integration teams and drives their work efforts if needed.

Altogether these organizational units form a comprehensive structure to assign decision rights and define accountability during the PMI of IT. However, it merely represents a heuristic proposition and guideline. Adjustments may be necessary for individual M&A.

5 IMPLICATIONS FOR FURTHER RESEARCH

In this paper, we presented a framework for IT governance in the PMI phase which is the preliminary result of a still ongoing research process. Building on the well-established definition of IT governance according to Weill and Ross, the ITGoPMI framework provides a blueprint for the specification of decision rights and accountabilities. Precisely, it outlines organizational units and their decision fields for the course of the IT integration. It aims at providing a means to ensure desirable outcomes of IT use, even during the fairly instable time when two companies and their IT functions merge.

Nevertheless, there might be limits in applicability for M&A processes in which small and medium-sized enterprises join forces. We see the need for further applicability checks to explore which structural elements of our framework can be regarded as universal and which are only needed in large-scale M&A endeavors. There may even be cases in which no integration of IT takes place at all and consequently such a framework guiding the IT integration process is not needed either.

As we have seen, there are different strategies for the post-merger IT integration. Hence, there is no single best way of how to integrate two former independent IT functions. Further research should analyze if varying strategies also require specific adjustments to the framework.

We learnt that developing a comprehensive framework for the IT governance in the PMI phase is a challenging task. So far, our empirical research was limited to interviews with German experts. Even in this relatively small sample of interviewees there were divergent perceptions of basic terms like ‘IT
governance’ and ‘framework’. This opened up controversial discussions about what IT governance actually is, especially during the post-merger integration phase. In spite of the heterogeneity of their perceptions, we have been assured by all experts we interviewed that our ITGoPMI framework already has the potential to serve as a beneficial guideline for post-merger IT integration in practice. Obviously, this opinion needs to be validated by empirical research on a larger scale.

As the output of design science research must be returned to the environment for evaluation (Hevner 2007), we will continue our research process by interviewing IT managers with M&A experience as well as by trying to apply the framework in practical M&A situations. This will possibly lead to further improvements. In the long term, we will strive for establishing it as a reference model for IT governance in the PMI phase.

ARCHITECTURES OF PARTICIPATION AND EMERGENT FORMS OF INTER-ORGANISATIONAL ACTIVITY: A PRELIMINARY ANALYSIS

Abstract

This research-in-progress paper explores ways in which inter-organisational networks can fulfil both collective (network) and self-interest (member) goals by implementing architectures of participation that govern and support participant interaction. We draw on recent studies to derive a conceptual framework consisting of technological, legal, economic and social mechanisms in inter-organisational networks, and using initial findings from three case studies of networks in Sweden and Denmark, we illustrate how these architectures operate. Our analysis shows the relative importance of these mechanisms in facilitating individual and collective value creation and we conclude by presenting our ongoing research plans.

1 INTRODUCTION

Over recent decades organisations have been radically transformed from single location hierarchical structures with well-defined boundaries to more flexibly organised and dispersed configurations. Indeed, arguments for flatter structures (Levitt and Whisler 1958, Snow et al 1992) and flexible forms (Drucker 1988, Starkey et al 1991, Bahrami 1992, Benkler 2002, 2006) have mounted. Advanced information and communications technology as well as an increasingly competitive environment have been cited as the main contributors to this change (Miles and Snow 1986, Peters 1992). Collaboration frequently occurs on an inter-organisational basis, as partnerships with suppliers and customers are critical in many sectors (Cash 1985, Christianse et al 2004, Tapscott and Williams 2006). Consequently, the boundary between organisations and their partners is becoming even less distinct with interdependencies between them being more important (Gulati and Kletter 2005, Premkumar et al 2005).

Although much inter-organisational activity has been production based, the exchange of specialised knowledge and skills is increasingly important (Bartlett and Ghoshal 1989, Sonnenberg 1992, Chesborough 2003). The image that emerges from these developments is one of an extended or virtual organisation where external boundaries are obscured by inter-organisational dependencies characterised by substantial communication and collaboration. The sharing of information, ideas and expertise becomes central to the success of such extended enterprises (Bartlett and Ghoshal 1989), and there is a realisation that external forces, rather than internal organisational, technological or managerial variables, are the keys to explaining organisational success (Joynt 1991).

Despite the importance of inter-organisational co-operation in relation to servicing consumer needs for products and services (Subramani 2004, Okamura and Vonortas 2006), organisations have been slow to harness the same type of external cooperation in relation to innovation (Lane and Probert 2007). Nevertheless, innovation is the result of combining different knowledge sets (Nonaka et al 2003, Tidd et al 2005), and such knowledge is frequently to be found outside the organisation (Chesbrough 2003, De Wit et al 2007). However, with the exception of notable examples of collective invention (cf. Allen 1983, von Hippel 1987), organisations have been slow to engage in open innovation (cf. Chesbrough 2003). In addition to worries about the quality and suitability of external ideas, organisations have resisted co-operative approaches to innovation due to perceived competitive necessities and issues relating to organisational control (Chesbrough 2004).

This paper presents research-in-progress on inter-organisational networks that aim to facilitate process, product and service innovation rather than just support inter-organisational transactions. The study seeks to establish ways in which inter-organisational networks can fulfil both collective (network) and self-interest (member) goals by implementing architectures of participation that govern and support participant interaction using technological, legal, economic and social mechanisms. Drawing on initial findings from three networks in Sweden and Denmark (a Danish business association, a group of Swedish public authorities, and a Swedish network with private, public and academic partners), we illustrate how these architectures operate and conclude by presenting our ongoing research plans.

2 CONCEPTUAL GROUNDING

The term open innovation has been used to describe the shift from a paradigm in which firms exclusively sought to create, improve, and exploit products/services within the boundaries of the firm, to one which “places external ideas and external paths to market on the same level of importance as that reserved for internal ideas and paths to market” (Chesbrough 2006, p. 1). In practice, the open innovation concept can be implemented in many ways, e.g. creating new/improved products/services by building on external ideas and innovations, creating new revenue streams by allowing external parties to exploit internal ideas and innovations, and forming alliances with complementary partners to
support ongoing innovation/exploitation processes (Gassmann and Enkel 2004). However, new products are not the only tangible manifestation of open innovation as services and process transformation can also be developed in this manner (Morgan and Finnegan 2008). Such activities require participating firms – whether they act as consumers, producers or partners – to engage with external parties; they therefore depend on the establishment and management of effective inter-organisational networks (Vanhaeverbeke and Cloodt 2006).

Participants in inter-organisational networks believe that collaboration will result in adaptive efficiency; “the ability to change rapidly and at the same time provide customized services or products, and at low cost” (Alter and Hage 1993). An inter-organisational network is a social action system as it exhibits the fundamental principles of any organized form of collective behaviour. These include the aim to achieve both collective (network) and self-interest (member) goals, interdependent processes utilized by network members, and the ability of the cooperative entity to act as a unit with a separate identity from its individual members (Van de Ven 1976).

While these activities can be supported by traditional inter-organisational governance structures like hierarchies, markets and brokerages (Feller et al 2008a), many examples of open innovation instead leverage what Benkler (2002, 2006) has described as peer production: a model for organizing production that does not rely on markets, hierarchies, property and contracts. Specifically, the collaborative creation of software by development communities (open source software) has been used as a defining example of the peer production model (Benkler 2002, 2006), and the engagement of firms with such communities and the products they create has been identified as a key exemplar of open innovation (West and Gallagher 2006).

Any understanding of open innovation processes must, therefore, not only include inter-organisational interactions embedded in traditional governance structures, but also those embedded in peer production contexts. In such contexts, the tension between the collective goals of groups and the individual goals of profit-seeking participants can be problematic. In the current work, we address this tension through the concept of an architecture of participation, which has emerged in the literature with two distinct meanings.

Firstly, an architecture of participation can be understood simply as the “various technologies and activities designed to facilitate and promote participation, communication and the active co-construction of meanings and knowledge” (Attwell and Elferink 2007); in other words, they are collections of mechanisms that allow the members of a community or network to interact. Secondly, and more subtly, the label has been used to describe systems that help transform individual activities into communal resources. Bricklin (2001) observed that the technical characteristics of peer-to-peer music sharing systems like Napster could potentially transform the “tragedy” of the commons into the “cornucopia” of the commons, where adding value to the system is an automatic result of using the system. Building on Bricklin’s insight, O’Reilly (2005) has applied the concept to open source software development, where he argues that such architectures “may actually be more central to the success of open source than the more frequently cited appeal to volunteerism. The architecture of Linux, the Internet, and the World Wide Web are such that users pursuing their own ‘selfish’ interests build collective value as an automatic by-product” (O’Reilly 2005, p. 476). Within the open source context, many different types of architectures have been identified; including technological architectures (e.g. collaboration and communication platforms, software development kits and application programming interfaces, etc.), legal architectures (e.g. software licences), economic architectures (e.g. direct and indirect incentives and rewards for participation) and social architectures (e.g. shared cultural values, reputation building through participation, etc.)(Feller et al 2008b).

Thus, the current work seeks to identify the technological, legal, economic and social architectures of participation used within the innovation networks studied, and to understand the roles played by these architectures in both enabling interaction (a la Attwell and Elferink 2007) and transforming individual activities into communal goods (a la Bricklin 2001 and O’Reilly 2005), as illustrated in Figure 1.
3 RESEARCH CONTEXT AND METHOD

The objective of this study is to explore architectures of participation in inter-organisational networks. Given the exploratory nature of this research, and the need to obtain rich data in a complex inter-organisational context, a case study approach, with embedded units of analysis, was considered appropriate. ‘A case study examines a phenomenon in its natural setting, employing multiple data collection methods to gather information from a few entities. The boundaries of the phenomenon are not clearly evident at the outset of the research and no experimental control or manipulation is used’ (Benbasat et al. 1987). Cases are most appropriate when the objective involves studying contemporary events, without the need to control variables or subject behaviour (Yin 2003). Our method is consistent with the case study approach of Benbasat et al. (1987) and Yin (2003) in that we study the phenomenon in its natural setting, employing multiple data collection methods to gather information from a few entities, without employing experimental control or manipulation. We follow in the tradition of Eisenhardt (1989) and Madill et al. (2000) by seeking to reveal pre-existing, relatively stable and objectively extant phenomena and the relationships among them.

Data gathering activities to date have focused on three networks with different characteristics and aims. The first is a Danish business association of private companies active in the open source software market. The second is a group of Swedish public authorities that cooperate in procurement processes. The third is a network including partners from the Swedish public sector, private sector and academia that focus on co-creation of public e-services.

The researchers first conducted an archival search of public domain material on the networks and their participants, including web resources and articles in the public press. Based on this preliminary analysis a case study protocol (cf. Yin 2003) was prepared in order to ensure the consistency of data gathered. Interviews with key informants were conducted during 2008 (see Table 1). The interviews, which followed an interview guide (cf. Patton 1980), were of 30-60 minutes duration and conducted in Swedish and Danish both in person and by telephone.

The interviews were transcribed and translated (by one of the authors), and follow-ups were made by e-mail and telephone to clarify and refine issues that emerged during the transcription/translation process. The interview transcripts were supplemented with 15 official documents provided to the researchers by the interviewees. The documents included policy statements, bylaws and project reports.
Content analysis was carried out on both the interview and document data sets. A coding system was derived using the conceptual framework illustrated in Figure 1, and a two-phase coding process was employed (c.f. Miles and Huberman 1994). During the first-level coding phase, each segment of the interview/documentation data was summarized and labelled. This was followed by a pattern coding process in which the segments of data were organized, analyzed and synthesized within the themes/concepts embedded in the conceptual framework. While the emphasis of the first-level coding phase was on description, the pattern coding process focused on explanation.

### 4 FINDINGS AND ANALYSIS

#### 4.1 Network, dynamics, composition and goals

The initial analysis of the three networks involved characterising them based on their dynamics, member composition, and goals (both individual and collective). Table 2 summarises these characterisations, which are discussed in detail below.

**Table 2. Network, dynamics, composition and goals**

The Danish Open Source Business Association [*Open Source Leverandører i Danmark*], or OSL, was founded in 2003 by five companies active in the open source solutions business sector. The members of OSL are a relatively homogeneous group of private sector organisations, all Danish-based companies that deliver solutions and services based on open standards or open source software. At the time of writing, OSL comprises 30 ‘full member’ companies and an additional 31 ‘supporting member’ companies. Most of the member companies are small (5-20 staff), but there are also a few multinationals with Danish headquarters (e.g. IBM, Sun and Oracle). The key dynamic evident in OSL is one of *association*, in which the network acts to provide a unified voice for its member companies. The member firms are motivated to participate in the network by a desire to develop individual business opportunities; however, the network acts as a lobby group for all of its members, seeking to enhance awareness of open source software in the Danish market and influence Danish IT policies. Specifically, the goal of OSL is “to promote a genuine market-based choice between different types of
software development and licensing in order to make the choice of open source software based on quality, price, usability and suitability ... The association will work to secure a genuine choice of IT-architecture in the public as well as the private sector” (OSL 2008). Thus, the network’s effectiveness as a brand building and policy influencing mechanism is enhanced by the active participation of individual companies, who in turn benefit from these activities.

‘Environmentally Procurement in County Västernorrland’ is an initiative, established in 2006, in which eight Swedish public authorities (the seven municipalities and the County Council in the county of Västernorrland) and the Association of Local Authorities in Västernorrland, have established a network for joint procurement activities. Other partners include the Swedish Road Administration (‘Region Mitt’), the Västernorrland Administrative Board, the Swedish Agency for Economic and Regional Growth and the Swedish Environmental Management Council. The network is thus a homogenous grouping of public authorities, in which the key dynamic is cooperation in the form of joint procurement activities. Individual authorities are motivated by a desire to lower costs by leveraging the negotiating position that comes from aggregating demand across the county. The network, in turn, seeks to implement public policy favouring “green” products (like low-energy lightbulbs and hybrid automobiles), which it can do through the joint purchasing power of its collective members.

‘The Sundsvall Group’ [no official name exists] is a network, established in 2005, to support collaborative software development activities amongst its members, who include Swedish public authorities (Municipality of Sundsvall), private firms (Logica), non-profit associations (Åkroken Science Park) and academic institutions (the CITIZYS Research Group at Mid Sweden University). The network was originally established with the aim of carrying out a single joint project (the development of a municipal e-service in the municipality of Sundsvall, ECHOES (Everyday Communication Home School)) but has evolved to support other projects. Because this collaborative network is heterogeneous in composition, the individual goals of the members vary considerably from member to member; e.g., the municipality delivers e-services at a lower cost, the academic partner enjoys access to research opportunities in an applied setting, the private company gets a new business opportunity, etc. Collectively, the network seeks to develop e-services that improve the quality of life for individual citizens through easier access to public information and services.

4.2 Architectures of participation

We found that the different kinds of networks have different sets of architecture of participation. We refer to the components that form the architecture of participation as the technical, legal, economic and social architectures.

Table 3. Architectures of participation
4.2.1 Technological architectures

All three networks were analysed in order to identify the technological architectures that enabled interaction between members and/or acted to transform individual activities into communal resources. Across all three networks, technologies such as email, websites and telecommunications were used to communicate within the network. In the procurement and software development networks, these same technologies were also used to explicitly coordinate activities as well as for communication. In the procurement network, such co-ordination activities were limited to specific procurement activities, while in the software development network longer term coordination took place. Finally, within the Sundsvall group, additional technologies supported the distributed collaborative development of software. These included version control tools, issue tracking systems, etc. Additionally, the software products created by the network were themselves architecturally designed to support future participation; i.e. the way in which ECHOES was developed meant that the code base could be largely reused in future projects. It is worth noting that with the exception of this final point regarding code reuse, the roles played by technological architectures in all networks appeared to be limited to enabling interaction, not transformation.

4.2.2 Legal architectures

Within OSL, where the primary collective goal was the creation of a joint voice for marketing and lobbying, the dominant legal architectures focused on the management of the association’s identity and of member behaviour through formal bylaws. For example, all potential members must demonstrate that their commercial activities are in-line with OSL’s intentions (i.e. the promotion of open source solutions). Furthermore, to become a full member, the applicant must be a company and be able to prove that during the last financial year they employed the equivalent of more that one full time employee. Smaller companies, and even individuals, are also entitled to membership but as supporting members without a vote in network level decisions.

Within the procurement (cooperative) network, legal architectures exist not only to manage network identity but also to ensure that the members are able to engage in procurement activities following agreed upon procedures. A complex system of agreements governs the joint procurement processes, including, national regulatory and legislative frameworks, local policy decisions made by public authorities, and purchase-specific agreements between the network members.

Finally, within the collaborative network, there is less evidence of legal architectures governing behaviour or identity. Instead, network identity is fluid (re-established with each new project), “rules” for behaviour are informal or absent, and the primary emphasis is on legal mechanisms to prevent conflict over the ownership of the collaboratively created software product (e.g. licensing decisions and sub-contracts with service providers, etc.).

In contrast with the technological architectures previously discussed, the legal architectures evident in the networks more directly support the transformation of individual efforts into communal resources. For example, in OSL the bylaws ensure that the membership act and speak with a cohesive voice; in the procurement group they are able to act as a single purchasing agent; and in the Sundsvall group there are clearly defined rights of collective and individual ownership.

4.2.3 Economic architectures

In OSL, annual fees provide a financial mechanism to support the day-to-day administrative activities of the network and also act as a signal of a firm’s commitment to the collective goals of the network. Annual fees are also used in the procurement network to offset administrative costs (primary the salary of the overall project leader). Additionally, financial agreements are made between a subset of the network membership for each specific purchasing event. Within the collaborative software development network, financial agreements are limited to specific aspects of projects (e.g. the
management of a specific project budget or sub-contracting of a particular activity). As with the technological architectures discussed previously, the economic architectures evident appeared to be focused more on enabling interaction than transformation.

### 4.2.4 Social architectures

Within OSL the formal bylaws governing member behaviour are complemented by several informal social mechanisms that both enable interaction and help ensure that the network as a whole benefits from individual activities. For example, the members of the association share a common goal (the expansion of the market for open source products and related services) and share the belief that they can all benefit from this expanded market without needing to directly compete with each other. There is also a shared ethos that the members should focus on winning customers from the proprietary software companies, not from each other. Although the association does not explicitly seek to facilitate cooperation between the member companies, many of the companies have formed relationships through the association, which can lead to exchanges of knowledge, contacts, etc. Interpersonal trust and knowledge about other actors were seen to play an important role in such interactions. Rumours about ‘bad’ jobs or ‘bad’ behaviour spread quickly, which effects decisions regarding potential cooperation or sourcing of competencies, but could also lead to collective sanctions e.g. exclusion.

Within the cooperative network the members also share a collective vision and a common goal of effectively implementing environmental procurement policies. Personal relationships and networking between the participants play an important role in building trust and sharing knowledge. Periodic meetings and workshops reinforce such relationships. As with the OSL, informants highlighted the importance of reputation in choosing procurement partners/leaders.

Finally, in the collaborative network, social architectures were seen to play an important role, particularly in the absence of written rules, bylaws, etc. Specifically, personal knowledge, trust, and a common view on the future of public e-services act as the uniting ‘glue’. There are no regular meetings; instead, new ideas and projects emerge from frequent contacts and discussions. Through the personal networks of the ‘core’ project members, new members are invited to participate in projects when there is a need for external competencies or expertise.

As with the legal architectures evident in the networks, the social architectures play a key role in the creation of communal resources. In all three networks, a shared worldview and an implicit acknowledgement of acceptable behaviour enable members to pursue individual goals while creating/preserving communal resources.

## 5 CONCLUSIONS

This paper has explored two connotations of *architectures of participation* in the association, cooperation and collaboration networks studied (see Figures 2, 3 and 4); as mechanisms for enabling interaction and as mechanisms for transforming individual action into collective resources. Both connotations are critical to the successful implementation of open innovation strategies.

First, open innovation activities are, by definition, extra-organisational and require mechanisms that facilitate interaction between participants. This study has given us insight into the wide variety of mechanisms employed by open innovation networks to meet this need; the use of technological, legal, economic and social architectures were all visible. The demonstrated use of a variety of mechanisms has implications both for practitioners and future researchers. For practitioners, this study suggests the need to move beyond a narrow technological viewpoint, and to consider all four types of architectures in managing network activities. For future researchers, including ourselves, there is a need to develop a better understanding of the interaction and interdependencies between the various mechanisms.

Second, as noted at the outset of the paper, issues of trust, control, and the potential “tragedy of the commons” can all play a role in dissuading organisations from participating in open innovation.
Therefore, mechanisms for transforming individual action into collective resources (i.e. enabling all participants to benefit from the collaboration) are critical. The study showed that although all four types of architectures have a function in enabling interaction, only the legal and social architectures have a strong role in transforming individual action into collective resources. It is noteworthy that informal/social mechanisms and formal/legal mechanisms both play a key role in the networks studied. For practitioners, this suggests the need to take into account both formal and informal mechanisms in making governance decisions and in dealing with issues of appropriation and sharing. For researchers, the findings signal the need to reconsider the formal/legal-centric view of inter-organisational networks dominant in extant literature, and contribute to the emerging characterisation of networks based on the interplay between formal and informal mechanisms (c.f. Feller et al 2008).

Figure 2. Architectures of Participation (Association)

![Figure 2. Architectures of Participation (Association)](image)

Figure 3. Architectures of Participation (Cooperation)

![Figure 3. Architectures of Participation (Cooperation)](image)
The analysis of technological, legal, economic and social architectures of participation described above provide us with an initial set of models for understanding the interplay between individual and collective value creation. By treating the three networks as abstract types (Association, Cooperation and Collaboration), we hope to stimulate related research focused on networks with similar goals/characteristics in other contexts. The work reported is research-in-progress, and our own plans for future research activity include (1) the identification of additional open innovation network types, (2) further data gathering in the existing networks (both through interviews with a wider range of stakeholders and the administration of a survey to network participants), and (3) focusing on additional embedded units of analysis (projects). In doing so, we aim to uncover a more exhaustive inventory of the various architectures of participation in use, and also develop a more sophisticated set of models for understanding how these architectures enable interaction and support transformation.

Abstract

The airline industry employs advanced e-commerce technologies to retain frequent customers and attract new passengers, but it is likely that not all airlines have clear knowledge about how many gaps should be filled between the status quo and an ideal website. This study proposes an integrated model for evaluating airlines’ websites in terms of the perspectives of “marketing mix 4Ps” and “website quality”. In order to verify the practicality and usefulness of this model, an empirical study of the Taiwanese airline industry is offered to illustrate the application of the proposed model. The model first applies the DEMATEL method to cope with the interdependencies between criteria. It then converts the criteria’s cause and effect relations into a visual structural map where the ANP method can help compute the weight of criteria. Finally, it uses the modified VIKOR method to rank e-commerce websites of the five Taiwanese airlines. Overall, the results show that the Taiwanese airlines still have a great deal of room to improve their websites. This proposed model not only provides helpful information for airlines to understand their websites’ quality level, but also contributes to industrial applications in terms of providing some worthwhile recommendations for building an ideal website.

Keywords: Decision Making, E-Commerce, E-Marketing, Web Site Analysis
1 INTRODUCTION

The Internet and information technology (IT) have become common practice of the airline industry and helped sharpen airlines’ competitive edge through operation efficiency improvement (Hanke & Teo 2003). One of the most valid solutions for enhancing business values and attracting more customers is to sell low-fair air travel tickets and facilitate boarding processes such as e-ticketing and online check-in through an airline’s own website (Wei & Ozok 2005). Currently, many airlines are utilizing dedicated websites to market their products to potential customers. Some airlines also offer discounts to customers who purchase their tickets online (Hanke & Teo 2003). With the ongoing trends of the Internet marketing, this raises the critical issue of how airlines can effectively measure their websites’ characteristics. Due to the multidimensional characteristics of website design in this issue, it must be appropriately addressed by multiple criteria decision-making (MCDM) methods.

Nowadays, there is no a standardized model for evaluating e-commerce websites of airlines, and existing ranking methods do not offer enough insights for airlines’ proprietors to determine whether their websites meet ideal levels in terms of the perspectives of “marketing mix 4Ps” and “website quality”. Therefore, an effective model is proposed that combines the Decision Making Trial and Evaluation Laboratory (DEMATEL) method, the Analytic Network Process (ANP) method, and the modified VIKOR (VlseKriterijumska Optimizacija i Kompromisno Resenje in Serbian, or Multi-criteria Optimization and Compromise Solution) method for an inter-website comparison of airlines. First, the DEMATEL method is applied to deal with the interdependence between evaluation criteria and also to convert the criteria’s cause and effect relations into a visual structural map. Next, the ANP method is employed to determine the relative importance of evaluation criteria. The ANP, a relatively new MCDM method, can systematically deal with network-like decision problems. Finally, the modified VIKOR method is used to evaluate and rank the websites of airlines. The VIKOR, a compromise ranking method, had been introduced by Opricovic (1998). It established an aggregating function based on the measure of closeness to the ideal solution. This ranking index of the VIKOR method is an aggregation of all criteria, the relative importance of criteria, and a balance between total and individual satisfaction (Opricovic & Tzeng 2004). Therefore, this integrated model is useful for an airline company to identify the performance level of its website in the airline industry, and then to take necessary actions to improve shortcoming for enhancing competitive advantages.

The purpose of this paper is to build an evaluation model of e-commerce websites for airlines. By suggesting comprehensive measurements based on the perspectives of “e-marketing” and “e-quality”, the proposed model can provide helpful information for airlines’ proprietors to understand the unimproved gaps of their websites. Moreover, this study contributes to industrial applications in terms of providing some worthwhile recommendations for building an ideal website. In order to verify the practicality and usefulness of this model, an empirical study of the Taiwanese airline industry is offered to illustrate the application of the proposed model.

2 THE CONCEPTS OF E-MARKETING AND E-QUALITY

2.1 The perspective of e-marketing

The Internet is especially valuable for coping with the intangible nature of service and transforming “marketing mix” variables to exploit the informational and transactional potential of the Internet (Baloglu & Pekcan 2006). The “marketing mix” concept was introduced in the 1950s, and the mix of different means of competitions was soon regrouped to 4Ps (i.e. product, price, place, and promotion) by McCarthy (Grönroos 1997). These 4Ps are useful to highlight some unique aspects of e-marketing (Kalyanam & McIntyre 2002).

To update the marketing mix for the Internet, Kalyanam and McIntyre (2002) proposed the
e-marketing mix that included new elements such as personalization, privacy policy, and website design. Dutta and Biren (2001) used the 4Ps model comprising customer relationships and technologies of interactivity and connectivity as a tested framework (called the Marketspace Model) for evaluating business transformation on the Internet. Blum and Fallon (2002) examined 53 Welsh visitor attraction websites according to product, price, promotion, place, customer relations, and technical aspects. In addition, Law and Leung (2000) evaluated the efficiency of airlines’ online reservation services according to online reservation services, provision of extra benefits, reservation time, and the availability of additional services/facilities.

2.2 The perspective of e-quality

The term “e-quality” is important for assessing e-commerce websites. Aladwani and Palvia (2002) considered Web quality to be a complex thing and multidimensional measurement in nature. Madu and Madu (2002) noted that the dimensions of e-quality may be different from the traditional practice of quality. DeLone and McLean’s updated information systems (IS) success model (2003) consists of three quality factors: information quality, system quality and service quality. Parasuraman et al. (1985) conceptualized service quality as the relative perceptual gaps between exceptions and perceptions of performance levels and then developed the gap model as an approach to measure service quality. According to this gap model, the SERVQUAL instrument, which includes the five dimensions of tangibles, reliability, responsiveness, assurance, and empathy, was developed by Parasuraman et al. (1988). Subsequently, Zeithaml et al. (2000) developed e-SERVQUAL to measure electronic service quality as an updated measure of traditional SERVQUAL model in the Web setting. This multi-item scale includes the seven dimensions of efficiency, reliability, fulfillment, privacy, responsiveness, compensation, and contact.

Website evaluation has been widely studied in the literature. Lee and Kozar (2006) evaluated online electronics and online travel websites by adopting DeLone and McLean’s IS success model and applying the Analytic Hierarchy Process (AHP) method. AHP can only obtain the relative weights of alternatives; it cannot compute gaps between the status quo and an ideal point. Büyüközkan et al. (2007) used the Fuzzy VIKOR method to evaluate 21 e-learning websites according to seven criteria. They ignored interrelationships between these seven criteria when determining their weights. Büyüközkan and Ruan (2007) used fuzzy AHP and fuzzy TOPSIS to rank 13 Turkish government websites according to six e-service quality dimensions. TOPSIS, however, has some limitations. According to Wang et al. (2007), TOPSIS’ closeness coefficient values do not reflect the superiority or inferiority of alternatives and therefore cannot be used for ranking purposes. Baloglu and Pekcan (2006) applied content analysis to analyze the websites of hotels in Turkey in terms of site design and marketing characteristics using a measurement variable of yes-or-no (one-or-zero). The shortcoming of binary variables is that they cannot express the performance on each criterion. Wan (2002) also applied content analysis to evaluate the websites of 30 tourist hotels and 39 tour wholesalers using a 5-point rating scale. He took into account the performance on each criterion, but ignored the relative importance of various criteria. Shchiglik and Barnes (2004) used a 5-point scale and important ratings to evaluate website quality according to four dimensions (i.e. site quality, information quality, interaction quality, and airline-specific quality) for the airline industry in New Zealand. They took into account the global weighted average performance, but neglected to specifically consider the worst one.

As mentioned above, previous studies have failed to provide a comprehensive and systematic approach that quantitatively measures a website’s overall performance, and their research methodologies must be improved. Therefore, this study proposes an effective model for assessing e-commerce websites in terms of combined “marketing mix 4Ps” and “website quality” perspectives. This model overcomes the drawbacks of prior studies and offers enough insights for practitioners to accurately measure the current level of their websites according to critical criteria that determine their competitive advantages.
3 AN INTEGRATED EVALUATION MODEL

The assessment process of e-commerce websites required the construction of an evaluation model. To effectively evaluate e-commerce websites of airlines, an integrated MCDM model is proposed. The proposed model includes six phases: (1) defining the goal; (2) establishing the analytic structure; (3) using the DEMATEL method; (4) using the ANP method; (5) applying the modified VIKOR method; (6) finding the ranking of airlines’ websites. Accordingly, an overview of the integrated evaluation model for e-commerce websites is shown in Figure 1. The details of each phase are described as follows.

- (1) Defining the decision goal
- (2) Establishing the analytic structure
- (3) Using the DEMATEL to analyze interdependent relationship between criteria
- (4) Using the ANP to calculate the weight of each criterion
- (5) Applying the modified VIKOR to calculate the index of each alternative
- (6) Ranking alternatives and finding a set of compromise solutions

Figure 1. The integrated evaluation model for e-commerce websites.

The first phase defines the decision goal. The goal is to evaluate and rank e-commerce websites for the airline industry. In phase 2, the analytic structure, according to related literature and expert interviews, is used to assess e-commerce websites. The four groups are defined and identified in this structure, including: goals, perspectives, criteria, and alternatives. Such combination shapes an evaluation mechanism for airlines’ websites, as shown in Figure 2. As seen in this figure, this MCDM problem is considered in terms of two perspectives. There is no interrelationship between these two perspectives. On the perspective of “e-marketing,” the criteria help airlines create more sales such as advertising, price negotiation, online order and payment, and online community features. They are: “high value-added product (P1),” “product customization (P2),” “price negotiation (P3),” “low price (P4),” “discount (P5),” “advertising (P6),” “communication (P7),” and “transaction function (P8).” These eight criteria are then divided into four clusters: product, price, promotion, and place. On the perspective of “e-quality,” the criteria support the website’s designer to create a high quality website such as a personalized user interface and ease of navigation. They are: “reliability (P9),” “responsiveness (P10),” “credibility (P11),” “currency (P12),” “relevance (P13),” “personalization (P14),” “navigability (P15),” “security (P16).” These eight criteria are then divided into three clusters: service quality, information quality, and system quality. In addition, the “alternatives” comprises the five airlines’ websites.

Phase 3 applies the DEMATEL method prior to the ANP method in order to improve the procedure for dealing with the interrelationships between criteria. DEMATEL quantifies complex relationships between criteria and converts them into a visible structural map. It has been successfully applied in a wide range of situations such as e-learning programs evaluation (Tseng et al. 2007), safety measurement (Liou et al. 2007), and social responsibility programs selection (Tsi & Hsu 2008) problems. A series of steps are implemented to complete the analysis of this phase (for a detailed exposition of these steps, please refer to the above mentioned studies). Finally, the strength of
interdependence between criteria and an influence-relation-map are determined from the results of the DEMATEL.

![Diagram](image-url)

**Figure 2.** The analytic structure for website evaluation.

Phase 4 applies the ANP method to calculate the relative importance of each criterion. This method is a comprehensive decision-making technique that has the capability to comprise all the interdependent criteria in arriving at a decision (Jharkharia & Shankar 2007). The AHP suffers from the limitation of only being applicable to straightforward hierarchical structures while the ANP can be applicable to the complexities of many real world problems (Chang et al. 2007). In reality, however, such evaluation criteria are seldom independent (Liou et al. 2007). Therefore, instead of adopting the commonly used AHP method for solving these types of problems, we apply an ANP-based model for calculating the weight of each criterion. For the detailed steps of the ANP method the reader is referred to Saaty (2001).

Phase 5 applies the modified VIKOR method to compute gaps between the status quo and an ideal website. The VIKOR method provides measurements of determining the aggregate distance \(R_j\) to the ideal point. This method considers two distance measurements, \(S_j\) and \(Q_j\), based on an aggregating function \(D_p\)-metric in the compromising programming method. \(D_p\) represents the distance of an alternative from the ideal solution for different levels of \(p\). \(S_j\) is the \(j^{th}\) alternative with respect to all criteria as calculated by the average distance from the ideal solution. \(Q_j\) is the \(j^{th}\) alternative with respect to a specific criterion as calculated by the maximum distance from the ideal solution. The traditional \(R_j\) does not indicate how many performance variations exist between the status quo and the ideal point; therefore, following Ou Yang et al. (2008), we use the modified \(R_{j}^{mod}\) index to overcome this drawback. Eq. (1) is used instead of the traditional \(Q_j\). Then, the modified
\[ R_{ij}^{mod} \] index is listed in Eq. (2).

\[ Q_{ij}^{mod} = \max_i \left\{ \left( \frac{x_i - x_j}{x_i} \right) \right\} \text{ for } j = 1, 2, \ldots, m \] (1)

\[ R_{ij}^{mod} = v S_{ij} + (1 - v) Q_{ij} \] (2)

Finally, phase 6 obtains the ranking of e-commerce websites and a set of compromise solutions according to the modified VIKOR index.

4 AN EMPIRICAL STUDY OF THE AIRLINE INDUSTRY

To describe the proposed model clearly, an empirical study of the Taiwanese airline industry was conducted in order to demonstrate the efficacy of this model for assessing and ranking e-commerce websites. There are five domestic airlines in Taiwan: China Airlines, Eva Air, Uni Air, Mandarin Airlines, and TransAsia Airways. Their e-commerce websites are indicated as A1 (China Airlines), A2 (Eva Air), A3 (Uni Air), A4 (Mandarin Airlines), and A5 (TransAsia Airways), respectively. We invited 32 experts to express their opinions in September 2008. Nineteen of them were from various industries and the remaining ones were from academics and research institutes. These experts are professionals who have been designing e-commerce websites or studying on various projects about the Internet marketing for a certain time; therefore, their answers to the questionnaires can appropriately reflect the status quo of e-commerce websites of the five airlines.

4.1 Calculation of the weights of evaluation criteria

First, the experts examined the status quo of the five airlines’ websites beforehand and then used the cut-off value method with the 9-point scale to screen for proper criteria. According to the survey results, 16 criteria were constructed as very important to the evaluation of airlines’ websites, with a mean value exceeding 6.0 (i.e. cut-off value) for each criterion. Second, a zero–four DEMATEL scale was used for determining the relationship structure among the 16 criteria. Once the relationships between criteria had been measured by the experts, an initial direct-relation matrix could then be obtained. On the basis of the initial direct-relation matrix, a normalized direct-relation matrix was obtained by using the DEMATEL formula. Next, a total-relation matrix (including D, R, D+R and D–R) was identified (Table 1). Finally, a threshold value was chosen as 0.66 to filter the minor effects in the element of the total-relation matrix. After deciding on the threshold value, the influence-relation-map could be obtained by mapping a dataset of (D+R, D–R) (Fig 3).

</table>

Table 1. The total-relation matrix of the 16 criteria.
As shown in Figure 3, communication ($P_7$), with the highest value of D–R, was called the master dispatcher. Similarly, product customization ($P_2$) obtained the second highest value of D–R and became the second powerful criterion. Navigability ($P_{15}$), with lowest value of D–R, was the master receiver.

Subsequently, the ANP method was employed to determine the relative importance of each criterion. The experts first responded to the questionnaire through a series of pair-wise comparisons with Saaty’s one-nine scale, comparing the relative importance of one element over another. A scale of one to nine ranges from equal importance to extreme importance (Saaty 2001). Super Decisions 1.6.0 software was applied to aid in the calculations. This software is an easy-to-use tool for constructing network-like decision models with the ability of calculating the weight of each element. Due to space limitations, the pair-wise comparisons are not shown. Second, consistency ratios of all the pair-wise comparison matrices were calculated. The consistency measure is very useful for identifying possible errors in judgments. When consistency ratios are less than 0.1, the judgments are considered to be reliable. In this study, consistency ratios were less than the acceptable threshold value and the eigenvectors displayed were appropriate to enter into the unweighted supermatrix. Third, the experts conducted the pair-wise comparisons on the clusters. Then, the unweighted supermatrix was transformed to be column-stochastic as shown by $M^W$ after completing the pair-wise comparisons of the clusters. Finally, the weighted supermatrix was raised to limiting powers of $M^L$ to capture all interactions and obtained a steady-state outcome. The limit supermatrix is shown in Table 2. The results of the limit supermatrix yielded ($P_1$, $P_2$, $P_3$, $P_4$, $P_5$, $P_6$, $P_7$, $P_8$, $P_9$, $P_{10}$, $P_{11}$, $P_{12}$, $P_{13}$, $P_{14}$, $P_{15}$, $P_{16}$) = (0.084, 0.024, 0.115, 0.129, 0.130, 0.011, 0.014, 0.128, 0.088, 0.049, 0.081, 0.042, 0.026, 0.015, 0.028, 0.036). Ranked by the weights, the top five evaluation criteria in order of importance were: discount ($P_5$), low price ($P_4$), transaction function ($P_8$), price negotiation ($P_3$) and reliability ($P_9$), respectively. This implies that airlines’ proprietors need to pay more attention to these five criteria for achieving sustainable competitive advantages in the e-marketplace. Under the perspective of e-marketing,

Figure 3. The influence-relation-map the 16 criteria.
discount ($P_5$) had the highest weight of 0.130. This criterion is a key factor for successful e-marketing. Apparently, the use of online discount is essential requirement for effective promotion.

4.2 Performance measurement of the websites

After finishing a series of pair-wise comparisons, the experts were asked to provide linguistic values for evaluating the five airlines’ websites. In this study, linguistic values were used to design the evaluation questionnaire. These performance values, which were very good, good, median, poor, and very poor, were transformed by scaling them into the numbers 100, 75, 50, 25, 0, respectively. The results of evaluation are shown in Table 3. This table shows that all five websites were not utilize the Internet to its full potential and performed poorly in terms of price negotiation ($P_3$), low price ($P_4$), responsiveness ($P_6$), and communication ($P_7$). In addition, a coordinate diagram (Figure 4) was acquired by mapping the dataset of (e-marketing score, e-quality score), where the horizontal axis was “e-marketing” score, and the vertical axis was “e-quality” score. Figure 4 shows that $A_2$ had the best overall performance and was the closest to the ideal point ($A'$). Nevertheless, $A_2$ was the farthest from the ideal point, both “e-marketing” and “e-quality” performed poorly. These two perspectives needed the most improvement.

Next, the experts determined that a score of 100 represented the positive-ideal solution ($x^+_i$) and a score of zero represented the negative-ideal solution ($x^-_i$). The performance score was calculated using normalized formula (i.e. $x_i^+ - x_j^-$) to obtain performance variance rates between the status quo and the ideal point. Finally, $S$, $Q^mod_j$, and $R^mod_j$ were computed by selecting $\nu=0.5$ (Table 4). Given these results, we observed that $A_2$ did not have an acceptable advantage; in other words, $R^{[2]} = 0.001 \leq DR = 0.021$. On the other hand, we observed that $A_2$ was stable within the decision-making process; in other words, it was the highest ranked in $S^1$. Therefore, we proposed $A_1$ and $A_2$ as a set of compromise solutions. Looking at Table 4, the values $R^mod_j$ are ($A_1$, $A_2$, $A_3$, $A_4$, $A_5$)=(0.436, 0.435, 0.485, 0.518, 0.494), in which the ranking is: $A_2 > A_1 > A_3 > A_5 > A_4$, where $A > B$ indicates that A is preferred to B.
The results show that the comprehensive variance rate of A2 was 0.435. This website still needed improvement in order to achieve its ideal point or desired level. On the other hand, A4 was the farthest from the ideal solution, as its $R^\text{mod}_j (0.518)$ was larger than all others. A particular attention should be given to price negotiation (P3) and low price (P4) because these two criteria had higher weights and lower performance than others. Price negotiation (P3) was in most urgent need of improvement for airlines’ proprietors. Consideration should also be given to the possibility of developing an “online price negotiation” area for special customers such as group traveler. In addition, we suggested that the airlines should try to improve their pricing mechanisms.
4.3 Discussions

The value of the weight $v$ had a central role in the ranking of alternatives. According to the VIKOR, when $v$ was larger (>0.5), the value $R_j$ will prefer majority rule. A scenarios analysis can be undertaken by setting $v$ systematically to some values between 0 and 1. To give a valuable insight for the change of evaluators’ preferences (or concerns), we proposed another six scenarios for evaluating e-commerce websites; six sets of different weights were associated with six scenarios. Table 5 presents six sets weight values and the ranking of the VIKOR. The results of this table indicated that alternative $A_1$ was the best ranked, with an acceptable advantage, for scenario 1. From scenario 2 to scenario 6, the compromise sets were obtained {A$_1$, A$_2$}, the first ranked alternative had no advantage to be a single solution.

It was interesting, however, to note that the value $S_j$ of $A_2$ was the smallest in Table 4 but the value $R^\text{mod}_j$ of $A_2$ was the second smallest in scenario 2 and scenario 3. In other words, $A_2$ had the smallest average variance rate, but it only obtained the second ranking order in the VIKOR method. Moreover, $A_2$ had the smallest variance rate and the best ranking order in scenario 4, scenario 5 and scenario 6. On the other hand, when $v$ was smaller than 0.5, $A_1$ had the smallest variance rate and the best ranking order. $A_2$ had the largest variance rate and the worst ranking order in all scenarios. According to the results of these scenario analyses, we could find the benefits of the VIKOR method since it additionally considers the value $Q^\text{mod}_j$ which is the farthest from the positive-ideal solution (i.e. the largest variance rate) in the VIKOR index. On the contrary, the shortcoming of traditional performance evaluation is that it only takes into account weighted average scores and neglects to specifically consider the worst one. Thus, the decision-makers can select a suitable weight ($v$) in terms of their preferences (or concerns) to make an appropriate decision.

*Table 5. Ranking of the five websites in six scenarios.*
5 CONCLUSIONS

In view of the pressure from the current fierce competition and high oil costs, airlines gradually turn to the Internet marketing methods to increase competitive advantage. Airlines are concerned about how to build an ideal e-commerce website by comprehensively considering the role of a website on technology, service and marketing constructs.

This study proposed an integrated model combining the DEMATEL method, the ANP method and the modified VIKOR method for evaluating e-commerce websites of airlines and provided some directions to airlines on how to improve overall e-commerce performance. First, the DEMATEL were used to construct the interrelationships between criteria. Second, the ANP were employed to calculate the relative importance of each criterion. The weights obtained through ANP were then combined with the modified VIKOR method to compute performance variance rates between the status quo and the ideal point for ranking the five Taiwanese airlines’ websites. The results showed that $A_1$ and $A_2$ were the two best websites and that $A_4$ was the worst one. Moreover, a scenario analysis based on the change of experts’ preferences was also provided. The objective of scenario analyses was to provide an insight to decision-makers when a parameter was changing. Finally, the overall results showed that the Taiwanese airlines did not utilize the Internet to its full potential and still had a great deal of room to improve their websites. All five websites performed poorly in terms of price negotiation ($P_3$), low price ($P_4$), responsiveness ($P_{10}$), and communication ($P_7$). To apply the Internet marketing effectively, these airlines should put efforts to add an “online price negotiation” feature to site and adjust pricing strategies. Airlines can use their websites to gather information about customer needs, buying patterns and preferences. This information can be a worthwhile input to the development of high value-added products and services. Furthermore, although this paper is related to the airline industry in Taiwan, the same concept can be applied and extended to other industries to handle any evaluation problem with interdependent criteria. However, this study also has some limitations. First, survey data were collected from a limited number of visits to each website at a specific time. Due to the highly dynamic nature of these websites, similar studies at different times are quite likely to show different results. Second, this study transformed linguistic values into five crisp numerical values for measuring a website’s performance, but this might not be true in the real world. Concerning future research, it would be beneficial to extend this study to a fuzzy environment. In addition, the benchmarking analysis provides a means to enhance the websites’ competitive advantages by learning from the best practices of the industry. Researchers could also extend this study to the benchmarking analysis.

Abstract

In this paper, we build an evaluation tool for assessing the business impacts of an electronic order-to-payment cycle. Based on a literature review and expert interviews, we formulate a three-stage model which includes performance indicators for electronic order, electronic invoice, and electronic payment processes. In addition, we pinpoint the inter-process linkages. We test the proposed evaluation tool in a business context and find that the impacts of automating the order-to-payment cycle relate closely to cost avoidance. However, a strong emphasis on asset utilization can be observed as well – better use of IT could enhance utilization of existing human resources and capital, affecting company profitability.

Keywords: Performance indicators, evaluation tool, e-order, e-invoice, e-payment.
1 INTRODUCTION

How can we utilize information technology (IT) to increase productivity? What IT innovations enable us to perform tasks in smarter ways than we used to? One important source of productivity growth lies in improving the processes of the financial administration. Using IT in financial administration has been recognised as one of the most important sources of profitability growth in Europe (European Commission 2007; EU 2006). As an example, EACT has estimated that by moving from paper-based invoicing to electronic invoicing, companies could save 243 billion euros in processing costs alone (European Commission 2007). Therefore, increasing productivity by using information technology (IT) in the financial administration is high on the EU agenda (EU 2006).

The extant literature provides a plethora of metrics and measures related to supply chain performance and financial administration. What is missing, though, in the current literature, is a holistic analysis on the potential productivity gains that could be derived from a full-scale digitalization of the order-to-payment cycle. Therefore, the objective of this study is to pinpoint the potential productivity gains from adopting an electronic order-to-payment cycle. To do this, based on an extensive review of the existing literature and expert interviews, we divide the order-to-payment cycle into three distinct processes (ordering, invoicing, and payment) and build an evaluation tool to assess the potential productivity gains. In addition, we report the findings of a multiple case study, testing the proposed evaluation tool in a business context. The proposed evaluation tool is developed from the point of view of the buying organization.

The structure of the study is as follows. In the second section, we discuss the literature on business value of information technology. In the third section, we develop the evaluation tool. In the fourth section, we test the proposed evaluation tool in the context of a Finnish design company. In the remaining sections, we provide some anecdotal evidence from two other case studies, draw conclusions, and suggest avenues for further research.

2 BUSINESS VALUE OF INFORMATION TECHNOLOGY

Effective measurement of information system success has been a serious concern for both managers and scholars - attempts to quantify the benefits of IT have often resulted in inconclusive or inconsistent results (Byrd et al. 2006). Research in IT business value examines the organizational performance impacts of information technology, such as productivity and profitability improvement, cost and inventory reduction, competitive advantage and other performance measures (Melville et al. 2004). There is a vast amount of studies regarding IT business value and almost as many proposed instruments to evaluate it; quantitative financial measures, information value measures, service quality tools (SERVQUAL), and multi-dimensional analysis have been used, among others (see Cronk & Fitzgerald 1999 for review).

2.1 Productivity paradox and beyond

In spite of the great promise of IT driving the biggest technological revolution men have known, there has been heated debate in the IS literature for the past decades about whether IT usage actually pays off (Brynjolfsson 1993). Labelled the productivity paradox of information technology, Brynjolfsson (1993) explains that although computing power in the (U.S.) economy has increased by more than two orders since 1970s, productivity seems to have stagnated. Particularly in the 80s, many studies claimed that the overall IT productivity impacts are neutral or even negative (e.g. Salerno 1985). Robert Solow, winner of the Nobel Price in economics 1987 stated that “we see the computer age everywhere except in the productivity statistics” (New York Times Book Review 1987). Yet, the well established view today is that IT-intensive firms are more productive (e.g. Dedrick et al. 2003, Aral et al. 2006).
According to Brynjolfsson & Hitt (1998), the critical question for IT managers is not “Does IT pay off?” but “how can we best use computers?” Brynjolfsson & Hitt (1998) refer to the business value of IT as its ability to contribute to productivity growth. Productivity growth comes from using resources more efficiently, or as Brynjolfsson & Hitt (1998) express it “productivity growth comes from working smarter”. This is the promise of computers; this is what IT should be able to offer. According to Tallon et al. (2000), some insights into IT payoff can be attained by firm-level research on the “productivity paradox”, principally in the form of returns on IT investment (IT productivity on the company level can be measured by comparing some IT factor to an organizational performance measure, e.g. annual IT expenditure vs. pre-tax profit). They argue, however, that too little attention has been given to other IT impacts such as improved inventory management, greater product variety and customer service. To be able to fully understand the benefits, they claim, additional indicators should be considered.

Although the discussion so far has provided few practical tools for assessing the business value of IT regarding this study, some valuable points have emerged. First of all, it is crucial to see that there is a variety of tangible and intangible variables to consider – not all IT investments are made simply to cut cost. Second, a process management and design view should be highlighted when building the evaluation tool. Gonzales-Benito (2007) found that IT investments have positive effect on operational purchasing performance since the use of IT allow companies to adopt certain purchasing practices and facilitates greater strategic integration of the purchasing function. Finally, it has become clear that the majority of the literature reviewed so far aim to measure direct impacts of IT on company level performance or even on a wider scope. Now the question remains how to measure business impacts of an electronic order-to-pay process; one specific business activity inside a company?

According to Silvius (2006), there are two distinct approaches to be found in IT business value literature; the variance approach investigating what the relationship between IT investment and organizational performance is, while the process approach tries to find out how this relationship works. Most research presented so far try to explain the productivity paradox by investigating direct company level impacts of IT and thus falls under the “variance approach” category. A growing body of IT business value research, however, prefer the process approach, suggesting a multi-dimensional impact structure in the organizational hierarchy.

2.2 Process-oriented approach for evaluating IT business value derived from the order to payment cycle

To gain insight on activity-specific impacts inside the process, it has to be split open into smaller phases and try to identify attainable benefits in each phase. This will, however, result only in a group of operative-level performance indicators which hardly give much insight on business impacts of automating the entire chain. On the other hand, the overall company, industry or macro-economic level analysis of IT productivity impacts are too general and cannot provide information that is accurate enough for process monitoring purposes. Thus, there should be some instrumentation in the middle to combine the lower-level and the top-level business impact indicators.

According to Barua et al. (1995), the growing concern of scholars is that IT effects on the enterprise level performance can be identified only through a web of intermediate level contributions - there is some evidence that IT impacts exist and that they can be detected by lower-level analysis in the organization. The lower level impacts, in turn, are expected to affect higher level performance. To evaluate these, Barua et al. (1995) propose a process-oriented methodology, which involves a two stage analysis of intermediate and higher level output variables. They strive to open up the black box of IT usage, detect and measure IT impacts where they occur - their main thesis is that economic contributions of IT can be measured at the operational level, where IT systems are implemented. The higher order impacts can be then traced through a chain of relationships within the organizational hierarchy.
An important side note to make here is that actually, the functions; ordering, invoicing and payment are better yet sub-processes of the order-to-pay activity. Tallon et al. (2000) argue that IT creates value for the company via individual business processes, or inter-process linkages, or both – the greater the impact of IT on processes and inter-process linkages, the greater the contribution of IT to firm performance. This encourages investigating IT impacts of individual sub-processes e-ordering, e-invoicing and e-payment but also pay great attention to IT impacts on inter-process linkages – in other words investigate the impact of electronic integration in an order-to-pay process.

We divide IT impacts to three levels; application-specific impacts (e-ordering, e-invoicing, and e-payment), integrated process level impacts (order-to-pay) and finally the company level business impacts. First of all, the use of IT affects sub-processes directly, resulting in some impacts which are specific to each function. Second, IT usage impacts the entire order-to-pay process via inter-process linkages thus enabling full chain optimization. Finally, linkages between the process and the company level reveal the contribution to company level business value of IT. In short, automating an order-to-payment process yields application-specific impacts and through some yet unidentifiable intermediate variables contributes to overall IT business value for the company.

### Figure 1. Conceptual framework for the study.

#### 2.3 Uncovering the hierarchy: identifying the chains of IT impacts

To better identify the chains of different stage indicators for IT impact evaluation, some studies have borrowed a very well known multi-stage framework from the strategy literature. The Balanced Scorecard is a tool that translates a company’s mission and strategy to a comprehensive set of organizational performance measures (Kaplan & Norton 1996). The Balanced Scorecard communicates a holistic model that links individual efforts and accomplishments to business unit objectives through a consistent series of objectives and measures. The idea is that each individual person could see how their efforts contribute to achieving broad organizational goals, thus offering means for organizational learning and improvement. To be able to track these linkages, however, the model needs to be more than a collection of critical indicators – the scorecard incorporates a complex set of cause-and-effect relationships among outcome measures and the related performance drivers. These relationships can be then traced through sequences of “if-then” statements.

Respectively, efforts to increase IT intensity in a specific function could be seen to affect company level financial measures through a similar chain. Following this idea, Epstein & Rejc (2005) introduce the IT Balanced Scorecard which is a tool for tackling the problem of properly evaluating IT payoffs. The authors argue that an IT performance measurement and management system must focus determining the key drivers of IT success and the causal relationships among them and develop numerous performance measures to track IT performance.
3 METHODOLOGY

Since the purpose of this study is to find out how IT creates business value in the order-to-payment cycle context, the first logical step was to conduct an extensive review on the general subject of business value of IT. It soon became clear that there are two quite different approaches to evaluate the impacts of IT, the variance approach studying what the impact is and on the process approach studying how this value is created. The process approach was chosen because of its suitability regarding our research question i.e. to answer the question “how”. A group of process-oriented models were reviewed next. Due to the specificity of the context, we soon realised that there is not a possibility to choose only one model and use it as such, but rather combine elements of a couple of them and create a modified evaluation tool.

As the second part of the literature review, we collected benefits regarding e-ordering, e-invoicing and e-payment to gain in-depth knowledge of order-to-payment cycle automation potential. Also, interviews with field specialists were conducted to get comments and new ideas along the way. The expert interviews were particularly useful in determining the value created by IT impacts on the inter-process linkages – it is something that until now was implicitly understood by business people but not explicitly stated in the books.

To illustrate and test how the proposed evaluation tool works, we chose to use the case study methodology to make an in-depth analysis in one case company. The case study methodology has distinct advantage when a “how” or “why” question is being asked about a contemporary set of events, over which the investigator has little or no control (Yin, 1994). The case study methodology was especially suitable for our research as we investigate how companies use information technology in their financial administration and what performance indicators they perceive as important in the process. Furthermore, the strength of the case study approach is that it enables the capture of “reality” in considerably greater detail and the analysis of a considerably greater number of variables than is possible with many other approaches (Galliers, 1991). This was especially important in our work as the objective of this research was to find the underlying performance indicators to IT investments in financial administration, and not just the company policy statements.

More specifically, to develop the evaluation tool, we conducted 10 industry expert interviews (leading specialists in companies providing e-payment, e-invoice, and e-procurement services, the Federation of Finnish banks, the Finnish Information Society Development Centre etc.) and academic professionals (professors at Finnish business universities). For the illustrative case part, at Marimekko, we interviewed six people in total each from different functions that were relevant regarding our study. We covered extensively the entire order-to-payment cycle by interviewing people from buying, invoice handling, treasury, IT system development, and supply chain management. In addition, we conducted supplementary case studies in two large Finnish companies. These case studies included altogether eight interviews.

4 DEVELOPMENT OF THE EVALUATION TOOL

In developing the evaluation tool to analyze the order-to-payment cycle, we adopt the process view discussed above and divide the order-to-payment cycle into three distinct processes: e-ordering, e-invoicing, and e-payment.

4.1 E-ordering impacts and performance indicators

The classic argument for adopting e-procurement systems is that it creates substantial cost savings (e.g. Bakos 1997). To find out how these savings can be achieved, Johnson & Klassen (2005) discuss three different dimension of e-procurement in their article; e-sourcing, e-coordination and e-communities. Many e-procurement studies address e-sourcing issues e.g. the emergence of electronic
(reverse) auctions and other transparent e-marketplace structures which have, e.g., allowed companies to negotiate better prices for purchases and reduce search costs. E-communities, on the other hand, refer to different e-procurement systems platform structures. Proprietary platform procurement systems are point to point links between buyers and suppliers (often EDI-systems), open platform procurement systems are open Internet-based systems, and hybrid platforms have elements of both.

Johnson & Klassen (2005) note that reported benefits of e-coordination are diverse and varied, including cost savings from process improvements (less slack and reduced rework due to errors), price reductions, greater visibility of orders and enhanced inventory turnover and accuracy, among other things. Also, it has been reported that fewer Request for Proposals (RFPs) elicit no bids when sent electronically. Ordering automation can lead to purchase price reductions due multiple reasons. First, since e-ordering allows for a more coordinated and centralized buying process, orders can be bundled to be able to negotiate volume discounts. Second, e-ordering systems provide a transparent bidding platform for a growing number of suppliers, thus increasing price competition. Reduced probability of human mistakes in ordering and storing due to the use of IT allows improved inventory accuracy. Enhanced inventory turnover, in turn, is largely due to reductions in average inventory levels.

Inventory level reductions come from increased inventory accuracy and enhanced transparency of incoming raw material and replenishment deliveries. Other effectiveness and efficiency gains provided by e-ordering systems include lower transaction costs mainly due to less manual work in the process (Presutti 2003) and shorter order cycle times meaning that users receive requested goods or services faster (e.g. Johnson & Klassen 2005, Presutti 2003, Reunis et al. 2001). The following figure (Figure 2) depicts the performance indicators for the e-ordering process.

![E-ordering performance indicators diagram](image)

Figure 2. E-ordering performance indicators.

4.2 E-invoicing impacts and performance indicators

The benefits from the electronic invoicing process of invoicing stem primarily from the decreased processing costs and numbers of errors, reduction of materials use, and decreasing handling times. Penttinen & Hyytiäinen (2008) argue that adopting e-invoicing has clear benefits; transition from
paper bills to e-invoicing brings considerable financial savings. It has been estimated that an incoming paper invoice incurs cost of 30-50 euros to the receiving company. By moving to electronic invoicing, these costs can be cut considerably mainly due to reduction in handling costs (Penttinen 2008). The following figure (Figure 3) depicts the performance indicators for e-invoicing process.

Figure 3. E-invoicing performance indicators.

4.3 E-payment impacts and performance indicators

The promise of e-payment has been that they ease payment and lower transaction cost (Southhard 2004). Cotteleer et al. (2007) listed top ten attributes based on perceived value for B2B e-payment users across multiple U.S. industries and found that transaction cost savings was considered most valuable. These cost savings come from improved processing efficiency – no more manual feeding of payment information is needed etc. Shorter payment cycles can also result in savings for the buyers in form of possible vendor discounts for early payments (Jolly 2007). The following figure depicts the performance indicators for electronic payment process.

Figure 4. E-payment performance indicators.
4.4 Links between the processes

So far, we have reviewed a group of indicators that can be more or less assigned to each function along the order-to-payment cycle. This is insufficient due to a couple of reasons. First, in real-life, the situation often is that operational level indicators are in active use but too often there is not a proper connection to business thinking. This leads to operations-driven improvement, rather than business-driven improvement – people in operations do not necessarily know the business impacts of their efforts. Also, some of the indicators used to evaluate process level performance can be included in cross-organizational service level agreements (SLAs) without actual knowledge of their economic effects. Second, it was already proposed that in addition to the individual sub-process level impacts, IT usage actually impacts the inter-process linkages as well. Therefore, we must strive to uncover the linkages between IT inputs on the grass-root level and the company level economic outputs as well as between the three functions. In developing the holistic evaluation tool (illustrated in the next section through the case example), we identified a number of links between the processes. Due to page limitations, these links will only be available as an appendix (Appendix 1).

5 CASE

To test the proposed evaluation tool, we conducted an in-depth case study at Marimekko Corporation, which is a leading Finnish textile and clothing design company that was established in 1951. The company designs, manufactures and markets high-quality clothing, interior decoration textiles, bags, and other accessories under the Marimekko brand, both in Finland and abroad (for further details see www.marimekko.fi). We conducted six face-to-face interviews with representatives from the company’s financial administration, purchasing, logistics and IT departments.

Using IT in financial administration is nothing totally new to Marimekko – they adopted e-banking systems and even electronic ordering already a few years ago. However, they have only quite recently adopted electronic invoice handling systems for incoming invoices. Approximately 16,000 – 17,000 invoices flow through their invoice management system (IM) every year. Although they have systems at place, they do not currently measure the impacts of IT usage in this context. However, they consider measuring important, particularly as basis for process development and as justification for the recent IT investments.

First, we decided to analyze the current state of processes; examining which phases exactly along the order-to-payment cycle are automated and which are still conducted manually. Further, we asked people from different functions to intuitively identify benefits that they consider important regarding process automation in the financial administration. Benefits they assigned for e-buying were mainly related to cost avoidance and time savings but also enhanced user satisfaction was reported. As for future challenges, enhanced asset utilization was considered most critical due to the fact that Marimekko currently holds substantially large inventories. Reported benefits regarding electronic invoice handling included centralization, decreasing circulation time and also reliability of electronic document exchange compared to regular mail. Perceived e-payment benefits were undisputed: reduced manual feeding leads to fewer errors, handling time reduction, and cost savings.

Finally, we asked people from different functions to comment our evaluation tool (regarding e-ordering, e-invoice handling and e-payment). It was very much a pleasure to see that during this exchange of thoughts, other important impacts were identified in addition to the ones that were first intuitively stated. The collected feedback regarding each measure was categorized (high, medium or low) according to expressed importance. Appendix 1 illustrates the evaluation tool from the point of view of Marimekko. We colour-coded the indicators so that green stands for highly important, yellow is medium, while red stands for low. After this, it was quite easy to draw “critical paths” for each sub-process. The ones marked with thick solid arrows illustrate the most critical mechanisms of value
creation. Dashed arrows show the paths that were considered slightly less critical yet worth considering.

E-payment systems in the case company are fully developed and well integrated into invoice management systems. Accounts payable sends a batch of payment proposals to the cashier and after that it takes only three clicks and approximately half a minute to approve and complete payments. Hence, there is limited potential for improvement in the payment section. That is why most of the boxes in payment are green and critical paths were not even drawn between them – there is hardly anything “critical” left to be improved in the payment side. Challenges at Marimekko relate more to the electronic integration aspects between payment and the other functions, particularly in how the order information could be better utilized in cash flow management and forecasting (illustrated by yellow boxes and the dashed path in payment).

It became clear that the yet untapped potential lies mainly on automating invoice handling and ordering even further. Critical paths in e-ordering include the above mentioned inventory level challenges and its effect on holding costs as well as asset utilization (turnover). One major challenge would be to automate inventory management even further to save buyers’ time. Additionally, reduced routine work enhanced user satisfaction. Another e-buying related issue is visualized by a dashed path: currently, buyers go manually through stock listings in order to identify purchase requirements and inevitably miss some requirements. This will of course lead to longer lead times and late deliveries to customers. If information systems would manage inventories automatically and alarm buyers when needed, human mistakes would decrease and thereby they would be able to deliver on-time to their customers. This could, through improved customer satisfaction, increase sales and thus create economic value for the company. The problem is, however, that these revenue side impacts are difficult to measure.

In invoice handling, circulation time was considered more critical than actual handling time and related costs. The largest obstacle was actually identified to be “approval delays” which refer to the time each invoice has to wait for approval at each person’s “desk”. Another related critical phase is getting purchased goods visible in stock as soon as possible. Standardization of documents was also considered highly important in order to avoid mistakes and needless rework. The same goes for system integration, where the question is how to standardize documents so that systems would understand each other leading to fewer mistakes and how to utilize the potential of information visibility in order to promote dialogue between purchasing and sales?

Part of the proposed indicators (such as inventory levels and some cost items) could be translated into relevant metrics directly; they could be derived from data already stored in company information systems. Others would require field studies, for example measuring the handling time spent on particular activities or user satisfaction. In fact, an important lesson learned from this case study is that the actual metrics have to be agreed upon according to individual characteristics of each case company.

All in all, it seems that in the case of Marimekko, impacts of automating the order-to-payment cycle relate closely to cost avoidance as intuitively stated. Yet contradictory to the intuition, a strong emphasis on asset utilization can be observed – better use of IT could enhance utilization of existing human resources and capital, affecting company profitability. They also leave the door open for revenue impacts with some reservations; the message was that these impacts are important yet difficult to observe and evaluate. However, it seems that the evaluation tool can be used in a real-life company context as an instrument for communicating, categorizing and sketching impacts and related measures. To be able to really measure and get accurate quantitative results, one would have to dig deeper to identify actual metrics that best indicate desired impacts and make efforts to collect relevant data.
6 DISCUSSION AND CONCLUSIONS

In this paper, we set out to build an evaluation tool to assess the impacts of the electronic order-to-payment cycle. We reviewed the extant literature and conducted expert interviews. Based on these, we built an evaluation tool that was divided into three sub-processes: e-ordering, e-invoicing, and e-payment. We then conducted a case study at Marimekko to illustrate how the proposed model works in real-life context.

In addition to case Marimekko, we tested the model in two supplementary case companies. Cost related effects were repeatedly emphasized which further supports the argument about impacts of automating order-to-payment cycles being cost-centric. However, the message was that once applications were implemented, challenges and post-auditing efforts related closely to better asset utilization. As a comparison, a retailing company reported that the share of e-orders in direct buying is already close to 100%, whereas current challenges relate to digitizing and centralizing indirect purchases. Concerning the e-invoice indicators, enhancing efficiency of the e-invoice “approval loop” was considered as a major challenge in all case companies.

The use of IT offers undisputed potential for process improvement in financial administration. Companies are making efforts in this area, yet progress is slow. Most companies have already well-established e-payment systems at place and electronic invoice management systems seem to be the current area of concern. Probably the largest unutilized potential lies in developing smart electronic applications for ordering. Despite of the potential, companies do not often monitor impacts of IT usage in this context. They rather implement, see what happens and never actually quantify the benefits. This might have undesirable effects – it is difficult for the companies to improve operations and further IT development investments might be impossible to justify. Measurement could thereby enhance the already great potential of process automation, yet it is rarely utilized. This contradiction acted as motivation for the whole study.

We developed an evaluation tool which strives to visualize mechanisms of value creation in the electronic order-to-payment cycle. The tool offers visibility over and across the entire business activity. As the case study showed, it works quite well at least as an instrument for cross-functional communication. Also, hierarchical categorization of metrics turned out to provide a useful skeletal structure for identifying critical cause-and-effect linkages between impacts. The purpose of building the model was to raise thoughts, promote awareness and provide a platform for productive dialogue. Based on the first company case, we can safely say that this objective was already fulfilled. Exact measurement would require extensive field studies within the organization.

Abstract

The Internet changed from a pure information media to a distribution channel, challenging companies in measuring the performance of their online distribution channels. Multi-channel retailers are particularly concerned since they need to coordinate their efforts with traditional, offline retailing activities. The paper at hand presents a corresponding metrics system derived from literature and a Delphi study, allowing for comparability with offline channels.

Keywords: Multi-channel retailing, Metrics system, E-commerce, Performance measurement.
1 INTRODUCTION

The development of the Internet from a pure information media to an increasingly important distribution channel resulted in significant intra- and inter-organizational changes for firms. Intensified by the collapse of the new economy by the turn of the millennium, stakeholders increasingly ask for performance measures tailored for online distribution channels, especially in the context of multi-channel retailers. Companies, however, are confronted with issues such as lack of experience and benchmarks, and missing or insufficient IT support. Challenges specific to multi-channel organizations include cannibalization effects and synergies as well as coordination tasks between online and offline channels (Schäffer & Weber & Freise 2002, Wall 2002, Welling & White 2006, Hienerth 2006).

There is already considerable work presenting models for e-commerce success (Hess 2001, Straub & Weber & Steinfield 2002). However, many of them are pure theoretic approaches whose applicability to real situations still needs to be evaluated. A closer look also reveals that some models either lack a precise definition of the research target, or focus on selected success factors such as web shop usability. Further, the supply chain and the corresponding business processes have changed with the increasing importance of online channels, thus limiting previous results valid for traditional organization models (Hansen 1997, Picot 1991, Gosh 1998). Hence, there is still a need for new metrics systems tailored to the requirements of specific business models (Schäffer & Weber 2001, Wall 2002).

Additionally, recent advances in IT multiplied Internet-based business models, fostering the development of new web/e-metrics such as Visits or Page Impressions, making the choice of meaningful, decision-relevant metrics even more difficult (Welling & White 2006). Also, these new metrics create a number of new technical challenges related to data collection and storage. Therefore, the relevance of these measures is still a matter of debate among researchers and practitioners alike (Schwickert & Wendt 2000, Marr & Neely 2001, Link & Schmidt 2001, Bhat & Bevans & Sengupta 2002, Palmer 2002, Nikolaeva 2005).

The paper at hand presents a metrics system specific to the performance measurement of online distribution channels of multi-channel retailers. The model in particular allows for comparability with traditional channels, supporting an integrated controlling system of a company's sales process. The model is based on existing literature on the one hand, and on the results of a Delphi study conducted on the other. The remainder of the paper is structured as follows: In Section 2, we first present design and results of the empirical study. In Section 3, these are combined with theoretical results from literature to a new model, which is then compared to metrics for stationary shops to demonstrate the comparability of both distribution channels. Section 4 concludes.

2 EMPIRICAL STUDY

2.1 Design of the Delphi study – Selection and number of participants

The two-stage Delphi study presented here was carried out using an e-mail based online questionnaire. First, we contacted 54 experts\(^1\) with a strong background in retailing and e-business, either conducting research or doing business in Austria or Germany. The choice was based on an extensive literature and internet review, as well as on recommendations from the experts themselves (Mullen 2003, Häder 2002). From these, 32 accepted to participate. In the run-up of stage 1, an extensive list with

\(^{1}\) We used Beckers (1974, p. 146) definition of expert.
performance metrics derived from the literature was provided to all participants. Five participants quit due to time restrictions, nine other claimed to be unfamiliar with the presented metrics.

In stage 1, the list of experts comprised 18 participants: six web shop managers, three researchers with background in e-commerce / retailing, four members of inter-trade organizations and certification authorities, and five executive consultants. Stage 2 involved 14 experts: four web shop managers, three researchers from the field of e-commerce / retailing, three members of inter-trade organizations and certification authorities, and four executive consultants.

2.2 Objectives of each Delphi stage

The objective of the stage 1 was to evaluate the importance of several metrics deduced from Palloks’ Model to measure the success of the online distribution channel. To this end, the experts evaluated 101 metrics within nine categories deduced from IS/e-business literature (especially from the main scholarly journals). Additionally, they were asked to supplement missing metrics and to point out metrics for measuring cannibalization and synergy effects between the web shop and the stationary shops. The first online questionnaire included 26 questions. The first five questions were intended to introduce the topic and to replace a qualitative preliminary study, which is recommended when applying a Delphi study. The remaining questions measured the importance of the listed metrics using a 5-point Likert Scale (1 = very unimportant, 2 = unimportant, 3 = neutral, 4 = important and 5 = very important).

The goal of stage 2 was to rank the most important metrics within the same categories from stage 1, defined as those with an average score of at least 4. All participants received the consolidated results from stage 1, summarized by mean and standard deviations. In total, the experts had to rank 42 metrics (within the different categories). In addition, the experts were asked to evaluate the importance of the metrics for measuring cannibalization and synergy effects between the web shop and the stationary shops, which they completed in the first stage. For this, again a 5-point Likert scale was used. Here again, we selected those with a score above 4, yielding five more metrics that were added to the system. The final model thus comprised 47 metrics in total.

2.3 Results

The 15 most important metrics according to the mean scores to evaluate the success of an online distribution channel for a multi-channel retailer are, in descending order:

1. system availability, 2. number of repeat customer, 3. product availability, 4. delivery time, 5. average server response time, 6. error rate, 7. online sales growth, 8. delivery quality, 9. return, 10. number of first buyers, 11. profit margin per customer, 12. acquisition cost per visitor, 13. acquisition cost per first buyer, 14. service level, and 15. order growth.

Clearly, from the experts’ point of view, the most relevant metrics for evaluating the success of the online sales process assess the performance of the information system (e.g., system availability) and goods handling/logistics activities (e.g., delivery time, product availability). This underlines the central importance of information systems in online selling. Also, the choice of metrics such as number of first buyers, number of the repeat buyers, and profit margin per customer shows that “classical” customer metrics from the offline-world are equally valued, particularly regarding the determination of the customer structure, customer retention and customer satisfaction. The same applies—with a grain of salt—to financial metrics such as total acquisition cost, acquisition cost per visitor, online sales, and return on sales.

We now turn to the 15 least important metrics, still according to the mean scores, and listed in ascending order:
42. online sales per daytime, 41. online sales per day of week, 40. online sales per employee, 39. day of week with the highest visit frequency, 38. time of day with highest visit frequency, 37. shop finder rate, 36. cross selling click rate, 35. product impressions, 34. focus, absence time, 33. online sales per payment method, 32. cross selling conversation rate, 31. no referrer, 30. number of clicks, and 29. one-click-rate.

Given the top metrics results, it seems surprising at first that the three most unimportant metrics (online sales per daytime, online sales per weekday, and online sales per employee) are also financial metrics. Obviously, compared to classical controlling figures, a more differentiated view is needed for online channels, taking into account existing structural differences. It is clear, for example, that input factors such as human resources will not have the same importance in online and offline channels.

Another unexpected result is the relatively minor importance attributed to web metrics (e.g., no referrer, focus, product impression, cross selling click rate, and cross selling conversation rate) for the success evaluation of the online distribution channel. Our results do, therefore, not confirm the work from other researchers (e.g., Weischedel et al. 2005) who attach strategic meaning to web metrics. This might, in fact, stem from technical issues such as collection and storage problems, or from a lack of guidance in interpreting these numbers (Novak & Hoffman 1996, Bensberg & Weiß 1999).

3 A NEW METRICS SYSTEM

3.1 Palloks’ model as a starting point

Our model is based on the hierarchical sales controlling system by Palloks (1995), consisting of 24 metrics organized in three main- and several subcategories: structural analysis (sales process, market), profitability analysis (performance of sales activities, efficiency of logistics processes, product profitability), and current state analysis. There are several reasons for choosing this model as a starting point: First, it matches our assumption that online sales activities can completely be represented and analyzed as a distribution channel on its own, a view supported by many authors (e.g., Vishwanath & Mulvin 2001, Chan & Pollard 2003, Hukemann 2004). Second, because of the model’s broad scope, it accounts for many influencing factors, opportunities, and risks influencing online sales activities, and thus supports management effectively and comprehensively (Steinfeld & Bouwmann & Adelaar 2002, Anderson & Srinivasan 2003, Wirtz & Schilke & Büttner 2003, Zentes & Schramm-Klein 2006). Third, our goal is to maintain the comparability to traditional sales channels as much as possible. Fourth, it complies with our definition of success as achieving distributional objectives (Zhuang & Lederer 2006, Wade & Nevo 2006).

3.2 Deduction and scope of the new model

The final model (see Figure 1) was deduced from Palloks’ model and the results of the empirical study. The starting model was modified to account for the process differences in online and offline retailing, as well as for the unequal use of input factors (e.g., staff and IT). The subcategory: “Efficiency of Logistics Process” was therefore split into “Handling & Logistics” and “Information System” to better account for IT-related factors, playing an essential role in online retailing. Further, the subcategory “Market” is extended to “Market & Customers”, customer-oriented figures being key especially in the start-up stage of online shops. As described above, the metrics were selected according to the Delphi ranking at stage 2, comprising the most important indicators in each category, as well as the five most important metrics for measuring cannibalization and synergy effects.

The final model comprises 47 quantitative and qualitative metrics. It can be employed by small- and medium-sized retailers as well as by web shop managers of larger multi-channel companies to measure the operational performance of their online sales activities. In addition, the model takes into account future developments of the web shop in the “Current State Analysis” category, supporting
strategic decisions for the development of the web shop and the company-wide marketing strategy. The system is generic and needs to be further adapted to the special conditions of a concrete firm implementing the model. It is limited “by definition” to multi-channel retailers, i.e. to companies offering tangible, movable goods in both stationary shops and a web shop.

3.3 Comparability with stationary shops

As mentioned above, it is challenging to directly compare online and offline channels by means of performance metrics due to significant differences of processes and input factor use. Such a comparison is, however, of vital importance to multi-channel retailers in order to assess cannibalization effects and synergies, and to optimize their overall marketing strategy (von Oelsitz 2006). In the following, we compare our metrics system to the integrated controlling model of Becker & Schütte (2004) for stationary retailers and discuss comparability issues.

We categorized the metrics into three groups according to the degree of comparability between online and offline channels, based on a comparison of their formulas and the required data sources. Table 1 lists metrics from both models that are identical or can directly be compared. Table 2 comprises performance measures that have similar semantics. Table 3 shows metrics without stationary counterpart. Note that in practice, the actual measurement of some metrics can be difficult due to technical or organizational issues. Also, most of the metrics listed are not uniquely defined, possibly causing biased values if different formulas are used for compared values.

As can be seen from the tables, most metrics (e.g., return, complaint rate) in fact allow direct comparison. Some others, more technical ones (e.g., system availability, down time) can be compared by analogy with corresponding metrics calculated for the ERP/POS-system used in the stationary shop. Only a few metrics (e.g., most frequent search term) have no matching counterpart in the stationary world. This supports the claim that, even though e-commerce has transformed the value chains, business principles have not changed after all (Hansen & Neumann 2005).

The comparison, however, raises another important issue regarding the implementation of the system: even though most metrics are identical conceptually, the required raw data in both channels often stem from different systems and data sources (e.g., log files versus database of ERP system). Differences in data quality and actuality might therefore cause additional variance in comparisons. It is therefore recommended to avoid redundant, external controlling systems, and to favour an integrated systems approach instead.

Table 3. Metrics without comparability to stationary shops.

The following example should illustrate the notion of the comparability of both distribution channels and the meaning of this comparison for the management. Let us assume an average purchase value per repeat buyer of 45 Euros in the web shop and of 30 Euros in the stationary shops. This could indicate that web shop buyers are different (e.g., income, gender, ...) to the stationary shop visitors. Further, in this situation, the management should have a closer look at the market share growth. If, e.g., the web shop grows by 6 percent and stationary shops grow by 2 percent, the management should foster the online channel and accordingly allocate more resources to it. Moreover, it should investigate the consumers’ motivations for choosing the online distribution channel and adapt the corporate strategy accordingly. In any case, the different metrics employed should be monitored over time to capture important structural changes.

4 CONCLUSION

This paper presents a new metrics system suitable to measure the performance of online retailing systems. The metrics are based on literature and the results of a Delphi study. The system...
comprehends 47 quantitative as well as qualitative metrics. Despite the structural differences of online and offline retailing regarding the work flows and priorities of input factors, the system allows comparisons between web shops and stationary shops. Comparative analyses over time should reveal cannibalization and synergy effects, effectively supporting the management of both online and offline distribution channels in a coordinated way.

The presented metrics system is limited to multi-channel retailers offering movable goods to their customers. Also, the validity of the results is limited by the relatively small number of participants of the Delphi study. There is, however, no clear recommendation in the scientific literature on the minimum number of participants in Delphi studies. Also, the small number of participants (and especially their drop-off from stage 1 to stage 2) might indicate some lack of awareness among practitioners regarding the existing metrics, and the need for researchers to investigate and publish case studies where metrics are employed in practice.

Eventually, the efforts of investigating metrics systems for online and offline channels should result in the development of a comprehensive multi-channel controlling system. To this end, further investigation of existing interaction effects between the different channels is needed, especially with regard to the customers’ switching behaviour and the optimal allocation of marketing resources.

Abstract

As the sole production of goods is more and more becoming a commodity, many manufactures start bundling their physical products with related value-added services in order to differentiate their value propositions. The process of developing such customer-oriented combinations of products and services is an innovation process that requires the input of creative individuals. In this design-oriented paper we describe the conceptual design and prototypical implementation of an IT system that supports creative individuals performing such creative development efforts. The conceptual design builds on the provision of explicit knowledge by means of multi-perspective, hierarchical navigation structures. We argue that this concept (a) fosters information access that accords with the creative nature of a product development process and (b) furthering creative thinking through the provision of three distinct types of stimuli that actuates new entry points in a person’s cognitive network. The conceptual design of the system has its underpinnings in associative theories on creativity.

Keywords: Creativity Support, Product-Service Bundles, Information Retrieval, Navigation Hierarchies
INTRODUCTION AND RESEARCH DESIGN

Over the last decades, in most developed countries we have been witnessing a transition from a primarily goods-based to an increasingly service-based economy (Vargo & Lusch 2008). One explanation for the growing importance of services is the observation, that the sole production of physical goods is more and more becoming a commodity which can be almost equally provided by a constantly growing number of companies around the world (Rai & Sambamurthy 2006). At the same time, services are advancing as increasingly differentiated value propositions that are thought to lead to higher levels of customer satisfaction and loyalty (Howells 2003). Consequently, many traditional manufacturing companies try bundling their products with related value-added services to offer integrated customer solutions. Examples of such product-service bundles can be found in the automotive (e.g. automobile plus insurance, maintenance, trade-in, etc.) or telecommunication (e.g. mobile phone plus calling plan, messaging, music downloads, etc.) industry, but also in B2B markets like the machine tools industry (machine tool plus transport, integration, start-up, training, operating personnel, etc.).

The development of innovative product-service bundles comprises the discovery of prospective combinations of products and services. This innovation process can be characterized as a creative act. Creativity is the process of generating valuable products, services, processes, or ideas that are both novel and useful (DeGraff & Lawrence 2002, May 1959). This process results in innovations that are thought to effectively address a specific purpose in order to prosper (Amabile 1998). Against this background, product-service bundles can be characterized as innovations. A bundle’s value proposition must be new in order to stand out from competitors and it has to meet customer expectations or stimulate new demands. Accordingly, frameworks and models for product and service engineering (Scheuning & M. 1989) put creative acts like brainstorming or idea generation at the very beginning of a development process.

In order to support such creative processes, particularly two types of IT systems must be considered. First, research on so-called creativity support systems (CSS) has examined how computer systems can positively influence creativity (Massetti 1996). CSS implement different creativity techniques in order to provide guidance through the idea generating process (Malaga 2000). Second, theories on creativity identify a person’s knowledge as one major antecedent to the ability of being creative (Amabile 1998, Weisberg 1999). Knowledge management systems aid the creative process as they store organizational knowledge and support the creative individual in information retrieval (Shneiderman 2000). Yet, to our knowledge, there have been few efforts on integrating knowledge management and creativity support systems.

The purpose of this paper is to address the question of how to construct an IT system, which supports both creative thinking and information retrieval in the development process of a product-service bundle. The designed artefacts resulting from this design research process are a model and an instantiation (March & Smith 1995). We develop a model that explains how multi-perspective, hierarchical navigation structures can be applied to access digital information repositories in order to appropriately support creative persons in their effort of developing product-service bundles. Since models “that work ‘on paper’ will not necessarily work in real world contexts” (March & Smith 1995), we also present a prototype which is meant to serve as an evaluation object in a subsequent step of our research agenda demonstrating the feasibility of the proposed model. Our design rational is based on a theoretical underpinning from literature and theory. The design of the prototypical implementation incorporates results from an empirical study we conducted in the field of product-service bundle development. The focus of our research in its current state is to rather derive a sound design based on the existing body of knowledge in the IS field than to empirically validate the artefacts. However, our implementation is meant to provide the basis of consecutive evaluation steps.

The remainder of this paper is structured as follows: In the subsequent section we introduce a theoretical model that describes the conceptual basis of an IT system supporting the creative
development process of product-service bundles. To do so, we gradually develop the facets of our model from literature and theory (section 2). This is followed by the description of a prototypical implementation (section 3). In doing so, we exhibit the graphical user interface which reflects how the different aspects of the conceptual model expand into the prototype (section 3.1). Since hierarchical navigation structures play a prominent role in our approach, we subsequently apply the results of a survey on classification schema for product-service bundles to derive the navigation structures for the domain in focus (section 3.2). For the reason of presenting our design proposal in a more tangible manner, we present an example illustrating the intended value of our artifacts (section 3.3). The paper concludes with a discussion of contributions and limitations and an outlook to our future research agenda (section 4).

2 THEORETICAL MODEL

Creativity in an organizational context can be analysed on various levels. Woodman, Sawyer, and Griffin (1993) consider three levels of analysis: the individual, the group, and the organizational levels. Their model provides a comprehensive account on factors that impact creativity on these different levels and the interrelations that exist between them. The present study focuses creativity on an individual level. The theoretical model is meant to conceptualize how an IT system may aid a creative individual in solving her creative task.

Creative tasks are characterized by a high demand for flexibility and result in both deliverables and process orchestrations that are hard to predict and control in advance (Seidel & Adams & ter Hofstede & Rosemann 2007). For instance, the structure of the development process and the information needed are different whether a mobile phone is combined with a lifetime insurance against theft (e.g., gather relevant legal formalities, undertake risk assessment) compared to developing a bundle that valorises a mobile phone by providing a subscription for a music download service (e.g., contract negotiations with music labels, develop technical infrastructure). Thus, creative persons need a high level of autonomy in utilizing and controlling instruments they apply. We further argue that an approach towards creativity support must address several aspects of creative work. Our argument rests in the literature that identifies three primary components of creativity: motivation, expertise, and creative-thinking skills (Amabile 1998). While motivation is crucial to become creative at all, the way people approach problems and solutions (creative-thinking skills) and their knowledge about the domain of their work (expertise) also fundamentally contribute to the quality of a creative task’s output (Amabile 1998). Existing knowledge is a critical factor in the creative process; being creative often means “to put existing ideas together in new combinations” (Amabile 1998). For example, running shoes (product) that transfer one’s exercise performance online to a physician who analyses the data and elaborates a personal training schedule (service) constitute a highly creative product-service bundle. However, its parts are well-known. Thus, creative work comprises of both the convergent process of identifying relevant, existing ‘things’ (Weisberg 1999) and the divergent process of fusing these in novel ways (Seidel & Rosemann & Becker 2008b); “for a creative person to produce socially useful products, his or her divergent thinking must come hand in hand with convergent thinking” (Woodman et al. 1993, p. 299). IT systems may support this processes by providing its users additional expertise and furthering their creative-thinking skills.

In the remainder of this chapter we introduce an approach that aids both facets of creative work simultaneously: it provides explicit knowledge to support convergent thinking in a way that allows for the particular features of creative tasks and it provides means to foster ones creative-thinking skills in order to advance divergent thinking processes (Seidel & Müller-Wienbergen & Rosemann & Becker 2008a).

Throughout this work we rely on the assumption that knowledge positively correlates with the creative capacity of an individual. Although this is strongly supported by literature, there is literature which claims that existing knowledge can actually be a hindrance for creativity and innovation. The main aspect is often seen in the danger of biasing creative people by providing knowledge and thus limiting
their imagination (Cheung & Chau & Au 2008, Levitt & March 1988). This is the reason why we argue in favour of a combined provision of existing knowledge and means for stimulating creative thinking to prevent individuals from merely running down well-known alleys. Carlile and Rebentisch (2003) take a critical stance regarding the suitability of knowledge reuse in complex and novel situations. They argue, that if the circumstances surrounding the original knowledge development have changed, the knowledge is no longer relevant and its reuse can even be problematic. However, in creative problem solving situations the mere adoption of existing solutions never is an option. To be creative such a solution has to be novel by definition. Thus, reusing existing knowledge in creative tasks always involves its transfer into the new problem context. Carlile (2002) exposes that knowledge proves both a barrier to and a source of innovation in new product development. Its negative impact comes into effect when different communities of practice participate in an innovation process since boundaries between them hinder effective communication and cooperation. However, these boundaries neither exist within a single community of practice nor do they bear relevance for the individual level, which is the focus of the present study. Against this reasoning, we stick with Amabile (1998) by claiming that existing knowledge can fuel the creative process.

A database that provides a diverse set of information related to products and services establishes the basis of our approach. Such a database can broaden the expertise of persons involved in the development process of product-service bundles. For instance, checking the feasibility of a product-service combination often requires expert knowledge related to technical specifications of the product or legal formalities on the provision of services in individual countries. As the central concept of our model, we propose multi-perspective navigation structures as a means of accessing such digital information items. We argue that this approach to information retrieval is in favour of the convergent aspect of creative problem solving. First, hierarchical navigation structures support a creative problem solver with the explication of her information needs: Due to its creative nature, requirements for a product-service bundle are often rather vague. Thus, people involved in this creative process are often not capable of stating explicit search queries. Hierarchies can serve as an intuitive representation for the notions of abstraction and aggregation (Furnas & Zacks 1994). They can lead individuals along a stepwise refinement process in order to satisfy their information needs (Brelage 2006). Second, multiple navigation hierarchies that represent diverse perspectives on digital information provide access to the database by different users in different problem solving situations. The explicit knowledge that is considered relevant by a person as well as how this knowledge is accessed depends on both a person’s worldview and the specific situation’s context (Mey 1982, Polanyi 1975). Thus, information retrieval is about aligning the cognitive structures of a system’s users, its designers, and the information providers (Ingwersen 1992). Consequently, we argue that a single hierarchy is not sufficient to serve the often very heterogeneous (Markus & Majchrzak & Gasser 2002) group of possible information seekers (Furnas & Zacks 1994). Third, multi-perspective navigation means can provide a powerful device to expressing restrictions on the result set of an information retrieval process. As multiple hierarchical navigation structures classify the assigned items from different perspectives they may be applied to formulate multi-dimensional, set-theoretic constraints. In a system that provides the functionality of browsing the different navigation structures simultaneously, the user may refine constraints interactively. Such a dynamic approach of expressing information needs is in favour of the highly vital process of identifying relevant knowledge in creative problem solving situations. A similar approach is known from the area of business intelligence, namely the concept of online analytical processing (OLAP) (Pendse & Creeth 1995) which is applied to navigate through comprehensive sets of structured data.

In addition to providing appropriate means for the convergent aspect of creative work, we suggest to also aid the divergent facet of the development process for product-service bundles, so as to support a user’s creative-thinking skills. Associative theories explain the theoretical underpinning of our approach (Runco 2007). Mednick (1962) detected that truly creative ideas originate from remote associations within an person’s cognitive network. Likewise, Santanen and Briggs and de Vreede (2000) suggested that creativity is a function of the distance between the areas of an individual’s cognitive network that have been activated and combined to form a solution. According to Taylor
(1975), the areas of a cognitive network – mental states as he refers to them – are linked and via these connections the different mental states tend to activate each other provoking new ideas. The more remote the activated states are the more likely is the generation of a creative idea. In this context the concept of associative hierarchies becomes relevant. Such hierarchies denote the strength and organization of a person’s cognitive associations (Mednick 1962). Individuals with steep associative hierarchies tend to be less creative than people with rather flat associative hierarchies. For the former, it is harder to leave the very strong connections between their mental states and recall the more remote associations (Malaga 2000). Thus, an approach to supporting a person’s creative-thinking skills has to provide stimuli to break up inflexible associative hierarchies and to activate more remote mental states that otherwise will not be reachable via an individual’s associative connections.

Based on the above discussion, we propose an information retrieval system that is accessible via multi-perspective hierarchical navigation structures in order to provide stimuli. At this, a stimulus is not meant to provide immediate value by explicating a concrete example of re-arranging existing things and thus constituting a creative idea itself. It rather fuels the creative process of experimentation and exploration by activating a new entry point into a creative person’s cognitive network to initiate the process of going beyond the already known. The path this cognitive process takes is definitely outside the scope of an IT system. We argue that such a system is suitable to provide three primary types of stimuli (cf. Table 1). In the following we describe the different types in detail.

<table>
<thead>
<tr>
<th>Stimulus pattern</th>
<th>Stimulus source</th>
<th>Intended creativity impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intra-perspective stimulus</td>
<td>Navigation structure</td>
<td>Hierarchies provide a multi-level, disjoint categorization of database items. Starting from a category in focus, they give a glance at the range of possible alternatives at the current level of abstraction. These alternative options may serve as stimuli, as the user may not have considered all of them.</td>
</tr>
<tr>

</tbody>
</table>

Table 1: Stimulus patterns

Intra-perspective stimulus

A navigation hierarchy can indicate alternatives that a creative person has not considered before. It represents a stepwise, disjunct categorization of the digital items contained in an information repository. All the navigation nodes on a selected hierarchy level that a system’s user does not choose along her navigation path to a specific item of interest may reveal alternative options, which lay outside her associative hierarchies. In becoming creative “everything is raw material.” (Coutu 2008) We refer to this stimulus pattern as intra-perspective stimulus.

Inter-perspective stimulus

“Within the mind of an individual, diversity enhances creativity.” (Amabile & Khaire 2008) The existence of multiple navigation hierarchies may motivate a system’s user to consider a different perspective onto the problem at hand. If a single repository item is accessible via discriminative navigation hierarchies, these hierarchies represent different classification schemas. Every schema may be understood as a different perspective on a repository’s content. Thus, the diverse navigation structures not only serve users with discriminative world-views as an appropriate means to access information items; the explication of these different world-views may also stimulate a user of such navigation hierarchies so as to consider different perspectives on her creative task. This way she is
empowered to identify additional entry points into her cognitive network. This stimulus pattern we call
inter-perspective stimulus.

Content stimulus

Apart from the navigation structures, the information items themselves can serve the purpose of
providing stimuli to a user. Digital artefacts contained in an information repository as sketched above
exist in various formats. Such different formats address different human senses. According to the dual
coding theory (Paivio & Lambert 1981) human memory and cognition are served by two separate
symbolic systems which are interconnected but also capable of functioning independently. One system
handles verbal information and the other system processes non-verbal information. Due to the linkage
between both systems, representations in one system can evoke associations to representations in the
other system. For instance, a picture can be named, and images may leap into someone’s mind while
reading a specific word (Malaga 2000). Experiments evidence that using lexical and pictorial stimuli
simultaneously amend one’s ability to recall an association from memory (Paivio 1983). Furthermore,
the separation between both systems implies that naming a concept and visualising the same concept
can stimulate different associations and thus provokes different ‘creative’ ideas. Moreover, different
individuals have different abilities in verbal and visual problem solving strategies (Malaga 2000).
Hence, different content formats activate different potentials in becoming creative. Against this
background, providing an ample set of contents in various formats and styles proves reasonable in
order to stimulate divergent thinking. These types of stimulus we refer to as content stimulus.

3 PRACTICAL INSTANTIATION

3.1 Graphical User Interface

Part of our research is the development of a prototypical instantiation that is ought to both proof the
theoretical model’s feasibility and serve as a tool for evaluation (Hevner & March & Park & Sudha
2004). As this research aims at designing an IT system that supports human creative performance, we
rather focus our descriptions on user interface than dwelling on internal data structures and algorithmic
issues. Thus, in the following we describe the graphical user interface and illustrate how the different
conceptual aspects of the above introduced model were implemented. The theoretically informed
model imposes several requirements on the user interface:

1) It has to present hierarchical navigation structures.
2) It must support the user in browsing several hierarchies in parallel.
3) Alternative navigation nodes have to be visible on every hierarchy level in order to provide intra-
perspective stimuli.
4) Alternative navigation hierarchies on a database item or navigation node have to be evident so as
to serve as inter-perspective stimuli.
5) Various content formats have to be pictured simultaneously catering for different user preferences.

We decided to not use classical tree structures as known from browsing file systems for the following
reasons. First, presenting a deep and broad hierarchy in a tree structure consumes much space on
screen. Especially if several hierarchies are presented simultaneously, this approach is not feasible.
Second, navigating along a tree structure by dynamically expanding and collapsing branches results in
constantly changing positions of the nodes and, thus, in a very restive navigation experience.
Therefore, we apply a navigational concept, which is to some extend leaned on the approach of
collapsible cylindrical trees as proposed by Dachselt & Ebert (2001). Child nodes in a hierarchy are
mapped onto rotating, three-dimensional cylinders while the path to the currently focused navigation
node is illustrated by means of a list above each cylinder (requirement 1) (cf. Figure 1). This approach
exhibits several advantages: The width of every hierarchy illustration is constant which results in an
easy segmentation and good utilization of the available screen space. Because hierarchies grow to the
bottom, several navigation structures may be placed side by side on one screen (requirement 2). Moreover, the appearance of the navigation structures is more static and thus easier to comprehend and less strenuous to use.

![Diagram of conceptual design of graphical user interface]

**Figure 1: Conceptual design of graphical user interface**

Although rotating cylinders intuitively display hierarchy levels of variable breadth on a screen area of constant size, they lack the ability to show all elements of a hierarchy level at the same time. Hence, they fall short of providing intra-perspective stimuli. In order to overcome this shortcoming, we implement the ability to expand a cylinder or path element to show all available alternatives at a corresponding hierarchy level (requirement 3). As a means to implement what we referred to as the inter-perspective stimulus, the interface highlights every content item or navigation node that is related to a navigation hierarchy different from the one in focus with a small badge. This badge expands to list all related navigation hierarchies, which may be chosen in order to change the navigation ‘perspective’ (requirement 4).

In order to select relevant content items from the database, the user can select multiple navigation nodes from different navigation hierarchies to work as a filter. The current filter expression is shown on the right of the navigation cylinders, while the related content items reside in the bottom area of the screen. The database items are represented by previews of their content and, thus, provide an immediate content stimulus (requirement 5). Furthermore, the system can retrieve remotely related content for every database item that is arranged around the item in focus, in order to function as another source of content stimuli. An algorithm determines the contents’ relatedness independently of the navigation structure but calls on content-based similarity metrics (Knackstedt & Kuropka & Müller & Polyvyanyy 2008).

### 3.2 Navigation Hierarchies

As indicated, we suggest hierarchical navigation structures as a device in order to stimulate creative thinking and to further information retrieval. To do so, such structures must provide means of information access that fit to the context they are applied in. In order to illustrate this, in the following we present the results of a survey on classification schema for product-service bundles that provides an empirical basis on which appropriate navigation structures for this particular domain could be developed. The underlying, highly iterative process of data collection was conducted as follows.
Quality | Quality properties (e.g. reliability, credibility) of the service | 1.59 | 0.925 |
Personnel | Qualification, experience and competences of provider personnel | 1.70 | 0.898 |
Availability | Availability in terms of time (e.g. 24 hours, 7 days a week) and location (e.g. only in Germany) | 1.73 | 1.025 |
Price | Price per unit of measurement (e.g. per use, per time period, flat) | 1.74 | 0.942 |
Function | Goal or purpose of the service | 1.76 | 0.949 |
Rights & duties | General rights and duties of the provider and consumer (e.g. confidentiality) | 1.79 | 0.990 |
References | References to past projects or customers | 1.79 | 0.944 |
Utility | Utility for the consumer (e.g. sales increase, cost cutting) | 1.85 | 1.105 |
Resources | Resources (e.g. tools, information) employed by the provider during service provisioning | 1.86 | 1.040 |
Ratings & rankings | Independent benchmarks or official certifications of the provider | 1.87 | 1.040 |
Service process | Sequence of activities executed during service provisioning | 1.92 | 1.100 |
Terms & conditions | Definition of contractual obligations (e.g. regarding payment or delivery) | 1.95 | 1.144 |
Product lifecycle | Reference to the lifecycle stage of the related physical product | 1.98 | 1.013 |
Industry sector | Industry sector for which the service is provided | 1.98 | 1.123 |
Customer input | Which resources (e.g. objects, information, personnel) has the customer to provide during the service provisioning process | 1.99 | 1.098 |
Frequency | Units and time intervals of service provisioning | 2.02 | 1.158 |
Contract duration | Duration of the service contract (e.g. one-time, subscription) | 2.17 | 1.270 |

Table 2: Empirical relevance of perspectives on product-related services

First, we conducted a broad review of the literature in order to identify perspectives for which navigation hierarchies could be identified. We concentrated our efforts on literature on conceptual models, ontologies, and standards of the services domain. The considered work covers both, a primarily business-oriented view (e.g., Baida 2006, DIN 2002) and a more technology-oriented view (e.g., Oaks & ter Hofstede & Edmond 2003, W3C 2004, W3C 2005) of the domain. We identified 37 initial perspectives (Knackstedt et al. 2008), which we consolidated into 17 central perspectives (cf. Table 2).

In a second step, over a period of six weeks in summer 2008 we conducted a telephone-aided questionnaire-based survey in the German mechanical and electrical engineering industry in order to empirically validate the relevance of the identified perspectives. Sales and marketing managers, responsible for cross-selling product-related services together with their core physical products, from 200 different companies (only one interviewee per company) participated in the study. The sample is nationally representative in terms of company size (number of employees), product technology, and industry subsectors. The participants were asked to rate the relevance (on a 5-point Likert scale from 1 (very relevant) to 5 (not relevant at all)) of the 17 consolidated perspectives when describing product-related services to their customers. All perspectives were attested in terms of relevance (cf. Table 2),
with quality (1.59), personnel (1.70), availability (1.73), price (1.74), and function (1.76) being the five most relevant.

In a third step, having validated the empirical relevance of the consolidated perspectives, we identified concrete navigation hierarchies for each perspective. In doing so, we relied on existing classification schemas (e.g. taxonomies) where possible. Table 3 lists an exemplary selection of such available classification schemas. For some perspectives several schemas could be easily identified. For example, the North American Product Classification Schema (NAPCS), the United Nations Standard Products and Services Code (UNSPSC), and the eCl@ss standard are promising candidates for a navigation hierarchy concerning the ‘function’ perspective. Likewise, there are numerous published lifecycle models that can be applied for navigating through the ‘product lifecycle’ perspective. Appropriate hierarchies for other perspectives, e.g. ‘quality’ or ‘price’, are dependent on the product or service at hand and have to be custom-made.

Table 3: Examples for publicly available classification schemas

In the following section we illustrate the application of these classification schemas to form the proposed multi-perspective, hierarchical navigation structures.

### 3.3 Example Case

We now demonstrate the presented creativity support approach using an example case. The portfolio manager of a global provider of enterprise communication solutions wants to develop a novel product-service bundle. The company so far only offers installation services when selling a telephone system. Browsing to installation services in an IT system realizing the presented approach, the portfolio manager notices that installation is classified as a ‘pre-use’ service in the ‘product lifecycle’ hierarchy. She realizes that there also is a ‘use’ and ‘after-use’ lifecycle stage (intra-perspective stimulus). She selects the ‘after-use’ stage and a collection of related documents appears on her screen. Since the result set contains more than thousand items, she sets a further filter by selecting ‘EU’ within the ‘availability’ hierarchy. Within the shrinked set of documents, she picks a newspaper article that is about the latest European regulations on disposal of electrical waste and the financial burdens that arise from these responsibilities. The article also elucidates novel approaches of some industries to recycle and re-market used equipment in order to generate additional revenues (content stimulus). By reading this, she comes up with the idea of developing a similar re-marketing strategy for her company. Customers should be motivated to return used telephone systems when they switch to a new
model. These will then be refurbished and sold again via a special web shop. The portfolio manager creates a service description for this new idea. When she adds the document to the system she is asked to classify it along several dimensions. One of the presented perspectives is ‘frequency’ of service provisioning which in her case is ‘one-time’ (inter-perspective stimulus). Getting this new perspective on her product-service bundle encourages her to think of possible services that are repeated on a subscription basis. From the frequency hierarchy she selects the ‘subscription’ category and discovers amongst others ‘remote diagnostics services’. The respective content screen offers a short description and diagram explaining that the service is completely virtualized and no extra hardware is involved (content stimulus). This evokes the idea in the portfolio manager’s mind that it could also be an option to completely virtualize a telephone system and merely handing IP-telephones to the customer. So, her company can substitute the error-prone and expensive telephone hardware by a software system that is centrally hosted.

4 CONCLUSION

Design research is concerned with “devising artifacts to attain goals” (Simon 1996). In this paper we presented a conceptual design and prototypical implementation of an IT system that supports creative work by both facilitating information retrieval and activating creative thinking in an integrated manner. We contribute to the IS body of knowledge by developing two artefacts: First, we developed a conceptual framework that is grounded in the existent literature and particularly draws from associative theories on creativity. The framework explains how multi-perspective navigation structures answer the aforementioned purposes. It can serve as an analytical and descriptive framework that can inform future research. Moreover, the framework provides a starting point for the development of new or the adaptation of existing information systems artefacts to support creativity. Second, we developed a prototypical implementation in order to evaluate the framework. We used the creative process of product-service bundle development to both elucidate and exemplify our design ratio.

Design research consists of the two basic processes of build and evaluate (March & Smith 1995). It must be noted that thus far, this research lacks evaluation that goes beyond a ‘proof of concept’. However, an evaluation in terms of a ‘proof by demonstration’ assessing the artefact in use is part of our future research agenda. For this purpose, a development process of a product-service bundle, as outlined in this paper, will provide the evaluation case. The developed system instantiation will be applied within this evaluation case to give evidence of the different stimuli types by analyzing the users’ interaction with the system while solving a creative task. In addition to supporting the evaluation of the theoretical framework, the IT system may become subject matter of assessment itself. Along with testing the system based on criteria such as efficiency, simplicity, ease-of-use, and elegance (March & Smith 1995), the impact on its users’ creative performance can be assessed. Firestien (1993) states that “the evaluation [of a creative product] must occur on a number of levels; not with a single factor, or a single total effective criterion score.” O’Quin and Besemer (1989) have developed a scale that allows to test whether a product is ‘creative’. It is called the Creative Product Semantic Scale (CPSS) and consists of three dimensions. These are novelty, resolution, and elaboration and synthesis. Particularly the first two dimensions (novelty and resolution) correspond to the understanding of creativity underlying this research that defines a product as being creative if it is original (novel) and if it is purposeful or appropriate (Seidel et al. 2008a).

FROM DATA WAREHOUSES TO TRANSFORMATION HUBS –
A CONCEPTUAL ARCHITECTURE

Kemper, Hans-Georg, University of Stuttgart, Breitscheidstraße 2c, 70174 Stuttgart, Germany, kemper@wi.uni-stuttgart.de
Baars, Henning, University of Stuttgart, Breitscheidstraße 2c, 70174 Stuttgart, Germany, baars@wi.uni-stuttgart.de

Abstract

Originally, Data Warehouses (DWH) were conceived to be components for the data support of controlling and management. From early on, this brought along the need to cope with extensive data preparation, integration, and distribution requirements. In the growing infrastructures for managerial support (“Business Intelligence”), the DWH turned into a central data hub for decision support. As the business environment and the underlying technical infrastructures are fostering an ever increasing degree of systems integration, the DWH has been recognized to be a pivotal component for all sorts of data transformation and data integration operations. Nowadays, the DWH is supposed to process both managerial and operational data – it becomes a transformation hub (TH). This article delineates the relevant motives that drive the trend towards THs and the resulting requirements. The logical composition of a TH is developed based on data transformation steps. Two case studies exemplify the application of the resulting architecture.

Keywords: Data Warehousing, Data Transformation, Business Intelligence, Enterprise Systems.
1 INTRODUCTION

Business Intelligence (BI) denotes integrated approaches to decision support (Baars & Kemper 2008). In recent years, BI has been increasingly recognized as a pivotal subject for IT management (Gartner 2009). One of the subjects in the domain of BI that is currently been focused both by BI practitioners and BI researchers is how to extend BI infrastructures to tactical and operational levels and how to achieve a closer coupling of operational and BI systems. There is a puzzling variety of intertwined concepts that can be subsumed under this general theme: Business Activity Monitoring (DeFee & Harmon 2004), Operational Business Performance Management (Golfarelli & Rizzi & Cella 2004), Embedded BI (Hashmi 2004, Klawans 2008), Real Time Analytics (Raden 2003), Active and Real Time Data Warehousing (Akbay 2006, Brobst 2002, Raden 2003), and Operational BI (Chemburkar & Keny 2007, Marjanovic 2007). Each of those terms represents a different facet of the general trend to either utilize BI infrastructures for the support of operational decisions or to further bind operational and managerial systems together (hence the term “operational BI” (Eckerson 2007)). There is also one commonality on the architectural side: They are all built upon core components for the integration and exchange of data (White 2005).

The established centre for data integration, storage, and exchange in BI environments is traditionally the Data Warehouse (DWH). Inmon defines a DWH as “...a subject-oriented, integrated, time-variant and nonvolatile collection of data in support of management’s decision-making processes...” (Inmon 2005). Although this conception still captures the heart of most DWH installations, it becomes somewhat diluted when the DWH is utilized in operational environments. While still fulfilling the tasks known from traditional management support, the DWH additionally needs functionality for storing and exchanging real-time transactional data. To reflect the changed role of such “enhanced DWHs” in the enterprise, this paper introduces the term “Transformation Hub” (TH). Here, a TH is understood to be a logically central component that concentrates functions for data integration, enrichment, and exchange. It is designed to serve for managerial, analytical and operational applications alike.

As the TH differs in content and structure from classical DWHs, the underlying models, structures, and approaches also need to be modified and be rearranged under consideration of state-of-the art components and architectural designs. This paper addresses the respective issues. It specifically focuses on the derivation of a conceptual architecture of a TH which captures relevant functional components and their interplay from an application oriented view. About 20 years ago, IT adopted the term “architecture” and applied it to almost every structural aspect of hard- and software systems – including DWHs (Hammergren 1996).

As this paper takes a more business oriented perspective, it concentrates on a conceptual system structure. The resulting architecture is designed to act as a starting point for the delineation and design of system components and their interplay solely based on application needs. This differentiation is of particular importance in the realm of current TH infrastructures where the essential logical design easily comes out of focus as it is superimposed by more realization-driven design layers, e.g. for the data exchange and middleware architecture, for data-feed-approaches (i.e. data consolidation, federation, or propagation) (Brobst 2002, White 2005), for event handling mechanisms (push vs. pull) (Brobst 2006), etc. Notwithstanding the importance of those aspects, they are secondary in nature in the conceptual design which runs down to selecting functional components for defined business contexts and to specifying how they are supposed to work together.

The objective of this paper is to derive a conceptual architecture for a Transformation Hub. The course of the discussion is as follows: After relevant concepts in the vicinity of the TH are put into context, its actual role is pinpointed by distinguishing and discussing motives for the implementation of THs. This is the foundation for a derivation of the architecture which is mostly based on logical steps of data transformation as known from the data warehousing domain. For each of the different transformation
steps, the peculiarities of the TH are discussed and matched with the concepts introduced before. The application and the relevance of the framework are illustrated with two case studies.

2 RELATED CONCEPTS

There is a long tail of research on the architecture design of a Data Warehouse with some influential contributions coming from Inmon (Inmon 2005) and Kimball (Kimball & Ross 2002). The former stands for a strongly centralized, application-independent approach while the latter proposes a more decentralized data management that is bound together semantically by the use of shared dimensions (“dimensional bus”). Empirical research shows that both approaches can be found in similar numbers in current enterprises and that both are to be preferred over less-coordinated approaches (Ariyachandra & Watson 2006). Besides this, a distinction needs to be made between application-specific data excerpts – usually known as Data Marts – and a central and logically integrated data storage – the “Core Data Warehouse” (Inmon 2005).

Providing near time, transactional data is one of the most significant modifications to classical core Data Warehouses (Inmon 1999). To handle the different access profiles, reliability requirements, and update time-frames, dedicated components have been proposed which have become known as “Operational Data Stores” (ODS). Inmon introduced the concept of the “Information Factory” for ODS-enhanced DWHs (Inmon & Imhoff & Sousa 1997, Kelley & Moss 2007). Being a more technical and data storage oriented concept, the literature on Information Factories can serve as an outline for the realization options of the data management components of a TH.

There are several contradicting definitions for the term “ODS” (Inmon 1999, Sherman 2005) and not all of them are suited for the TH approach, e.g. an ODS as a mere replication of operational data base tables. In this paper, a ODS is conceptually understood to be a component that provides integrated data (Kelley et al. 2007) and for this purpose enables bringing together transactional data from multiple sources. This involves data cleansing and integrity checking. Here, the ODS, the DWH, and the Data Marts are conceived as the main data provision roles that a TH has to incorporate.

ODS-enhanced DWH architectures allow building Closed-loop and Active Data Warehousing solutions. In Closed-loop Data Warehousing, results from analytical processes are directly fed back into DWHs or operational systems (Brobst 2002). Active DWH systems automatically trigger actions based on defined data constellations. As the respective application scenarios frequently go along with the need for current data, “Active and Real Time Data Warehousing” is often combined to a fixed phrase (Akbay 2006, Raden 2003). In Closed-loop and Active Data Warehousing the DWH can turn into a data source for the operational systems.

From an application oriented standpoint, a DWH is by its very nature a component for a data driven application integration. Recently, however, some scenarios are proposed that leave this data centric approach: It has been suggested to complement a DWH with components that focus on providing data processing functionality rather than actual data. These components are usually conceived to be based on the paradigm of service oriented architectures (SOA). The name that has been coined for this approach is Embedded BI. It is “embedded” as the BI functions are conceived to be seamlessly integrated into operational systems, working directly against the local, transactional data, rather than against the integrated repository of a DWH (Hashmi 2004, Klawans 2008).

The above discussed components abstract from the applications they actually support. One of those with immediate relevance for a TH is Business Activity Monitoring (BAM). BAM is built upon the idea of providing software for the near-time monitoring of the status and the results of business processes. For this purpose, data from the involved application systems needs to be extracted, integrated and presented in a meaningful way (DeFee et al. 2004, Golfarelli et al. 2004, Melchert & Winter 2004). BAM heavily focuses on the data presentation aspect, especially in the form of “dashboards” and “cockpits” and can be applied both within the confines of an organization or across enterprise borders (Eckerson 2006), e.g. for logistics or production processes.
The idea of BAM is closely interlinked with Business Process Management. Business Process Management highlights the integrated management of business processes. In this regard, BAM can be understood as a tool that supports a subset of the tasks for Business Process Management (DeFee et al. 2004, Golfarelli et al. 2004, Melchert et al. 2004, Verner 2004). Further reach full-fledged “Business Performance Management” approaches which aim at the integrated, strategy-oriented steering of an entire organization based on consistent indicator systems for all managerial levels (Eckerson 2006, Golfarelli et al. 2004). By interlinking the complete reporting hierarchy, they reach well beyond Business Process Management, although the latter can be smoothly embedded within the former. If realized that way, Business Process Management can be understood as Operational Business Performance Management (oBPM).

3 APPLICATION DOMAINS FOR TRANSFORMATION HUBS

A closer look at the literature reveals a variety of interdependent motives that drive the evolution from the classical DWH to the TH:

Integrated management concepts, especially within the realm of Business Performance Management as discussed above. Approaches like the “Balanced Scorecard” (Kaplan & Norton 1996) or “Value Based Management” (Grant 2003, Rappaport 1998) are built upon the idea that a system of interdependent key performance indicators (KPIs) can facilitate the consistent steering of an entire organization. A consequence of pursuing such approaches is the need for an operational, process-level indicator gathering and communication, especially based on Business Process Management solutions. This entails the need to closely couple operational, tactical, and strategic decision support and to provide a consistent data socket (Eckerson 2006, Golfarelli et al. 2004).

Information logistics. With the diffusion of integrated applications, e.g. for Customer Relationship Management (CRM) or Supply Chain Management (SCM), and the demand for application-spanning services like security-checks, pro-active fraud-detection, or on-site localization of service issues, the potential of Business Process Management and BAM solutions becomes apparent: respective solutions require infrastructures for data exchange, integration, harmonization, and distribution (Furness 2004, Chemburkar et al. 2006, Nguyen 2005, Raden 2003, Stefanovic & Radenkovic & Stefanovic 2007, Watson 2005, Baars & Kemper & Lasi & Siegel 2007). As THs are innately designed for mass data processing, they are ideal building blocks for large-scale integration solutions. In contrast to the integrated concepts discussed before, these approaches are focusing more on data exchange along processes (Bucher & Dinter 2008) than across managerial levels. Closed-loop and Active Data Warehousing are often following information logistics initiatives, as they draw additional value from the achieved data integration.

Analytical access for lower managerial levels. In a turbulent business environment there is value in an analytical access to historical data even for lower managerial levels – which can be provided more conveniently with flexible, BI based reporting and analysis tools (Klawans 2008, Marjanovic 2007).

Centralization and utilization. A powerful rationale for utilizing a TH in an operational context is the centralization of data transformation: The TH is identified as a centre for all kinds of mass data processing activities. A particular concept that can be subsumed under this rationale is Embedded BI. This efficiency based argumentation not only permeates all motives discussed above. It also transcends it, and some of the supported applications can hardly be considered to be “Management Support” or even “Decision Support”. The concentration of all administration, monitoring, and resource related tasks for data transformation facilitates unlocking economies of scale and utilizing learning curves that are further fostered by dedicated organizational units. Such BI competence centres have already become widespread in the realm of BI (Unger & Kemper & Russland 2008).

Figure 1 illustrates the role of the TH in this conglomerate of applications: It connects analytical and operational systems, feeds BAM and/or Business Process Management solutions with near time data, extracts and harmonizes data for information logistics purposes, binds together key performance
indicators based on Business Performance Management concepts, and provides transformation functionality for further applications.

Figure 1: Role of the Transformation Hub

4 THE TRANSFORMATION HUB - ARCHITECTURE

The TH architecture proposed in the following section is designed to support all application settings discussed in the above sections. It is conceived to be vendor-neutral and invariant to physical design choices in order to allow for a sustainable mapping not only of already realized and projected solutions but also of possible development trajectories. It enhances a conceptual ODS enhanced DWH framework that has been iteratively developed over a course of over a decade and that already incorporates a large body of study results (Baars & Kemper 2008, Kemper 2000, Kemper & Finger 2006). Figure 2 depicts the architecture. It consists of the following main components:

- The transformation components (Filtering, Harmonizing, Enrichment, and Aggregation) form the heart of the TH. All application domains discussed above are aiming at some kind of data processing – be it a simple integration operations for monitoring tasks or complex enrichment and harmonization procedures for Business Performance Management.
- Associated repositories for data storage and data access play the roles of the ODS, a Data Warehouse and/or Data Marts. They can be logically differentiated by the respective subsets of transformation steps the data needs to have undergone.
- Interfaces for service provision, i.e. for embedded BI solutions. In fact, the whole range of transformation functionality can be made available for third applications.
- Administration interfaces which allow for a secure and documented access to relevant data for the user, support the configuration and monitoring of the operational data upload, and provide documentation.
- Meta data management that delivers the contextual glue that binds all involved components and contents together and ensures both an efficient technical maintenance as well as a consistent usage of the TH contents. It addresses both technical meta data and semantic meta data.

The next paragraphs discuss the fundamental transformation steps and the associated data access components and match them with the related concepts from section 2. The following main types of transformational tasks are distinguished (Kemper 2000):

- Filtering encompasses the data extraction and the correction of defects in syntax and semantics.
- Harmonizing is the process of granularity adaptation and merging data to defined subject areas.
- Aggregation addresses the summary of data to predetermined levels of detail
- Enrichment adds calculated indicators to the data.
4.1 Filtering and pre-access components

The filtering process starts with the extraction of data from operational data repositories. From a conceptual viewpoint it is imperative to check the quality of the operational data sources (systems, fields) that are considered as inputs for the TH (English 1999).

Regarding the actual extraction process, there are basically two basic options (Akbay 2006):

- Periodical updates that adhere to a classical Extract-Transform-Load (ETL) logic or
- Continuous, real-time streams (“trickle feed”) that directly mirror changes in the operational systems.

The two approaches need to be distinguished conceptually because of the consequences regarding timeliness, costs, performance impact on the operational systems (Brobst & Morrey 2002), and data quality (handling incomplete/wrong transaction data, time buffer for quality checks). As the TH is supposed to feed both real time applications like BAM and data analysis applications based on historic data, components for both might be necessary (Brobst & Rarey 2002).

When actually conducting the extraction, a variety of syntactic and semantic incompatibilities or defects needs to be taken care off. In a near-time setting, the options to tackle semantic errors that cannot be automatically corrected or not even be detected are naturally limited. A way to narrow down the respective error handling times is to implement tightly defined work flows which ensure a minimal timeliness of the respective activities and that might be tracked and controlled by a workflow management system (Bartel & Schwartz & Strasser 2000).

For applications that rely on near-time, local data, the results of the extraction and the automated error corrections might already be relevant. In this paper, components to read out the respective intermediate data are labelled “Pre-Access” as the data is still not consistent across different sources.

4.2 Harmonizing, the ODS, and BAM support

Systems supporting operational processes rely on data that normally differs in granularities, definitions, time periods, etc. (Kemper 2000). Clearly, harmonization is not a mere technical issue but
rather a conceptually challenging task which needs business support (Berg & Heagele 1997). Bringing heterogeneous data together is one of most fundamental tasks of a TH.

The respective merging operations pertain to both syntactical and semantic inconsistencies:

- **Syntactic harmonization** means the coding of keys and attributes on the one hand and the handling of homonyms (attributes which carry identical names but have different meanings) and synonyms (attributes which are referred to by different names but have the same meaning) on the other. Usually this type of issues can be managed on a basis of defined routines and is of low criticality.

- More serious are cases of **semantic harmonization**. A common cause for the occurrence of such predicaments is of historical nature: In many enterprises a plethora of homonymous business terms is used, each with varying local definitions and connotations. Seemingly clear time-periods differ, and so do the definitions for performance indicators like sales, revenue, profit etc. Merging data together in a TH demands the harmonization of these terms across unit borders (English 1999). This type of harmonization activities can easily result in severe political and cultural problems (Kemper 2000) and needs to be backed by a tight meta-data management.

Providing filtered and harmonized data is a core feature of a TH. Following the definition in this paper, a data access system that ensures these two layers in near-time and on transactional level is an ODS. This kind of data provision also forms the heart of BAM- and oBPM applications.

### 4.3 Aggregation, enrichment, Data Marts, Data Warehouses, and BI support

On the third layer of transformation, the filtered and harmonized data is further refined by implementing hierarchy structures and calculating business indicators.

The hierarchy structures of the *aggregation* extend the idea to centralize the definition of semantics to the specification of pathways along which granular data should be analyzed (e.g. from store to country to world region). This can include parallel dimensions: The dimension “product group” can for instance be alternatively summarized over product categories (customer based) or profit centres (organization based) – both hierarchies stand for valid analysis corridors.

A centralized calculation of indicators (enrichment) guarantees the consistence of the business terms on the basis of homogenous definitions for entire fields of applications. A DWHs can and Data Marts do include aggregated and enriched data. This type of enrichment violates the paradigm of a separation between logic and data: There is a deliberate built-up of redundancy for purposes of performance and usability. As Data Marts are understood to be application driven, a simple and immediate provision of aggregated data is in fact often one of the main strengths of the Data Mart.

By incorporating the roles of the DWH and the Data Marts, the TH also takes over the function of the focal component for the support of a BI approach.

The powerful features for mass-data enrichment make the TH also interesting for a variety of operational systems: This functionality can be just as well utilized for operational data that does not require any form of harmonization, e.g. in a shop floor environment. Some of those applications lie well beyond the confines of even the widest conceptualization of BI.

### 4.4 Mapping transformation steps and application domains

Coming back to the application domains from section 3, their concrete relationship with the TH and with the transformation steps can be laid out (cf. Table 1).

**Integrated management concepts** aim at a vertical integration with a consistent set of indicators. This requires rigid data harmonization as well as a logically centralized indicator definition, calculation, and aggregation. It can thereby be concluded that special attention needs to be devoted to a meticulous definition and maintenance of meta data.
Information logistics driven applications are built on data exchange and harmonization. By the very nature of those approaches, they need to weave together multiple heterogeneous systems and therefore require strong extraction interfaces and respective filtering components.

When it comes to analytical access on operational levels, a Data Mart based access to historical data is needed that is seamlessly interlinked with current (near-time) data.

The centralization/utilization motive captures a whole range of applications. In essence, this demands for a flexible usability of the different components and their functions. The resulting requirement is that the architecture is defined in a modular fashion with building blocks that at best can be immediately used as self-contained, service-oriented units.

Table 1: Applications and Transformation Hub requirements

5 CASE STUDIES

Two cases are presented to illustrate the ongoing trend towards Transformation Hubs and to highlight relevant discussion areas. In both cases research projects have been conducted jointly with the respective organization. This allowed for deep insights into the solutions and approaches. Data gathering methods have primarily been workshops and qualitative document analysis.

5.1 Stock Exchange

The first case highlights the approach of a former national stock exchange that has over time turned into one of the largest stock exchange organizations in the world. By the end of the last century, the company not only faced new environmental conditions like increased dynamics in the verge of internet-based trading but also increasing requests of internal and external stakeholders for precise, trustworthy and real time decision support content. The developed BI solution is a real time TH. It acts as a hub for information distribution to a worldwide financial community and permits internal and external users a prompt analysis of market related mass data.

The solution of the stock exchange delivers both classical DWH services (aggregated, historical data for management analysis) as well as direct feeds into operational systems which are relying on harmonized financial data. The latter part is heavily information logistics driven.
Depending on the structure of the source systems and the time variance of the data, internal and external source systems are connected either in real-time or via periodical updates. The data transformation is completely meta data driven. Automatic filtering and harmonization are realized in a separate “validation layer” while unstructured data and semantic defects are dealt with based on a workflow approach. The (approved) results are gathered in a container with the label “single point of truth”. Eventually, there is a dedicated “analytical business layer” which is in fact a manifestation of the aggregation and enrichment layers discussed here. The results – denoted as “information products” – are delivered in a multitude of forms, including data streams to operational downstream systems, cubes prepared for data analysis, website content, reports, spreadsheet files, or even text messages.

![Diagram](image)

**Figure 3: The TH of Case 1 (under consideration of Detemple & Feidieker & Münch 2006)**

The mapping of the solution with the developed framework is visualized in Figure 3. Noteworthy are the systematic integration of manual activities and the consequently layered approach.

### 5.2 Manufacturing

In the second case, the move from classical BI to a full-fledged TH infrastructure is still in its conceptual phase, although it clearly shows the centralization forces at work.

The respective (large) manufacturing enterprise has already enforced a physically centralized BI approach, based on one obligatory data warehousing product that is used for all sorts of data refinement tasks. The results are used by a multitude of systems, among them diverse reporting solutions. Due to the historical development, a variety of independent Data Mart based solutions has grown that is not yet logically integrated: The solutions run on separated instances of the software and are individually customized. Over time, the solutions grew in number, data volume, and business relevance. Furthermore, multiple interdependencies between the different systems became apparent that were sources for blatant redundancies. To address this situation, the company has set up a large-scale consolidation initiative that addresses both inconsistencies between the diverse data repositories as well as the respective redundancies in the data transformation activities.

Among the various solutions in place quite a few are not directed at classical managerial support. Those applications often utilize just a subset of the functionality of the DWH solution, e.g. only the data extraction from the ERP system or the (efficient) data enrichment features.
Especially from the side manufacturing and logistics, first near time data transformations have been implemented – predominantly aiming at enrichment. This type of application is actually prone for an Embedded BI approach: Only local, unprocessed data is enriched and the data storage on the system is just temporary – the main strengths of the classical DWH environment are underused.

The logical structure of the TH is depicted in Figure 4.

![Figure 4: The TH of Case 2](image)

Currently it is investigated which types of solutions can indeed be embedded coherently in the conceived TH, which ones need to be handled with different (but logically integrated) components and which ones should be utterly separated into distinct systems for either technical or economical reasons. This development goes along with the implementation of an overall governance approach that safeguards the efficient and strategy-conform usage of the systems.

6 DISCUSSION AND OUTLOOK

The cases illustrate the development to extend classical Data Warehouses towards an integrated Transformation Hub. They also highlight the need to couple technical and organizational design – by thoroughly defining, embedding, and supporting processes for manual data transformations on the one hand and by purposefully implement overarching governance concepts to ensure the efficiency and adequacy of the solution on the other. A relevant best practice of the first case is the strict layer based approach that follows the transformation logic.

Clearly, additional research is necessary to unravel the interplay of the discussed conceptual architecture and lower level structures. Of particular interest should be research on the role of SOA in TH environments. Besides, further empirical research is needed that sheds light on the relative significance of the discussed developments and how they evolve in concert.

Conceptually, the discussed trends entail the necessity to redefine the future role of Business Intelligence – and subsequently for the organizational units that support them as well: the metamorphosis towards mission critical Transformation Hubs reaches well beyond issues of technology design.

Abstract

Science is a cumulative endeavour as new knowledge is often created in the process of interpreting and combining existing knowledge. This is why literature reviews have long played a decisive role in scholarship. The quality of literature reviews is particularly determined by the literature search process. As Sir Isaac Newton eminently put it: “If I can see further, it is because I am standing on the shoulders of giants.” Drawing on this metaphor, the goal of writing a literature review is to reconstruct the giant of accumulated knowledge in a specific domain. And in doing so, a literature search represents the fundamental first step that makes up the giant’s skeleton and largely determines its reconstruction in the subsequent literature analysis. In this paper, we argue that the process of searching the literature must be comprehensibly described. Only then can readers assess the exhaustiveness of the review and other scholars in the field can more confidently (re)use the results in their own research. We set out to explore the methodological rigour of literature review articles published in ten major information systems (IS) journals and show that many of these reviews do not thoroughly document the process of literature search. The results drawn from our analysis lead us to call for more rigour in documenting the literature search process and to present guidelines for crafting a literature review and search in the IS domain.

Keywords: literature review, literature search, rigour, IS journals, IS community, research methodology
1 INTRODUCTION

Reviewing the literature has been proposed as a scientific profession a long time ago (Garfield 1977; as cited in Garfield 1987, p. 113), since it represents an “essential first step and foundation when undertaking a research project” (Baker 2000, p. 219). A literature review seeks to uncover the sources relevant to a topic under study and, thus, makes a vital contribution to the relevance and rigour of research: On the one hand, relevance is improved by avoiding the reinvestigation of what is already known (cf. Baker 2000, p. 219). On the other hand, rigour is derived from an effective use of the existing knowledge base (cf. Hevner et al. 2004, p. 88). Hence, it is undisputed that literature reviews generally play a central role in scholarship (cf. e.g., Cooper 1988, pp. 104ff.) and in information systems (IS) research in particular (cf. e.g., Levy and Ellis 2006, pp. 181f.; Webster and Watson 2002, pp. xiii f.). However, as the term ‘review’ is one of the “more ambiguous” terms in scholarship (Garfield 1987, p. 114), there is still a significant confusion about the structure and format of literature reviews (Webster and Watson 2002, p. xiv). Nonetheless, it seems clear that in particular the process of literature search plays a fundamental role in crafting a thorough review on a topic (Zorn and Campbell 2006, p. 174).

According to Webster and Watson (2002), a literature search in essence comprises the querying of scholarly databases using keywords and backward or forward searches on the basis of relevant articles. Whereas backward search means reviewing the references of the articles yielded from the keyword search, forward search, in turn, refers to reviewing additional sources that have cited the article (ebenda, p. xvi; also cf. Levy and Ellis 2006, pp. 190ff.). The search process is a challenging part of an IS literature review, as it should include “all sources that contain IS research publications” (Levy and Ellis 2006, p. 183). However, searching for literature is extremely complicated in an emerging field such as IS, because an incredible (and still increasing) number of articles are published in a wide range of sources every year: For example, in 2003 Peffers and Ya identified 326 journals that publish IS research (p. 65), while the Index of Information Systems Journals lists 647 active IS journals today. Moreover, Peffers and Hui (2003, p. 168) found that between 1997 and 2001 about 38% more articles were published in ten “pure” IS journals (following Walstrom and Hardgrave 2001, p. 122) when compared to 1987–1991. As a result, conducting a literature search in IS can turn into a Sisyphean task, so that, quite necessarily, a multitude of work has to be omitted in the search process (cf. Cooper 1988, p. 114).

Against this backdrop, we argue that the process of excluding sources (and including respectively) has to be made as transparent as possible in order for the review to proof credibility. Only then are readers able to assess the exhaustiveness of a review and other scholars in the field can more confidently (re)use the results in their own research. Therefore, we set out to explore the methodological rigour of literature reviews in the IS domain. In doing so, we apply typical evaluation criteria, such as reliability and validity, for analysing review articles published in the ten top-ranked IS journals, according to the consolidated list provided by the Association for Information Systems (AIS). We find a surprisingly large number of review publications that do not provide any detail on the underlying literature search.

The remainder of this paper is structured as follows. In the next section, we give an overview of our study and spell out our research approach. In section 3, we then present the results of our analysis of selected literature reviews published in the IS domain. In doing so, we particularly point out shortcomings referring to the documentation of the literature search process. In section 4, we discuss our results and derive three propositions that aim at providing explanations for our results. Implications from our

---

research are subsequently presented in the form of both guidelines for conducting IS literature reviews, in particular the process of searching the literature, and a plea for more rigour in crafting and documenting a literature search (section 5). We conclude with a short summary and discussion of our work (section 6).

2 STUDY OVERVIEW

A literature review can be defined as “a summary of a subject field that supports the identification of specific research questions” (Rowley and Slack 2004, p. 31). The primary objective of this paper is to explore the methodological rigour in conducting literature reviews as part of IS research. More specifically, we focus on the process of literature search (cf. Levy and Ellis 2006, pp. 185ff.), which involves both the identification of high quality papers and the evaluation of their applicability to the study. Similar to ‘traditional’ research methods or studies, the term ‘rigour’ refers in particular to the reliability and validity of the search process (cf. Levy and Ellis 2006, pp. 183ff.; Patel and Giaglis 2004, p. 304). As such, validity characterises the degree to which the literature search accurately uncovers the sources that the reviewer is attempting to collect. The basic question is ‘Does the reviewer search right?’, it reflects decisions such as the selection of databases, publications (i.e. journals, conferences or books) and keywords, as well as the period covered, the articles considered in the literature search, and the application of backward or forward searches (Cooper 1988, p. 114; Levy and Ellis 2006, pp. 185ff.; Torraco 2005, p. 360; Webster and Watson 2002, p. xvi). Reliability, in turn, describes the replicability of the search process, hence, making it substantial for any review article to comprehensively document the literature search. “The literature is the data of an integrative literature review” and “learning about [it] and how it was obtained, including the keywords and databases used, is of particular interest to readers, who may wonder if the literature they are familiar with was examined” (Torraco 2005, p. 360). It is also obvious that evaluating the exhaustiveness of a literature review is complicated without a thorough documentation of the search process. That being said, other researchers in the field can hardly ground their own work on the review without sufficient knowledge on where and how authors have already searched for literature.

Consequently, the guiding research question of this paper is ‘Do IS researchers comprehensively document the process of literature search in their review articles?’ and, therefore, we investigate the degree of methodological rigour, i.e. the replicability and evidence, of IS reviews. In other words, we review IS review literature. Our own process of literature search and the results drawn from the analysis are described in the next section.

3 REVIEWING IS REVIEW LITERATURE

As commonly recommended, in the following we focus on review articles of high quality (Rowley and Slack 2004, p. 32). However, identifying high quality IS literature is complicated as there is not only a vast amount of potentially relevant sources but also a great deal of literature of diverse quality (Levy and Ellis 2006, pp. 183 & 185ff.). To this end, IS scholars are frequently evaluating the quality of IS journals in order to provide rankings, e.g. Ferratt et al. (2007, p. 716), Hardgrave and Walstrom (1997, pp. 121f.), Lowry et al. (2004, pp. 52ff.), Peffers and Ya (2003, p. 70), and Willcocks et al. (2008, pp. 165f.). A number of those rankings have been synthesised by Carol Saunders for the AIS, which resulted in a comprehensive list of more than 100 top-tier IS journals. We decided to include in our literature review the ten top-ranked, peer-reviewed IS journals according to this consolidated list. However, as Harvard Business Review (HBR) (#8) is not a peer-reviewed journal and because the IEEE Transactions (#9) subsume various journals of differing quality and relevance for IS research (e.g. the IEEE Transactions on NanoBioscience), these journals were not considered in our review. This selection led us to explore the ten journals displayed in Figure 1. The figure also outlines the accessed databases as well as the searching functionality applied and the period covered in the review. The key phrase we used in all searches was ‘literature review.’
As outlined in the previous section, a literature search involves both identifying and evaluating scholarly literature and, accordingly, we applied a similar procedure in our own review. As the search phrase ‘literature review’ has been used in a range of contributions, many of which cannot be labelled as review articles, the contributions identified by keyword search (‘hits,’ cf. Figure 1) have subsequently been evaluated, based on their abstracts, in order to assess their relevance for this study. The then remaining articles became the basis of our review (‘reviewed’). Subsequently, we analysed whether the identified review articles meet, i.e. document, the requirements explained in the previous section, namely: the (number of) articles considered in the review, the period covered, the (number of) journals and databases explored, the keywords used for the database and/or journal search, and, finally, whether a backward and/or forward search were conducted. The results drawn from our analysis are summarised in Figure 2; they show that 6 articles – or one fourth of the examined review literature – do not provide any information on the underlying search process. At least, 15 publications accurately document how many articles were included in the review. However, among these, there are only 11 reviews that state precisely, which articles were included. Whereas, more or less, half of the examined articles explicate the examined period of time, the number of databases queried has merely been stated in 7 articles. However, in many cases it again remains unclear, which databases were actually accessed. For example, Melville et al. (2004, p. 322) searched journal databases which “included” Business Source Premier and JSTOR and Pateli and Giaglis (2004, p. 304) explored “several” sources such as ScienceDirect, JSTOR, and InterScience. Perhaps even more notably, many reviewers conducted a journal search instead of a database search, though there is “no justification for searching by journal instead of searching by topic” (Anonymous; cited in Webster and Watson 2002, p. xvi), except when the goal of the review gives sufficient reasoning for such a proceeding (e.g. Jasperson et al. 2002, p. 403, or the review at hand).

All in all, some inaccuracies in documenting the search process can be found in all sources. For example, Leidner and Kayworth (2006) – whose review is still among the best-documented ones – examined “the leading journals in our field dating back to the early 1990s.” They apply search phrases

3 These numbers have been checked and double-checked on 2009-01-15. However, when finalising this paper and reviewing the results once more on 2009-03-15, it turned out that some of them have considerably changed, in particular when again searching Informs (ISR and MS) and ScienceDirect (DSS). Referring to ScienceDirect, these differences can, at least partly, be reasoned by new issues released in the meantime. However, the results gained from the two Informs queries differ so significantly (ISR: 30 vs. 46 hits; MS: 108 vs. 228 hits) that we are likely to assume that the underlying searching mechanisms have somehow been changed in recent times (since our license contracts with both providers definitely stayed the same). Therefore, please note that the numbers described in Figure 1 have been gained on 2009-01-15.

4 Since 2001, the MISQ provides a special review section. Therefore, keyword search has not been applied for searching MISQ. However, all articles published in the MISQ review section have been considered in this review.
“such […] as ‘IT culture’, ‘information systems culture,’ and ‘IT values’” and conducted a search of ABI/Inform and Business Source Premier and “similar searches” in ScienceDirect. Furthermore, they “looked through” the references of “key articles” to not “overlook other articles” (pp. 360ff.). That being said, though they applied a backward search (as one of only a few articles), it is not fully replicable, as is the entire search process. However, most striking is the fact that only 2 articles comprehensively document the underlying search phrases (Gerwin and Barrowman 2002, p. 942, and Ngai and Gunasekaran 2007, p. 4). So even though we firmly believe that all the above listed contributions represent fundamental and way-leading reviews in their particular fields, we herein question whether it is in fact sufficient to state that “key words from our definition of IT business value” (Melville et al. 2004, p. 322) were used or that the search was conducted “by using relevant keywords” (Xiao and Benbasat 2007, p. 140). In the same way, Pateli and Giaglis (2004, p. 304) claim that “the selection of journals” (Fjermestad and Hiltz 1998, p. 9) is most likely to be valid, whenever the search process is only described very briefly, the search cannot be replicated and, thus, it can hardly be considered rigour. Drawing on these results, the question emerges: ‘Why is it that many IS researchers do not comprehensively document their literature search process?’

### DISCUSSION

When crafting a literature review on a topic, one should be aware of the fact that, unlike for other empirical studies, there are only few explicit methods or standardized guidelines (cf. Bem 1995; Jackson 1980, p. 440; Torracco 2005, p. 359). In 2002, Webster and Watson remarked: “as the initial senior editors for MISQ Review, we quickly learned that many IS scholars are not familiar with the structure and format of reviews” (p. xiv). This leads us to formulate a first proposition for explaining our results: (1) IS researchers cannot refer to established guidelines for documenting the literature search process.
Our second proposition provides an alternative reasoning: (2) IS researchers are not fully aware of the importance of rigorously documenting the literature search. Please note that it is not our intention to imply that IS researchers are unwilling to conduct their search process in a rigorous way – in particular referring to the outstanding contributions described above. However, conducting and documenting a literature search are two sides of the same coin and perhaps IS authors sometimes in fact prefer ‘the pears to the apples,’ i.e. they rather put emphasis on rigorously summarizing and synthesizing findings gained from the literature search than on documenting the long way they walked along for uncovering them.

Finally, our analysis also revealed that review articles in IS research differ considerably in terms of length, reaching from six pages (Glass et al. 2004) to 143 pages (Fjermestad and Hiltz 1998). Furthermore, there are many review articles that are not even longer than twenty pages. However, it is undisputed that literature reviews commonly require far more pages than ‘regular’ articles (cf. e.g., the MISQ submission guidelines). Consequently, the question arises ‘Why are so many review articles that short (and exclude the process of searching the literature), assuming that IS researchers know how (ad 1) and are willing (ad 2) to rigorously document their literature search process?’ We believe the answer is most likely to be found in the submission guidelines and page limitations provided by various IS outlets. More specifically, information on the literature search process, which exists in the beginning, might be excluded during the subsequent editing process in order to free space for addressing the reviewers’ comments. Only three of the journals we examined provide a special review section (CACM, AI and MISQ) and only another three journals (DSCI, EJIS and ISR), more or less, welcome review articles in their editorial statements. Please also note that – according to the results gained from our analysis – in the case of four of the journals in our sample no review articles were published at all. This leads us to question whether literature reviews play the key role they undoubtedly deserve in IS research and to formulate a third proposition: (3) It is the conditions of the publication process that often prevent a detailed description of the literature search. For example, Kari and Rozenberg (2008, p. 83) acknowledge this perception by stating that “the upper-bound placed on the number of [40] references” turned out to be a “real limitation” for their review published in the CACM.5

In summary, we conclude that IS reviewers may sometimes be either (1) unable to refer to adequate guidelines for rigorously documenting the literature search, (2) not fully aware of its importance or (3) hindered to transparently describe their literature search in its full extent due to editorial constraints. Here, we do not aim to evaluate our propositions, but rather formulate both guidelines for crafting an IS literature review and search (ad 1) as well as a plea for more comprehensive documentation of the search process (ad 2 & 3).

5 Note that this review could not be identified following our search strategy (limitations are discussed in the next section).

5 IMPLICATIONS

5.1 Guidelines for Literature Reviews

In response to proposition 1, we propose in the following a framework for conducting IS literature reviews, with particular focus on the process of searching the literature. The framework is displayed in Figure 3 and reflects a “circularity that exists when […] undertaking a literature review” (Baker 2000, p. 221). That being said, as things use to change and knowledge continuously grows, literature reviews often become out-of-vogue after a certain time, giving reason for an extension and update of the review (cf. Pervan 1998, p. 158).

A major challenge in reviewing the literature lies in defining an appropriate scope and flavour of the review (phase I). Reviews can be critical, interpretive, speculative, state of the art, and historical and
can vary referring to subject matter, period covered, and degree of coverage of sources (Manten 1973; Woodward 1972; as cited in Garfield 1987, p. 114). Furthermore, literature reviews can serve a wide range of, sometimes very different, purposes, reaching from gaining new and synthesising existing research outcomes to identifying research methodologies or techniques commonly used in a field (cf. Hart 1998, pp. 27ff.). In order to clearly define the scope of a review, we propose to draw on an established taxonomy for literature reviews presented by Cooper (cf. Cooper 1988, pp. 109ff., and Figure 4 in the follow-up). Cooper’s taxonomy is comprised of six constituent characteristics, each containing certain categories, some of which are mutually exclusive (perspective and coverage), while others can be combined (audience, organisation, goal, and focus). The focus (1) of a literature review is concerned with what is of utmost importance to the reviewer. Most literature reviews focus on research outcomes, research methods, theories, and/or applications (cf. Bem 1995; Torraco 2005, p. 361). Common goals (2) of literature reviews include summarising, criticising, and/or integrating findings (cf. Jackson 1980, p. 438). For organising a literature review (3), Cooper suggests a historical, conceptual or methodological structure. The perspective (4) of a review reflects whether a certain position is espoused or not; the audience (5) particularly determines the writing style of the author(s) (cf. Bem 1995, pp. 173ff.).

Figure 3. Framework for literature reviewing

This paper is based on the perception that in particular the degree of coverage of sources (6) is crucial for reviewing the literature on a topic. According to Cooper, four levels of coverage can be distinguished, namely: exhaustive (including the entirety of literature on a topic or at least most of it), exhaustive with selective citation (considering all the relevant sources, but describing only a sample), representative (including only a sample that typifies larger groups of articles), and central (reviewing the literature pivotal to a topic) (Cooper 1988, pp. 110ff.).

![Figure 4. Taxonomy of literature reviews (following Cooper 1988, p. 109)](image)

While the above framework does not provide immediate answers to the questions of literature search, its application is a necessary first step of clarification in any literature review, which bears implications for the later search process. An exemplary application of Cooper’s taxonomy is also given in
Figure 4 by highlighting categories that characterise our own literature review presented in section 2: We did not focus (1) on the research outcomes or theories described or applied in the above analysed articles, but rather on their underlying research methodology. We criticized (2) the way these reviews document the literature search process, since it was our position (4) that such documentation is crucial to ensure the replicability of the literature search. As the purpose of our review was not to summarise or synthesise, but rather to evaluate scholarly literature, the categories proposed by Cooper relating to organisation (3) can hardly be applied to our case. It is hoped that our results are of some value for the whole IS community (5) – even though we did not consider all IS review articles ever published in our study, but restricted the analysis to a small sample of literature reviews only. However, this proceeding can be reasoned by the fact that it was our explicit objective to analyse high-quality review articles that may be considered as representative (6) for the IS domain.

In a next step, attention should be paid to the fact that a review must begin with “a broad conception of what is known about the topic and potential areas where knowledge may be needed” (phase II) (Torracco 2005, p. 359). Therefore, working definitions of the key terms should be provided at this point (Zorn and Campbell 2006, p. 175). Baker (2000, p. 222) suggests that one should firstly consult “those sources most likely to contain a summary or overview of the key issues relevant to a subject,” such as seminal textbooks, encyclopaedias, or handbooks. A reasonable way for identifying key concepts is represented by concept mapping, which also provides the opportunity to uncover relevant search terms (in particular related concepts or synonyms and homonyms) that can be applied in the subsequent literature search (cf. Rowley and Slack 2004, p. 36). Accordingly, we began our study by consulting the seminal textbooks on literature reviews by Arlene Fink (2005) and Christopher Hart (1998) and introduced a working definition of the term ‘literature review’ in section 2. However, the various synonyms of the term ‘literature review,’ such as ‘meta-analysis’ or ‘research synthesis,’ have been disregarded in our study. Therefore, it is possible (or indeed even likely) that several articles which may be labelled as ‘literature reviews’ have not been included in our study, which again shows that our search strategy can hardly be labelled as exhaustive – even referring to the small sample of IS journals examined.

As we already noted, the search process (phase III) involves database, keyword, backward, and forward search, as well as an ongoing evaluation of sources (cf. Figure 5).

![Figure 5. Literature search process](image)

As they have typically been peer-refereed before publication, it is commonly recommended to focus on articles published in scholarly journals (Rowley and Slack 2004, p. 32) or proceedings of renowned conferences (Webster and Watson 2002, p. xvi). However, one should note that the quality of contributions in conference proceedings is usually considered lower and less mature than those in journals (cf. Levy and Ellis 2006, p. 187). Thus, authors who intend to include conference articles in their reviews should concentrate on the better ones (e.g., Walstrom and Hardgrave (2001, p. 121) and Willcocks et al. (2008, p. 166) provide rankings for IS conferences). Consequently, the identification of journals makes up the first sub phase of our framework – even though we would agree that it rather makes sense to query scholarly databases allowing for a topic-based search (cf. Webster and Watson 2002, p. xvi). However, one challenge definitely lies in identifying proper databases. We propose to...
search those databases (sub phase 2) providing access to the leading IS journals (identified in sub phase 1) – a proceeding which finally allows for ensuring that all the top-tier sources are included in the review. The identified databases have then to be queried on the basis of a keyword search (sub phase 3). It is commonly recommended to use a precise (set of) search phrase(s) in order to exclude contributions covering topics or research questions which are not necessarily relevant (Rowley and Slack 2004, p. 35). Querying EBSCOhost using the search term ‘literature review,’ for example, reveals hundreds of possible information sources; when adding the term ‘information systems’ however, the amount of literature is significantly reduced. By also adding the supplementary search phrase ‘Europe,’ the huge pool of potentially relevant articles is finally restricted to merely a handful of papers. This example illustrates that keyword search is crucial, since the selection and combination of the search phrases sets “the parameters of the research itself” (Baker 2000, p. 222). Thus, particularly the applied keywords have to be documented precisely, so that other scholars can evaluate whether they sufficiently match the topic under investigation. According to Webster and Watson (2002, p. xvi), the process of backward search refers to reviewing older literature cited in the articles yielded from the keyword search and forward search means reviewing additional sources that have cited the article (sub phase 4), e.g. by querying the ISI Web of Knowledge by Thomson Reuters (note that Levy and Ellis (2006, pp. 190ff.) discuss additional forms of backward and forward search in detail). Evaluation in all phases means limiting the amount of literature identified by keyword search as well as backward and forward search to only those articles relevant to the topic at hand. We therefore propose an evaluation of the articles’ contents, which may mean to analyse their titles, abstracts or even full texts. As described above, the review at hand is based on applying a keyword search (‘literature review’) to a sample of ten journals. That being said, though these journals were accessed via online databases, a ‘pure’ database search has not been conducted. Moreover, backward or forward searches were also not part of our literature search strategy.

After collecting sufficient literature on a topic it has to be analysed and synthesised (phase IV). As we focus on the search process, we herein only briefly touch upon this phase. For the analysis, a concept matrix, as developed by Salipante et al. (1982) and adapted for IS literature reviews by Webster and Watson (2002, p. xvii), can be used, which subdivides topic-related concepts into different units of analysis (cf. Figure 6). This allows for arranging, discussing, and synthesising prior research.

![Concept matrix](image)

**Figure 6. Concept matrix (Webster and Watson 2002, p. xvii)**

However, as underpinned by several IS reviews (e.g., Ahuja 2002, pp. 30ff.), the synthesis of literature is further expected to result into a research agenda (phase V), comprised of sharper and more insightful questions for future research (Webster and Watson 2002, p. xix). The research agenda provides the basis for extending the review in order for the IS community to keep up-to-date and it may be developed based on the proposed concept matrix. That being said, certain fields of the matrix, which remain ‘blank’ during a literature study, often highlight research areas that are significantly under-researched.

### 5.2 A Plea for More Rigour in Searching the Literature

We hope that the above section provides some insights on how to rigorously conduct a literature review and search in the IS domain. However, we did not intend to present ‘yet another guideline’ for reviewing the literature – we rather consider our explanations as both a rationale for our own literature study and a response to scholars who are likely to estimate our first proposition to be the most striking one (‘IS researchers cannot refer to adequate guidelines for rigorously documenting the literature...')
search’). Nonetheless, we think that most IS scholars – and in particular those very renowned ones cited above – indeed have a good understanding of how to conduct a literature search. Moreover, we firmly believe that the literature search process underlying (at least most of) the analysed articles is certainly a highly rigorous one. However, it is simply not documented rigorously enough, leading us to question the role the literature search process plays in the IS domain. Thus, one may also consider this paper as ‘yet another call’ for more rigour in IS research; in this case, for documenting a literature search. In the following, we appeal to the authors of IS articles (proposition 2) as well as to the editors of IS journals (proposition 3) to not only conduct and write (or support the writing of) literature reviews that are of high quality, i.e. reviews that are thoroughly crafted, useful and interesting, but also to allow for adequate documenting of the review process, including the specifics of the search process.

When writing a literature review, we advocate authors to invest in planning and describing the literature search process in detail. In the majority of cases, literature reviews serve as the means to reveal open research gaps and are part of a larger research endeavour. Planning and accomplishing the literature search process in a rigorous manner will help to discover similar research endeavours early and prevent the researcher from doing redundant work. Moreover, it will allow for a better understanding of where to find relevant articles in the jungle of different sources available and how to retrieve them later. Rigorously documenting the literature search in particular means to share these experiences with the community. As a result, a well-documented review will be gladly used, extended and cited by other researchers, which will in turn positively affect scientific impact.

We hope for more editors to consider establishing a dedicated literature review category within their journals. Moreover, the rigorous accomplishment of a literature review should not be impeded by article length or reference restrictions. One possible solution may be the publication of two versions of the same review – a shorter one that contains the major findings and is published in the printed version and a comprehensive one that outlines the whole literature search process and states how and where the sources were discovered and which is published online (see Kari and Rozenberg (2008) for an example). Moreover, we suggest demanding the documentation of the literature search process as an important review criterion for judging the quality of literature reviews.

6 CONCLUSION

Research is a collaborative endeavour, since each researcher builds on what has been developed and worked out before. Thus, literature reviews play an important role in scholarship. In this paper we argued that documenting the literature search process is a crucial part in any review article. However, drawing on the results gained from an analysis of literature reviews published in ten of the most important IS outlets, we showed that many of these reviews do not thoroughly document the process of literature search, e.g. by not comprehensibly explicating the queried databases, the applied keywords or the examined period of time. This is why we presented both guidelines for conducting a literature search and review as well as a plea for more rigour in documenting the search process.

Certainly, most IS scholars know what it actually takes to craft high-quality reviews, and we would agree that our suggestions are likely to further impede this challenging task. But our guidelines do not intend to imply that conducting a literature search means to uncover and analyse all sources ever published. A review that considers only five research papers, but sufficiently states which ones were chosen for whatever sensible reasons, may be of more value to both its authors and the community than a review that analyses a broad range of contributions, without providing sufficient information on where, why and what literature was obtained, hence, making it hard to judge its quality and the scope of its contribution. In addition, a well documented literature search offers the potential to being extended and transferred to, for instance, other domains, additional journals, or newer/older volumes. Against this background, search results are better comparable and a well-documented search process thus provides the basis for a review article to contribute to a cumulative effort of reviewing literature.

AN EVALUATION OF USER ACCEPTANCE OF A CORPORATE INTRANET

Barnes, Stuart, Norwich Business School, University of East Anglia, Norwich NR4 7TJ, UK, stuart.barnes@uea.ac.uk
Vidgen, Richard, School of Management, University of Bath, Bath BA2 7AY, UK, richard@vidgen.com

Abstract

Intranets represent an important organisational resource for knowledge sharing. However, as yet, there has been little research into the quality of intranets and the impact of quality on intranet user acceptance. In the study reported in this paper, an intranet quality assessment tool comprising the dimensions usability, design, and information quality, is combined with perceived usefulness and social influence from the technology acceptance literature to create an intranet acceptance model. The model is applied to the sales and marketing division of an international manufacturing company. Data is collected via a Web survey (n=131, response rate = 65.5%) and tested using the partial least squares approach to structural equation modelling. The results show that intranet quality is a significant factor in determining behavioural intention to use, although it is less important than perceived usefulness and social influence. Comments collected from respondents are used to illustrate the findings and provide an insight into user behaviour. The discussion considers the implications, future research (e.g., the role of social influence in intranet usage) and limitations. The paper rounds off with a short summary.
1 INTRODUCTION AND BACKGROUND TO THE RESEARCH

While the Internet allows organizations to reach new markets and new consumers the corporate intranet represents a key medium for access to organizational memory and to company and product information. Skok and Kalmanovitch (2005) see intranets in the context of the larger issue of knowledge sharing, identifying three views of the role of the intranet: cognitivistic, connectionist, and autopoietic. The cognitivistic view sees the intranet as a culturally and socially neutral repository of explicit information. The connectionist sees the intranet as a tool that brings communities together to share and interpret information, making hidden organizational information locatable. The autopoietic view recognizes that much knowledge is tacit and the role of the intranet is to provide data that helps identify relevant staff to contact. Notwithstanding the fact that researchers may debate the finer distinctions of data, information, and knowledge the intranet, as a technical artefact, undoubtedly has a role to play in knowledge sharing and the quality of the intranet would be expected to contribute to intranet acceptance and ultimately to the effectiveness of knowledge sharing.

There is a surfeit of research literature with respect to evaluating the quality and user acceptance of Web sites on the public Internet and e-commerce applications, adopting a range of approaches and theoretical bases. For example, Liu and Arnett (2000) highlight four factors in Web site quality: information and service quality, system use, playfulness, and system design quality. Yoo and Donthu (2001) developed the SITEQUAL scale to measure the perceived quality of an online shop, leading them to identify four dimensions: ease of use, aesthetic design, processing speed and security. Barnes and Vidgen (2002) developed the eQual scale with five dimensions: usability, design, information, trust, and empathy. Loiacono et al. (2002) created the WebQual™ scale, composed of thirty-six items and twelve dimensions: informational fit to task; interactivity; trust; response time; design appeal; intuitiveness; visual appeal; innovativeness; flow (emotional appeal); integrated communication; business process; and substitutability. Further, Parasuraman et al. (2005) developed the e-SQ scale with seven dimensions of service quality: efficiency, system availability, fulfilment, privacy, responsiveness, compensation and contact.

A range of theoretical bases for Web quality evaluation have been drawn upon in the salient literature, including the technology acceptance model, service quality/marketing, and information systems success. These approaches are typically supplemented with items from ancillary areas such as human computer action and information quality. Typical dependent variables are intention to use, intention to purchase or re-purchase, loyalty, and overall satisfaction.

Compared with the research on Web site and e-commerce quality and acceptance there is, in comparison, a dearth of research on the evaluation of intranet effectiveness. Following many years of studying intranets Stenmark (2005) finds that intranets differ from the public Internet insofar as content is provided top-down by a small group of professionals, content is objective and business-related, and content is organized consistently according to a corporate taxonomy. Stenmark (ibid.) says that the latter is a source of weakness in intranets, which can be difficult to search and navigate as they are seldom built from the consumer’s perspective. The intranet exists in an environment with a formal organization structure and a management hierarchy that is absent in an e-commerce application and we would thus expect social influence to play a significant role in intranet use. Coming from a quality perspective, Leung (2001) draws on the ISO model and evaluates the intranet as a software artefact using the dimensions of functionality, reliability, usability, efficiency, maintainability, and portability.

Previous research on intranet quality and acceptance is clearly very limited. Thus, we perceive an important gap that deserves further research attention. The aim of this paper is to show how the effectiveness of an intranet can be assessed in terms of outcomes, principally in performance effectiveness (i.e., how useful is the intranet in supporting organizational work) and intention to use. Our approach is the development and testing of a model of intranet acceptance. The model is
subsequently tested in a real case study setting of a major multinational organisation. Data is collected using a survey and analysed using the partial least squares approach to structural equation modelling.

In the next section we explicate a model and theory developed to contribute understanding in this very new area of investigation. This is followed by a discussion of the methodology adopted for the study. Consequently, the research results - quantitative and qualitative analysis of respondent comments - are examined in section four. The findings, implications for research and practice, and limitations of the research are discussed in section five. Finally, the paper rounds off in the last section with a summary.

2 MODEL AND HYPOTHESES

In this section we describe the theoretical model adopted for the study. We discuss this in two parts: (1) intranet quality assessment; and (2) intranet acceptance and associated constructs. Let us examine each of these in turn.

2.1 Intranet quality

The eQual instrument (Barnes and Vidgen, 2002) identified five dimensions of Web quality: usability, design, information, empathy, and trust. Of these five dimensions, empathy consistently scores lower in terms of importance in e-commerce applications and is also unlikely to play a major role in a corporate setting where there will be at least a degree of uniformity of corporate culture. Although trust is a key factor in e-commerce, in a corporate setting trust is implied through the corporate and closed setting of the intranet. We thus focus on usability, design, and information quality in constructing an instrument to assess the quality of an intranet.

The usability dimension draws from literature in the field of human computer interaction (Davis, 1989, 1993, Nielsen, 1993) and information systems quality (Bailey and Pearson, 1983) while the design dimension draws on Web usability (Nielsen, 1999, 2000, Spool, 1999) and service quality (Parasuraman et al. 1991, Zeithaml et al., 1990). Information quality follows Strong et al. (1997) with provenance in the work on IS quality and IS success by Bailey and Pearson (1983) and DeLone and McLean (1992). In summary, intranet quality is expressed using the dimensions usability, design and information quality (see Barnes and Vidgen (2002) for further details of the provenance of the intranet quality items). We expect, as from previous research, for the quality construct to appear as a second-order combination of these three first-order constructs and we hypothesise the following:

H1. Intranet quality is positively related to behavioural intention to use an intranet.

2.2 Intranet acceptance

Although intranet quality would be expected to impact behavioural intention to use the intranet it is clear from the literature that other factors will likely play a part. In his seminal paper on technology acceptance, Davis (1989) defines perceived usefulness as “the degree to which a person believes that using a particular system would enhance his or her job performance” (p. 320). In a later version of the model, TAM2, Venkatesh and Davis (2000) included the construct “subjective norm”, which considers social influence as the extent to which an individual perceives that people important to him or her think he or she should or should not perform a behaviour, such as using an intranet. Latterly, the unified theory of acceptance and use of technology (UTAUT) brings these strands together in a large and wide-ranging instrument (Venkatesh et al., 2003). Despite its grand scale the explanatory and predictive power of the UTAUT in a broad range of contexts has yet to be fully demonstrated.

Part of our research agenda is to produce an instrument suitable for use in the corporate world where lengthy surveys are likely to be ignored. We therefore happily accepted the requirement that the instrument be parsimonious in terms of the number of items and we are, in a way, getting back to the
simplicity and elegance of the original TAM. First and foremost, an intranet must be useful to employees in doing their jobs. Second, we argue that social influence in the form of senior managers, peers, and co-workers will also play a key role in intention to use. From the TAM/UTAUT we therefore hypothesise:

**H2.** Social influence is positively related to behavioural intention to use an intranet.

**H3.** Perceived usefulness is positively related to behavioural intention to use an intranet.

Finally, behavioural intention is expected to have an influence on actual usage, hence:

**H4.** Behavioural intention is positively related to actual intranet use.

The above hypotheses contribute to the construction of the research model, as shown in Figure 1.

![Research Model](image)

**Figure 1.** Research Model

### 3 METHODOLOGY

To test the research model we worked with the sales and marketing division of a multi-national manufacturing company, which will be referred to pseudonymously here as SalesOrg. The company had recently employed a Web design agency to build a new intranet site to support their sales and marketing operations. The old intranet was fragmented in terms of design and content and was not widely adopted by the sales and marketing teams. The organization now wished to create a single and enhanced repository of sales and marketing data containing material about SalesOrg’s values, processes, and methods along with tools and templates, case studies, best practice examples, news items, resources (e.g., product information), and e-learning units. In sum, the new intranet is to be a single point of access for all the formalized resources that all personnel working in sales and marketing need to draw on to do their job effectively. The survey reported here was conducted three months after the initial intranet implementation.

The survey was implemented online and pilot tested with a small group to check that the questions were comprehensible and the survey easy to complete. Responses to the pilot survey showed that it was relevant and comprehensible and SalesOrg agreed to roll the survey out to a wider audience in February 2008. The survey questions are shown in the Appendix. For the items in Table 1 five-point Likert scales were used with the anchors “1 = strongly disagree” and “5 = strongly agree”. Respondents were allowed to select “not applicable” to avoid forcing responses. Actual use was measured using a single item, “In an average week, how much time would you say you spend connected to the Intranet (for any kind of service and counting all the possible sessions over the week)?”, with responses as “1=Don't use it at all”, “2=Less than 15 minutes”, “3=Between 15 minutes and 30 minutes”, “4=Between 30 minutes and 1 hour”, “5=Between 1 and 2 hours”, “6=Between 2
and 4 hours”, “7=Between 4 and 10 hours” and “8=More than 10 hours” (mean=3.66, standard error=0.139). The survey was implemented online and publicised by email to the 200 members of the SalesOrg division. A total of 131 usable responses were received, representing a respectable response rate of 65.5%.

Data analysis was performed using a variance maximization approach to structural equation modelling (SEM) and associated statistics for validity and reliability. More specifically, we used the partial least squares (PLS) technique with reflective indicators in Smart-PLS 2.0 (Ringle et al. 2005). The PLS technique has become increasingly popular in information systems research, marketing and in management research more generally in the last decade or so, influenced by its flexibility; indeed, PLS does not have the same distributional assumptions of normality for data and is able to handle small- to medium-sized samples (Chin 1998, Compeau & Higgins 1995).

SEM caters for two types of analysis: construct and measurement. The construct model is used to assess the structure of the observed and latent variables (e.g., do the three survey items capture the latent variable “Perceived Usefulness”?). The measurement model considers the hypothesised relationships, or paths, between the variables and latent variables, e.g., is the relationship between intranet quality and behavioural intention significant and if so how strong is the relationship?

4 RESULTS

4.1 Characteristics of survey respondents

Of the 131 usable responses to the survey, 63.36% were male (36.64% female), with approximately half being in the median age range of 36 to 45 years of age (48.09%). The respondents were very experienced employees in the sales and marketing profession with 69.47% having more than 10 years experience (90.84% over 5 years). Similarly, the employees had been with the company for quite some time, with more than half over 10 years and 81.68% over 5 years. The respondents were only moderate users of the Internet, with a median of 4-10 hours per week spent connected to the Internet in an average week. The use of the intranet in an average week was generally quite low, with around three-quarters of users using it for less than an hour (74.81%) and a median of 15 to 30 minutes.

4.2 Tests for Validity and Reliability of the Measures

To test the constructs we performed a confirmatory factor analysis and reliability analysis. Table 1 demonstrates that the scale items exhibit high levels of convergent validity – the extent to which theoretical scale items are empirically related. The loadings of the measures on their respective constructs in the model range from 0.756 to 0.930, with all being significant at the 0.1% level.

Table 1 also demonstrates that all of the constructs fulfil the recommended levels with reference to composite reliability (CR) and average variance extracted (AVE). All items were higher than the cut-off of 0.50 for AVE recommended by Fornell and Larcker (1981), ranging from 0.607 to 0.802. Similarly, the values for composite reliability are very good, ranging from 0.882 to 0.948, well above the reliability values of 0.70 and 0.80 that are typically advised for building strong measurement constructs (Nunnally 1978, Straub & Carlson 1989).

As an additional test for discriminant validity we utilized the cross-loading method of Chin (1998). The method prescribes a requirement for measurement items to load higher on a construct than the scale items for other constructs and for no cross-loading to occur. Item loadings in the relevant construct columns were all higher than the loadings of items designed to measure other constructs; similarly, when glancing across the rows the item loadings are considerably higher for their corresponding constructs than for other constructs. Note that the three first-order constructs for
intranet quality, usability, design and information quality all loaded on a single second-order construct, as expected. This underlines the point that intranet quality is a holistic concept in its own right.

Table 2 examines the extent to which question items measure the construct intended or other related constructs, otherwise known as discriminant validity. Fornell and Larcker’s (1981) standard test for discriminant validity was used, whereby the square root of average variance extracted for each construct is compared with the correlations between it and other constructs; discriminant validity is demonstrated if the square root is higher than the correlations. Table 2 clearly indicates that each construct shares greater variance with its own measurement items than with other constructs with different measurement items, and with a good margin of difference.

4.3 Test of the Research Model

The results of PLS path modelling are shown in Figure 2 (intranet quality is included as a second-order construct). A power analysis in G*Power 3.0 (Faul et al. 2007) shows that the sample size \(n=131\) has good power for explaining medium population effects \(f^2=0.15; \alpha=0.05; 1-\beta=0.95\), and is thus suitable for the testing of the model under these conditions. The results show strong support for the theoretical research model. Indeed, all paths in the model are supported at the 1 percent level of significance or higher. Specifically, the results show that H1 (the influence of quality on behavioural intention to use the intranet) is supported at the \(p<0.01\) level and that H2, H3, and H4 are supported and significant at the \(p<0.001\) level. The strongest determinant of the behavioural intention to use the SalesOrg intranet is perceived usefulness \((\beta=0.365)\) followed closely by social influence \((\beta=0.327)\) and lastly by a slightly weaker intranet quality \((\beta=0.201)\).

4.4 Analysis of comments

The quantitative data shows that the intranet was particularly well received by the users in the sample with the quality average score being 4.167 (standard error=0.051) where the maximum, 5, represents “strongly agree”. Table 1 shows that the evaluations for each of the quality scale items were well over the neutral point (neutral=3), with the three constructs averaging 4.227, 4.188 and 4.104 for usability, design and information respectively. It seems that the intranet was particularly well received as a
technical artefact and this view is supported by the open comments that respondents supplied as part of the survey. For example:

“Many thumps [sic] up for a remarkable revamp of the site”

“The site provides accurate and important information that helps to improve the training strategy it is been implemented in my country, it is friendly and easy to use.”

“Great Tool!”

Although some reservations were expressed about the quality of the site with respect to performance - “It’s slow to download files” and “site hangs once in a while from our end” - the overwhelming view of the site, as expressed through the Likert scores and accompanying comments, is positive.

The great majority of comments related to the usefulness of the site and in particular the contribution to forms of knowledge sharing. All were positive about the usefulness of the intranet and just a few are included here for illustration:

“I consider the [SalesOrg] intranet site a very comprehensive resource center for sales trainers.”

“The [SalesOrg] site has been useful resource to me in my day to day job. It helps to widen my knowledge and new ideas to implement in local countries.”

 “[SalesOrg] material is a unique contribution to our professional development. The website has finally made the workshop materials available for reference and dissemination within the local teams.”

“I really find the [SalesOrg] site a complete library of learning. It has given me so much help in crafting my training plans for my team.”

“We find the site very useful to us. We get to know more about the best practices of other countries.”

The respondents also highlighted areas for development, including translation into other languages (most notably into Spanish) and concerns were raised about the need to update the content of the intranet more frequently.

With regard to social influence, there was strong agreement amongst respondents that the site could be promoted more effectively:

“the site is not marketed very properly”.

“Site has not been promoted to me discovered it by chance because Pam mentioned it to me.”

“I think senior management is not truly aware of [SalesOrg] website. There are many programs in Sales and Marketing areas that could be helpful, but in my own experience, outside my department (Training and Development), nobody has commented me something, about this site.”

“I think in our area marketing the site need to be taken more seriously and sessions for clarification for users should be conducted plus that senior managers should indorse this initiative and ask their teams to use.”

Some of the respondents were first time or relatively new users and the quality survey proved to be a useful way of promoting the SalesOrg intranet site:

“We find the site very useful and attractive, however we must admit that we did not use it much due to lack of time. Our intention is to increase the time of navigation in order to take advantage of all of the contents of the site.”

“I have not used the Site, feel it can add value, will endeavour to use in the future.”
5 DISCUSSION

The results show that the quality construct is robust and is a reliable measure of intranet quality. Unsurprisingly, perceived usefulness is the strongest indicator of intention to use the intranet, followed by social influence. Quality is significant but does not have as large an impact on intention to use as do social influence and perceived usefulness. We speculate that once a quality threshold is surpassed attention turns to contextual factors such as whether the site is useful in doing a job. It seems reasonable to conjecture that a poor quality site would have a greater impact on behavioural intention because a poor quality site is a barrier to use while a high quality site merges into the background allowing usefulness and social influence to emerge to become of central concern. Social influence is likely to be a stronger factor in intranet applications than it is in general e-commerce applications due to the existence of formal management and organizational structures as well as powerful (but often hidden) social networks in organizations (Cross et al., 2001). Each organization will have a different balance and mix of formal and informal networks and this mix needs to be considered in any in-depth analysis of social influence through techniques such as social network analysis (Vidgen et al., 2007).

The relationship of behavioural intention and actual usage although highly significant is not strong. This is likely due to actual usage data being collected at the same time as intention data. Actual usage is a lagged effect and needs to be assessed at a different time than intention. Ideally, actual usage would be measured by objective data such as web server logs rather than being self-assessed. However, this is not straightforward since it requires that respondents are tracked through a unique code which means that the survey can no longer easily be administered anonymously.

There are numerous implications for practice and SalesOrg. First, an intranet acceptance survey can be a good way of promoting a new intranet site to new users. Second, the impact of social influence suggests that the site must be promoted and supported by senior management in order to build usage. This deployment of the formal organizational structure should be complemented by a study of the informal social networks (Cross and Parker, 2003) that support knowledge sharing in organizations (Cross et al., 2001), possibly leading to the nurturing of communities of practice (Wenger et al. 2002). Third, the content needs to be updated frequently to maintain user interest and repeat visits, and to bolster perceived usefulness and information quality. Fourth, the qualitative comments suggest that international aspects such as multi-lingual capabilities and performance/bandwidth constraints should be considered.

Although the findings of the research are significant, it is worth considering some of the limitations of the current study. First, although the sample has good explanatory power for medium-sized effects \( \beta^2=0.15; \alpha=0.05; 1-\beta=0.95 \), a larger sample could help to reveal smaller population effects. A further limitation of our research model is the absence of demographic and other factors, such as age, gender, geographical location, experience, use intensity, and so on. Since we may have a heterogeneous sample of a global nature, capturing and analyzing information on the sample may help to understand the behaviour of different groups of global employees. Second, the model was tested with a specific case study. Although the model is parsimonious, further work is needed to test whether it can be more widely applied to other contexts. For example it would be useful to examine corporate intranet sites that score low on the quality dimension to see if low quality has a relatively greater impact on behavioural intention. Third, the research is limited in terms of the measure of actual usage. The research is limited in that it adopts a single self-reported and unlagged measure of usage as a proxy for actual usage. This is not uncommon in similar studies. However, to tackle this deficiency, we hope that, in the future, a longitudinal study could be designed to measure actual usage over time.

6 SUMMARY

This study has successfully tested a model of intranet acceptance in the context of the sales and marketing department of a large multinational manufacturing company. The model is robustly
supported by the data and shows that behavioural intention is strongly driven by perceived usefulness, social influence and intranet quality, a second-order intranet quality construct comprising usability, design quality and information quality. In summary, this study has shed light on the considerably under-researched topic of intranet quality assessment and user acceptance. We hope that this research paves the way for others to begin investigating aspects of user behaviour and knowledge sharing surrounding this very important type of Web-enabled corporate information system.

References

APPENDIX: SURVEY INSTRUMENT

Intranet Quality

Usability
Learning to operate the site is easy for me
My interaction with the site is clear and understandable
I find the site easy to navigate
In general, I find the site easy to use

Design quality
The site has an attractive appearance
The design of the site is appropriate for this type of site
The site conveys a sense of competency
The site creates a positive experience for me

Information quality
The site provides accurate information
The site provides timely information
The site provides complete information
The site provides easy to understand information

Acceptance

Social Influence
People who influence my behaviour think that I should use the site
People who are important to me think I should use the site
The senior management have been helpful in the use of the site
In general, the organization has supported the use of the site

Perceived usefulness
Using the site enables me to accomplish tasks more quickly
Using the site increases my productivity
Overall, I find the site useful in my job

Intention to use
I intend to use the Site on a regular basis
I predict I will continue to use the site on a regular basis
I plan to use the site on a regular basis
Integrating Value-Driven Feedback and Recommendation Mechanisms into Business Intelligence Systems

Abstract

Business intelligence (BI) systems and tools are broadly adopted in organizations today, supporting activities such as data analysis, managerial decision making, and business-performance measurement. Our research investigates the integration of feedback and recommendation mechanisms (FRM) into BI solutions. We define FRM as textual, visual, and/or graphical cues that are embedded into front-end BI tools and guide the end-user to consider using certain data subsets and analysis forms. Our working hypothesis is that the integration of FRM will improve the usability of BI tools and increase the benefits that end-users and organizations can gain from data resources. Our first research stage focuses on FRM based on assessment of previous usage and the associated value gain. We describe the development of such FRM, and the design of an experiment that will test the usability and the benefits of their integration. Our experiment incorporates value-driven usage metadata - a novel methodology for tracking and communicating the usage of data, linked to a quantitative assessment of the value gained. We describe a high-level architecture for supporting the collection, storage, and presentation of this new metadata form, and a quantitative method for assessing it.

Keywords: Business Intelligence, Data Warehouse, Decision Support Systems, Metadata.
1 INTRODUCTION

Data repositories, along with the information systems (IS) utilizing them are critical organizational resources. While in the past the primary goal of managing data was to enable business operations, recent years have witnessed a transition toward extended use of data for business analysis and decision support, as firms attempt to gain competitive advantage by developing advanced data-analysis capabilities [Davenport, 2006]. Our research investigates the integration of feedback and recommendation mechanisms (FRM) into business intelligence (BI) system, which support activities such as data analysis, managerial decision making, and business-performance measurement. We define FRM as textual, visual, and/or graphical cues that are embedded into front-end BI tools and guide the end-user to consider using certain data subsets and analysis forms. The working hypothesis of our study is that the integration of FRM into BI tools will improve their usability and increase the benefits that end-users and organizations can gain from data resources.

BI involves acquisition, interpretation, and analysis of data to support managerial decision making. The software market offers a plethora of commercial platforms for supporting BI activities. Such platforms typically offer a variety of presentation capabilities (e.g., tables, charts, statistics, and advanced analytics), rapid-development utilities, and administrative tools. BI tools permit different forms of data usage such as reports, spreadsheets, OLAP (On-Line Analytical Processing), digital dashboards, and data mining. This variety of presentation and analysis forms confers the flexibility to use the same data resource for supporting different analytic tasks and to adapt the presentation style to end-users’ capabilities and skills. BI solutions often use a data warehouse (DW) as an infrastructure. The DW stores historical data about past business behavior, patterns and trends, covering a broad range of business perspectives and activities. In a typical DW, datasets are imported from internal organizational IS, such as enterprise resource planning (ERP) systems [March and Hevner, 2005], and/or from external sources, such as commercial data vendors or the Internet [West, 2000]. The imported datasets are being cleansed, transformed, consolidated, and stored in a centralized repository. This DW infrastructure is then used for creating smaller databases (also known as data marts) that can accommodate different analytical needs and thus serve as a platform for supporting BI activities.

The number of firms engaged in DW/BI implementations and the volumes of data managed in DW/BI environments have grown immensely in recent years. The increasing popularity of DW/BI can be attributed to benefits such as gaining broad business coverage, leveraging data-collection investments, and shortening implementation cycles [Counihan et al., 2002; March and Hevner, 2005]. BI systems enable analytical data usage toward supporting important decisions such as evaluation of corporate strategies [Cooper et al., 2000], optimization of financial investments [West, 2000], and customer segmentation [Even and Shankaranarayanan, 2008]. Yet, exploiting DW/BI environments is challenging both technically, due to the many components and the complexity of configuration decisions involved [Shankaranarayanan and Even, 2004], and organizationally, due to the substantial managerial support and financial resources needed [Wixom and Watson, 2001]. Moreover, DW/BI design and configuration decisions are often associated with substantial cost-benefit tradeoffs [Even et al., 2006]. So far, despite the increasing popularity of the DW and the BI concept in recent years, so far these concepts have attracted only limited academic research aimed at the challenge of increasing the effectiveness of DW/BI utilization from the end-user’s perspective.

A major limitation of current BI systems is that the common end-user, in search of an answer to a business question, often finds complex DW repositories too difficult to navigate for reaching the right data, and BI tools too difficult to use for answering the question. Furthermore, it is even not uncommon for end-user to know neither the right business question to ask, nor the full range of capabilities offered by DW repositories and BI tools. This limitation exists in current BI solutions, more so with sophisticated interactive tools, which offer advanced visual and analytical capabilities for dynamic and flexible investigation of data, and less so with simple static tools, which offer “snapshot” views in forms such as pre-defined dashboards, reports, or charts. The former classes of tools are
geared toward addressing the needs of the data analyst and often require a high level of expertise and an in-depth understanding of the data-resource analyzed, whereas the latter are geared toward supporting the novice user. In terms of economic tradeoffs [Even at al., 2006], sophisticated interactive BI tools offer higher benefit potential, but are costlier in terms of licensing fees and learning curves, whereas simple static BI tools are easier to implement and learn, but offer limited capabilities, and hence, lower benefit potential.

We suggest that FRM capabilities can facilitate more effective and efficient navigation by helping to reveal undiscovered potential of unused data and analysis forms, and thus add business value. In the reminder of this paper, we present the concept of integrating FRM into BI tools and highlight a few possible approaches for generating them. We focus on FRM that are based on assessments of previous usage of the data resource, and the associated value gains. To generate this form of FRM, we propose a novel methodology for tracking the use of data resources, termed as value-driven usage metadata, which integrates in assessments of both the frequency of use and the value gained. We describe architecture for supporting the collection, storage, and presentation of this new metadata form and a quantitative method for assessing it. We then describe the design of an experiment that will test the usability and benefits of FRM integration. To conclude, we highlight the potential contributions of the new concepts that we present – the integration of FRM into BI systems, and the collection of value-driven usage metadata - and discuss directions for future research.

2 FEEDBACK AND RECOMMENDATION MECHANISMS (FRM)

In this study, we propose to integrate FRM capabilities into BI systems in a manner that would maintain simple and easy-to-learn BI functionality, while highlighting new usage directions with a high benefit potential. We define FRM as textual, visual, or graphical cues that are embedded into BI tools, providing the end-user with feedback on the actions that s/he has taken so far, and guiding him/her to consider further actions – e.g., to use certain data subsets and/or to apply certain analysis forms. Providing recommendations is a common tool used in commercial website for enhancing the end-user’s experience. Such recommendations can be generated by other users, or by automatic agents, and they have been shown to have great influence on the end-user’s decisions [Adomavicius and Tuzhilin ,2005]. We suggest that similar enhancement of BI systems may have important contribution to a better usage of the BI tools, and improve the decisions made.

Figure 1 offers a simplified illustration of integrating FRM capabilities into a BI tool. The original tool (on the left-hand side) lets the end-user navigate through sales data along certain dimensions (customer, location, date, etc.). This BI tool treats dimensions equally in the sense that it offers access to all dimensions and leaves navigation decisions to the user. In the FRM-enhanced version of the BI tool (on the right-hand side), navigation decisions are still left to the users, who are now provided with some additional visual cues. The cue that Figure 1 demonstrates, for example, is a color-coding that suggests giving higher navigation priority to certain dimensions. Obviously, there are other possible
forms for visualizing an FRM besides color-coding, such as textual or graphical pop-up messages and side bars. Such FRM forms could indicate, in addition to the actual recommendations, the level of confidence and relevance of each recommendation based on the parameters that construct it.

We suggest that FRM, when being integrated into BI tools, can facilitate more effective and efficient navigation. This, in turn, may help revealing undiscovered potential of unused data and analysis forms thereby may increase the effectiveness of DW/BI utilization and add business value. In a preliminary assessment we have identified, at a high level, a few possible methods for constructing FRM:

(a) **Value-driven usage tracking:** Information resources contribute value through usage and experience. In the DW/BI context, the value can be conceptualized, for example, as an objective measure of usage success (e.g., in terms of revenue gained and/or costs saved), or subjectively via an assessment that reflects user satisfaction and willingness to pay [Ahituv, 1981]. Quantitative assessments of the value associated with the use of data resources have been applied to optimize data processes [Ballou et al., 1998], configure DW datasets [Even et al., 2007], and develop data quality metrics [Even and Shankaranarayanan, 2008]. The latter study has highlighted the importance of recognizing inequality in the value of data, suggesting that data objects (e.g., tables, attributes, and records) may vary significantly in their value contribution. Further, by evaluating a large real-life data resource, that study shows that quantitative assessments of inequality (e.g., Gini’s index), have important implications for key data management decisions, such as the prioritization of data quality improvement efforts. We suggest that tracking data usage and the associated value can be used to construct FRM in BI tools, toward directing data analysis and exploration, and improving decision outcomes – this by providing users with feedback on the outcome of their own usage, as well as an opportunity to benefit from learning how other users have gained value from using the same data.

(b) **Task and user characteristics:** The same DW/BI environment can be used to support a plethora of business processes and tasks, each with very different data usage needs. FRM capabilities can take into account such needs, by creating either task profiles that capture specific task characteristics or by asking expert users to identify certain data elements or analysis results that are more useful and relevant for a given task. For example, referring to the illustration in Figure 1, an FRM-enhanced BI tool could direct the end-user to slice the sales data along certain dimensions (e.g., customer and product) upon designing a promotion campaign, versus focusing on other dimensions (e.g., location and date) upon optimizing distribution policies. Likewise, an FRM-enhanced tool could recommend using certain presentation styles or navigation forms that can be driven by individual preferences, e.g., presentation in textual style versus graphical visualization, or navigating data systematically and incrementally versus using heuristics. Such preferences can either be explicitly identified by asking the user to state his or her preferences or implicitly inferred via a learning process, tracking and understanding the user’s interaction and identifying more-often used data and presentation formats.

(c) **Data mining:** FRM capabilities can also be driven by analysis of the data using algorithmic data-mining techniques. Data mining algorithms typically explore the information contained in data sources automatically and provide end-users with quantitative assessments and to enable them to extract and evaluate knowledge from this information. Data mining can suggest alternatives to decisions and actions that are about to be taken and allow users to re-consider these decisions and actions. Notably, some data-analysis tools include functionality that actively guides users through large data repositories, based on some statistical analysis of the data resource (e.g., Bissantz-DeltaMaster, [http://www.bissantz.com/deltamaster](http://www.bissantz.com/deltamaster)). A possible drawback of using statistical analysis and data mining methods to derive FRM is the risk that the recommendations, in this case, will be based solely on the data itself, not taking into account the context in which the data is used. This limitation is addressed to an extent by the two former methods, and should be considered when further researching the use of data-mining techniques for developing FRM.

Initially, our research will focus on the first approach for generating FRM (denoted (a) above), while the exploration of other two will be deferred to later stages. This form of FRM will be based on a novel methodology for tracking the usage of data resources, described in the following section.
3 VALUE-DRIVEN USAGE METADATA

Data environments are often described as a complex manufacturing process, consisting of interconnected acquisition, processing, storage, retrieval and usage stages [Ballou et al., 1998]. These processes can be conceptualized as having two high-level stages – data administration versus data consumption (Figure 2) - each associated with different stakeholders, goals, motivations and tasks [Lee et al., 2004]. Data administration addresses technical aspects – providing the ICT capacity needed to store and process data (e.g., hardware, databases, and back-end processes), and the tools for implementing information products. Conversely, data consumption would seek to transform information products into business value, through their usage. As the typical goal of data consumers is gaining business benefits and increasing profitability, they would be more focused on the value gained by effective use of data resources and less on the technical aspects associated with managing them.

Usage metadata - tracking the usage of data objects (e.g., tables, attributes, and records) and applications - has been identified as an important form of metadata [Shankaranarayanan and Even, 2004]. Usage tracking utilities are offered by some specialized commercial solutions and, to an extent, by DBMS and BI platforms. We term the common approach implemented by today’s solutions as frequency-driven usage metadata (the left-hand side of Figure 2). This approach is based on tracking queries and, by analyzing them, identifying the data objects being most-frequently used. The assumption underlying this approach is that frequent usage reflects higher importance. Accordingly, usage-tracking results may affect the configuration and the administration of data resources - e.g., transferring less frequently-used data to archives, and/or giving it lower quality-improvement priority.

</table>

Illustrative Example (part 1) - Assessment of Frequency-Driven Usage Metadata
To illustrate the creation of frequency-driven metadata, we use a simplified example above (extended later). The table in this example is used by marketing associates to decide which customers will be approached when promoting a new product. An associate would use a BI tool to investigate previous sale transactions, and the tool will generate queries directed to the customers tables, such as those demonstrated, to specify the subset of customers that will be targeted. Each query can be analyzed to detect which records and attributes are used to specify the selection (e.g., by parsing the WHERE clauses in the SQL statement) and, accordingly, the frequency of usage can be calculated. Frequency-driven metadata collection may provide important inputs to the data administrator, toward improving system design and prioritizing administration efforts. It is common in databases, as highlighted by the example above, that some records and attributes are accessed more frequently than others. In a larger real-world databases, this differentiation may lead to a decision to grant the more frequently used records and attributes a higher priority in terms of data quality maintenance – i.e., watch these database objects more closely, detect and correct defects, and make sure to keep them up-to-date.

While seeing the merits of collecting metadata on usage frequency for data administration, we question - does it truly address the needs of data consumers? One could argue that, to an extent, frequent usage reflects higher significance of certain data components to data consumers; hence, higher value-contribution potential. On the other hand, we suggest that frequent usage may reflect certain stagnation and a tendency to "dig into the same well" - re-using certain data subsets repetitively, while possibly ignoring unused subsets with high contribution potential. Therefore, a potential risk with basing data management decisions solely on frequency-driven metadata (e.g., due to a removal of data that is less-frequently used from the active repository into an archive) is a possible loss of opportunity to benefit from records and attributes that data consumers have neglected to use so far, which may permit new forms of data usage.

There is possibly no "clear cut" answer to this question, as it largely depends on the business context and the usage tasks. However, we suggest that important insights can be gained from tracking and considering not only actual data usage, but also the associated value gains. The benefits gained from the use of information products have been conceptualized as *utility* [Ahituv, 1980]. Utility assessments have been used to optimize the configuration of data processes and resources [Ballou et al., 1998; Even et al., 2007] – tasks typically associated with *data administration*. We suggest that, beyond the benefit offered to data administration, collecting quantitative assessment of the business-value gained as a form of metadata can improve *data consumption* as well. Business value can be measured, for example, in terms of decision outcomes (e.g., production increase, customers’ purchase intent), revenues and profitability. Organizations capture such value measurements today, but rarely link them to the data resources and the decision-support tools that were used in the process of value generation.

Value-driven collection of usage metadata (Figure 2) aims at establishing such a link. To demonstrate this approach, we have successfully implemented a working prototype of a module that captures and stores value-driven usage tracking as a metadata layer. In its base, the module applies a similar approach to the one described earlier for collecting frequency-driven metadata - capturing the queries directed at a data resource, and parsing them into specific components. However, the module also collects different types of value measures (e.g., throughput, performance, and income), which are associated with a specific decision task. In certain cases, value assessments can be based on the same data resource (sale transactions, for example, can often be linked to a specific marketing campaigns that were based on a certain analysis of previous sales). In other cases – such assessments may use other information resources such as CRM and accounting systems. The module associates the value with certain decision tasks and then, through a mechanism of inference (e.g., by comparing the user-name and the time stamp), to the queries that have supported each tasks. Establishing this link between decision tasks and the underlying queries permits the creation of integrated metadata that associate business value with specific data components. An API (Application Programming Interface) can provide this form of usage metadata upon demand through function calls. Such metadata can be integrated into front-end tools, enhance the presentation, and communicate important information on the frequency of usage and on the associated value to both data consumers and administrators.
Once the link between decision tasks and queries is established, different methods can be considered for attributing value to specific data objects. For illustration, we describe here a relatively simple method, which assumes that value is attributed to the last in a sequence of queries that support a decision task. We assume that to support a certain decision, users query repetitively a certain tabular dataset with \( N \) records indexed by \([n] \) and \( M \) attributes indexed by \([m] \). We consider \( Q \) queries indexed by \([q] \), each associated with a business value \( V^q \). The binary indicator \( R_{n}^q \) indicates whether record \([n] \) was retrieved by query \([q] \) (\( R_{n}^q = 1 \)), or not (\( R_{n}^q = 0 \)). Similarly, \( R_{m}^q \) indicates whether attribute \([m] \) participated in query \([q] \) or not. The value of a certain query \((V^q)\) is attributed between the participating data items, using a certain value-attribution function \(V_{n,m}^q = u(V^q, R_{n}^q, R_{m}^q)\), such that \( V^q = \sum_{n,m} V_{n,m}^q \). For simplification, we use here an equal attribution of value among all participating data items. Accordingly, the overall value of a certain data items \( V_{n,m}^q \) is given by:

\[
(1) \quad V_{n,m}^q = \sum_{q=1}^{Q} V_{n,m}^q = \sum_{q=1}^{Q} u(V^q, R_{n}^q, R_{m}^q) = \sum_{q=1}^{Q} V^q / \left( \sum_{n=1,N} \sum_{m=1,M} R_{n}^q R_{m}^q \right),
\]

- \( Q, q \) - The number of queries performed, and the corresponding index, respectively
- \( M, N \) - The number of attributes (indexed \([m] \)) and records (indexed \([n] \)), respectively
- \( V_{n,m}^q, R_{n}^q, R_{m}^q \) - Query \([q] \) value, its attribution to data item \([n,m] \), and the attribution function used
- \( R_{n}^q, R_{m}^q \) - Binary indicators of the participation \((=1)\) of record \([n] \) and attribute \([m] \) in query \([q] \)

To demonstrate the value allocation described above, we extend the previous example. We assume that each query has led to a certain promotion campaign in which a group of customers has been approached. Some customers may have responded to the campaign by making certain purchases, and the overall value attributed to a query is the total purchase amount. As illustrated, this value proxy may significantly vary among queries. We now use the allocation (Eq. 1) to assess the relative value of each data object. As illustrated by color-coding – some records, and attributes may turn out to have significantly higher value than others, and the value attribution “map” may look significantly different than the one when basing the attribution of usage frequency.

**Illustrative Example (part 2) - Assessment of Value-Driven Usage Metadata**

We can potentially gain important insights by analyzing the value distribution, along with the assessment of frequency of use. For example, the **Income** attribute, which was not frequently used, is associated with the highest value, while the **Children** attribute, which was more frequently used, is associated with lower value. Insights as such can be transformed into valuable recommendations for a marketing associate the next time s/he plans to run a similar campaign. The decision value of each of the participants is being saved in a metadata repository. Using the API, a BI tool, which was designed to access to the value-driven usage metadata can now demonstrate value differentials and distribution, toward improving the decisions made, as demonstrated in the experimental design described next.
4 EXPERIMENT DESIGN

This section describes the design of a lab experiment, currently under final preparation stages, that tests the integration of FRM based on previous usage and the associated value.

4.1 Research Model and Working Hypotheses

The first research stage will be directed by the theoretical model shown in Figure 3. Some model variables will be measured with the test experiment tool described in the following section, while others will be assessed using a previously-tested questionnaire.

**Dependent Variable – Performance:** The dependent variable, reflecting the ability of a user to effectively perform a task with tool support, will take one of two forms:
- Objective – actual decision outcome and time it takes to complete the decision task
- Subjective – perceived usefulness and ease of use

Previously tested models, such as TAM (technology acceptance model [Davis, 1989]), have suggested that a higher sense of usefulness and ease of use increase the likelihood of user acceptance. While this study intends to focus mainly on performance, the experiment described below will permit assessing acceptance and validating the anticipated link between performance and acceptance.

**Independent Variables:** The independent variables will be Experience and FRM inclusion:

a) **Experience** can be measured in terms of:
- Learning curve – the time a user spends using and mastering the tool
- Familiarity – the extent to which the user has previously used similar tools in the past

It is reasonable to assume that an experienced user (in terms of learning curve and/or familiarity) will perform better than a non-experienced user; hence,

- **H1:** Usage Experience positively affects Performance

b) Our key assumption is that the inclusion of an FRM will offer a major improvement in the usability of BI tools and therefore in user performance; hence,

- **H2:** FRM inclusion positively affects Performance

As discussed in the previous section, we suggest that value-driven collection of usage metadata is superior to frequency-driven collection; hence:

- **H2a:** The Performance effect of FRM that are based on value-driven metadata will be superior to the effect of FRM based on frequency-driven usage metadata alone
It is reasonable to assume a possible synergistic effect between the two independent variables, i.e., that the overall effect of Experience and FRM inclusion is higher than the effect of each alone. Hence,

- **H3: The interaction effect between Experience and FRM inclusion is positive**

**Moderating Variables:** It is reasonable to assume that certain user characteristics will moderate the effect of Experience and FRM inclusion on Performance. The moderating variables that will be tested are Motivation, the user’s motivation to perform well, and Expertise, the extent to which the user is knowledgeable in the particular task domain. Studies (e.g., Siegel and Watts-Sussman [2003]) have shown Motivation (or involvement) and Expertise to have moderation effects on the usefulness of information resources and hence on their acceptance and adoption. Hence,

- **H4: The greater the user’s Motivation, the more Experience affects Performance**
- **H5: The greater the user’s Motivation, the more FRM inclusion affects Performance**
- **H6: The greater the user’s Expertise, the more Experience affects Performance**
- **H7: The greater the user’s Expertise, the more FRM inclusion affects Performance**

**Control Variables:** The experiment will control for a few additional variables - age, gender, language fluency, and possibly others.

### 4.2 Experiment Procedures and Tool

The model and the derived hypotheses will be tested in a laboratory setting. In the planned experiment, all participants will be asked to perform a certain decision task repetitively, aided by a BI tool. The decision outcomes, as well as the actual usage of the tool and the data resources will be tracked and measured. This will enable data collection that will allow measuring some of the variables (as described later in Table 1). In addition to tracking decision outcome and actual usage, users will be asked to complete a questionnaire, which will enable data collection on remaining variables.

Due to space limitations, we do not describe here in details all the experiment preparation procedures, but rather explain the principles that guide its design.

**The decision task:** the participants will act as marketing associates on behalf of a firm that offers a certain product or service to its customers (e.g., a vacation package). To decision will be aided by a large database that includes two main tables:

- **A list of customers,** in which each associated with a given set of attributes (e.g., Income, Gender, Marital Status, and Number of Children). Based on the mix of attribute value – each customer \([t]\) will be associated with a set of likelihood numbers \(P_{t,z}(z = 0, 1, 2, \ldots)\) of purchasing \(z\) units within a given time period, such that \(\sum_{z} P_{t,z} = 1\), and \(Q_{t} = \sum_{z} z P_{t,z}\) is the mean number of purchases.

- **Purchases transactions,** based on the purchase likelihoods defined per customer. A random generator will produce a large number of purchase transactions for a broad period of time.

Given access to this database, the participants will be asked to choose a customer segment that will be targeted. Approaching a customer and offering him/her a promotion has a given cost (e.g., the mail delivery fee, or the time needed for a phone call); hence, the larger is number of customers approached – the higher is the cost. Each customer is associated with certain likelihood to purchase a certain quantity of the service and, accordingly, the overall decision value is defined as:

\[
(2) \quad V = \sum_{i=1}^{T} I_{i} (SQ_{i} - C), \quad \text{where}
\]

- \(V\) - The overall decision
- \(T\) - The number of customers (indexed \([t]\))
- \(S, C\) - The revenue per service item sold, and the promotion cost per customer, respectively
- \(Q_{i}\) - The expected number of item that customer \([t]\) will purchase \((Q \geq 0)\)
- \(I_{i}\) - A decision whether to include customer \([t]\) in the promotion campaign \((=1)\) or not \((=0)\)
A decision to include a customer may increase revenue, but at a cost. Obviously, a decision maker would prefer to include only customers for which the expected revenue is higher than the cost (i.e., only $t$ for which $SQ_t > C$). The expected quantity $Q_t$ is defined in advance, but not exposed to the decision maker explicitly. The user will be asked to infer which customers are likely to purchase the service by observing customers’ past purchases. Moreover, the decision maker will not select specific customers, but rather will be asked to define customer segments. The segment definition will be based on a given set of customer attributes and a selection of a certain criterion per attribute (e.g., “All high-income married male customers, with 2 children or more”), where the user may choose to avoid defining selection criteria in certain attributes.

To aid the decision, each participant will be provided with a BI tool, such as the one illustrated by Figure 1. The BI tool will permit exploring past transactions, analyze purchase activity, and determine the revenue associated so far with each customer segment. The tool presents the distribution of certain measures (Revenues associated with past transactions) along certain customer attribute. The visual display imitates a decision tree. Starting at the high-level node, which reflects the entire population of customers, the user may choose an attribute (e.g., Children) along which he wishes to segment the data. For a given attribute value (e.g., Children = 2), the user may choose to segment the data along another attribute (e.g., Status), and so on. Based on the different customer segmentations that are explored by using the BI tool – the user finally selects the customer segments that will be targeted. Once the selection is made – the overall value of the selection is calculated (Eq. 2), the value is attributed among the different attributes and records (Eq. 1), and the attribution is saved in the value-driven usage metadata module. As the experiment participants keep performing the decision tasks repetitively – the value-driven usage metadata is accumulated and enhanced.

The left-hand side of Figure 1 illustrates the BI tool in its basic form, which does not include FRM. The enhance form, illustrated in the right-hand side of Figure 1, includes certain FRM enhancements – indication of the total value and the value distribution (a variance measurement) associated with the different attributes, at each node. The recommendations change dynamically, depending on the node that the user selects. The FRM enhancements are based on the usage metadata that was accumulated while participants keep performing the decision task repetitively. To help testing the hypotheses, the group of participants will be divided into a few sub-groups, and some variability will be created in the tasks that each sub-group is asked to perform (Table 1).

<table>
<thead>
<tr>
<th>Hypothesis</th>
<th>How the hypotheses will be tested</th>
</tr>
</thead>
</table>
| H1: Experience affects Performance | • Participants will be asked to perform the same task repetitively  
• Some participants will provided with the same BI tool in all sessions  
• Participants will be asked about past experience with similar tools |
| H2: FRM affects Performance | • Initially, participants will perform the task using BI tools with no FRM  
• Later, some participants will be offered BI tools with FRM  
• Some participants will perform the task with no BI support at all |
| H2A: Value-Driven FRM are superior to Frequency-Driven FRM | • Some participants will be provided with FRM enhancement based on value and frequency assessments, while others will be provided with FRM enhancement based on frequency alone |
| H3: Experience-FRM interaction | • Experience/FRM – same as the above  
• Certain statistical regression methods permit testing interaction |
| H4, H5: Motivation moderation | • Experience/FRM – same as the above  
• Some participants will be offered performance-based compensation |
| H6, H7: Expertise moderation | • Experience/FRM – same as the above  
• Participants will be recruited from different expertise populations |
| Control | • The test will validate assumption that the control variables have no substantial effect in the given setting |

Table 1. Hypotheses Testing
5 CONCLUSIONS

Our research investigates the integration of feedback and recommendation mechanisms (FRM) into BI tools. The working hypothesis that guides our study is that the integration of FRM into BI tools will improve their usability and increase the benefits that end-users and organizations can gain from data resources. We have described an experiment, currently under preparation, for testing the usability and the benefits of such integration in terms of improving decision-making processes. We see this experiment as a first “proof of concept” step of testing the FRM-integration idea, toward gaining insights on its usability and benefits. The controlled lab environment, in which we intend to apply the test, will permit a more precise data collection on usage patterns and value generation – what is often hard to achieve in real-world environments. Nevertheless, testing FRM integration in real-world environments would be an important follow-up step in furthering this line of research.

Another key contribution of our study, which links to the previous, is the introduction of a novel approach for usage tracking in data environments. This approach suggests that integrating quantitative assessments of usage-frequency together with the associated value gained may offer substantial benefits to data administration and consumption. Joint frequency and value assessments can help identifying unused data subsets with high value-contribution potential, may highlight flaws with repetitive use of data and, consequently, motivate new usage forms. Further, value assessment can direct design decisions, and help prioritizing data maintenance efforts. Relying on usage frequency alone might promote usage stagnation and loss of opportunity to gain new forms of benefits. Complementing frequency assessments with value assessments may help “closing the loop”, in terms of providing feedback based on usage performance, and reducing the potential risks. First, value allocation gives higher weight to past usages with high contributions. Second, it can reflect variability in the importance of different subsets depending on the usage context. Lastly, it can help detecting data subsets with high contribution potential that have not been frequently used. Obviously, future extensions to our study will need to address some key limitations of this approach:

(a) Quantifying value – organization maintain performance measurements (e.g., productivity, income, and profitability) that can be possibly linked to decision tasks. However, decision performance may depend on other resources such as human knowledge and financial assets. Further, the value depends on the usage context, and value assessment for a certain type of usage tasks does not necessarily apply to others. Further, value is time-dependent, as data that can be used effectively at a certain point of time, might become obsolete later. We hasten to say that the value-allocation methodology, which we apply in this study, appears to be a better fit to operational environments in which decision tasks have a high degree of repetition, and causal relations between data usage and business performance are easier to establish. Promotion-campaign management, such as in our illustrative example would be a good representative for this type of decision-making. Financial-investment decisions would be another example for data-driven decisions, in which outcomes are measurable (e.g., the change in the value of the financial asset) and linkable to the data resources being used. Conversely, quantifying the value of decision outcomes might turn out to be more challenging in strategic decision scenarios, which are not repetitive in nature and often relay on information sources other that organizational data repositories.

(b) Linking value to specific queries - performance assessments are rarely linked explicitly to the data resources and tools used. Our preliminary prototype includes inference mechanisms for creating implicit links – e.g., based on the user name, and/or time proximity. Obviously, implicit links cannot be absolutely precise and might bias the value allocation significantly. Establishing explicit links will require stronger metadata integration between systems and, likely, redesign of data environments (e.g., joint codes that link each decision task and queries). One could question whether or not making such a high investment in redesigning data environments and BI tools would justify the benefits gained.

(c) Attributing value to specific data objects – the attribution system has critical impact on the results. Our prototype attributes value only to the last query in the sequence that generated the decision, and distributes the value equally between all the data that were retrieved. A different allocation method
may consider, for example, spreading the usage value along all queries and/or consider possible interactions among attributes – hence, unequal allocation.

Finally, we would suggest that future extensions of this study should further explore links to the research of recommender systems. Recommender systems are common in web-based user interfaces (e.g., rating systems in E-commerce sites), but less so in BI tools. Adomavicius and Tuzhilin [2005] identify the need to incorporate contextual information into the recommendation process. As value assessments depend on the context in which data is used [Even and Shankaranarayanan, 2008], we would suggest that the value-driven metadata approach may help such incorporation.

WHY DO PEOPLE BUY VIRTUAL ITEMS IN VIRTUAL WORLDS? AN EMPIRICAL TEST OF A CONCEPTUAL MODEL

Yue Guo, Norwich Business School, University of East Anglia, Norwich, United Kingdom, yue.guo@uea.ac.uk

Stuart Barnes, Norwich Business School, University of East Anglia, Norwich, United Kingdom, stuart.barnes@uea.ac.uk

Abstract

In the past few years, virtual worlds – such as Second Life, World of Warcraft and RuneScape – have demonstrated the potential to be a promising online business model. Millions of paying users around the world now participate in virtual worlds and trade virtual items with each other. However, little empirical research has been conducted into players’ purchase behaviour in virtual worlds. To address this research gap, the current study develops and tests a conceptual model of purchase behaviour in the context of virtual worlds. An online survey was conducted within Second Life (n=250) and SEM-PLS (Structural Equation Models by Partial Least Squares) was used to confirm the conceptual model. Among the statistically significant paths found in the conceptual model, effort expectancy, performance expectancy, perceived value, customisation, habit, advancement and enjoyment all have strong impact on virtual world residents’ purchase intention. The study rounds off with a discussion and conclusions, highlighting implications for practice, research limitations and promising areas for future research.

Keywords: Structural Equation Model; PLS; Virtual World; Purchase Behaviour; Second Life.
1 INTRODUCTION

In the past few years, virtual worlds have demonstrated the potential to be a novel online transaction environment compared to the Web-based context; thousands of participants may not only interact with one another, but also buy and sell virtual items in a virtual world. At present, popular 3-D virtual worlds are mainly divided into two categories: game-oriented virtual worlds (e.g. World of Warcraft, RuneScape and EverQuest) and socially-oriented virtual worlds (e.g. Second Life, There and HiPiHi) (Bainbridge 2007, Guo & Barnes 2007). The major difference between the two types is that a game-oriented virtual world provides a story-lined scene and fixed contents while a socially-oriented virtual world attempts to provide near unlimited freedom in a simulated world in which participants use their imagination to create desired world contents. Regardless of virtual world type, typically virtual items can be traded for real world currencies within virtual worlds or via other third-party exchange platforms. DFC Intelligence (2007) estimated that virtual worlds will produce US$13 billion and over 40% of revenues will be attributed to trading virtual assets by 2012. In the face of such a large quantity of virtual item transactions, understanding the latent psychological processes that typically induce players’ purchase behaviour in virtual worlds becomes of obvious importance.

The majority of previous studies in this area have focused on legal issues with regard to virtual item transactions (e.g. Lastowka & Hunter 2004, Lederman 2007) or have explored the impact of virtual worlds on the real world from a purely economic point of view (e.g. Castronova 2001, 2002). Although several prominent explanatory models of behaviour-expectation, such as the Technology Acceptance Model (TAM) (Davis 1989), have been developed and applied to explaining online shopping behaviour or the adoption of information systems (IS), virtual item purchase behaviour in virtual worlds is likely to be quite different and requires new conceptualisations. Moreover, we also need to examine whether factors related to online purchase behaviour still exert considerable influence in the context of virtual worlds. A few recent studies have begun to notice virtual item transactions and offered new insights into players’ purchase behaviour in virtual worlds (e.g. Yee 2005, Lehdonvirta 2005, Oh & Ryu 2007, Nojima 2007). Nevertheless, these studies are limited in the sense that they are only based on a descriptive or theoretical analysis of virtual item transactions and they lack the rigour of empirical analysis. Their research findings need to be tested by further quantitative research using large-scale samples before making generalisations.

In order to detect factors determining purchase behaviour in virtual worlds for theory building, this research empirically develops and tests a theoretical model of virtual item purchase behaviour in virtual worlds based on established behaviour-expectation theories and previous exploratory research into virtual item transactions. The research employs a survey in the virtual world of Second Life (SL) and analyses the research model by way of a structural equation modelling approach. The outcome from this research is an extension to existing behavioural theories via new constructs validated in the virtual world domain.

The paper is organised as follows. In the next section we examine the salient literature on virtual item purchase behaviour. This is followed by an explication of the research model. Section four describes the study design and method adopted in the research, and the results are presented in section 5. Finally the paper rounds off with a discussion and conclusions, including limitations and implications for future research and practice in this very new area of investigation.

2 REVIEW OF EXTANT LITERATURE ON VIRTUAL ITEM PURCHASE

Although virtual item purchase behaviour is a relatively new transaction phenomenon and therefore research is limited, the prediction of purchase behaviour in the context of Web sites has been long studied by previous literature using prominent behaviour-expectation models, such as the Theory of
Reasoned Action (TRA) (Fishbein & Ajzen 1975), the Theory of Planned Behaviour (TPB) (Ajzen 1991) and TAM. These established theoretical models have shown high reliability and the predictive power of social behaviour across a variety of contexts. We thoroughly reviewed previous studies published since 1992 on the adoption of IS especially related to Web-based shopping behaviour. According to the literature, the most common construct variables for Web-based online purchase behaviour are performance expectancy, effort expectancy, social influence, perceived enjoyment, IS quality, facilitating conditions, trust and risk. Guo and Barnes (2007) first developed a theoretical model for explaining purchase behaviour in virtual worlds based on five prominent theoretical models such as, TAM, TPB and UTAUT (Venkatesh et al. 2003). Guo and Barnes (2009) further revised the preliminary theoretical model using focus groups and offered a deep insight into the whole psychological processes of virtual item purchase behaviour in virtual worlds from three perspectives: motivators for pursuing advanced virtual items, the reasons for using virtual world trading platforms to obtain desired virtual items, and factors with regard to making a specific purchase decision. All of the above factors were introduced into the revised theoretical model based on focus group findings—except for risk. On the one hand, many kinds of risk are not as relevant to virtual items, such as performance risk (Guo & Barnes 2009); on the other hand, the influence of risk on purchase behaviour in the context of virtual worlds is mediated by trust.

Yee (2005) focused on investigating players’ motivations for participating in massively multiplayer online role-playing games (MMORPGs). Yee’s research findings showed that customisation and achievement were players’ two major motivations for pursuing advanced virtual items in virtual worlds. Oh and Ryu (2007) analysed the item-selling based payment model used by two virtual worlds, “Kart Rider” and “Special Force”. Their research explored some factors stimulating players to pursue valuable virtual items in virtual worlds including improving game capability and quickly upgrading levels. Lin and Sum (2007) pointed out that virtual world operators may not only charge subscription fees, but also obtain significant profits by selling functional or decorative virtual items. A functional virtual item may increase a character’s overall ability to compete (e.g. advancing character levels or moving one’s avatar more quickly) while a decorative virtual item helps players to customise the appearances of their characters.

Based on Guo and Barnes’ (2009) research findings, we realise that it is necessary to distinguish between general purchase behavioural intention and special purchase behavioural intention in this research. With regard to real product/service purchase behaviour, general purchase behavioural intention refers to the subjective probability of one’s engagement in purchasing desired products/services through the Web-based purchase manner while special purchase behavioural intention can be viewed as an immediate indication of an individual's readiness to perform a given purchase from the specific Web site for a specific product or service. General purchase behavioural intention demonstrates an individual’s intention to purchase desired goods/services through the Web-based manner rather than other manners, such as offline stores, telephone and catalogue, even if the individual still has no idea where he/she will make a purchase (i.e. identifying a specific Web site). Users possibly form their special purchase behavioural intentions and immediately result in an actual purchase when they browse an online shopping Web site. Most previous studies on Web-based shopping behaviour did not explicitly distinguish between general purchase behavioural intention and special purchase behavioural intention because an individual’s belief about shopping in a specific Web site and about the Web-based shopping manner are the same in most cases. In other worlds, factors related to users’ a choice between the Web-based purchase manner and other purchase manners are the equivalent of factors identifying a specific shopping Web site, such as, convenience, price, service quality, risk and so on. For example, if a user perceives that using a specific Web site is convenient, he/she usually believes that the Web-based shopping manner is more convenient than other purchase manners. Similarly, if users consider that the Web-based shopping manner is more convenient than other purchase manners, they usually have enjoyed the convenience of shopping in a specific Web site.
However, the situation in virtual worlds is quite different and more complex because players have other virtual item obtaining manners in addition to the in-world purchase manner. For example, players may get desired virtual items in virtual worlds through in-world non-purchase manners, e.g. fighting with non-player characters (NPCs), which may randomly drop virtual items, or by finishing quests in game-oriented virtual worlds, and via self-design in socially-oriented virtual worlds, in addition to buying from other players. Furthermore, buying from other players can be achieved through Web-based platforms or face-to-face approaches (i.e. out-of-world purchasing manners). Compared to virtual items, perhaps purchasing in the real world (i.e. using real money) is the only method to get desired real products/goods and very limited in-world trading platforms have been used for purchasing real products/goods so far (i.e. using virtual currencies).

With regard to virtual item purchase behaviour, general purchase behavioural intention refers to the subjective probability of one’s engagement in obtaining desired virtual items through the purchase manner in virtual worlds while special purchase behavioural intention is only an immediate indication of an individual’s readiness to perform a given purchase from a specific vendor for a specific virtual item in virtual worlds. First, general purchase behavioural intention in the context of virtual worlds is determined by an individual’s overall belief that in-world shopping manner has greater relative advantages and lower complexity than other in-world non-purchase manners and out-of-world purchase manners. Second, special purchase behavioural intention is mainly determined by a player’s belief that a specific virtual world vendor has relative advantages than others (e.g. good reputation and reasonable price). With respect to virtual world transactions, players still have to make a series of specific decisions (e.g. identifying a specific vendor) prior to actual purchase even if they have formed a strong intention to obtain desired virtual items through buying in virtual worlds (i.e. general purchase behavioural intention). Consider the following example of a player in a game-oriented virtual world for further illustrating the differences between general purchase behavioural intention and special behavioural purchase intention. A player has planned to obtain advanced weapons for improving a character’s power through buying from other players in the virtual world, which refers to a general purchase behavioural intention. However, he or she has to identify a specific purchasable virtual item based on his/her personal conditions prior to making an actual purchase from enormous range of alternatives because every virtual item has various attributes (e.g. strength, level requirements for use or durability) even though two virtual items may be of the same item type, e.g. a virtual sword. Moreover, he or she also needs to identify a suitable vendor for the desired virtual items. In case the player has formed intention to purchase a specific virtual item from a vendor, we claim that he or she has formed a special purchase behavioural intention at this point.

In this research, we only focus on capturing key determinants influencing players’ general intention to purchase virtual items in virtual worlds rather than special purchase intention with a focus on specific purchase decisions. A clear distinction between general purchase behavioural intention and special purchase behavioural intention with a focus on players’ specific purchase decisions can keep our conceptual model parsimonious as much as possible. A parsimonious model is easier to comprehend and should obtain a high degree of generality. Factors identified by previous literature are not included this research if they relate predominantly to players’ special purchase intention, e.g. trust (Guo & Barnes 2009, McKnight 2002). It is worth noting that the term “purchase behavioural intention” used in later sections pertains primarily to general purchase behavioural intention unless otherwise noted.

3 FORMULATION OF A CONCEPTUAL MODEL OF PURCHASE BEHAVIOUR IN VIRTUAL WORLDS

Based on a thorough review of previous studies on virtual worlds and a focus on players’ general purchase intention, a conceptual research model was formulated (see Figure 1). Eight constructs appear to be significant determinants that influence players’ virtual item purchase behavioural intention and actual purchase behaviour in virtual worlds including: effort expectancy, performance expectancy, perceived value, advancement, customisation, perceived enjoyment, social influence and
habit. Moreover, performance expectancy, effort expectancy and perceived value are identified as extrinsic motivators, while perceived enjoyment, advancement and customisation are three intrinsic motivators based on Verhagen et al.’s (2008) typology of motivations for adopting virtual worlds. Extrinsic motives refer to the technical performance of an activity, which are relevant to the achievement of goals/benefits external to the system-user interaction while intrinsic motives refer to users undertaking an activity for creating pleasurable experiences, which are derived from the system-user interaction per se (Van der Heijden 2004; Koo 2009). The importance of effort expectancy, performance expectancy, perceived enjoyment and social influence has been broadly discussed in previous literature on behaviour-expectation in different contexts include general IS adoption, Web-based shopping and virtual world purchase behaviour (e.g. Venkatesh et al. 2003, Guo & Barnes 2007, 2009, Davis et al. 1992). For example, Guo & Barnes (2007, 2009) proposed that the two constructs, effort expectancy and performance expectancy are utilitarian factors contributing to explaining the relative advantages of using in-world trading platforms, which in turn influence players’ purchase channel choice when considering buying desired virtual item from others. Similarly, Venkatesh et al. (2003) suggested that effort and performance expectancies are two major beliefs with regard to system characteristics in the context of IS adoption (i.e. in-world trading platforms in this case). TPB, DTPB (Taylor & Todd 1995) and UTAUT proposed that social influence has an important impact on behavioural intention. In addition, some prior studies (e.g. Van der Heijden 2004, Dahlberg et al. 2003, Lee et al. 2006, Moon & Kim 2001, Guo & Barnes 2007, 2009) proposed the importance of hedonic factors (i.e. perceived enjoyment) for explaining users’ IS adoption behaviour. In the remainder of this section, we place emphasis on providing the theoretical justification for four new empirical constructs (i.e. advancement, customisation, perceived value, and habit).

First, we viewed “customisation” and “advancement” as two subcomponents of general achievement because they represent players’ two major desires to achieve in a virtual world. Lehdonvirta (2005) applied Yee’s (2005) motivations to analysing four different virtual worlds. According to their research findings, all motivations contributing to virtual item purchase behavioural intention can be covered by the two constructs. On the one hand, players can derive a great sense of achievement from becoming powerful, rapidly increasing game level through purchasing functional virtual items or accumulating rare virtual items or money. On the other hand, players may get self-esteem and a sense of satisfaction through personalising their character appearances or showing a unique style using decorative virtual items (Yee 2005). For example, in the famous socially-oriented virtual world, “Three.com”, “much attention is given to personal appearance, and one of the main activities in There is designing virtual clothes and selling them” (Brown & Bell 2004, p. 1). Therefore, we propose that “advancement and “customisation” should be two important intrinsic motivators for purchasing virtual items in virtual worlds in addition to perceived enjoyment.

Second, perceived value has been defined as “the consumer’s overall assessment of the utility of a product based on perceptions of what is received and what is given” (Zeithaml 1988, p. 14). Within this definition, Zeithaml (1988) proposed four kinds of meanings of value: (1) low price, (2) whatever one wants in a product, (3) the quality that the consumer receives for the price paid, and (4) what the consumer gets for what they give (p. 14). A product of perceived value is usually measured according to the difference between the perceived benefits that a product delivers and its perceived costs, or the ratio of the perceived benefits to the perceived costs. Here, costs include monetary costs (i.e. currency) and non-monetary costs (i.e. time and energy). Previous studies have proposed that there are different channels to get desired virtual items in virtual worlds. Thus, players first need to make a selection from these channels when pursuing desired virtual items through a comprehensive virtual item benefit and associated cost valuation (Castronova 2001, 2003, Guo & Barnes 2009). Consequently, it seems that the construct “perceived value” is appropriate to cover these dimensions.

Third, many previous studies proposed that habit and purchase behavioural intention may be used as two independent antecedents of actual behaviour (e.g. Mittal 1988, Tuorila & Pangborn 1988). Moreover, the moderating effect of habit on the relationship between purchase behavioural intention and actual purchase behaviour is added to the conceptual model. Limayem et al.’s (2007) research
findings proposed that the relationship between behavioural intention and actual IS continuance behaviour may be weakened when an individual has established a strong habit to use it. Here, we place research emphasis on one-off purchase behaviour rather than continuance behaviour because the latter is quite difficult to measure in the context of virtual worlds. Unlike other IS adoption behaviour, it is impossible that a player never uses virtual world trading platforms in virtual worlds especially so in a new virtual world. Inexperienced players are relatively unaware of outside trading channels (e.g. Web-based platforms or face-to-face). During the early stage of virtual world participation, Second Life users may purchase basic virtual items for daily life in virtual worlds. Moreover, an individual may obtain many free virtual items through Second Life trading platforms. Therefore, we believe that Second Life players may have established the habit of using virtual trading platforms to some extent even if they first spend considerable money on purchasing valuable virtual items for meeting their intrinsic motivators. These basic or free virtual items have low market values as they can only satisfy players’ basic survival requirements, which are not our research target. In this research, we only consider players’ commercial purchase behaviour for achieving their goals (i.e. buying valuable virtual items for advancement and customisation) in a virtual world. Thus, there is no conflict when adding habit into the conceptual model even if we focus on initial purchase behaviour towards valuable virtual items.

Table 1. Constructs and definitions used in this research.

Note that, in this research, perceived enjoyment is defined as the extent to which fun can be derived from participating in virtual worlds instead of using virtual item trading platforms (systems). Guo & Barnes (2007, 2009) suggested that when a player perceives that participation in a virtual world is an enjoyable experience, he or she will have an incentive to obtain advanced virtual items for achieving personal goals thereby possibly purchasing virtual items in virtual worlds. Therefore, we suggest that perceived enjoyment should significantly influence a player’s behavioural intention to purchase virtual items in virtual worlds.
4 STUDY DESIGN AND METHOD

In this research, Second Life was selected as the target virtual world. Second Life is the most popular socially-oriented virtual world at present (KZero 2008). Since opening to the public in 2003, it has grown explosively and today is inhabited by nearly 16 million residents from around the globe (Second Life 2008). An online survey was carried out in SL. The URL to the survey Web site was disseminated by means of virtual world internal communication facilities, official Web sites and professional game forums. A total of 262 completed responses were received and 12 invalid responses were deleted. Therefore, a total of 250 qualified responses were obtained for quantitative analysis. Prior to data collection, the required sample size was computed based on the power analysis technique using G*Power 3.0 (Faul et al. 2007). For our conceptual model and a medium effect size (1-β=0.8, α=0.05) the sample size should therefore be 160. Thus, we can confirm that 250 responses are enough for detecting a medium effect size and using the SEM-PLS technique.

4.1 Measurement

A major issue associated with using questionnaire surveys in social science research is how to develop valid and reliable measures of the latent constructs (i.e. the unobservable constructs) (Churchill 1979). In this research, multi-item scale measurement was employed. For each construct, items were drawn from previous empirical studies related to the adoption of IS and behaviour-expectation. Theoretical guidance and judgment was used to select the items that best reflect the dimensions of constructs developed in this research. Although, where possible, we encapsulated items examined in previous studies to maintain consistency, some items were reworded to relate specifically to this research. The final version of questionnaire contained 43 questions (13 general questions and 30 scale items). Perceived enjoyment and perceived social status were measured using 7-point semantic differentials. All other items on the questionnaire were scored on a 7-point Likert scale with a score of 7 indicating ‘strongly agree’ and a score of 1 indicating ‘strongly disagree’. A 7-point scale excels at capturing smaller differences, which is an important condition leading to a higher reliability (Nunnally 1978). In addition, the research used self-reported previous purchase frequency and money spent as a proxy for actual purchase. Prior to the formal online survey, questionnaire pre-testing was carried out among 20 players who have high levels of participation experience in different virtual worlds; the aim was to further enhance content validity by assessing the differences between the understanding of participants on measurement items and the definitions of the variables that they are intended to measure.

4.2 Data Analysis

The hypothesised relationships developed in this study reflect general propositions to theoretically explain virtual item purchase behaviour. The proposed model and hypothesised relationships among constructs were evaluated using SEM-PLS modelling in SmartPLS 2.0M. Partial Least Squares (PLS) is a component-based structural modelling technique that has become popular in modern business research, particularly since it has specific advantages including minimal demands on measurement scales and sample size (Chin 1998a). What is more important is that the PLS technique excels at causal-predictive analysis in which hypothesised relationships are complex and few theoretical bases have been established (Gefen et al. 2000). This research is an initial attempt to empirically test a conceptual model of virtual item purchase behaviour in virtual worlds grounded in few theoretical foundations on behaviour-expectation in the context of virtual worlds.

4.2.1 Convergent validity and reliability

To test the convergent validity and reliability, two metrics were used: average variance extracted (AVE) and composite reliability (CR). AVE measures the amount of variance that a latent construct
captures from its indicators relative to the amount of variance from measurement error (Chin 1998a, p. 321); an AVE of 0.5 or higher is usually acceptable, meaning that 50 percent or more variance of the indicators is accounted for (Chin 1998a, Fornell & Larcker 1981). The second criterion used was the composite reliability, which indicates the internal consistency of measurement items of one latent construct; typically CR should be greater than the benchmark of 0.7 to be considered adequate (Fornell & Larcker 1981). As illustrated in Table 2, all the values of AVE and composite reliability for all constructs are considered satisfactory, with composite reliability at 0.746 or above and average variance extracted at 0.584 or above. It thus can be deduced that the measurement items used in this research are converging on the same latent construct.

### 4.2.2 Discriminant Validity

One way to test discriminate validity is to examine whether the square root of the AVE for each factor is much larger than the correlations between it and all other constructs (Fornell & Larcker 1981, Chin 1998b). To assess discriminant validity, we developed a matrix of correlations between constructs with reflective measures in which we replaced the diagonal with the square root of the AVE (see Table 3). We found that the squared root of AVE for each construct is higher than the elements off the diagonal (i.e. the correlations between it and all other constructs). According to Churchill (1979), we can further assess discriminant validity of constructs through making a comparison between the loadings of an item with its associated construct and its cross-loading on other constructs. For our model, we found that all items loaded on their corresponding constructs much more strongly than their cross-loadings on other constructs (details not shown here due to space constraints). Therefore, the above evidence provides strong empirical support for the reliability and validity of the constructs used in the research model.

5 RESULTS

We calculated t-statistics and path significance levels for each of the hypothesised relationships through the bootstrapping method (with 1000 resamples). Path coefficients and $R^2$ values were obtained by running the PLS algorithm to assess the predictive performance of the structural model. The construct for purchase intention had an $R^2$ value of 0.453 indicating that the research model accounts for 45.3% of the variance in SL players’ general purchase intention. Moreover, the research model explained some variance in SL players’ actual purchase behaviour ($R^2=0.258$). Overall, the empirical results strongly confirm the explanatory power of the developed research model over players’ virtual item purchasing behaviour in virtual worlds. The important research findings of the empirical test are summarised below.

Figure 1. The research model with empirical results.

Overall, as we can see in Figure 1, there was strong support for most of the relationships in the research model. The extrinsic motivators in the model were all strong determinants of purchase behavioural intention at the 0.1 percent level of significance. The intrinsic motivators also showed significant relationships. The influence of customisation on purchase behavioural intention was particularly strong – the path coefficient being the largest of all direct relationships on purchase behavioural intention in our research model ($p<0.001$). Perceived enjoyment was also significantly related to purchase intention, albeit at a lower level of significance ($p<0.05$). However, our research findings showed that the path between advancement and purchase behavioural intention in SL was negative and significant at the 5 percent level. Compared to game-oriented players, SL players may freely design and create any virtual items they imagine – which is a major attraction of socially-
oriented virtual worlds. It seems that SL players intend to design rather than purchase desired virtual items for achieving advancement, which is contrary our expectation. The path between social influence and purchase intention was not supported and the path coefficient was close to zero. As mentioned above, this research focuses on explaining players’ general intention to purchase virtual items rather than a specific purchase decision. Thus, our research findings suggested that social influence had little effect on forming players’ general purchase intention, which does not demonstrate that social influence has no impact on making a specific decision relating to virtual item purchase (i.e. special behavioural intention), such as identifying a vendor.

It is worth noting that the research findings showed that although habit exerted a strong direct and positive influence on actual purchase behaviour (p<0.001), habit did not act as a moderating variable of the relationship between behavioural intention and purchase behaviour in the context of SL, which was inconsistent with previous published research (Limayem et al. 2007). Unfortunately, existing studies on exploring key factors that determine the relationships among habit, purchase behavioural intention and actual behaviour are quite limited and we believe that further research on this area is needed to solve the issue.

6 DISCUSSION AND CONCLUSIONS

This research has attempted to gain an understanding of the factors influencing virtual item purchase behaviour in virtual worlds. From a theoretical perspective, our findings indicate that the extant literature on online shopping behaviour does not adequately explore factors that either discourage or encourage players to purchase desired virtual items when participating in virtual worlds. To our knowledge, this research is the first explanatory study of virtual item purchase behaviour, which is the heart of virtual world transactions. A major gap in the existing body of knowledge regarding virtual item transactions is a lack of explanatory model with practical measures. The research has introduced a model for the measurement of virtual item purchase behaviour in virtual worlds by using previously developed constructs as well as newly developed constructs. The conceptual model was empirically tested based on a large-scale survey in SL. The statistically tests provide good support for the proposed conceptual model and a significant contribution to the body of knowledge regarding behaviour prediction in the context of virtual worlds. The rigorous testing of the conceptual model will not only extend the application of established theory models (e.g. TAM) to a new environment, but also offer a theoretical foundation for further studies on virtual item purchase behaviour.

If the research findings were to be successfully replicated in other virtual world settings, they could be of value in assisting virtual world developers in the development and design of virtual worlds. The knowledge of factors influencing players’ virtual item purchase behaviour, coupled with effective items of measurement are useful for virtual world developers to prioritise their resources in terms of manpower, investment, time and allocation, in the most effective and efficient way. Effort expectancy is an important factor that influences intention to purchase virtual items in virtual worlds. Hence, virtual world developers must ensure that they provide detailed guidance on virtual world trading platforms, design effective information search functions and simplify purchasing procedures in virtual worlds. According to our results, transaction platforms should be integrated into gameplay in an intuitive and enjoyable manner and provide clear benefit and value to the players. Players should also be afforded the freedom to easily customise their own avatars, which provides an important driver for purchase behaviour – as individuals will seek to purchase items to fulfil this desire. Developers should use interface and game design that is easy to use that enforces habitual transaction behaviour. Although the freeform nature of SL appears to suggest more individualistic behaviour it is possible that other game-oriented virtual worlds encourage more collectivistic and socially-oriented purchases.

It is necessary to recognise the limitations and possible future directions of the research. First, we cannot claim that the results obtained here hold equally well in other virtual worlds especially in
game-oriented virtual worlds because characteristics unique to specific virtual worlds can potentially alter the relative importance of factors influencing players’ purchase intention and actual purchase behaviour. The conceptual model and constructs should be further examined and revised in game-oriented virtual worlds, such as World of Warcraft (WoW), RuneScape or EverQuest. Second, another potential limitation of this research is that it adopts self-reported measures of previous purchase frequency and money spent as a proxy for actual purchase. To date, researchers still cannot find valid and reliable measures of actual purchase behaviour in the context of virtual worlds. To tackle this deficiency, we hope that, in the future, a longitudinal study could be designed to measure players’ purchasing behaviour over time. As shown in Figure 1, in this research, all seven independent variables have been modelled as a direct determinant of behavioural intention expect for habit. Thus, it do not minimise the explanatory ability of the conceptual model even if we lack appropriate items for measuring actual purchase behaviour in view of placing emphasis on general purchase intention. However, care should be given in interpreting or generalising from these findings when applying them to the overall population (i.e. all virtual worlds). Third, although the research developed most measurement items based on previous studies, this is the first time that these items have been examined in the context of virtual worlds. Moreover, most research on virtual world transactions were carried out in the context of game-oriented virtual worlds. The ability of these items to reflect the complexities of players’ perceptions and intentions in virtual worlds has not been fully explored. Therefore, the measures for the conceptual model should be viewed as preliminary and future research should be targeted at more fully developing and validating appropriate measurement items with an emphasis on new constructs lacking previous empirical testing, such as advancement, customisation and perceived value.

ADOPTION OF CROSS-COMPANY RFID: AN EMPIRICAL ANALYSIS OF PERCEIVED INFLUENCE FACTORS

Abstract

Although the use of RFID in the supply chain still lags behind expectations, its appeal to practitioners and researchers remains unabated. Apart from technical challenges, the profitability of an RFID deployment is a major concern for potential customers. A promising way to increase an RFID solution’s profitability is to use RFID transponders in several companies along the supply chain and share the cost and implementation effort. This paper represents a first attempt to identify the factors affecting the perceived likelihood that cross-company RFID is adopted. Our empirical results indicate that profitability is a key influence factor in this context. Related important factors are the uncertainty of costs and returns and the possible imbalance of costs and returns among the supply chain participants. The influence of organizational factors, such as power, leadership and experience, is negligible in comparison.

Keywords: RFID, Inter-organizational Information Systems, Empirical Study.
1 INTRODUCTION

The potential of Radio Frequency Identification (RFID) for boosting supply chain efficiency has been stressed repeatedly by practitioners and researchers alike (Niederman et al. 2007). However, the actual adoption of the technology in supply chain monitoring applications has been unexpectedly low to date. In 2006 the biggest share of RFID transponders produced worldwide (556 million) went to applications such as ‘smart’ cards, keys, passports and tickets (IDTechEx 2007). Only 388 million transponders were sold for the purpose of identifying goods including drugs, tools, books, apparel and other consumer products (153 million) and logistical units like packages, cases and pallets (235 million). Industry experts expect the RFID market to take off as soon as item level tagging in logistics applications becomes economically feasible for selected industries (such as the apparel industry). The current market price of passive RFID transponders (about 7 Eurocents) is the pivot parameter of most profitability calculations. The efficiency gains achievable in the logistics operations of organizations such as labour cost savings and prevention of process errors has to outstrip RFID transponder and infrastructure costs. Otherwise, the vision of pervasive RFID tagging is unlikely to become a reality.

Given today’s increasing division of labour, physical items usually enter and leave the control spheres of several organizations during their lifetimes. Enabling as many supply chain participants as possible to use the same RFID transponders attached to these physical items is a straightforward measure to increase the overall financial return on tag investment. The backend-infrastructure required for the processing of RFID data can also be shared by several organizations. The final vision is the Internet of Things: the worldwide interconnection of all databases containing object-related data. Industry consortia like the Auto-ID labs and EPCglobal continue to work on the technical standards that are supposed to form the basis of the Internet of Things (Brock 2001).

Unfortunately, the introduction of cross-company IT systems has always been a difficult and time-consuming task. A well-known example of such systems from the supply chain domain is Electronic Data Interchange (EDI) which took decades to be successfully introduced. Among other things, asymmetric costs and benefits, different risk attitudes and capabilities across the supply chain participants can complicate the adoption and efficient usage of inter-organizational information systems (Scala and McGrath Jr. 1993).

In this paper we focus on the factors related to the adoption of inter-organizational RFID systems. We identify a number of candidates and empirically test the corresponding hypotheses using data from a recent survey. To the best of our knowledge, this is the first empirical work conducted on non-technical influence factors of cross-company RFID systems.

In Section 2 we provide an overview of related literature. Our hypotheses and a conceptual model are presented in Section 3. In Section 4 we describe the employed methodology and the results of an empirical study. Section 5 discusses managerial implications of our work. Section 6 concludes.

2 RELATED WORK

The academic literature on RFID and its use in supply chain management is already substantial. Recent literature reviews include Ngai et al. (2008). Most of the publications directly related to our research topic can be allocated to one of two groups: (i) conceptual and empirical research on RFID adoption on the company level, and (ii) analytical research on the distribution of RFID benefits between a prototypical manufacturer and retailer.

A number of papers belonging to the first group concentrate on collecting the views of practitioners concerning the benefits of RFID within their organizations with different emphases. Leimeister et al. (2007) investigated the perceived strategic importance of RFID among IT decision makers. They found that the perceived strategic importance is correlated with industry affiliation and company size. Seymour et al. (2007) have developed a framework of possible factors of RFID adoption based on
several accepted theories on technology adoption and diffusion, e.g. Bakry’s (2003) e-readiness model and Rogers’ (2003) Innovation Diffusion Process. Sharma et al. (2007) propose a model for RFID adoption on the company level that is among other things grounded in the literature on inter-organizational systems; they adopt a number of factors form research on the adoption of Electronic Data Interchange (EDI), in particular Chwelos et al. (2001) and Teo et al. (2003). Madlberger (2008) investigated the influencing factors on the introduction of RFID in supply chain management applications and found that internal process improvements, inter-organizational benefits, technical advantages and the costs of RFID, but not the company size, have an influence on the introduction of RFID. Using data from a survey among 146 German companies Gille and Strüker (2008) measured how the type and sophistication of benefit and performance analyses conducted before and after RFID introduction impact the productivity gains achieved by RFID. They found that the frequent use of particular measurement methods is strongly correlated with to the improvement of target variables such as lead time and labour cost. In another paper, the same authors address specific aspects of small and medium sized companies (Strüker and Gille 2008). They found that RFID adoption is easier in smaller enterprises.

Some researchers have begun to investigate the distribution of benefits across prototypical supply chains; this automatically leads to the question how RFID transponder costs should be shared optimally in case benefits are distributed unequally. Gaukler et al. (2007) investigated this research question using an analytical model. They showed that sharing the tag costs results in overall profit maximisation if the manufacturer is the more powerful than the retailer. However, if the retailer is more powerful, there is a need for sharing tag costs in order to realize the maximum profit. Unfortunately, the analytical model is based on a highly stylized supply chain model and only captures information benefit and tag cost while ignoring the benefits resulting from labour and error cost savings.

This paper empirically investigates the factors that determine the adoption of cross-company RFID. The focus on the entire supply chain instead of single companies sets it apart from previous empirical business research on RFID. While using an empirical approach makes it easier to grasp real world conditions, our findings leave more room for interpretation than results obtained from analytical models.

3 HYPOTHESES AND CONCEPTUAL MODEL

Our conceptual model consists of one major dependent variable, namely the perceived likelihood of cross-company RFID adoption. The model is designed to reveal the influence of several factors on this dependent variable. These independent variables include the expected degree of RFID profitability across the supply chain, the uncertainty of RFID benefits, the uncertainty of RFID costs, the asymmetry of RFID profitability across the participants, the existence of a driving organization that takes the initiative in planning cross-company RFID deployment, the existence of a dominant supply chain participant who can force the introduction of cross-company RFID, and the existing RFID experience in the supply chain. In addition to this greater model we also investigate how expected degree of RFID profitability is impacted by two more independent variables, namely the depth and the breadth of the inter-organizational RFID implementation. We propose the following related hypotheses:

H1: The expected profitability of cross-company RFID positively influences the perceived likelihood of adoption.

By this hypothesis we imply that higher stakes provide an incentive for better coordination. In other words we hypothesize that if the supply chain participants expect a higher profit for the supply chain as a whole they will be more motivated to collaborate in order to realize (and possibly redistribute) this return. This factor profitability appears in many studies on technology adoption; however it is usually decomposed into benefits and costs (cf. Sharma et al. 2007). We focus on profitability since we are interested in the ‘size of the pie’ to be distributed among all the supply chain participants.
The current uncertainty involved in estimating the costs and benefits of RFID may cause risk-averse decision makers to not participate in or bail out of cross-company RFID projects. Transaction cost theory suggests that in situations where the outcome of a joint investment is highly uncertain and the assets are highly specific, the emerging negotiation, monitoring and legal costs can be significant (cf. e.g. Williamson 1979). Furthermore, the fear of opportunistic behaviour can result in a complete failure to coordinate on technology adoption. We therefore hypothesize that the uncertainty of RFID benefits as well as the uncertainty of the eventual cost of the RFID implementation have a negative effect on the perceived likelihood of adoption.

H2: The uncertainty of the benefits provided by cross-company RFID negatively affects the perceived likelihood of adoption.

H3: The uncertainty of the costs of cross-company RFID negatively affects the perceived likelihood of adoption.

With regard to the consumer products industry it has often been argued that RFID will provide higher benefits for retailers than for manufacturers (Byrnes 2003). Whereas the former can use it for various purposes on the shop floor, the latter may not be able to reap substantial benefits (Weber and Jensen 2007, p. 34). Without efficient and incentive-compatible methods to redistribute RFID costs, a concerted deployment of RFID along the supply chain will be hard to achieve. Although its importance has been repeatedly stressed, RFID cost redistribution remains an open issue (Bensel et al. 2008). The more asymmetrically profitability is distributed among the supply chain participants, the more incentives in different forms have to be provided by those participants who gain more. Due to the company-centred vantage point of the existing literature, this factor has no been considered in previous work. Against this background we formulate the following hypothesis:

H4: The asymmetry of RFID profitability in the supply chain has a negative effect on the perceived likelihood of cross-company RFID adoption.

One or several supply chain participants can play a crucial role in initiating and supporting the RFID introduction process. Regarding cross-company RFID there are two prominent examples for such leading organizations: Wal-Mart and Metro. Although their methods of fostering RFID introduction differ, they both stand out as main supporters of the technology in the respective supply chains. Wal-Mart took unilateral action in planning the deployment of RFID and issued mandates to their suppliers (Romanow and Lundstrom 2003). Metro actively involved suppliers and other companies by starting the future store initiative (Loebbecke 2005). In particular, they offered non-monetary compensation to their suppliers, including the timely communication of relevant sales data. If they exist, such companies usually take the lead in coordination and standardization activities. We hypothesize that the existence of such RFID ‘leaders’ has a positive impact on the perceived likelihood of adoption, irrespective of the means that they apply to foster the adoption process.

H5: The existence of a RFID leader in the supply chain has a positive influence on the likelihood of cross-company RFID adoption.

We would like to stress that a RFID leader does not necessarily have to be powerful in the sense that it can ‘mandate’ the supply chain wide adoption of RFID (irrespective of the mentioned examples). However, the existence of a powerful player in the supply chain can have an influence just as crucial as the existence of a RFID leader (cf. Sharma et al. 2007). From an economics point of view, power asymmetries can intensify incentive problems regarding the adoption of shared information technology. If a supply chain participant is economically dependent on another one, it will fear that this other organization will impose its will when the parties disagree on some issue during the implementation process. In joint projects, such as cross-company RFID introduction, this dependency can be reinforced by large upfront investments. In anticipation of such opportunistic behaviour, the weaker party may refuse to cooperate right from the start. Against this background one would expect adoption failure if there are power imbalances in the supply chain. In the empirical IS literature, however, the contrary hypothesis seems more common, namely that the (potential) influence of a
The existence of a powerful player among the supply chain participants has a negative impact on the adoption of cross-company RFID.

If the stakeholders involved in a cross-company RFID project have gained experience with the technology upfront, they should also have a more realistic view of the cost-benefit tradeoffs and technical challenges of its inter-organizational use. This in turn should make them more confident to avoid pitfalls in the planning and implementation phase. We therefore expect that decision makers estimate the probability of cross-company RFID adoption to be higher if there is more extant knowledge about the technology in the supply chain.

A higher degree of RFID experience in the supply chain positively affects the perceived likelihood of cross-company RFID adoption.

The more details about the movement of goods through the supply chain can be obtained from RFID-enabled information systems, the higher the potential for supply chain process automation. Experts in the field have long argued that benefits are likely to increase when moving from pallet to case and case to item-level tagging (Michael and McCathie 2005). At the same time, the more processes are restructured and adjusted to each other in order to effectively use the additional data capturing capability provided by RFID, the higher the ROI of the transponders becomes. However, increasing the depth of an RFID implementation does not necessarily improve its profitability since it comes with higher implementation and integration costs. Just think of the additional transponders required to tag single products instead of cases or the effort involved in redesigning all supply chain processes instead of just one or two. Although this cost-benefit trade-off is non-trivial, we hypothesize that the depth of the inter-organizational RFID implementation has a positive impact on the expected profitability.

The depth of the inter-organizational RFID implementation has a positive effect on its expected profitability.

Similar to the depth of a cross-company RFID implementation, its breadth should have a positive effect on the expected profitability. Breadth denotes the number of different organizations participating in the RFID application. If each additional supply chain organization that participates in the inter-organizational RFID application can benefit from the RFID transponders moving through the supply chain, the overall ROI of the transponders should increase with the number of participants. The following hypothesis reflects this reasoning.

The breadth of the inter-organizational RFID implementation has a positive effect on its expected profitability.

Figure 1 shows the conceptual model and the corresponding hypotheses graphically.
4 EMPIRICAL STUDY

4.1 Survey Design and Sampling

In order to test the hypotheses outlined in the previous section we developed scales that measure the different variables. In the forefront of the survey several industry experts and representatives were interviewed in a small workshop. The wording of the questionnaire was discussed in order to make sure that the all terms and formulations were clear and interpreted correctly and equally by the practitioners.

The developed questionnaire was appended to a more general survey on RFID in logistical applications. Its online completion was possible in German or English language. Sample collection took place from April 1st to September 2nd 2008. 947 personal invitations were emailed. Additionally, the survey was announced in a number of popular logistics and RFID publications and forums. After several weeks the invited persons were reminded of the survey by phone.

The data collection effort resulted in 153 answered questionnaires. 107 out of the 153 were responses to the personal invitations, the rest (46 responses) were filled out anonymously in response to the public announcements. Not considering the anonymous responses, the response rate was 11.3%.

Table 1. General sample characteristics.
In order to evaluate the representativeness of the sample, we analyzed its distribution with respect to four general company profile indicators: size of revenue, number of employees, industry affiliation, and the role that the respondent’s company plays in the supply chain. Table 1 summarizes the general sample description. None of the indicators exhibits any unexpected concentration. The companies represented in the sample take on different roles in the supply chain: as the corresponding sample description data indicates, our data reflects the opinion of managers who represent suppliers, manufacturers, retailers, logistics service providers and IT service providers. This ensures that questions referring to the supply chain as a whole are answered from different vantage points and therefore increases the validity of our results.

In addition to the basic company profile, we provide descriptive statistics on RFID implementation progress indicators. These indicators include the number of respondent organizations that have implemented RFID pilots and running applications, the duration of RFID usage and the budget of a typical RFID project within the respective company. Table 2 summarizes the RFID-related statistics. They show that the sample is dominated by respondents who have gained substantial experience with the RFID technology.

### 4.2 Descriptive Results

Table 3 provides descriptive statistics of the obtained survey data. A darker cell background indicates a higher concentration of the respective answer. As the results show, the majority of survey participants judge the profitability of cross-company RFID (EP) positively. Slightly more participants believe that cross-company RFID will be adopted (LA) in their supply chain; almost half of the respondents are undecided. Surprisingly, more participants indicated that they find it rather easy to estimate costs and benefits of cross-company RFID ex-ante.

4.3 Statistical Methodology and Results

The purpose of our statistical analysis is to test the hypotheses presented in section 3 using our data sample. In this section we outline and justify the applied statistical methodology.

The subset of the collected data used to test the hypotheses of our conceptual model consists of 10 times 68 values encoded on a range from 1 to 5. These values represent ordinal measurement points of the defined indicators. Our aim is to determine whether the independent variables in the model have a significant effect on the dependent variables and if so whether the effect is positive or negative. A suitable statistical methodology to estimate these effects is ordinal logistic regression. We apply this method to the general and the subordinate model with the dependent variables LA and EP respectively. In a first step, we conducted regressions of all independent variables onto the corresponding dependent variables. All statistical computations related to this paper were done using the Zelig library for the statistical software R (Imai et al. 2008). Table 4 summarizes the results of the monovariate ordinal logistic regressions.

</table>

Table 4. Results of monovariate ordinal logistic regressions.

The statistical effect of the IB variable on the EP variable and the effect of both RL and RE on LA turned out to be insignificant at the 90% level.

Further, the results of the monovariate regressions reveal a significant positive effect of the ID on the EP variable. The variables EP, BU, CU, AP and PP all have a statistically significant effect on LA. While the impact of ID and EP is positive, the impact of BU, CU, AP and PP is negative. The effect of the variables BU and PP is only significant at the 90% level whereas the other variables’ significance reaches higher levels.

In order to compare the relative explanatory power of the independent variables, we also employed multiple regression analysis.

When conducting multiple regression analysis so-called multicollinearity can cause problems (Mason et al. 1975): a high degree of correlation between the independent variables in a multivariate regression model can cause the regression coefficient estimates to vary erratically in response to small changes in the model or the data. In particular, the regression coefficients of all independent variables may change drastically depending on which variables are included or left out of the model. Thus, using the regression output without controlling for the adverse effects of multicollinearity on model estimation can lead to wrong interpretations.

In order to identify potential sources of multicollinearity in our data we calculated the correlation of the independent variables of the two multivariate regression models using Spearman’s rank correlation coefficient. Table 5 summarizes the results of this analysis.

The correlation coefficients and the significance levels provided in Table 5 reveal a number of significant correlations between the independent variables used in the model. In particular, there are strong positive correlations between the variables DI and BI, BU and CU, AP and EP, PP and CA, as well as between PP and AP.
Table 5. Results of correlation analysis (Spearman’s rhos and p-values, cell shading indicates strong and significant correlation).

Multicollinearity can be removed in a number of ways. One is to simply remove independent variables one by one until there is no correlated predictor variables left in the model. This process has to be conducted carefully; variables should only be removed if they cause an intolerable degree of multicollinearity.

In a first step we removed the highly correlated variables BI, RL and RE. The results of the monovariate regressions indicate that the influence of these variables on the respective dependent variables is insignificant; therefore they do not represent important predictors anyway.

The remaining correlations between independent variables include the one between CU and BU, AP and EP, and between PP and AP. In order to test whether these correlations cause problems with respect to parameter estimation, models without one variable out of each correlated variable pair were estimated and the corresponding regression coefficients were compared with the estimates from the initial model. These computations revealed that whereas the correlation between the CU and BU variable causes problems when estimating their regression coefficients within the same model, the correlation between AP and EP was unproblematic with respect to parameter estimation.

The impact of the PP variable turned out to be insignificant in the multivariate model and did not contribute to the model fit measured by the Akaike Information Criterion (AIC); we therefore dropped it from the model which eliminated the correlation between PP and AP.

Table 6. Multivariate ordinal logistic regression results after controlling for multicollinearity.
In summary, only the correlation between the BU and the CU variable could not be eliminated without significantly decreasing the explanatory power of the model. In order to resolve this problem, we estimated two models each containing one of the two variables.

The regression results for the final multivariate models after controlling for multicollinearity are provided in Table 6.

As stated earlier, the results of the multivariate regressions allow for a comparison of the different independent variables regarding the strength of their impact on the dependent variables. The estimated regression coefficient (abbreviated by Est. coef. in Table 6) indicates the direction (positive or negative) and the strength of the impact (absolute value). The obtained significance levels are sufficiently high (95-99.9%) to assume the existence of the postulated relationships with some confidence.

The PP variable becomes insignificant when it is estimated in the multivariate model. This suggests that its explanatory power is dwarfed by the other independent variables contained in the model. The AP variable has a stronger effect on LA than EP both if BU or CU is included in the model. If BU is included in the model, its impact is stronger than EP’s but weaker than AP’s. If CU is included, its impact is about twice as high as EP’s and AP’s.

As the results of the regression analysis indicate, hypotheses H1, H2, H3, H4, and H8 are supported by our data. The support for hypotheses H3, H4 and H8 is particularly significant. The statistical support for hypotheses H5, H6, H7, and H9 is not significant. Possible implications of the statistical results are discussed in the following section.

5 DISCUSSION AND MANAGERIAL IMPLICATIONS

The support for H1 suggests that the respondents who expect a high financial return on the introduction of cross-company RFID in the supply chain are more confident with respect to its realization. It implies that higher stakes in the form of unrealized profit make coordination on collaborative RFID introduction more likely. This result appears intuitive. More intriguing is the strength of the statistical support for H1 compared to the effect that uncertainty (BU and CU) and asymmetry of profitability (AP) have on the perceived likelihood of adoption. Higher uncertainty of both benefits and costs reduces the likelihood of adoption more strongly than the expectation of higher overall profitability. The same applies to the impact of a more unequal distribution of profitability (AP); the negative impact of asymmetric profitability on the perceived likelihood of cross-company RFID introduction is stronger than the positive impact of expected profitability. These results suggest that the adoption of cross-company RFID can be seriously threatened by both the uncertainty of its profitability and the imbalance of the financial returns realized by the different participants – even in situations where the overall profitability of such applications is judged very positively.

Our results indicate that cost uncertainty has a much stronger effect on the likelihood of adoption than benefit uncertainty. In other words, uncertain costs make decision makers more pessimistic regarding the introduction of cross-company RFID than uncertain benefits. Given the current problems of accurately quantifying RFID benefits this result comes as a surprise. However, it could be explained by a possible bias towards cost-based assessment of RFID applications in general. An indication speaking for this theory is the finding of Gille and Strüker (2008) that the costs of RFID applications are currently quantified more frequently than their benefits because they can be quantified more easily.

The lack of statistical support for hypotheses H5, H6 and H7 indicates that compared to the examined cost-benefit factors, the considered organizational factors have a less crucial influence on the perceived likelihood of cross-company RFID adoption. Neither does the promotion of RFID by a leading organization seem to play a decisive role (H6), nor do our results indicate a substantial influence of dependencies due to the existence of powerful supply chain participants (H7). The degree of extant RFID experience in the supply chain does not seem to be relevant either (H8).
The lack of statistical significance of H7 corresponds with the results of Chwelos et al. (2001) who tested the influence of dependency on intent to adopt EDI. However, we believe that it is still interesting since it encourages further research on the usefulness of RFID mandates such as the one issued by Wal-Mart.

The strong statistical support for H8 suggests that the benefit gain achieved by increasing the depth of cross-company RFID implementations is steeper than the corresponding cost increase. H9 can neither be supported nor rejected based on our data: the breadth of an inter-organizational RFID application in terms of participating organizations does not seem to affect its expected profitability. The economic network effect implied by this hypothesis would justify more upfront funding of initiatives that develop and standardize scalable system architectures for the Internet of Things: if profitability increased with the number of participants, the emergence of large clusters of companies that are connected by a common RFID backend infrastructure would become more likely. We believe that more research on possible economic network effects related to the use of RFID is definitely warranted.

Summarizing our interpretations of the statistical results, the main adoption hurdle of cross-company RFID implementation is the unequal distribution of profitability and the difficulties involved in estimating costs and benefits on the supply chain level. The influence of the considered organizational factors was dwarfed by the considered economic factors. In the light of high expectations regarding the profitability of cross-company implementation of RFID (see Table 1), our results suggest that in order to advance here, managerial efforts should now concentrate on the development of adequate cost sharing arrangements and tools that support more accurate ex-ante cost and benefit estimation.

6 CONCLUSIONS

Our research has lead to a number of insights regarding the factors that are perceived to influence the adoption of cross-company RFID. The impact of all considered cost-benefit factors – namely the expected overall profitability of RFID across the supply chain, the uncertainty of costs and benefits, and the asymmetry of profitability – was statistically significant. The influence of the considered organizational factors – in particular the existence of a powerful player, the existence of an RFID ‘leader’ and the extant RFID experience in the supply chain – could not be proven. Our results therefore indicate that the role of organizational factors may be overstated in the given context – at least in direct comparison to cost-benefit factors. However, the collection of more empirical data and the application of more sophisticated statistical methods are warranted in order to legitimately draw conclusions along those lines.

Technical challenges related to the use of RFID in supply chain operations, in particular the often criticised lack of technical standards for RFID hard- and software, have not been considered in our model although they could be an important determinant for RFID adoption. Follow-up research should therefore explicitly address technical issues and evaluate their impact on the adoption and success of cross-company RFID.

Based on our results we recommend that future non-technical RFID research should focus on effective and more reliable ways to estimate and measure RFID costs and benefits across the supply chain and to share RFID technology costs in an incentive-compatible way.

Abstract

To cope with the emerging demand for individual products and services, new approaches for handling the individualization in dynamic supply chains are needed. Our object of investigation is to establish Situation-awareness (SA) in an assistant information system for supply chain partners to cope with individualization-driven demands. Our contribution is an event-driven architecture design to enable situational planning using the Situation Calculus upon distributed contextual information. Sensors raise events among supply chain partner’s information systems, which are combined to context events in order to derive situations on partner level. Our works follows the Design Science in Information Systems Research to design and evaluate the architecture design. The preliminary descriptive evaluation uses life stock transports as an example.

Keywords: Event-driven architecture, context-awareness, Situation Calculus, product individualization, supply chain management
1 INTRODUCTION

After a period of mass production, the demand for individualized products with prices similar to mass products is growing (Piller 2003; Pine II 1993; Reichwald and Piller 2006). In order to produce individualized goods, supply chain partners with special capabilities get together in adaptive multilevel supply chains. They work together for a limited period of time or for fulfilling the demand of only few customers. Afterwards that they participate in other supply chains to bring in their special production capabilities there (Dietrich et al. 2007). New mechanisms are needed to help combining the right production capabilities quickly and to ensure a high level of product quality as well as supply chain efficiency. Individualization research is about these adaptive mechanisms for participating organisations, products and supporting information systems in dynamic multi-tier supply chains (Kirn et al. 2008). Fleisch et al. (2005) show the past and ongoing development of information technology usage in companies from using IT for single functions to individualized 1:1 coordination with customers across company borders. In logistics individualized goods lead to an atomisation of delivery with more frequent deliveries and smaller quantities (Freitag et al. 2004). To support these future needs, real-time-management based on ubiquitous computing technologies and identification of individual products will be needed. Our work focuses on an information systems concept supporting the product individualisation process while using context and situation interpretation. Stated by Mertens (2004) Situation-awareness of information systems evolves into a major field of interest for Business Information Systems (BIS) research.

Our research is motivated by a lack of information system architectures supporting multi-tier product individualization in an autonomic manner. Object of investigation is an event-driven architecture which implements situation-based planning. The situation planning is done for each partner on top of shared context information in a dynamic multi-tier value system. The perspective taken is the decoupling of context generation and its interpretation through situation logic. This allows to access varying context information based on partner specific situation logic. Partners can join the value network and collect available context information relevant for their value transformation from all other partners to adjust their planning based on their own needs. We argue that situation logic on top of distributed context information in BIS supports individualized monitoring of the production, storage and logistics in dynamic value networks. We will present an instantiation of the architecture in life stock transports to monitor the transport for different supply chain participants. Our work follows the Design Science in Information Systems Research proposed by Hevner et al. (2004).

Our work uses a livestock transport example for evaluation of the proposed framework. Long journey livestock transports need monitoring of different parameters during transport. Architectures today, as shown in the technical specification proposed by the European Union (2006), use static rules causing alarms based on sensor events recorded by the transport company. To show the individualization supporting potential of our approach, we propose a company border crossing approach enabling situation planning for all partners in the livestock supply chain. This allows the optimization of business processes for the involved partners according to the goods situation. The situation can be set to the individual customer needs of a product, for example meat from well treated animals.

The rest of the paper is organized as follows: In the second section related work in mass customization, context and situation information systems research is shown. In section three we describe our architecture and in section four present an evaluation of the theoretical approach in life cattle transports fulfilling the European decree for long journey transports (2004). Finally we give an outlook on future work in section five.
2 THEORETICAL FOUNDATION

After decades of unifying production and products in order to achieve Economies of Scale and Scope, approaches in Mass Customization aim to support individualization and to keep the cost advantages of mass production (Piller 2003; Pine II 1993). Differentiation from competitors becomes even more important in a global economy. In future there will be more options for individualizing goods which are more suitable for differing customer needs worldwide. An example in shoe industry brings up promising results for customized goods engineered in multitier supply chains (Dietrich et al. 2007; EwoMacs 2007). To achieve this, significant changes in information system design for supply chain information systems have to be applied (Dietrich et al. 2006). On top of the findings of Mass Customization, Kirn et al. (2008) use a value system centric approach to individualization of goods and services. According to Porter (1985) a value system couples single value adding activities across more than one company with certain roles like suppliers, OEM, retailer, service provider or customer, which can be described using the Porter Value Chain model. The hypothesis in individualization research is that individualization of goods and services itself is an exclusive value for the customer that he or she is willing to pay for. Context and situations obtain a major role in building BIS for supporting pervasively adaptive value systems. Goods can be produced and monitored individually to support individualization in mostly automated manufacturing processes in an economic manner. Value system partners can be involved according to the needs of a special good without high cost efforts and the costs for individualization will decrease enormously. To achieve this, adaption of the value system in time, space and economy is implied. We realize adaption of value systems using invoked actions based on detected context and situations in our architecture.

In 1999 Dey, Salber and Abowd (2001) present the context toolkit. It offers a solution for rapid prototyping of context-aware applications and shows an integrated approach to context-awareness. The six main features of the context toolkit are encapsulation of sensors, access to context data through a network API, abstraction of context data through interpreters, sharing of context data through a distributed infrastructure, storage of context data and basic access control for privacy protection. To provide these functionalities, the following objects are considered in the context toolkit. Context widgets give access to context information for applications using the context. Interpreters can raise the abstraction of a piece of context. Aggregators are used to collect multiple pieces of context information that are logically related into a common repository. Services execute actions on behalf of applications. In contrast to a context widget retrieving state information a service changes state information in the environment via an actuator. Finally the Discoverer maintains a registry of context capabilities (widgets, interpreters, aggregators and services) actually existing in the framework. The context toolkit is a framework for dealing with context elements on different levels of abstraction, but Dey and Abowd do not explicitly define situations. The term situation can be derived from their definition for context (Dey and Abowed 1999): “Context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves.” Following this definition a situation is seen as a combination of context elements and reflects the detection of these elements. It does not cope with the requirements of a situation which may occur in future or try to work with special requirements a situation may bring up by its dynamic state in time. The Context Toolkit integrates important functionalities for dealing with context elements, and hence we adapt some elements of their approach to handle context information in our architecture.

Some approaches aim to individualize process execution according to a given context. Schicker et al. (2007) follow the approach of Case Based Reasoning (CBR) to find similarities between processes and electronic services within the processes to enforce the reuse of already existing knowledge. Once a process similar to the actually needed is found, its structure is changing using the adaptive CBR mechanisms. The possible operations are add, delete, change order and change of structural relations to adapt the dimensions within the CBR process. The proposed architecture implies high manual effort.
in setup and maintaining. Unknown context elements are not considered in order to have a complete picture of the process. These shortcomings are addressed in our work. Instead of forming processes based on services, we change the process based on upcoming situations. A situation defines the context it needs to know.

Handling vague context information using situation mechanisms is made by using methods applied in artificial intelligence. Bachfischer et al. (2007) make use of Bayesian Networks in order to adapt user interfaces according to given context information. Their approach optimizes complex modern car interfaces for accessing entertainment, air conditioning, navigation system, telephone and more functions. The Bayesian Network is used to estimate the driver’s situation using sensor input from the car. After the interface of the car is adapted the driver can reach functions in which he or she is most probably interested in the current situation on top level. A high temperature inside the car may lead to a high ranking for the buttons to control the air-conditioning. Currently, their implementation tries to anticipate the driver’s situation and displays a set of POI1 accordingly, e.g. the display shows gas stations when the gas level is low. This solution is possible in closed systems like a car, but cannot be prewired in dynamic supply chain networks. Anagnostopoulos et al. (2007) make use of the fuzzy logic theory to cope with imperfect observations of context. They use and define situation-awareness as “the particular kind of context-awareness, where situations are viewed as logically aggregated pieces of context” (Anagnostopoulos et al. 2007). Their definition is one of only few definitions differentiating between context and situations, but finally implies the aggregation of context only. For them a situation-aware application has “to estimate the user’s current situation(s) and react appropriately” and to “autonomously adapt to the user’s current situational context” (Anagnostopoulos et al. 2007). They propose a situation estimation architecture, which applies rules for situation detection and action determination by exploiting the user’s reactions in order to become more pervasive. According to a given estimated situation of a user the system applies actions based on an ontology containing relations between situations, persons and contexts. The context is differentiated into personal, temporal, special and artefact context. Using fuzzy algorithms and learning capabilities is a considerable future enhancement for our work. But the approach Anagnostopoulos et al. take has its limits in changing sensor environments, which we will cope with.

There are also situation- and individualization-related approaches adapted from artificial intelligence methods in supply-chain research. Freitag et al. (2004) describe the autonomous logistic concepts developed within the CRC 637 – Autonomous Cooperating Logistics Processes: A Paradigm Shift and its Limitations. They establish autonomy and a new control paradigm for logistic processes. Decisions about a process can be made without human intervention using autonomous software agents, sensor networks and mobile computing in a transport entity. According to sensor data input, autonomous agents representing each involved entity make decisions within these ubiquitous surroundings to optimize the transport. The approach is one of only few approaches not being user-centered in context aware system design. In contrast to our distributed situation planning approach for each partner, they shift the control paradigm in value networks to autonomous control without human intervention. Our approach relies on similar sensor approaches to integrate the system into adaptive business processes and to rely on decisions made by a system, but does not use autonomous agent technology.

In 1969 John McCarthy and Patrick J. Hayes (1969) pick up a situation description for machines in “Some philosophical Problems from the Standpoint of Artificial Intelligence”. They propose the Situation Calculus capable of handling situations in information systems. They form situations based on fluents, causalities, actions, strategies and knowledge, and abilities. A situation is defined by McCarthy and Hayes as “... the complete state of the universe at an instant of time”. All changes to the universe are result of an action, which are applied to a fluent. Changing fluents in a current Situation leads to a new Situation. Using a model of a situation, a machine would be capable of taking

---

1 POI (Point of interest) is an overlay map containing spatial information about certain topics as the location of restaurants, gas stations, sights etc.
actions while only limited knowledge would be needed. Further work from Reiter (1991) helped solving the frame problem (sometimes) in the Situation Calculus. The extended Situation Calculus based on Reiter is a logic containing elements for describing a situation, but does not contain any reasoning or representation abilities. The programming language Golog presented by Levesque et al. (1997) bases on Reiter’s findings to model complex operations based on the Situation Calculus. Meanwhile Golog emerged in many ways. There are approaches enhancing Golog to using concurrency (Giacomo et al. 2000), incremental program execution under incomplete knowledge with interleaved action, planning, sensing and exogenous events (Sardina et al. 2004), and decision theoretic planning for robot soccer (Ferrein et al. 2005). Li and Iijima (2007) stated in their analyses of the Situation Calculus use in IS, that “despite of the existence of these problems, the Situation Calculus could be applied to business systems when some tradeoffs are made between expressiveness and reasoning”. Li and Iijima propose Web Service Composition, Context Awareness and Business Process Management as fields of application for the Situation Calculus. We use the Situation Calculus based on Reiter’s approaches to build the situation logic for planning situations according to goals and based on context information. There are different extensions considered, as for example incremental program execution under incomplete knowledge proposed by Sardina et al. (2004).

Already researchers make use of the Situation Calculus in BIS. Dong et al. (2004) use it to apply autonomous computing in ubiquitous computing services. Their approach separates available fluents into a precondition fluent base reflecting the maximum of fluents affecting a situation, decisive fluents affecting a situation and non decisive fluent not affecting the situation. The Validity Theory ensures only valid components are Compared to approaches using Finite State Machines for situation detection, the Situation Calculus allows the detection of non-predefined situations during runtime. The Validity Theory formalizes application-specific validity requirements to validity-ensured policies, on which computers can autonomously choose to serve a service request. The approach is a promising way of reasoning using the Situation Calculus and Validation Theory in ubiquitous computing, but research is still at its beginning. The authors argue that commercial development methodologies are not available for the Situation Calculus, and that it is still difficult to deal with the Situation Calculus on engineering level. The works of Dong et al. are the main starting point for our situation-related work.

Concluding the related work there is no satisfying approach to use situation logic on top of real world information represented by sensor-based context information, but there are many promising approaches in context and situation research already. We include suitable research identified from context and situation research, especially the ideas from the Context Toolkit from Dey et al. (2001) in our context layer and the Situation Calculus with its extensions in our situation layer (McCarthy and Hayes 1969).

3 AN EVENT-DRIVEN APPROACH TO DYNAMIC SITUATION DETECTION

In this section we propose an event-driven architecture which is capable of situation handling on top of distributed real world information. It enables higher-level IS to use the paradigms of context- and situation-awareness based on sensor information. The novelty of our work compared to other approaches is the combination of a Situation Calculus approach for situational reasoning with an event-driven context abstraction logic based on sensors. This enables partners in collaborative environments like dynamic supply chains to maintain their own situation logic expressing their need, whilst product-related context information can be accessed from all partners in the collaborative environment. The following is a presentation of the three-layered design of this approach.

Today context- and situation information is used mainly in optimizing the human computer interface (HCI) design. An example for this field of application is the use of information about the position of a device which minimizes the data presented to the user to the information relevant for the current
location. This context service is called location-based service as described by Wehrmann (2004) in his work about situation-dependent mobile services. Beyond location nearly any context information can be used in a way to simplify interaction with a device. By traditional means an application becomes context-aware if it causes actions according to changing context information. The definition of context-awareness presented by Dey (2001) emphasizes the need for a user: “A System is context-aware if it uses context to provide relevant information and/or services to the user, where relevancy depends on the user’s task.” In contrast to this user-centred view we follow a more system-centred one. Distributed sensors in collaborative environments offer their information in an event-driven manner. This is matched with situation logic and its reasoning capabilities. Context sources become exchangeable and situations are detected and processed upon their availability. Our architecture integrates situation reasoning based on assumptions and targets on top of dynamic context knowledge. A sketch of the architecture including two partners sharing their context information is shown in figure 1 and described in the following sections.

![Figure 1. An architecture model for dynamic situation detection](image)

At first we introduce the elements of the Sensor Abstraction Layer (SAL) operating on event level. The Sensor Services (sens) hide the specifics of a certain sensor. All communications with the sensor are leveraged to a unified XML-based format. A short history of sensor values, stored in a database of the sensor hosting node, is implemented to allow queries involving the past. Information about the sensor range and the position are stored in the database as well. It is developed similar to the concept of Widgets from the Context Toolkit and extends them in standardization using Web Service technology (Dey et al. 2001). For the description of sens we use a simplified Sensor Model Language (SensorML) as proposed by the Open Geospatial Consortium (2007). SensorML itself is a very powerful sensor description language. Beyond the sensor description itself SensorML stores metadata about the sensor, especially the sensors position, its availability or its range in space. We used SensorML to develop our corresponding database.
Besides physical sensors, already available data can also be accessed through the sensor abstraction layer. The data can be encapsulated like conventional sensors in SensorML using a standard sens services. Examples for explicit information interesting for encapsulation could be weather information, traffic information or data from a company’s database. All sensor services are part of a partners system and are accessible by other partners for the purpose of a specific supply chain need.

On the level above the SAL, the Context Layer (CL) contains Context Composition Services (ccs). The ccs contain a composition logic and combine elementary sensor information or other ccs information with higher aggregated context information. These are similar to the concept of Aggregators Dey et al. used in the Context Toolkit expect the fact a ccs can integrate other ccs (Dey et al. 2001). The ccs raise the level of context in a cascading manner. A possible combination, for example, is having one sensor detecting the current outside temperature and another sensor detecting the illumination level in the same local area. These can be combined to a ccs delivering information about day and night time more accurately. The ccs are valid depending on their relationship in space and time (for example “in the same room at the same time”) and can expire according to the availability of underlying sens or other ccs.

The Access and Registry Service (ars) gives access to one instantiated context framework on top of a cascade of ccs or even only a single sens. It contains a registry of underlying sens and ccs and is the entry point for other partners accessing one partners services. The ars can be combined with other partner’s ars. In this case all lower services become available in both ars. The combination of different ars is applied to connect different partner domains for a limited time or to reduce handling complexity in case of larger networks.

All element names from SAL, CL and SL use the concepts of a common Matching Ontology (MO). Thus we can estimate the closeness of two elements and even match similar elements of every layer.

Formally the CL is a multidimensional undirected graph, in which R are all available edges, \( \alpha : R \rightarrow (SENS,CCS,ARS) \) being the starting points and \( \omega : R \rightarrow (SENS,CCS,ARS) \) being the endpoints of an edge. Within this configuration, each \( ccs \in CCS \) can be connected to any \( sens \in SENS \) or other ccs to generate higher levels of context:

\[
CL = ((SENS,CCS,ARS),R,\alpha,\omega)
\]

Each Sensor is connected to one sens exclusively. A valid minimum CL is one sens and one ars to access the sens:

\[
CL_{min} = ((sens,ars),R,\alpha(sens),\omega(ars)) \text{ and } |R| = 1
\]

One level above the shared and common CL, the partner-specific Situation Layer (SL) is located, which is using the Situation Calculus from McCarthy and Hayes (1969) as well as further developments from Reiter (1991). The SL’s main task is to detect a situation \( s \) upon situation template axioms \( s^* \) taken from a situation template repository \( S^* \).

The Situation Calculus is a first-order language with some second-order features for representing dynamic domains. According to its definition, all changes to the world are result of an action and the situation “represents the complete state of the world at an instant of time” (McCarthy and Hayes 1969). Thus a world history is a sequence of actions and is represented by the first order term situation. The constant \( S_0 \) denotes the initial situation in which no actions have yet occurred. Objects catch everything else relevant depending on the situations domain. All \( a \in ACTION \) are specified by an action precondition axiom and a successor state. The action precondition axiom is highly important for our work, because we need to find relevant preconditions fulfilled for a certain situation according context detected:

\[
Poss(A(x_1,\ldots,x_n),s) \equiv \Pi_d (x_1,\ldots,x_n,s)
\]
Πₐ is a formula uniform in s with free variables xᵢ. To define the closeness of a situation to a success, Dong et al. (2004) use special fluents on top of Reiter’s approach to estimate the closeness to a successor state. Their concept of incremental successor states containing the distinguished binary function \(\text{do}(a, s)\) denotes the situation resulting from performing action \(a\) in situation \(s\). \(\Psi_{Fₐ}\) helps to find the way coming closer to a better situation \(s\) performing an action \(a\) instead of having a binary function like in traditional Situation Calculus:

\[
\text{Poss}(a(x), s) \supset F(\text{do}(a(x), s) = \Psi_{Fₐ}(x, F(s))
\]

Dong et al. (2004) argue that the definitions for a fluent in standard Situation Calculus would be too general, and therefore propose an extension to make it capable of comparing situations. They classify into functional fluents \((\overline{FF})\) meaning all available fluents, decisive fluents \((\overline{DF})\) meaning a minimum set of fluents for a situation, non decisive fluents \((\overline{NF})\) meaning possible fluents for a situation and a precondition fluent base \((\overline{PFB})\) containing all fluents which may affect a situation:

\[
\overline{FF} \subset \overline{PFB} = \overline{NF} \cup \overline{DF} \text{ and } \overline{DF} \cap \overline{NF} = \emptyset
\]

Decisive fluents are all atomic fluents or ones that cannot be derived by other fluents for a specific situation. Based on the differentiation from Dong et al. (2004), a comparison of situations according to fluent classification is done in our approach.

Using situation validity based on Validity Theory, Dong et al. (2004) define a minimum set of relational fluents to ensure the situation validity. For one situation a possible validity fluent is defined as:

\[
VA(\bar{y}, s): \text{Object}^* \times \text{Situation} \rightarrow \text{boolean}
\]

All \(VA\) in the vector \(y\) contain special terms in which a situation \(s\) is valid. The situation \(s\) is valid only if all \(VA(s)\) in \(y\) hold. A situation can have none, one or more validity arguments to define the state in which a situation is valid. This is used in our approach to ensure that certain situations only come true when valid configurations of events occur.

We are using the Situation Calculus in the SL to match with context information available from CL for a current situation \(s_i^*\) from all available situations \(S^* \in S^*\). The syntax of actions, objects and fluents in SL is taken from the MO. This ensures a unique syntax in CL and SL. The matching process starts within the SL matching precondition axioms to \(ccs\) or \(sens\) of the CL. The search starts at the highest level in CL, the most upper \(ccs\), going down the graph along the \(ccs\) to the \(sens\) using graph search algorithms in order to find a best match to a situation template \(S^* \in S^*\). Using the MO a possible combination of \(sens\) and \(ccs\) can lead to new \(ccs\) matching a specific precondition axiom. Detectable situations are all \(s_i^* \in S^*\) with a matching between precondition axioms and \(ccs\) or \(sens\):

\[
s_i^* = \max \{ \Piₐ(x_1, \ldots, x_n, s_i^*) \cap (CCS \cup SENS) \}
\]

Once all detectable \(s_i^* \in S^*\) have been found, the plans can be applied to a detected situation. A plan can lead to new detectable situations within the SL with new matchings to the CL. The MO is used as taxonomy in order to have a unique vocabulary to find similarities between the elements of the CL and SL. In order to prevent a time-consuming search for a best match when applied to the available \(SenS\) and \(CCS\) in CL, prebuilt graphs for all elements of the CL are generated every time there is an update in the CL. Additional functional validity fluents can be used to ensure validity of a \(ccs\) or \(sens\) in space and time in more complex environments.

In this section we presented the theoretical approach of our event-oriented architecture. It allows new sensors and services to be added and removed from the CL during runtime (Michelson 2006). If new sensors including their corresponding \(sens\) are integrated, they register with their correspondent \(ars\) which may spread the information to other related \(ars\). The \(ars\) inform current subscribers in SL about
the new service, which may book the service then. The architecture ensures the possibility to compose dynamic value systems containing many sensors from changing value system partners. Also mobile sensors which are changing their context in space and time can be handled dynamically, for example the sensors of a livestock transport can be added logically to the system of the butcher.

4 EVALUATION

The empirical evaluation of the implemented framework in livestock transports will be determined in the future. Instead we use a descriptive evaluation to detect the situation heat shock for animals in trailer for the animal transport company and heat stress for the butchery now.

At first we model the CL as a graph starting with the ars on top of the sensors and containing direct links from ars to every sens in the trailer and is aware the ars from the farm:

\[ CL = (\langle sens_1, sens_2, sens_3, ars \rangle, R, \alpha(ars), o(sens_1, sens_2, sens_3)) \]

The object to be manipulated by the situation heat shock for animals in trailer for the transport company in SL\textsubscript{transport} is the route the transporter will take. To alter an existing route (res\textsubscript{routeo}) in situation s we need the situational preconditions low water consumption before transport (con\textsubscript{low}), high temperature in trailer (temp\_hi) and no drinking water in trailer (¬wat) fulfilled:

\[ \text{Poss}(\text{res}(\text{route}_o), s) \equiv \text{con\_low}(s, \text{route}_o) \land \text{temp\_hi}(s, \text{route}_o) \land \neg \text{wat}(s, \text{route}_o) \]

Altering a route\textsubscript{o} in a situation s should lead to a new route\textsubscript{n} which either has enough water consumption before the transport detected, or has enough drinking water for the resulting driving time, or has no high temperature for the resulting route. A successor state after altering the route\textsubscript{o} in situation s to a new route\textsubscript{n} is:

\[ \text{route}_n(\text{do}(\text{res}(\text{route}_o), s) \equiv \neg \text{con\_low}(s, \text{route}_n) \lor \neg \text{temp\_hi}(s, \text{route}_n) \lor \text{wat}(s, \text{route}_n) \]

The situation validity is ensured checking against the maximum driving time \( t_{\text{max}} \) allowed for long journey livestock transports. In European law this is set to a maximum of 8 hours without a break for the animals (European Union 2004):

\[ VA(s) \equiv (t(\text{route}_n) \leq t_{\text{max}}) \]

Using an MO with values for livestock transports the elements con\_low can be matched to sens\textsubscript{3} with a minimum amount each animal has drunk before, temp\_hi is matched to sens\textsubscript{2} with a certain minimum level of temperature detected and wat is matched to a low-level-indication of sens\textsubscript{1}. The maximum journey time is set in the MO as well. Each possible route\textsubscript{n} considered does fulfil the successor state above. In case there is no route alternative, the driver is informed according to the given situation.

With the same sensor information we can conclude to a different situation for a different supply chain partner. The object to be manipulated by the situation heat stress in the butchery’s SL\textsubscript{butcher} is the heat stress for the animals transported, which can be detected using temperature and water consumption sensors. Water consumption uses the history of water levels in order to calculate the water consumption. The heat stress condition is important in order to estimate the quality of the meat. The preconditions needed only depend on a high temperature exposure high temperature (temp\_hi) and a high level of water consumption (Δwat):

\[ \text{Poss}(\text{de}(\text{heatstress}), s) \equiv \text{temp\_hi}(s, \text{heatstress}) \land \Delta\text{wat}(s, \text{heatstress}) \]

Depending on the precondition fulfilment, the rest time of the animals before being butchered can be determined by the butchery.
All fluents described in the examples are within the $\overline{DF}$, because they affect the current situation. But we could also detect the situation if we would have an additional parameter like a considered traffic jam, but no sensor to match to. Then the route would also be altered ignoring traffic jams and the traffic information is part of $\overline{NF}$. This becomes important when dealing with large amounts of fluents.

Using the proposed architecture for monitoring the transports leads to an adaption of the transport process during runtime in contrast to single alarm events like high temperature or low water in other installations of a monitoring environments for long journey livestock transports (Joint Research Centre 2008). This helps not only notifying in case something goes wrong, but preventing something might go wrong and assist finding solutions. Also other solutions don’t provide individual situations to be detected by different partners. We presented the detection of two simple situations heat shock for animals in trailer for the animal transport company and heatstress for the butcher in order to optimize the company’s business processes based on sensors of the truck and the farm. The sensors are interchangeable enabling new applications in environments with changing sensor sources.

5 CONCLUSION

We presented the concept of an architecture which uses information about the situation on top of context information for complex context-based decisions in pervasive computing. The framework is currently under development and the approach in this work is of theoretical nature. There are still open issues to solve within the design, especially developing an efficient matching of the elements in the $CL$ and the situation templates $S*$ based on the $MO$ and an efficient structure of the $MO$.

Our approach is limited to static situation execution yet. As long as parts of the situation are detected and no argument is invalid, the situation is considered true. In our future work we need to add the ability to handle uncertainty in situation detection, for example when two of three preconditions are fulfilled. Vassos and Levesque (2007) have an interesting approach using the Situation Calculus with incomplete knowledge of an agent.

A next major step is the implementation of the livestock sensor scenario using IndiGolog proposed by Sardina et al. (2004). We will use RFID for animal identification, and sensors detecting conditions in the trailer as well as external parameters. Other supply chain partners are represented by their own situation client. Within the implemented scenario we will be able to test scalability issues which will be a challenge to deal with.

In our future work a connection between the framework and a higher level transport information system will be implemented to demonstrate the advantage of situation handling in logistics. Whereas new situations based on a changing context are determined, an automated adaption of the planning process is achievable. Furthermore interesting topics cover human feedback to enhance the system making more precise situation detections or continuous sensor values substituting other values at a certain level. An integration of digital world models in our architecture could enhance the capabilities of the framework by using spatial relations. Nicklas et al. (2001) explore using spatial aware applications in digital world models. This could enhance our situation reasoning by physical distance of objects, for example causing a situation “Possible infection transfer” by two animal transports being next to each other on a rest area.

Our architecture is not limited to animal transports. It can be used whenever distributed systems share a common data in an event based manner. Thus it can be used in many setting in supply chain BIS. We are still at the beginning of discovering situation potential in supply chain BIS, and we expect an increasing level of automation and lower coordination costs.

Abstract

The paper presents a process model to deduce utility specific requirements within the utility industry beyond unbundling. It is based on a case study. Due to the market transition, Business Intelligence (BI) and its tasks of extracting, transforming, and analyzing data at different enterprise levels becomes relevant within this industry. Whereas utilities were formerly protected by regional monopolies, they had to change to competition nowadays. Therefore, getting information in the appropriate quality, at the right time, and in every situation is important for all management levels. According to empirical studies, the BI usage within the utility industry is low. The companies invested a lot of money into hard- and software, but had no time to fulfill business requirements. One reason is that priority tasks like unbundling had to be implemented first. Such projects were time consuming so that there were no resources left for additional vertical information flow oriented activities. Moreover, current BI implementation models do not consider utility specific requirements. Due to this reason, the contribution of this paper is to present a business flow orientated process model that deduces requirements by presenting the main business processes, data volume, and complexities on a department level, especially in context of the European unbundling directive.

Keywords: Business Intelligence, Utility Sector, Unbundling
1 INTRODUCTION

The liberalization of the energy market has dramatically changed the European power market since 1998. The former monopolistic market structure has been broken and abruptly substituted with competition (EU 2007, Steger et al. 2008, p. 20). Moreover, the liberalization induces that the management have to satisfy also investors' demands. Due to this reason, supporting the management with internal and external information is of increasing importance in context of planning, forecasting, and budgeting (Appelrath & Chamoni 2007, Horvath 2006). However, traditional planning and controlling tools are neither flexible nor structured enough to support the management with information and to bridge the gap between strategic and operative business processes (Kemper et al. 2006, Oehler 2006). Therefore, Business Intelligence tools (BI) are used in order to ensure fast, reliable, and integrated planning and controlling. According to Howard Dressner, BI includes all decision support information systems,\(^1\) from collecting data to storing data and its presentation (Gartner 2008). Its core applications imply adequate tools and applications in order to improve both the decision making process and communication with the users. The goal of BI is to design and implement business applications, enabling qualitative and quantitative analyzes (Gluchowski & Dittmar 2008, pp. 89). Consequently, the contribution of BI is a flexible corporate management on all management levels. Furthermore, BI is an instrument for knowledge generation, knowledge distribution, and knowledge usage (Gluchowski & Dittmar 2008, pp. 319). However, introducing BI does not work automatically. Existing reference models for BI strategy and BI implementation, e.g. Steria Mummert (Czochter 2008) and BARC (BARC 2007) do not imply utility specific requirements. Instead, they present a multitude of criteria that are either too general or do not concern utility specific requirements. Due to this drawback it is the paper’s goal to present utility specific requirements as a basis for BI software evaluation and successful implementation. The selection and weighting of requirements serves as a guide for coming BI implementation within the utility sector.

The research objective is realized by a process model that is based on a case study with a German utility company. Additionally, the research objective is to deduce department- and business-oriented as well as unbundling-conform requirements in favor of an enterprise wide BI-system. The paper is structured as follows:

- The necessity of formulating utility specific demands is explained by describing the background of the European energy sector (section 2).
- IT strategy is explained, because the characteristics of the energy sector influence the requirements so that they are very specific and a copy&paste from other economic sectors is not adequate.
- The meaning of vertical information supply is described as well as its influence for BI in the energy sector (section 3).
- The reference framework is presented in order to substantiate the chosen research method.
- Chapter 4 deals with the explanation of the process model in order to deduce requirements. The contribution of this chapter is a business task oriented information flow from data sources to their destinations in utility companies. This is summarized in a data-flow oriented architecture (process-system-map). This enables us to determine so called gravity centers (defined by their amount of data and complexity of algorithms) to characterize the departments and to define a generalized strategy map which is done the first time within utility companies.
- Following, the BI requirements and their impact in respect of the utility industry are presented.
- Finally, the paper ends with the conclusion.

---

\(^1\) The term was mentioned by IBM in 1958, but refers to a more general sense (Luhn 1958).

\(^2\) It is not the paper’s goal to analyze the different BI definitions and describe the BI process. These definitions and explanations can be found in (Gluchowski & Dittmar 2008a; Watson & Wixom 2006; Kemper et al. 2006).
2 RESEARCH BACKGROUND

This section explains the transformation of the European energy market. It illustrates the necessity of BI within the utility sector. Moreover, the problem of formulating utility specific BI requirements is described.

2.1 The European Energy Market Transition

The majority of the European utility industry is still structured by monopolies and oligopolies (Storr 2007). In Germany and France for example, the five largest utility companies hold 95 percent of the high voltage grid and generate more than 80 percent of the total power generation (NA 2004, EDF 2007). The monopolistic structure is based on a vertical integration of the utility companies from power generation, transmission and distribution (T&D), and retail services. Nevertheless, the monopolistic structure has some advantages. Firstly, building up a second grid is expensive and wasteful, because the T&D system is a natural monopoly. Therefore, it is easy for utility companies to reach economies of scale by increasing their capacity at a progress rate to gain decreasing average cost. Secondly, a vertical integration leads to economies of scope. Because of extensive investment cost, monopolies can realize synergies by coordinating and concentrating both investment and operations (Hung-po et al. 2005). But this aspect contrasts the goal of the European Union (EU) which is characterized by economic integration in order to eliminate the economic frontiers between two or more countries (Pelkmans 2001, pp. 2). In context of the European energy sector, the EU has started a single market for electricity and gas (EU 2003) by opening the market for competition and incrementing transparency and data protection. While the progress may differ within the EU countries, the one thing they all have in common is the unbundling of the utility companies’ business activities and the highly volatile trading of commodities such as fossil fuels, electricity and even water (Felden 2002). Unbundling means that the main operation, T&D and retail in vertical integrated companies are separated from each other to enable third parties a non-discriminating access to the market. According to the directive, the member states have to implement regulatory authorities that secure competition, free market access and fair compensation fee for the unbundled grid (the grid still remains as a regulated monopoly). Moreover, the directive is distinguished into legal, operational, accounting and informational unbundling. Legal unbundling deals with the company legal entity of the Distribution Service Operator (DSO). Accounting unbundling separates the T&D from an accounting perspective, so that the market prices for electricity can be identified independently from T&D costs. Organizational unbundling ensures that the T&D unit operates independently from the utility company. Finally, the informational unbundling deals with the confidential treatment of sensitive and business oriented information. In summary, unbundling shall create equal market conditions for all grid users (EU 2003).

2.2 Problem Formulation

Integrated utilities are confronted with increasing competition whereby they had to implement the unbundling regulations first, before other demands could be fulfilled. Such an implementation leads to efforts caused by a large number of national legislations\(^3\) based on the EU directive (Nick 2006)\(^4\). Additionally, utility companies are faced with increasing market stress of competition, especially in the power generation and DSO units (Steger 2008). Hence, decision makers have a need to get the right information in context of energy trading and incentive based regulation (Nick 2007).

---

\(^3\) The German legislations are concerning grid access (both natural gas and electricity), incentive based regulation, and grid remuneration e.g. EnWG, StromNZV, StromGVV, StromNEV, GasNEV, GasGVV, EEG, Anreizregulierung.

\(^4\) E.g.: Business processes have to be checked to unbundling guidelines. Moreover, utilities are forced to prepare an unbundling report yearly.
Furthermore, the management is obligated to its investors. Both reporting oriented needs are usually not formulated, yet.

But whereas the power generation is capital-intensive, budgets are getting tighter. In this context, controlling tools like planning, forecasting and budgeting are of major importance (Horvart 2006). Surprisingly, especially these tasks are often done manually within the utility sector. It is quite evident that the considerations about unbundling determine both the business oriented horizontal and also the vertical information flow. An information flow can be described as a path from a supplier to an end user or customer independently from their locations (Felden 2008). Management decisions are based on information that is gained from the vertical information flow. With regard to unbundling and particularly competition, BI offers opportunities in order to fulfill information requirements and to handle the increasing data volume in utility companies. Empirical studies show also that the technical premises for a BI system are already established in utility companies. But BI maturity studies explain an initial status of BI usage. It is limited to distinctive departments, ad-hoc reporting is not established, and reports are created manually and redundantly (Chamoni & Gluchowski 2004). Moreover, the business requirements remain unclear, so that the actual system’s usage is low (Czotscher 2008). This defines the need for BI within the utility sector. Due to this, we set up a case study to be able to identify BI-oriented requirements of the utility sector so that a functional BI implementation is easier to handle.

3  IT IMPACT

The unbundling directive determines the IT-architecture of utility companies. Securing non discriminating access to the market and information preservation of sensitive and confidential data are the core messages of informational unbundling (§10, 3 EnWG5). In context of a horizontal information supply, business processes and its information are faced with unbundling, although they were fully integrated before6 (Abel 2005). Unbundling determines data that can be of technical, economical, or legal nature. From a technical point of view, especially ERP and metering systems are focused with unbundling. On the one hand, it is necessary to adapt the interfaces of formally integrated systems in order to comply with unbundling directives. On the other hand, the user authorization concept has to be mentioned. In this context, the Need to Know policy plays an important role. Need to Know means those users are allowed to see just the information concerning their business needs (Hartmann & Bitz 2008). This principle enables the opportunity that every DSO customer is able to access its user data that are recorded within the DSO (Nick 2007). National authorities advise the separation between data sources that are used from DSO, retailer, and a generation unit. Moreover, unbundling requires a detailed documentation of data and folder structure (§10 EnWG).

The consequences of unbundling are that the IT architecture and strategy determine the horizontal information flow. Due to the increasing competition, the management is more interested in appropriate and aggregated information at the right time in order to take decisions comprehensively (Oehler 2006). So, the unbundling within the horizontal information flow influences heavily the vertical, BI-oriented information flow. Thus, it is necessary to consider unbundling directives to identify and analyze critical business processes. The identification implicates the effect that utility companies have to think about their business processes by identifying the process operations, the responsible person, the trigger, the interfaces, and the expenses (Nick2007). The contribution of BI is the integration of measured processes performance data from operational systems like an Energy Data Management system (EDM). Consequently, unbundling and the requirement to identify business processes is a device to accelerate the implementation of internal cost allocation. In this context, BI contributes to the strengthening of competitiveness while supplying the information demand. But the collected data

---

5 EnWG is the abbreviation for Energiewirtschaftsgesetz.
6 E.g.: change of supplier, metering services, changing master data, business data query, and grid-use-billing.
at the different company levels have to comply with the defined unbundling requirements. These requirements are relevant in context of integrated planning and decision support systems. Also specifically, such requirements are not valid for other industries.

4 PROCESS MODEL FOR BI ARCHITECTURE

This section presents the research framework to explain the chosen research method. After the explanation, a process model is described in order to deduce specific requirements.

4.1 Research Framework

We are using a case study as an empirical method, in order to describe the construction of a process model for a BI-strategy to be able to deduce utility specific requirements. Yin has described the case study as an empirical inquiry, “…that investigates a contemporary phenomenon within its real-life context…” (Yin 2003). We have chosen this method, because the direct involvement into business processes was very important to us. Speaking face to face with department managers and system users in order to understand their issues and identify requirements of BI systems in the energy sector is important, because current studies (Czotscher 2008, BARC 2007) ignore usage characteristics and specific requirements. Furthermore, companies are confronted with numerous surveys so that it is disputable, if they participate with the necessary engagement, if another anonymous one is approaching (Pendse 2007).

4.2 Process Model for a BI Architecture

The current procedure is based on the project model of VDI directive 2221 (VDI 1993). This approach is appropriate, because other process models are too specific in context of a service design (e.g. Scheuing & Johnson 1989, Shostack & Kingman-Brundage 1991), are focused on software development (e.g. Royce 1970, Boehm 1988, BMI 2006), or ignore utility sector specific requirements in context of a BI implementation (Totok 2006, Knoell et al. 2006). Due to the reason that the VDI directive gives advice on an aggregated level, we are able to adapt its general rules in favor of the study. The study uses the first four steps of the VDI approach, because the focus is not the development of new software but the construction of a process model for BI architecture. These steps are:

- Defining the problem;
- Identifying the functions and structures of the determined departments;
- Searching for solution principles and its structures;
- Classifying modules;

In the first phase, the problem definition is done by interviewing managers of the strategic management and the IT department. Furthermore, the projects goal and budget are defined. In the second phase, the status quo is established via an expert survey in different departments. Its goal is to describe an actual handling of information and the department functions. The survey concentrates on controlling, IT-services, investment, customer service, DSO- and sales department managers. BI is relevant for these departments, because controlling needs standardized reporting tools whereas the other departments use complex analyzes in order to plan investments, understand customers’ requirements, and to forecast grid capacity and grid costs. The results of this phase are use cases for the business processes. In the third phase, all use cases are consolidated to a process-system-map...
that describes the main business processes within the departments. After that, a consolidated PSM of the utility company and the DSO is built. Its goal is to illustrate the main company processes by showing which business process runs, which data sources are used as input, and which data are produced as output. At the end of this phase, each department and the whole company are skipped into a maturity model. This model is based on the Mummert BI Maturity Model [biMM] (Mummert 2004). This model is chosen, because of its empirical evidence, especially in Germany (Chamoni & Gluchowski 2004). The model’s intention is to clarify the interrelation between maturity and return on investment. On the first stage, a company does not have any integrated databases. Therefore, it focuses on data integration. Within the second stage a company has reached a first level of standardization by implementing a BI tool for reporting. At the third stage, a company involves a data warehouse [DWH]. In addition, extensively BI functions are provided, e.g. OLAP. At the next stage, companies have the opportunity to use data mining algorithms in order to discover implicitly information in databases. Finally, companies which are placed on the highest maturity stage are able to use data mining results directly to improve their processes. The fourth phase uses the results from the previous phases. Its goal is to deduce department specific requirements. At first, BI gravity centers are built. The centers are symbolized as bubbles, whereas each bubble represents a department. The bubble’s surface area describes the number of users and its locality symbolizes the grade of complexity and data volume. The surface shows which department has a critical status in context of information supply. Additionally, it is a basis for the BI architecture. It combines the different management levels with functional requirements. The resulting three components (PSM, maturity model, and gravity centers) engage all dimensions that cover specific requirements. These requirements are consolidated in a BI architecture that consists of different dimensions. Finally, specific requirements are deduced from the set of results. The requirements are weighted in consideration of comprehensibility and clarity. Additionally, they constitute the present situation.

It is evident that the current procedure of deducing requirements reflects a process view that describes a strategic development process. A BI strategy is necessary in order to describe how to deal with information (Totok 2006). It defines the information supply and its meaning for the company (Horvard 2008). A utility company should implement a BI strategy that is congruent with its company strategy. The BI strategy defines functional and technical requirements by implementing a BI architecture (Totok 2006). Whereas a BI architecture describes the information supply, a process model based BI roadmap constitutes a schedule in order to realize the architecture. Such a road map is the result of this case study and it supports in different phases how to reach the architecture.

5 RESULTS

This section presents the PSM, because it describes the survey results in the second phase. Additionally, gravity centers are explained. Its function is to present the impact of BI in the different utility applications. Finally, the requirements are mentioned and the evaluation method is illustrated.

5.1 Process-System-Map, Gravity Centres and BI Maturity

The process-system-map presents the results of the expert survey within the department managers. As already mentioned, two PSM are created in respect of unbundling: one for the utility company and one for the DSO. The map itself is built upon a two dimensional one. The first dimension deals with the business processes that are faced with BI within the utility. The PSM clarifies the data flow from incoming data, data transformation and outgoing data for each BI relevant business process in the utility industry. Due to this reason, relations between business processes become obvious. On the basis

---

7 The name process-system-map belongs to the presentation of main activities of each department, although business processes run across several departments.
of the risk assessment processes the PSM and its meaning for deducing BI requirements is explained. Furthermore, it identifies the status quo and is the basis for BI maturity classifications and the definition of gravity centers.

- First, the report recipients are identified. By identifying the recipients it becomes obvious which report aggregation level is necessary. This conclusion is important to deduce requirements in context of report presentation and drill down functions. Furthermore, requirements of report distribution can be deduced.
- Second, the incoming data objectives are examined. The examination provides information about requirements of data sources. The risk assessment department has both technical and functional data sources that have to be integrated. Therefore, the BI system has to integrate local sources, need interfaces to the geographical information system (GIS) and utility specific systems.
- Third, the outgoing data object is explained by describing its report presentation and distribution format. Hence, graphical functions for presentation are enumerated as requirements. Moreover, architectural artifacts, like client platform, supported browsers and clients, play an important role in distributing reports.
- Fourth, the PSM describes the data requirements. The description distinguishes between structured and unstructured data in general. The risk assessment department enumerates financial data, geographical data and maps. Financial and geographical key figures and their meaning are mapped. This mapping facilitates the allocation of revenues to distribution stations and net customers, as well as analyzing the state of distinctive assets. Therefore, a BI system must consider techniques like data plausibility check, simulation methods to forecast revenues, and also report features like quick views and calculation within a report. Moreover, working with customer data requires a sensitive handling.
- Fifth, the PSM lists these systems supporting the business processes. In case of risk assessment, SAP BW, SAP R3, GIS and MS-Office applications are needed. Therefore, a BI system should processes relational and multidimensional data sources. Furthermore, it needs certified interfaces to SAP BW and GIS. Especially the GIS and SAP IS-U interface is an industry specific BI-requirement.
- Sixth, the purpose of the business process is described to improve the functional understanding.

**Figure 1: Process-System-Map of the DSO**
Considering the PSM, the meaning of the controlling department in context of planning, forecasting, and budgeting within the utility sector is important. It has the function to consolidate reports from utility and unbundled sales and the DSO division. Moreover, it has to distinguish between financial and action planning. In context of financial planning, the generation of planned and actual data is a core application of BI. Additionally, analytical processes, like knowledge discovery in databases (KDD), forecasting and operation research methods become more important. Thereby, it has to be distinguished between DSO and Sales. A DSO customer refers to competitors of the utility company, whereas the utility customer is defined as an end consumer. Methods like data mining afford a better customer relation management (CRM) by analyzing customer behavior in order to plan and optimize marketing activities and improve customer service programs. Furthermore, incentive based regulation becomes interesting for DSO. This leads to the need of analytical tools that enable excellent grid capacity, power consumption and peak load forecast.

The PSM emphasizes the information flow within a business process. It describes the data transformation by explaining incoming data objects, their transformation, and the outgoing data to supply information requirements. Furthermore, the presentation is the basis for the further examination of necessary interfaces, especially if data are transformed manually. So, unbundling-sensitive data are identified.

Whereas the PSM describes the data centric view on business processes to understand the operational workflows and to deduce requirements for a BI system, it does not give information about the contribution of BI within the processes directly. Due to this reason, gravity centers are built to describe both the complexity of BI requirements and the data volume for each business process. A maturity classification also clarifies the contribution of BI within an utility company.

Besides the complexity of requirements, the data volume is very extensively, too. On the one hand, the sales department deals with a big set of data; on the other hand, the DSO is confronted with capacity data, geographical data, and legal data for the regulatory authorities. Whereas in the three mentioned departments both requirements and data volume are high, the controlling department concentrates on reporting. Therefore, it is not focused on analytical methods (in the meaning of using complex algorithms), but on reporting consolidation.

The maturity classification bases on the process-system-map. In context of the case study, the utility company is placed on the second level because it focuses on reporting. But in regards to the intensifying competition, analytical methods are of increasing importance. Therefore, it is the goal to reach the fifth level in the intermediate term (Chamoni & Gluchowski 2004). Furthermore, our classification is supported by current maturity classifications of BI within the utility sector, because it shows comparable results.

Figure 2: Gravity Centers and biMM

---

8 E.g. grid capacity planning and investment-planning.
5.2 Deducing Requirements

Formulating requirements is essentially in order to establish a BI architecture. Besides, copying requirements from recent studies like BARC (BARC 2007) and TEC (TEC 2008) offer a multitude of BI criteria. Many of them are not relevant for an adoption within the utility industry. It is evident that a list of requirements does not match with industry specific requirements. The PSM and the gravity centers are the basis for deducing requirements. By giving information about the business workflow, their functional complexity, the data volume, and the requirements ensure an appropriate contribution of BI to support business processes.

Nevertheless, not every requirement has the same significance. Hence, they are ranked on a scale from 1 to 10; a scale of 1 means that the requirement is relevant for a BI implementation, but it is not as important as other requirements. A scale of 10 reveals that the requirement is very important. The scaled requirements are the result of a second survey with the department managers after presenting the deduced requirements. The following Figure 3 and Figure 4 present in different radar charts the significance of each deduced requirement. The ranking is basis for a comparison of BI software and help evaluating an appropriate BI software for the utility sector.9

The following section presents the deduced requirements which are separated in four parts. The first part deals with general requirements like user support within the implementation and usage, vendor size, administration, and reference customers. Usually, big BI vendors are synonymous with good performance, but small vendors normally show greater engagement (BARC 2007). Moreover, the price is an important criterion, whereas it is separated into implementation cost, cost of development, training cost, and maintenance cost.

The second part contains requirements concerning the administration. These criteria determine a BI architecture and its implications to performance, especially load sharing, authorization scheme, and metadata administration. In context of performance optimization, the server architecture is decisive, because load advantages can depend on partitioned servers. Furthermore, administration with its authorization scheme is very important, because of unbundling requirements. The more flexible the user authorization is, the higher is the transparency. The reason is that authorization can be constricted at the lowest level. Moreover, they treat with system stability which is a very important demand, especially in context of energy trading and net metering.

![Figure 3: Requirements at BI in context of general and administration criteria](image)

The third part examines the platform, software interfaces, operating system integration, and the kind of data sources. The platform determines the load performance and user scalability. Additionally, the supported programming languages, supplied programming tools and interfaces have an impact to data integration. It is important that data integration is easy and powerful in order to adapt numerous data sources, i.e. relational or multidimensional databases. Within the utility industry, interfaces to common systems like SAP IS-U or GIS are necessary.

---

9 A software evaluation is not the paper’s object.
The final part determines the application functions that are discriminated between graphical representation, report distribution, and the usage of technical methods. It is of major importance for users, to control the layout in order to satisfy their own information need appropriately. Therefore, potential users take emphasizes on aggregation of different data sources, zero row and zero column elimination. Because utility companies have to send several reports to national authorities (like federal net agency), it is important to describe report artifacts with annotations (comments about the measures). Moreover, users prefer to have graphical visualizations to understand complex interrelations. Due to this reason, dashboards or cockpit functions are significant BI applications. In regards of cockpit functions, the ability of navigation within diagrams is mentioned. With regards to a report distribution, BI systems should have extensively printing functionality. Finally, the technical methods are essential for the report quality. As shown in the gravity centers, the sales and the DSO department deal with large data sets. Thus, users take emphasis on data plausibility verification. The following Figure 4 presents the results.

Figure 4: Requirements at BI in context of System Architecture and Report Features

6 CONCLUSION

The contribution of this paper is the deduction of requirements for a BI system in an unbundled utility company. Existing BI studies contain a multitude of criteria, but they do not consider industry specific requirements. It was not published which BI requirements are important and which applications are needed. Due to this reason, a process model based on a case study is presented. It takes emphasizes on process orientation by clarifying the data flow, specifying the input data, data transformation and output data. The process model is structured as follows. Firstly, the necessity of BI within the industry was explained. Since formerly vertical integrated utility companies have to unbundle their DSO to ensure open access to the grid, they are confronted with competition. Due to this reason, the information demand of the management increases to support the decision making process. Moreover, the management starts to think about their business processes, so BI can be an enabler for
harmonizing, collecting, and analyzing data. By implementing a BI system, the IT strategy is affected, because data have to be structured in an unbundling conformable manner. In fact, current studies offer a wide variety of requirements. But not every requirement is relevant for the adoption of BI in the utility industry and the significance of BI requirements is different. In order to deduce utility specific requirements and to scale its impact for a successful adoption, a process model was presented. The main processes are consolidated in a PSM for both utility and DSO based on a case study. In the following step, gravity centers were developed to show the impact in context of data volume and data complexity for each department. Moreover, the utility company was classified by using a maturity model. The goal of these artifacts is to show the meaning of BI on an aggregated level for each department, especially retail and DSO. In the following phase, specific requirements were deduced and weighted in respect to their meaning within the utility sector. Thereby, requirements are divided into four parts: general, administration, architecture, and application functions. According to the utility industry, system stability in context of net metering and energy trading is very important. In context of these two processes, data mining methods become more important. Furthermore, administration tasks play an important role, because of unbundling requirements. A BI system has to supply interfaces to common utility specific systems like SAP IS-U. Especially the DSO integrates a multitude of different data sources that contain both technical and financial data. These data have to be integrated in a single report. Finally, users demand a high layout control, easy navigation, and annotation function.

The presented enumeration of requirements constitutes a guide to a function oriented BI implementation and evaluation of BI software within the utility industry beyond unbundling. Concerning both deducing and weighting requirements, an evaluation of the results is necessary. Although, the developed process model and the deduced requirements are the outcome of a case study, current results cannot be presented. Even if the results of a BI implementation are deliverable, a verification of the artifacts has to be arranged. Such verifications can base upon models that compare the actual and the specified state and formulate the degree of compliance.

Abstract

Critical social research in information systems has been gaining prominence for some time and is increasingly viewed as a valid research approach. One problem of the critical tradition is that there is a lack of empirical research. A contributing factor to this gap in the literature is the lack of agreement on what constitutes appropriate methodologies for critical research. The present paper contributes to this debate by outlining the role that focus group research can play in the critical approach. The paper outlines the main characteristics of critical research with an emphasis on its emancipatory faculties. It then goes on to review the focus group method in general and gives an account of two research projects that used focus groups as a method of data collection. It is argued that focus groups can contribute to emancipation of researchers as well as respondents. This argument is built upon the critical theories of the two most prominent theorists currently relied upon in critical social IS research, namely Jürgen Habermas and Michel Foucault. Focus groups can improve communication and move real discourses closer to the Habermas’s ideas speech situation. At the same time, they can contribute to the challenging of prevailing orthodoxy and thereby overcome established regimes of truth in the Foucauldian tradition. The paper ends with a critical reflection of the shortcomings of focus groups as a critical method and of the specific approach chosen in this paper.

Keywords: critical social research, focus groups, research methodology, information systems
1 APPROACH AND MOTIVATION

IS researchers have embraced the critical approach as a viable and adequate alternative to study IT problems (e.g., (Orlikowski and Baroudi 1991; Trauth and Jessup 2000; Richardson and Robinson 2007; Stahl and Brooke 2008). The critical approach allows for a departure of the purely descriptive approaches commonly used in IS. As Richardson and Robinson (2007) indicate: “Critical research in IS serves as a reminder that IS is about the people as well as the business strategy, competitive advantage or systems development regardless of human cost”.

Despite increasing prominence of the critical approach in the field of information systems (IS), there is no agreement on appropriate methodologies for critical studies (McGrath 2005). While it has been observed that questions of methodology are not necessarily central to the critical agenda (Avgerou 2005; Walsham 2005), it would still be desirable to have a clearer understanding of the relationship between certain methods and critical research. The present paper contributes to this debate by offering a discussion of focus groups as a method of data collection and its relationship to critical research.

The potential of the use of focus groups for critical research has been investigated by social researchers (Kitzinger and Barbour 1999; Webb and Kevern 2008). Quality criteria of critical theory research are related to historical situatedness and its ability to overcome ignorance and misapprehensions which can facilitate emancipation. The focus group method can support these criteria as each participant comes in with their own experiential insights, which may change as they learn of the experiences and insights from other participants.

This paper contributes to the literature by discussing how the experience of focus groups as a critical method can be used and built upon in IS research. It argues that emancipation as the central aim of critical research can be furthered using focus groups. Emancipation can be supported for different stakeholder groups, most notably for researchers as well as focus group participants. Developing the argument requires us to give an account of the main concepts, i.e. critical research and focus groups, and to show that these are conceptually compatible. We will then describe and contrast two separate studies to support the argument empirically.

2 CRITICAL SOCIAL RESEARCH

In the field of IS, critical research is often referred to as a paradigm, which offers an alternative to the more established paradigms of positivism and interpretivism (Orlikowski and Baroudi 1991). In order to clearly distinguish our view of critical research, we follow the suggestion of Harvey (1990) and Klein (2008) and add the term "social" in order to render it clear that we follow a particular tradition of thought, which goes beyond the critical considerations of established facts, theories, and data that pervades all research. Critical social research can be defined using a number of different but interlinked characteristics. In this paper we follow Stahl's (2008)view that the most important defining feature of critical social research is its intention to promote emancipation. This critical intention finds its justification in a perception of the world as being imperfect and unjust and the belief that research should address this and aim to improve the status quo. This starting belief sets the critical approach apart from both the positivist and the interpretivist tradition, which are predominantly descriptive.

The concept of emancipation raises a number of complex issues. First, there is its definition. Even following a relatively wide and uncontroversial definition, such as the one suggested by Klein & Huynh (2004 p. 163): "Emancipation means that more people can achieve their potential to a greater degree," raises problems. How can we know what people's potential is and how can we know the best way for people to achieve it? What can the role of research be in promoting emancipation and what is to be done if the views of the research objects on their emancipation does not reflect the researcher's views. How do we avoid critical social research turning into a dictatorship of the intellectual (Stahl 2006)?
Despite these and other open questions, we believe that emancipation is central to understanding the critical view and that it explains most other characteristics of the approach. The interest in emancipation sharpens awareness of impediments and requires sensitivity to non-obvious facts and relationships. Critical social research has a history of concentrating on social structures that alienate humans, which notably include economic structures.

The emancipatory intention has implications for epistemology and research strategy. Critical scholars tend to be sceptical of truth claims that are based on an objectivist ontology. The constructed nature of social reality requires them to understand the process of construction of individual and collective life-worlds. This leads to a dialectical understanding of research, which is often described in direct opposition to positivist approaches. Critical researchers understand that knowledge claims are always contested and aim to understand under which circumstances they become accepted as truth. They also realise that all knowledge claims are based on particular interests and that there is no value-free and objective description of social realities. Knowledge must, therefore, be understood in its historical context. Given the scepticism of truth claims and the starting assumption that the world should be improved, critical social researchers tend to have an ambiguous relationship to empirical data, which can always only say what the world is like but rarely give indications of what it should be. This may to some degree explain the ongoing problem of methodology in critical social research in IS. In addition, the historically contingent nature of critical social research requires the researcher to continually reflect on their activities and the role they play in shaping the outcomes. Reflexivity is therefore a frequently cited aim of critical social research (e.g., Kvasny and Richardson 2006).

Another aspect of the critical approach that has bearing on the role of focus group research is that of theory. A considerable number of theories have been used in critical research. In the field of IS, one can observe that the work of two researchers has gained prominence: Jürgen Habermas and Michel Foucault (Brooke 2002). We will outline brief aspects of their theoretical positions which allow for a wider interpretation of the role of focus group research in the context of critical social research.

Habermas is often considered a leading representative of the Frankfurt School of social theory. Whereas the first generation of Frankfurt scholars were more closely aligned with Marxist thoughts, Habermas developed social critique by establishing the Theory of Communicative Action (TCA) (1981), which posits that there are different ways of coordinating social action and that the most desirable is that of communicative action. This means that interlocutors are accepted as equal and valuable individuals and that the aim of communication is the achievement of consensus on the basis of rational exchange of arguments. Central to this idea is the concept of discourse. In any speech act, the speaker raises a number of validity claims (truth, legitimacy, authenticity). Whenever these are contested, discourses take place where arguments are exchanged to clarify the differences and come to a conclusion. Such discourses presuppose the (counterfactual) ideal speech situation. This is a situation where all speakers are endowed with the same ability to express their views and are willing to accept each others' arguments. Due to the construction of discourses and their presuppositions, the TCA implies certain ethical views, which Habermas has developed in his discourse ethics (1983; 1991). Important aspects of his work that inform our interpretation of focus groups include the discursive nature of social reality, the ideal speech situation as an aim which indicates the way towards emancipation and the ethical nature of communicative interaction.

The second theorist who has gained prominence in critical social IS research is Michel Foucault. Similar to Habermas, he sees the importance of discourses in establishing social reality. Unlike Habermas, however, Foucault is interested in the question of who gets included or excluded from discourses and on what grounds (1971). Where Habermas implies a view of truth that is based on a consensus (albeit often a fictitious one), Foucault holds that there are "regimes of truth", which determine what can count as true in a particular context. In his extensive studies of different social realms, he undertook genealogies of historical discourses with the aim of determining the ways in which legitimate knowledge is created. For our purposes, some of the interesting aspects of his work include the emphasis on bodily discipline in establishing discursive dominance, the whole idea of regimes of truth as well as the importance of power relationships in discourses.
3 FOCUS GROUPS FOR CRITICAL RESEARCH

Focus groups have a long history in market research, social research (Morgan 1988), and more recently in medical research. However, they continue to be under-used in information systems research as a primary method of data collection, even though they can be particularly valuable in exploring and recognizing the socio-technical nature of information systems.

Powell et al. define a focus group as “a group of individuals selected and assembled by researchers to discuss and comment on, from personal experience, the topic that is the subject of the research” (1996 p. 499). The focus group draws upon respondent’s attitudes, feelings, beliefs, experiences, and reactions in a way that is not feasible using other field methods (e.g. one-on-one interviews, surveys, observation). An individual interview provides a one-dimensional perspective, whereas the focus group elicits multiple views through processes that can prompt reaction, synthesis of new information and experiences provided by others, and recall of the forgotten. Focus groups are a special form of group interviewing. General group interviewing has an emphasis on questions and responses between the researcher and participants. Focus groups are distinguished in that they rely on the collaborative construction within the group to inform topics provided by the researcher (Morgan 1997). The researcher prompts things to happen in a focus group in an organized fashion, as opposed to observational methods where the researcher waits for things to happen in a natural way.

Conversing among peers in a comfortable setting with limited moderator prompts may result in more information about organizational issues, knowledge structures, and interacting with users or IT staff than a participant may otherwise provide. Through group discourse, researchers tap into the many different forms of communication that people use in day-to-day interaction, including jokes, teasing, and arguing, (Kitzinger 1995). Gaining access to such variety of communication is useful because people's knowledge and attitudes are not entirely encapsulated in reasoned responses to direct questions, such as those presented in survey or one-on-one interview. Tapping into interpersonal communication is also important because this can highlight (sub)cultural values or group norms. Through analysing the operation of humour, consensus, and dissent and examining different types of narrative used, the researcher can identify shared and common knowledge. Furthermore, when an individual user’s or IT staff’s perspective is limited, focus groups can draw participants from the full set of involved stakeholders. And, because the participants are exposed to a wide range of ideas and perspectives of the information system of interest, these stakeholders can give a multi-perspective view of the technology of interest. The focus group method can highlight individual stakeholders’ reflections and build on these conceptual insights via other participants’ perspectives.

From critical theories such as Habermas's and Foucault's, we learn about the importance of power in any social interaction. Focus groups are no exception to this. Using the critical lens, scholars become more sensitive to power issues, which include obvious ones, such as the choice of focus group topics and selection of respondents, but also less obvious ones as expressed in moderation techniques or seating arrangements. It should not be assumed that groups are, by definition, inhibiting or that focus groups are inappropriate when researching sensitive topics. Group work can actively facilitate empowerment to discuss taboo topics because the less inhibited members of the group break the ice for shyer participants (Kitzinger 1995). Participants can also provide mutual support in expressing feelings that are common to their group, but which they consider to deviate from mainstream culture (or the assumed culture of the researcher).

Criticalists realize that one can never escape power relationships and that this would not even be desirable. The way to address them is to make them explicit and open them up to discussion and revision. The focus group discourse may expose asymmetric power relations in the organization and to allow silenced voices be heard. A focus group provides a means to obtain assessment from a group of stakeholders through collaborative construction of independent attitudes, experiences, and beliefs, rather than consensus or negotiation (Morgan 1997). From Foucault we can learn that power is always
bi-directional and all power leads to reactions, which are often unforeseen. The role of the researcher should, therefore, be discussed as well as other influencing factors, including the power that the focus group members have over the researcher. The critical perspective requires a different interpretation of research findings. Given the contingencies of power relationship and corresponding reality constructions, it is clear that no research, including focus group-based one, can produce a true representation of reality. Rather, all research needs to be understood as a contribution to the discourses that lead to accepted truth claims (Habermas) and that establish regimes of truth (Foucault). Focus groups are arguably better equipped to undertake this role than other means of empirical data collection because of their discursive nature, which allows for an easy recognition of factors of interest to critical research, such as ideology, hegemony, power, perceptions of rationality, etc. In the next section two research studies are used to illustrate how focus groups can be utilized for critical analysis.

4 DESCRIPTION OF TWO RESEARCH STUDIES

In this section we describe two different information systems studies within the healthcare context, which will be used to illustrate how the discursive nature of focus groups contributes to critical social research.

4.1 Emancipating Participants: Exploring Patient’s Concepts of Telemedicine Encounter Quality

The extent to which telemedicine positively impacts the health status of patients and equalizes access to care are social issues purported to be at the core of telemedicine. This is underscored by the motives of our organization and the socio-technical nature of the telemedicine encounter itself. The organizations participating in this study were part of a large government-run telemedicine network. Medical vision conferencing, the form of telemedicine addressed in this study, involves conducting patient encounters (i.e. clinical exams and consultations) using video conferencing equipment and related peripherals. The telemedicine network studied initiated medical video conferencing as a means to provide high-level speciality care to remote patients and as a means to reduce patient wait times for care, rural patient anxiety and time associated with travelling to an urban area for care, and travel reimbursement costs paid to patients. The purpose of this study was to identify the socio-technical attributes that contribute to a successful medical video conferencing encounter workflow and process.

A critical question arose among the research team regarding informants, namely who had the power (using Habermas's and Foucault's concept of power in social interaction) to define utility, efficacy, and process in the telemedicine context. In the telemedicine domain the business philosophy acknowledges that the patient is the icon that underpins each dimension of success and justifies each decision. Yet, this does not necessarily translate into participatory democracy or a public sphere that encourages debate deliberation, agreement, and action (Villa 1992). In a healthcare service encounter, the relationship between patients and medical providers is asymmetrical: the patient subscribes to the professional authority and knowledge of the physician in seeking medical care.

Even though patients may be considered partners in their medical care, patients have some degree of dependence upon medical care providers in the context of a medical encounter. Research indicates a patient’s dependence on a medical care provider (particularly physicians) is based on the physician’s command of an esoteric body of knowledge acquired through training and experience legitimizing the profession, the ability to justify his/her authority and the ability to evoke the client’s trust, confidence, and norm of obedience in following prescriptions for care (Parsons 1975). Despite this power difference, which is of intrinsic interest to the critical perspective, there are functional reasons for exploring patients’ views: their description of symptoms is required for diagnosis, they represent the “consumer” of healthcare, and they shape the competitive market of healthcare. It is, thus, plausible for a healthcare technology study to include data collected directly from patients.

Early forms of data collection in this study and reviews of telemedicine patient satisfaction literature recognize that studies indicate patients are satisfied with telemedicine (Collins, Nicholson et al. 2000),
but provide limited critical analysis from the patient perspective. Critical social research seeks, however, to question shared assumptions and unearth social realities behind such simplistic views. In their review, Collins, Nicholson, and Brown (2000) note some of the limitations of quantitative measurement of patient satisfaction including the propensity for patients to express high levels of satisfaction due in part to their reluctance to say the wrong thing or complain for fear of unfavorable treatment in the future. Direct observation provided relevant data for the general purposes of the study, but did not seem to adequately augment the patient perspective.

Focus groups were chosen to provide the means by which to give the patients a stronger voice in the study. In the spirit of ideal speech, every subject with the competence to speak and act is allowed to take part in the discourse (Habermas 1981). Patient encounters may be sporadic or limited precluding a rich breath of experience and the chance to share experiences with others to understand norms and nuances. We looked to focus groups to provide a means to obtain patient “expertise” through collaborative construction and learning from the related experiences of others (Morgan 1997). In addition, it was thought that the process of interactive discourse in the focus group may provided a collective strength to help empower the patient to overcome reluctance to say the wrong thing or provide an acquiescent response set.

Deliberate attempts were made in the design of the focus groups to enhance patient empowerment and the voice of individual patient participants that might find it more difficult to express their attitudes, desires, and needs. Efforts included the use of aliases by participant, rules to promote an “ideal speech” environment provided in writing before and read to the groups during the session, and the strategic placement of participants around the table.

An attempt to enhance and empower patients was also made through the use of a trained peer moderator the patients might see as someone they would generally have conversation with, as opposed to a research team member or healthcare provider. The assistant commanded a voice only at the end of the focus group to clarify areas of confusion, to facilitate complete information and accurate coding, and to provide a summary of interpretations of focus group comments at the end of the session. This closing discourse between researcher and focus group members was an initial effort towards validating interpretive analysis and some degree of sharing power with participants in the analysis process.

4.2 Emancipating the Researcher: Evaluating Data Quality in Health Policy Decision Making

The second study focused on issues of data quality. Healthcare enterprises can be regarded as ‘data rich’ (Abidi 2001) and the quality of this rich data is a crucial basis of strategic decision. This study proposed several data quality calculations and presentation methods meant to inform the decision maker of three data quality problems in a health planning/aggregated data environment: 1) missing data, 2) small sample sizes and 3) erratic trends in underlying data that could indicate incorrect data.

The focus groups were the final step in this study and were meant as an evaluation of the three data quality presentation methods. “Vignettes” or story lines were used to create fictitious decision scenarios based on current healthcare situations and sample healthcare data. (Table 1 contains some examples for cases of missing data). The strategy taken was to present the data with and without the data quality information in order to detect differences in the collective decision making processes. The moderator presented the experimental vignettes and encouraged the participants to play the role of a healthcare decision-maker. In order to analyze the data, the focus group guided the moderator in exploring the healthcare data. For example, participants were encouraged to ask the moderator to drill down or roll up the OLAP tool data in order to thoroughly understand and compare data for different counties as part of their decision making process.

</table>

The main researcher in this study intended to use the focus groups to empirically demonstrate the utility and efficacy of presenting data quality information to for improved decision making. However, the open-ended discourses generated by the focus group techniques perplexed the researcher. The researcher’s background as computer scientist had guided her research topic choices, initial assumptions and an objectivist approach to research. In the focus group discourses, the researcher noticed non-obvious facts and relationships on how decision support tools were used in decision making, which were contrary to her initial assumptions. This motivated the researcher to retrospectively analyze the focus group transcripts using a critical lens.

5 ANALYSIS USING CRITICAL APPROACH

When focus group dynamics work well, the participants work alongside the researcher, taking the research in new and often unexpected directions (Kitzinger 1995 p. 300). In this section we illuminate some of the unexpected directions the focus groups in the two referenced studies introduced to cause questioning of assumptions. We use Habermas’ concept of ideal speech and Foucault’s concept of regimes of truth to highlight some unexpected directions and the questioning of assumptions.

5.1 Study One: Patient Focus Groups and the Ideal Speech Situation

Though attempts to create a microcosmic public sphere supportive of debate, deliberation, agreement, and action were made and signs of such were evident, there is no guarantee that each and every participant was emancipated in the discourse (Villa 1992). Participants asserted positive views of process and action in the telemedicine encounters as well as incidents of imperfect experiences and possibilities for enhancement that they had not previously revealed by organizational or research surveys or on record as complaints or compliments. As the focus group conversation transpired, shared stories seemed to evoke a greater attention to detail and recall and the ability to more closely examine the process with a critical lens. For example, comments regarding potential issues with the provider interacting with technology included:

“Well, I found that there was a lot of time wasted in adjusting the cameras. Half the time was adjusting the cameras and instructing the nurse to focus in on different parts of my body, rather than to talk to me directly about my symptoms & my problems. I’m sure it was important, but to me that was a negative. In person he wouldn’t have to adjust anything.”

These issues were not suggested through survey responses, even in open-ended survey questions, nor by patient reactions in direct observation of telemedicine encounters.

Empowerment moved from a description of their reality to a more collective inter-subjective vision of what an ideal medical video conferencing encounter should be like. In building this vision, participants would interject prescriptions for process and performance. For example, in discussing the medical assistant responsible for operating cameras in the room with the patient, one patient commented that the assistant should:

“… be familiar with the doctor, have, you know, just don’t have, it has to be someone that and make them like a team. She is that doctor’s representative here and so she has to know the doctor well enough that if he does say something and it can be taken three different ways she usually knows which way he means it.”

Focus group participants also prescribed special training for medical professionals involved in such encounters as demonstrated by the following comment, “they have some video training and to have it critiqued on their performance, because it’s really a performance, they’re on television.”

For many such prescriptions, it seemed ensuing comments rallied support. However, not all statements produced unison. There were differing opinions on the mix of in-person with video exams, though
most groups contained members that supported the first vision in person as a means to start discourse with the doctor as described below:

“There’s a lot you can learn about the doctor by the way he handles you and how close he gets and his demeanour. It's important to the care of the patient and that’s what you get from that first visit in person.”

Some patients also seemed liberated to report on issues of their own shortcomings and awkward moments and stories seemed particularly forthcoming once one focus group member “broke the ice”. For example, some patients commented that they were captivated by the “television” and thus missed some of the doctor’s directives. In follow-up, another patient recounted that they did not realize they did not have to speak very loudly; and when told they did not have to shout, the embarrassment provoked them to cease free-flowing conversation with the doctor. A couple of other patients indicated they overlooked or were not informed that they were not having an in-person exam and shared their reactions as described below:

“I was shocked. I did not know I was having a television exam. My wife was with me and she says who’s talking? I said it was somebody over there. I’d just tell them to give us just a brief orientation, so that they would not be shocked.”

The question for the research team was whether and how to share the “patient voice” expressed in the focus groups beyond intended research outlets. The telemedicine coordinator and a leading doctor of the participating organization with the most telemedicine sites were invited to participate in the coding process to afford a more direct means of “seeing the voice” of the patients than general reports to participating organizations. The practitioners were trained; and practitioner coding was compared to researcher coding. In addition to providing the practitioners with direct access to patient comments, this process provided a means of analytical discourse among the researchers and the practitioners. The convergence found between the coding of the research and practitioner teams provided another level of validation to the study. In the spirit of ideal speech, it also introduced an unexpected discourse into the study. Though practitioners are often the subject and source of data in IS research, they are not often brought into the analysis process. Through their elevated role in this study, the practitioners voiced contextual experience as well as their emotional and intellectual reactions into the design, experiences, and observations associated with the analysis process. The researchers felt this discourse complemented and expanded their capabilities and insight.

In response to patient responses, practitioners involved in the coding and reconciling process were alarmed by some patient comments indicating they had not received a telemedicine encounter orientation to suit their particular concerns and needs for information. Transformation is enlisted in critical research in response to insight and critique. Once management was apprised of the patient orientation issues, the researchers were asked to work with the practitioners to develop patient orientation materials with content reflecting patient orientation needs as indicated by the focus-group discussion. To continue the discourse with patients, a validating survey was sent to patients participating in the focus group by the research team to confirm analytical insights. This procedure of soliciting patient feedback on patient education materials provides further indications of research and the patient voice transforming practice.

5.2 Study Two: Questioning the Orthodoxy: Challenging regimes of truth

The second study investigated issues of data quality in the context of public policy health planning. The intent was to aid human decision makers to better understand the quality of the data they had and in the presence of potentially incomplete and unreliable information from multiple data sources. The underlying premise held by the researcher at the start of the study was that additional data quality information would be valued. Thus, the core issue of the study was what data quality information to present and how best to present this information. Focus groups were used to inform the design and to evaluate if the enhanced decision support tool would improve decision making for public policy health planning issues. The loosely structured format of the focus groups (as opposed to an individual interview where there are structured questions, or a controlled experiment, where all variability is
carefully controlled) had an interesting effect. First, it allowed the conversation to navigate to areas that the researcher had not intended to cover, such as, why data quality problems exist. This new discourse added rich information to the research topic and contradicted some of the initial assumptions held by the researcher. Secondly, as focus groups became more comfortable in sharing their ideas, when they stumbled on to a particular aspect of the topic that excited them or bothered them, their resulting solidarity shifted the power from the moderator to the participants. Finally, because of the unintended discussions, the problems that motivated the researcher to pursue the study appeared in a different light, and forced her to question whether the chosen research focus of presenting data quality information to decision makers was the most pressing to investigate or even of importance.

The major underlying assumption made by the researcher was that decision makers understood that poor data quality was prevalent in many data sources. But in contrast, it appeared that most decision-makers were under the impression that data quality did not cause problems in their organizations. They indicated that they knew which data sources are not reliable, and they just avoid using them. This is evident in the following participant’s comment:

“I think some of it’s probably documented but there are some variables like that every researcher would know like don’t even bother using it. It’s so bad. But you know- it has a reputation for being bad. And you might know that by reading the literature but most likely you’re probably gonna know by informal network.”

In another vignette, participants were asked to determine whether there was a correlation between smoking and certain types of cancer in the presence of significant missing data. The participants indicated it depended on the stakeholder. The information about the missing data, along with the drilling capability of the OLAP tool could be used to either argue either side. This was treated with humour, but it was apparent that data could, and was at times, manipulated for the desired outcome.

Another assumption held by the researcher was that decision-makers would use the provided data quality information for improved decision making. Yet, when presented with the system prototype showing data quality information, the participants collectively began to speculate regarding the reason for the data quality problem, rather the concentrating on using the tool to help them with the test case decision tasks. For example, in the vignette where participants were asked to explore healthcare disparities in cancer screening for Hispanics, the participants speculated on the cause for the missing data, illustrating discourse deviating from the researcher’s initial intention:

“Years ago we started to do press screening in migrant Mexicans - among migrant Mexicans and we tried to give them the free ones and they didn’t feel like they deserved that kind of care. That that was for rich people and wasn’t for them which would you know sort of figure in some of the cultural issues related to this beyond just sort of race.”

The solidarity that formed among the participants had an interesting effect. In one particular focus group that consisted of Ph.D. statisticians at a large hospital centre, participant solidarity actually shifted the power and control from the moderator to the participants. The group disliked the decision task vignettes that were chosen as test cases and refused to make decisions with the data that was presented to them. This was interesting because the examples were based on simplified versions real decision-making scenarios within their context. This particular group resisted any sort of “watering-down” of tasks that were similar to their every day tasks. In retrospect, the participants were incensed that the task design did not consider the situational nuances and unique decision making skills they had acquired by doing this kind of work. They felt that the data quality issues that were being covered minimalized the actual issues they faced. For example, again with the Hispanic disparities case one participant noted:

“My concern is that the census classification of Hispanic allowed for people that aren’t Hispanic, for documentation purposes...Hispanic is anything that doesn’t fall under white or black or that some people may not consider themselves Hispanic if they are of a mixed race.”

In a similar fashion, this particular group nitpicked each task scenario, and the data quality information was ignored. As the moderator tried to re-focus their attention on the data quality issues and the
related tool, they participants basically revolted and said it was just too much to consider, given other information that they also needed to consider in the decision making process. Their overwhelming consensus was that the addition of data quality information to the decision support tool would force them to consider too much information and would actually decrease their decision making efficiency:

“I think that ideally your decisions would be more effective, but I can see you might spend a lot of time if you are digging through that (data quality information), and that time could be wasteful in an of itself”

As the researcher analyzed the conversation and some of the observed resistance to considering the data quality information in the test decision-making scenarios, the complexity of decision making with flexible decision support systems such as OLAP became apparent. Albeit, data quality is an important aspect in decision making, it is just a small part of the myriad of issues in health policy decision making. In fact, inserting more doubt about the fitness of the data used for these tasks may actually exacerbate or corrode the processes that health planners and clinical researchers use to make decisions.

6 REFLECTIONS

Critical research aims to be reflective and question its own assumptions, beliefs, and outcomes. This paper seeks to come to a better understanding of the role that focus groups can play in critical research or, to put it differently, whether and how focus group research can further emancipation.

6.1 Emancipation of the respondents

The stories shared by patients participating in the first telemedicine study eroded elements of ignorance and misapprehensions in sharing what was beneath the surface regarding their medical video conferencing experiences not revealed by other methods of data collection. Positive experiences were not negated, but perceptions of the ideal sometimes shifted. In the telemedicine study, each patient had unique telemedicine exam experience and opinion of success that they brought into the group. The sharing of unique situations and experiences and commonalities evoked a new virtual reality of what it would take to achieve an ideal telemedicine process. Though some individual differences in opinion still existed, a shared common knowledgebase of histories (to varying degrees) transformed the participants. A richer analysis evolved in recognition that even positive situations can merit from a critical lens and multiple organizations applied results from the study to move to a higher level of service and understanding regarding medical video conferencing. Conscious improvement of communication situations in accordance with Habermas' ideal speech situation can improve individuals' understanding of technologies and also lead to a better understanding of different stakeholder groups (e.g. patients and clinicians). Focus groups are uniquely suited for such improvement of speech situations because by their very nature they are close to discourse situations. Making positive use of social dynamics can help researchers enforce emancipatory consequences of qualitative research by using focus groups.

6.2 Emancipation of the researcher

The interaction and often camaraderie that is evident in focus groups guided the researcher to reflect about some of pre-conceived notions about decision making in an important context, health public policy decision-making in our second example. It should be evident that giving information about the quality of the data should empower the decision makers to improve how they approach decisions. Using Foucault's concept of regimes of truth, we experienced the power of focus groups of questioning established beliefs. IS researchers tend to use an unproblematic view of agents' rationality which translates into the belief that high quality data will lead to good decisions. Exploring discourses during the focus group research showed that this orthodoxy is fundamentally flawed. Respondents were not as interested in data quality as standard theories suggest they should or would be. In reality, most decision makers paid limited attention to data quality issues in comparison to alternative realities about decision making that emerged in this context. Personal biases in decision making (such as
questionable racial stereotypes), speculation about reasons for data quality problems, stakeholder issues and limitations in the amount of data that a person can or is willing to process objectively, were in themselves problematic. These findings allowed the researcher not only to come to new insights into data quality issues in healthcare settings but, moreover, to question the very assumptions that the research project was based on. By coming to this new position, the researcher was emancipated from prevailing thoughts and free to explore alternative explanations of social realities.

6.3 Focus Groups as critical method

We believe that this paper gives a convincing account of the positive contribution that focus group research can make to the critical tradition in IS. It can be emancipatory for participants as well as researchers and there are diverse theoretical explanations of the critical faculties of the focus group method. This should not be misunderstood as saying that focus group should be viewed as a "critical method" per se. There are weaknesses to focus group research in general and to our approach in particular that need to be kept in mind.

When using the focus group method for critical research, one needs to be aware that it can never achieve the (transcendental) ideal speech situation. The researcher will always play a central role that has a tremendous influence on outcomes. The researcher sets the topic, established legitimacy of research question, selects participants, influences discourse situations, has control over physical resources, and decides how to use the data. While the process can be made as transparent and democratic as possible, it will always remain skewed towards the perspective of the researcher. An awareness and sensitivity towards critical topics is necessary for the focus group research to display its critical characteristics.

Another problem with our approach is that it is fundamentally functional, i.e. it did not question the technology and its context of usage. It is not obvious whether the socio-economic framework in which our investigations took place is truly geared towards emancipation. Accepting the description of healthcare as a market raises a number of problems. It means that financial considerations are central to healthcare which certainly not all critical scholars would find acceptable. This has to do with questions of distribution and justice. Using a Habermasian perspective, one can say that it represents the colonisation of the life-world which he would not find acceptable. Our approach is thus open to the charge of being fundamentally uncritical because it uses the critical repertoire of ideas to improve a social context and use of technology whose legitimacy per se is not certain.

A further and fundamental problem of all critical social research is the question of successful emancipation. Due to a number of conceptual and epistemological issues, most active critical researchers settle for the idea of "transformative redefinition" (Alvesson and Deetz 2000) as the hallmark of success. The idea is that emancipatory change can be effected by allowing people to reconceptualise their world. The question for us then is whether the focus group approach is truly conducive to such transformative redefinition and whether it is possible to provide evidence of them. Our account of the research suggests that the interaction during the focus groups has given rise to such redefinition but whether they were truly transformative is a difficult question.

One can summarise this paper by saying that we think that there is a good case to be made that focus groups are a research method that goes well with the critical approach. At the same time it raises a number of questions, which require the critical researcher to remain careful. If is of particular importance to underline the fact that the choice of whatever method, including focus groups, will not automatically render a piece of research critical. Criticality requires ongoing attention to issues of emancipation, which may nevertheless remain elusive.

Abstract

The interest in audio and video technologies has surged as IT infrastructures and network capacities have improved. Surprisingly, there have been rather few studies on such emerging technologies in organizational settings. In this research-in-progress paper, we explore the impact of the use of an interactive video website, comprising videos promoting a company’s core values, on organizational learning. More specifically, we intend to study how the use of a video website affects the awareness of a company’s core values and whether this will also influence the behaviour of the employees. Two web surveys are being designed for the study. The first survey was conducted prior to introducing the video website. In this paper, we present initial results from the first survey. We are currently in the process of designing a follow-up questionnaire in order to assess cognitive and behavioural effects of introducing the video website. As a complement, we will also conduct interviews and observations of how the video website is used.

Keywords: Video website, information technology, organizational learning, cognitive development, behavioural development, internal communication.
1 INTRODUCTION

IT is increasingly used for internal communication. Often, employees drive this development by, for example, communicating with colleagues through instant messaging systems. In other cases, IT is introduced and promoted by the management of an organization. In the study of this paper, the management of a biotechnology and medical company decided to introduce an interactive website with functionality that is similar to YouTube. Figure 1 shows a screenshot of the website. Employees can watch and rate videos, post questions and share opinions regarding the content. We will refer to this technology as a video website. Notably, the interest in audio and video technologies has surged as IT infrastructures and network capacities have improved (Krishna, 2007). Surprisingly, there have been rather few studies on such emerging technologies in organizational settings. Videos that give a background to and describe the core values of the company have been produced. The reason for focusing on the core values was that the management felt that the awareness of the values, and how the values can guide work, needed to be improved. Over the last few years, the founder and management felt that the company stagnated and that the spirit of the enterprise had been lost. By implementing company core values with the overall focus on the entrepreneurial spirit, they believed that the employees’ attitudes and behaviour could improve. Also, they hoped that the employees would become more innovative.

Many scholars have stressed the importance of values and their effect on organizational performance over the years (Baum, Locke & Kirkpatrick, 1998; Collins & Porras, 1996; Ferguson & Milliman, 2008; Lencioni, 2002; Pattakos, 2004). Core values can be defined as describing what is important for a company and they can be used to guide employee behaviour (Ferguson & Milliman, 2008; Lencioni, 2002). A thorough implementation of carefully prepared values can lead to success while meaningless values might be highly destructive (Lencioni, 2002). Our case company has decided that it is time to enhance the employee’s knowledge about the company core values with the purpose to regain the entrepreneurial spirit in the company. In order to do so the core values, “simplicity”, “professionalism” and “innovation”, are being presented in four videos. In the first video, the history of the company is presented and it is emphasized that the core values have been important over the years, ever since the company was established. The founder of the company set up the business with these core values. The remaining three videos each present one core value.

In this research-in-progress paper, we explore the impact of the use of an interactive video website on organizational learning (OL). More specifically, we intend to study how the use of the video website...
affects the awareness of a company’s core values and whether this will also influence the behaviour of the employees. While there is some literature on the relationship between IT on OL (for a review, see Robey, Boudreau & Rose, 2000), the relationship between emerging technologies, such as Web 2.0 technologies, and OL has not been sufficiently explored. We extend previous research that has mainly been focused on text-based knowledge management systems, such as knowledge repositories of best practices, and communication systems, such as e-mail and groupware (Kane & Alavi, 2007; Robey et al., 2000).

While there are a number of competing theories that attempt to explain development, learning and change in organizations, the OL field has consistently emphasized these processes over the years (Argyris & Schön, 1978; Fiol & Lyles, 1985; March, 1991). The basic building block of most theories and models of OL is cognitive and behavioural development (Fiol & Lyles, 1985; Templeton, Lewis & Snyder, 2002). Cognitive development is commonly referred to as learning level (Fiol & Lyles, 1985) and can be described as developing shared understanding among members of an organization (Hedberg, 1981). Behavioural development is commonly referred to as change level (Fiol & Lyles, 1985) and can be described as the change of behaviour and actions of members of an organization (Argyris & Schön, 1978; Daft & Weick, 1984). Similarly, Argyris and Schön (1978) differentiate between espoused theories, i.e., theories we can state verbally, but which do not necessarily affect our behaviour, and theories-in-action, i.e., theories that actually affect our behaviour.

To explore the effects of the interactive video website on OL, we investigate the effect on cognition and behaviour, because these are established concepts and make it possible to extend previous research. This makes it possible to validate previous research in a new setting, contribute to developing a cumulative research tradition, and enables deeper exploration of foundational ideas (Kane & Alavi, 2007). More specifically, we explore how the video website can support or hinder cognition and behaviour, and posit the following questions: How and why does the use of the video website support or hinder an increased awareness of the company’s core values? How and why does the use of the video website support or hinder improved behaviour?

In the section below, previous research on IT, interactive video and OL is reviewed, and it is reflected on possible effects of using the video website. Then, the research setting and methods of the study are discussed. In the fourth section, we present initial results based on the first of two surveys. We conclude by discussing the next steps of our study.

2 INTERACTIVE VIDEO AND ORGANIZATIONAL LEARNING: LEARNING THROUGH TRANSMISSION OR INTERACTIVITY?

In this section, we first review research on IT and organizational learning and then discuss the potential impact of interactive video on learning. The section is concluded with a reflection on to what extent the interactive video website might support transmission versus interactivity.

2.1 Information technology and organizational learning

The relationship between IT and OL is receiving an increasing amount of attention because of the potential to affect organizational outcomes positively. In the literature on IT and OL, there are two streams of research: studies that apply OL concepts for implementing and using IT in organizations and studies focused on the design of IT applications to support OL (Robey et al., 2000). This study contributes to the latter of these streams, by designing and evaluating a video website for OL.

Information supports and stimulates learning and therefore it has been argued that IT can enable and facilitate OL (Janson, Ceccez-Kecmanovic & Zupančič, 2007; Robey et al., 2000). IT can effectively be used to support attributes of OL, such as acquiring, sharing, modifying, interpreting and storing information and knowledge (Templeton et al., 2002). Differences in OL when using IT can be related to characteristics of employees, such as individual learning rates (Kane & Alavi, 2007; March, 1991). For instance, IT may support OL in some situations (e.g., with fast learners) but may be ineffective or even hampering in other situations (e.g., with slow learners). IT has been described as a double-edged
sword, because it has the potential to both help and hinder learning (Kane & Alavi, 2007; Robey et al., 2000). Previous research suggests that successful use of IT as support for OL is dependent on the intertwining of both technical and organizational factors.

The right IT-enabled learning mechanism employed under the right conditions can benefit OL. However, the wrong mechanisms for particular conditions can be detrimental (Kane & Alavi, 2007). Thus, IT and its effect on OL can only be fully understood by examining the ways it is activated in organizational contexts (Leonardi, 2007). Members of organizations often use IT in different ways than managers or system designer intended (Orlikowski, 1996). By adopting the social information processing model (Salancik & Pfeffer, 1978) when studying how organizational members use media, scholars found that members of a work group shared similar attitudes toward IT and use IT in similar ways (Fulk, 1993; Fulk, Steinfield, Schmitz & Power, 1987). Another study by Fulk (1993) found that social influences on attitudes toward IT and the use of IT are consistently stronger if members of a work group are highly attracted to each other than if they feel low attraction to their work group. However, these social constructivist models are not deterministic, which means that they do not presume that social interaction is the sole explanation for acknowledged attitudes and behaviours toward certain IT (Fulk, 1993).

Particular tools, such as information repositories, where information can be stored and retrieved, promote homogeneity and tend to result in improved learning for the short term. Other tools, such as online communities, which connect employees who share common interests, promote heterogeneity and exploration and tend to lead to better long-term results, but are less effective for leveraging knowledge in the short term (Kane & Alavi, 2007). Robey et al. (2000) argue that communication technologies are useful for supporting organization-wide communication, which may support questioning of static assumptions and creation of new knowledge.

### 2.2 Interactive video and learning

As noted in the introduction, the interest in audio and video technologies has surged as IT infrastructures and network capacities have improved. However, there have been remarkably few studies on such emerging technologies in organizational settings. Studies that focus on organizational settings and emerging technologies emphasize the tremendous impact of emerging technologies on the interaction between corporations and their stakeholders, e.g. employees, shareholders and customers (Argenti, 2006; Vielhaber & Waltman, 2008). When reviewing research, we learned that most recent studies on video focused on technical issues, video conferencing or the use of video in educational settings. A number of studies on YouTube and similar technologies are also emerging, although we did not find such studies in organizational settings.

In a literature review on learning from video, Cennamo (1993) identified three key factors that can be expected to influence the mental effort of users. First, characteristics of the media, such as the content of the videos and the questions for discussion, may affect learning. Second, characteristics of the user, such as the perception of the usefulness of interactive video, may affect learning. Third, characteristics of the task, such as the purpose interactive video is used for, may affect learning.

Previous research has indicated that visual information is more memorable and that the combination of audio and visual information can increase comprehension and retention (Baggett, 1984; Kozma, 1991). These findings are supported by a more recent study with 147 psychology students. This study reported that digital video was more effective than text for presenting real-life situations in order to enhance learner satisfaction, comprehension and retention (Choi & Johnson, 2007). In studies of a management course and an English course, it was argued that digital video promoted contextual aspects of learning (South, Gabbitas & Merrill, 2008) and emotional involvement in the learning process (Hakkarainen, Saarelainen & Ruokamo, 2007). South and colleagues (2008) argue that digital video can provide situated cognition, i.e. connecting knowledge to relevant activities, contexts and cultures in which it is used (Brown, Collins & Duguid, 1989). When they compared video with a face-to-face setting, it was concluded that the first setting was characterized by learning through reflection, while the latter setting included more collaboration and conversation. In a study of YouTube, Lange (2008) suggested that social network technologies may need to support publicity or privacy depending
on different individuals’ and groups’ social needs. She argued that technical features could beneficially give users control in deciding whether to create public or private interactions, which may stimulate participation.

Drawing on the above, the use of the interactive video website has the potential to promote homogeneity and short-term learning of the company’s core values. OL theorists have, however, argued that mass communication, such as video messages, or mass meetings where managers communicate core values, are often not sufficient. Top-down communication is then applied and the transmission view on communication is in focus. Members of the organization commonly hear very different things in these situations and therefore the expectations of management are often not met (Schein, 1993). Successful organizational change communication is instead based on the creation of opportunity for the organizational members to be part of the communication and contribute to the organizational framework (Langer & Thorup, 2006; Weick, Sutcliffe & Obstfeld, 2005). Weick (1979) has gone as far as to argue that communication constitutes organizations and that people organize in order to solve equivocal information. A transmission view, i.e. top-down communication with the idea of the organization as a single body and the management voice as the one and only (Langer & Thorup, 2006), would in that sense be fatal for the organization. In order to avoid the transmission view, our case company has encouraged the members of the organization to ask questions and discuss the content of each video. Questions, such as how a particular aspect of the core values can be implemented in daily work, are suggested for discussions on the website. Thus, the interactive features of the website have the potential to, but will not necessarily, support discussion and exploration of ideas.

3 RESEARCH SETTING AND METHOD

The company studied in this paper is a biotechnology and medical device company that primarily develops, manufactures, markets and sells medical products. It was founded in 1987 and has grown rapidly ever since. The company has more than 700 employees in 20 countries, with 480 at the company’s head office and production facility in Sweden. Traditionally, meetings have been organized regularly which most staff has attended. However, as the company has grown, these meetings have turned into information meetings with a transmission view in focus, i.e. management is informing the staff but there is little room for discussions and questions from the staff. The management is therefore searching for new communication forums where questions and feedback from the staff are better supported and encouraged. This has included the use of an intranet and, more recently, the introduction of an interactive video website described above and four video productions. The website and videos were produced by a small company specialized on video, audio and website development. A video website was preferred over streaming video, because of the potential to support discussion and contributions from employees. The videos describe the company core values and include employee stories. The reason for focusing on the core values was that the management felt that the awareness of the values, and how the values can guide work, needed to be improved. With these stories, employees transform tacit knowledge about company core values into more explicit and usable knowledge by giving examples on how they implement company core values into their daily work. The employees are given the opportunity to comment on the videos, ask questions and rate the content. Currently, it is not compulsory to use the website and the discussions are not moderated. It is possible to give anonymous comments, although all participants so far have at least stated their first name. The question is if the interactive video website can support OL and lead to greater integration of company core values into the daily work (Weick et al., 2005).

3.1 Questionnaires

Two web surveys were designed for the study. The first survey was conducted in October 2008 prior to introducing the video website. The second survey is planned to be conducted in August 2009, after the introduction of the website and the four videos. By comparing the results of the surveys, it will be possible to explore the effects of the use of the video website on OL. The development and validation
of measures of OL is an important research contribution in itself as the most critical area of importance has been argued to be the development of methods for measuring OL and the impact of learning on organizations and their performance (Lyles & Easterby-Smith, 2003). A new video will be released every second month. The first questionnaire collected descriptive data describing the respondents and their preferred modes of communication. It also included measures on cognition and behaviour in relation with the company’s core values. The second questionnaire will also include measures on interactivity and employee satisfaction when using the video website.

For cognition, we drew on the concept of cognitive development (Fiol & Lyles, 1985), defined as developing shared understanding among members of an organization (Hedberg, 1981). Shared beliefs play a vital role for enabling the improvement of actions across an organization (Senge, 1990). However, cognitive development does not necessarily reflect behavioural development (Fiol & Lyles, 1985). For example, in the study of this paper, the use of the video website might support an increased awareness of the company’s core values but this does not necessarily mean that the organizational behaviour will change. The measure included six items and achieved a high level of reliability (Cronbach’s alpha = 0.88). For example, one item stated: “I can describe the company’s values for a friend”.

For behaviour, we built on the concept of behavioural development (Fiol & Lyles, 1985), defined as the change of behaviour and actions of members of an organization (Argyris & Schön, 1978; Daft & Weick, 1984). Behavioural development does not necessarily reflect cognitive development (Fiol & Lyles, 1985). For example, in the study of this paper, the use of the video website might stimulate employees to reflect on work practices, but behavioural changes do not necessarily reflect the company core values. We created eight items. The measure achieved a high level of reliability (Cronbach’s alpha = 0.83). For example, one item stated: “I work on the basis of the company’s values”.

In the second questionnaire, we will also include a measure on interactivity. In order to understand the influence of the video website on OL, it is important to understand whether they use it in an interactive way. The use of the video website might support heterogeneity, where employees contribute and share ideas, which has been argued to be one of the key dimensions of OL (Robey et al., 2000). The measure will mainly include items adapted from Webster and Hackley’s (1997) survey instrument. For example, one item is: “I was comfortable when communicating on the web site”.

We will also include a measure on satisfaction. It is important to assess whether employees enjoy using the video website. If employees do not want to use the website it is unlikely that it will support OL. The measure will mainly include items adapted from Webster and Hackley’s (1997) survey instrument. For example, one item is: “In the future, I will try to avoid using the web site” (reverse-coded).

It was estimated that 450 employees were located at the Swedish site when the first questionnaire was distributed. Out of these, 280 employees completed the questionnaire, representing a response rate of 62 percent. Their mean age was 40 years with ages ranging from 24 to 63 years. The mean for duration of employment at the company was 5 years, ranging from 0 to 17 years. Sixty-one percent (n=170) of the respondents were women.

3.2 Interviews and observations

Rather than simply surveying whether OL took place, we also want to explain why the members of the organizations were affected by the video website initiative. Individual interviews will be used in order to include opinions that employees often prefer to express in more private settings (Silverman, 2006). We will continuously observe how the video website is being used. Comments and discussions on the video website are stored and can subsequently be analyzed. We also have access to quantitative data, such as how many times each video has been accessed.
4 INITIAL RESULTS

The management of the company believed that employees were not aware of and affected by the company’s core values, which were underlying reasons for why they decided to produce a website with videos. However, as displayed in Table 1, the cognition measure indicates that employees are aware of the core values (M=5.2). This was especially apparent when asked whether they felt they had good knowledge on the company’s values (M=5.8). As shown in Table 2, the mean for the behaviour measure was slightly lower (M=5.0). Many employees felt they worked on the basis of the company’s values (M=5.4) and that these values could influence the company’s future positively (M=5.5). An interesting finding is that the means were much lower when respondents were asked if it is difficult for employees to work on the basis of the values (M=4.1) and if they think that most employees work on the basis of the company’s values (M=4.3).

The respondents were also asked how they felt they had gained information about the company’s values (see Table 3). Prior to this study, one web video had been distributed to the staff by sending a link by e-mail. In the video, the CEO discussed the future of the company and the company’s core values. 116 of the respondents (41%) felt they had gained information concerning the company’s core values through web video. The respondents were also asked how they would like to gain information (see Table 4). Most employees preferred other means of communication as compared to web video.

Table 4. Preferred means of communication (n=280, reverse-coded).

In Table 5, a correlation matrix is presented. It includes descriptive variables, the cognition and behaviour constructs, and the variables video experience and video preference. Video experience refers to whether employees felt they gained information concerning the company’s core values through web video. Video preference refers to the degree employees would like to receive information through web video. A number of strong correlations were identified. Older members of the organization were more likely to prefer web video for gaining information (r=0.19, p>0.01). Employees with a higher level of education were more likely to state that they had gained information concerning the company’s core values through video (r=0.20, p<0.01). In line with the OL literature, there is a strong correlation between cognition and behaviour (r=0.37, p<0.01), i.e., shared understanding among members of an organization is closely related with their behaviour and actions (Senge, 1990). A correlation, although it should be noted that it is rather weak, was also found between whether employees felt they had gained information concerning the company’s core values through web video and whether they felt their behaviour was in line with the core values (r=0.13, p<0.05).

5 INITIAL CONCLUSIONS AND FUTURE RESEARCH

The initial analysis of the first questionnaire reveals a number of interesting findings. In general, most employees felt they had good knowledge on the company’s values and felt they worked on the basis of the company’s values. However, when asked if they believe that their colleagues work on the basis of the company’s values, respondents were neutral. Notably, these findings differ considerably from the perceptions of the managers, who believed that the employees had limited understanding of the company’s values. It can also be noted that the employees prefer other means of communication as compared with web video. When we have conducted the second questionnaire, we will assess whether their opinions regarding web video have changed.

Rather unexpectedly, older members of the organization were more likely to prefer web video for gaining information, which contradicts research calling for ways to engage the “YouTube generation” (Duffy, 2007). Thus, the relationship between generations and new media are more complex than is often assumed – web video does not necessarily cater the needs of younger generations in organizational settings just because they are familiar with video websites. We have also learned that education might help explain why some individuals felt they gained information concerning the company’s core values through web video, while others did not. Although it should be noted that all employees at the company have computer access, one explanation might simply be that employees with a higher level of education use computers to a larger extent than those with a lower level of education who are more likely to work in the production line.

The presented results are based on self-reported data, which probably is the main limitation of this research-in-progress paper. However, we believe that these data give an indication of the impact of the use of an interactive video website on OL. As a complement, we will conduct a follow-up survey, observe the use of the video website and conduct interviews. We are currently in the process of designing a follow-up questionnaire in order to assess behavioural and cognitive effects of introducing the interactive video website. The development and validation of measures of OL is an important research contribution in itself as the most critical area of importance has been argued to be the development of methods for measuring OL and the impact of learning on organizations and their performance (Lyles & Easterby-Smith, 2003). As a complement, we will also conduct interviews in order to better explain the results of the surveys. For example, the results of the surveys can indicate whether the cognition and behaviour of the employees were improved in line with the core values, but they cannot explain how and why this occurred. Combining insights from conducting surveys, interviews and observations of the use of the video website will enable cross-validation of findings through triangulation and a richer, fuller description of the effects on OL. In our further research, we intend to explore questions, such as the following: Which are the cognitive and behavioural effects of using the video website? How do other factors, such as demographic factors, interactivity and satisfaction, influence cognitive and behavioural effects of using the video website?

Abstract

The practice of information sharing as an approach to mitigate identity fraud within, between and from Australian organisations is investigated. Organisations need more flexibility to verify legitimate customers in information system (IS) environments where ‘know-your-customer’ laws or protocols exist for ‘customer-not-present’ or ‘new customer’ transactions. An IS sharing approach is needed, whilst also protecting individual consumers, entities and other stakeholders from identity (identity theft, identity deception, and identity fraud) or related crimes (money laundering, terrorism, trafficking – people, drugs, weapons, or illicit material) and from the breach or abuse of private ‘identity’ information. Privacy, data provisioning laws and protocols need to be adhered to when sharing information whether verbally, coded, encrypted, or interrogating shared data sets through data mining, profiling or other identity crime mitigation techniques. Most information sharing literature to-date focuses within the organisation-level. Our contribution is across organisations as well as within and across, at the sector-level. Asymmetry in information shared between organisations is reduced when the aim is to mitigate a common phenomenon or cause, such as identity crime. However, this sharing relies on trust, integrity, and confidentiality between organisations both within and across industry sectors as well as between the private and public sectors.

INTRODUCTION

Organisations and government agencies since the September 11, 2001, United States (US) terrorist attacks, are often confronted with a ‘know-your-customer’ identity verification requirement for business dealings to mitigate identity fraud and related crimes. However, their preference is for mutual customer trust and integrity, and to not incur search costs and time tradeoffs to prove their customers identity indirectly. Indirect identity verification varies from simple questions where answers should only be known by the other party, to in-depth database cross-checks behind-the-scenes. Dichotomies between privacy of ‘identity’ information and identity (fraud, theft, deception) and related crime (money laundering, terrorism, or trafficking – drugs, people) mitigation have been reported in industry, but they have not yet been fully explained in the academic literature (Main & Robson 2001). To date, identity fraud mitigation has mostly been at the organisational-level (Jamieson & Winchester & Smith 2007), with some exceptions (Federal Deposit Insurance Corporation (FDIC) 2004, Middlemiss & Gupta 2007). Identity fraud “refers to the gaining of money, goods, services or other benefits through the use of a false identity” (Australasian Centre for Policing Research 2006, p. 9). ‘False identity’ is procured by prior identity theft or identity deception acts. Identity theft is where identity details are stolen, while identity deception is when information details or documentation are made up, changed, or lent (or some mix of) for real or fictitious individuals or entities (Jamieson & Stephens & Winchester 2007b). Identity crime is estimated to cost about A$1 billion in Australia (Cuganesan & Lacey 2003, Jamieson & Smith & Stephens & Winchester 2009, see Table 1).

The aim of this paper is to examine the implications of information sharing options available to policymakers in the public and private sectors (in Australia) targeted by identity fraudsters. In this paper, we contribute to the literature and fill an observed gap by examining information sharing (also known as data sharing, data matching and computer matching (in the US) in a database or data set context) laws, protocols, and practice as an identity fraud mitigation approach in Australia (Gordon & Willox 2006, see p.6). We use both an organisational sensemaking and learning lens for this examination in an IS information/knowledge management context. The selection of organisational sensemaking and learning models were based on our aim. Identity crime is an “instance of sensemaking because it involves identity, retrospect, enactment, social contact, ongoing events, cues, and plausibility” (Weick 1995, p. 3). Similarly, the learning lens was chosen because we wanted to understand the identity crime proof of identity (POI) issuers/users learning stage of this new phenomenon. A prerequisite for computerised information sharing across data sets is a common architecture (i.e., servers) that will allow them to communicate in a sharable format. Our analysis revealed that public sector agencies have formally implemented various information sharing strategies (e.g., protocols) to mitigate and detect identity and related crime acts. However, private sector organisations tend to share information in a less formal often bilateral context (verbal) or purchase data outright from third party vendors to help verify an identity. A growing trend is for private industry to reciprocate information sharing with government agencies in order to combat crime for example, fraud in tax or welfare agencies. Information sharing in the government context is (mostly) the computerised comparison of two or more government agency data sets of ‘identity’ and other records which relate to the same individual or entity through a unique identifier. In general, the sharing of organisational information between employees of other organisations on a bilateral or multilateral basis requires mutual trust to avoid asymmetrical knowledge transfer. Symmetrical information sharing or knowledge transfer in this paper would be defined as not holding back identity and related crime perpetrator details or their modus operandi from others in the information sharing ‘group’. There is also a need to create economic incentives to avoid free-rider problems (Gal-Or & Ghose 2005, Gordon & Loeb & Lucyshyn 2003). Gal-Or and Ghose’s (2005, p. 186) work suggested that information technology (IT) security information sharing may be more valuable in some instances than others, for example “when product substitutability is higher, implying that such sharing alliances yield greater benefits in more competitive industries”.

The next section reviews the literature. Section 3 describes theory and sensemaking and learning models. Section 4 explains our research methodology and Section 5 discusses information sharing results within and across organisations and sectors. Section 6 concludes and suggests future research.

2 LITERATURE REVIEW

Human ‘identity’ information consists of biometric, attributed and biographical attributes. Biometric attribute examples include: fingerprints; signature; hand geometry; and vein recognition. Attributed characteristics include: name; and mothers maiden name. While biographical attributes include: education and vocational history. Collectively, these attribute groups form an individual’s proof of identity (POI) documentation in Australia for identification purposes in opening bank accounts or accessing government welfare entitlements for example. Personal identifying information (PII) is closely related to an individual’s POI because of the knowledge sharing properties of issuance and confirmation. Personal identifying information has been referred to as ‘knowledge-based identification’ (Clarke 1994). Identification is the association of data with a particular individual. Identity authentication is the process whereby evidence of identity is assessed in order to establish a sufficient degree of confidence that data is being associated with the correct individual. In the context of information systems (IS), the purpose of identification is used to link a stream of data with an individual in a database (Clarke 1998). Individual and mass data surveillance can be enhanced by sharing information or data from distinct sources (knowledge management repositories i.e., databases). In addition, a more elaborate data compilation can be interrogated or analysed using data matching (Clarke 1994). In the context of identity validation, cross organisational data matching provides a means of enhancing the degree of confidence an organisation has that the individual they are dealing with is legitimate. This is critical if “other means of confirmation are unavailable, although of course, the mere existence of a matching identity record on an external database is not sufficient to ensure the identity is genuine” (Main & Robson 2001, p. 22).

Identity crime perpetrators have been categorised as organised crime, insiders, sophisticated, and opportunistic perpetrators (Jamieson & Stephens & Winchester 2007a). Perpetrators breach the privacy of individuals and other entities, to steal from or deceive their victims, obtaining their POI documentation and related PII, such as, bank account passwords. Provided with these details, perpetrators target customer bank accounts, retailers for goods and services, or a government agency for benefits thus, committing identity fraud acts (Jamieson & Land & Sarre & Steel & Stephens & Winchester 2008). Organisations need to be constantly investigating methods of improving procedures and systems to stay ahead of perpetrator innovations (Jamieson & Winchester & Smith 2007). The nature and extent to which individuals or organisations are able to share identity information as an approach to mitigating identity fraud perpetrators is based on two basic principles. Firstly, the rule of law and secondly, on the property rights of those holding private information (Gal-Or & Ghose 2005).

Strategies and policies (e.g., information sharing) to mitigate identity and related crimes have usually been modelled at the organisational-level (Cuganesan & Lacey 2003, Jamieson & Winchester & Smith 2007) or government-level (Jamieson & Land & Stephens & Winchester 2008). At the organisational-level, approaches often combine several specific anticipatory, reactionary or remediation elements. While at the national government-level a holistic methodology is often used. This has been the approach in countries such as, the US (e.g., Presidents Identity Theft Task Force), UK (e.g., Home Office), Canada (e.g., Reporting Economic Crime Online (RECOL)), among other countries (Fraud Prevention Expert Group 2007, Jamieson & Land & Sarre & Steel & Stephens & Winchester 2008, Pacific Islands Forum Secretariat 2004). Alternative perspectives on information sharing in IS research have been investigated through social construction, social presence, and task closure theories, while empirically based on small groups within organisations (see Nelson & Cooprider 1996, Miranda & Saunders 2003). A related strand of the literature focuses on information management. This includes: privacy of confidential identity information, and laws, protocols, and standards for protecting this information nationally and internationally (FDIC 2004, Wugmeister & Retzer & Rich 2007).
3 THEORETICAL BACKGROUND

In this paper we investigate information sharing within a knowledge management (Hedlund 1994) context, through a sensemaking in organisations (Weick 1995, Weick & Sutcliffe & Obstfeld 2005), and organisational learning lens (Thomas & Sussman & Henderson 2001). These models (see figure 1) have previously been used in IS research to study banking, manufacturing, education and identity fraud (Cecez-Kecmanovic 2004, Cecez-Kecmanovic & Jerram 2002, Jamieson & Stephens & Winchester 2007b, Janson & Cecez-Kecmanovic & Zupancic 2007). The six identified types of knowledge, corresponding to specific sensemaking levels are shown in Figure 1 with their interactions shown by directional arrows. Cecez-Kecmanovic and Jerram (2002, p.896) explain that the first level ‘individual knowledge’ involves a person’s values, beliefs, assumptions, experiences, and skills, that enable the individual to interpret and make sense of the environment, his/her own actions and the actions of others. The second level, ‘inter-subjective or collective knowledge’ represents shared understanding that emerges through social interaction”. The third level, ‘organisational knowledge’ denotes generic meanings and social structures that emerge in and reproduce within an organisation. The fourth level, ‘knowledge embedded in culture’ assumes a stock of tacit, taken-for-granted convictions, beliefs, assumptions, values, experiences and norms that members of an organisation draw upon in order to make sense of a situation and create meanings at all other levels.

The outer two circles in Figure 1 (left) apply to information sharing across organisations, industries, sectors and jurisdictions – nationally and internationally. The second outer (level 5) circle in the left diagram in Figure 1 named ‘inter-organisational knowledge’ is facilitated throughout organisations and individuals within those organisations (or from sections/departments in) collaboratively sharing information to solve new phenomena e.g., identity fraud (refer Jamieson & Stephens & Winchester 2007b). It brings to an individual organisation, shared knowledge from another or many organisations, and participating individual(s) through their social interaction (levels 1 to 4). While the outermost circle (level 6) ‘intra- and inter-sector knowledge’ encompasses knowledge within and across industry (intra-sector) and sectors (inter-sector). This may span jurisdictions within and across countries (see figure 2, for an Australian example). This will involve synthesising ‘industry culture’, ‘national culture’, professional culture’, and ‘wider cultural contexts’ for sensemaking and learning (see outside level 6 on the left diagram and right diagram in figure 1). As described by Cecez-Kecmanovic and Jerram (2002), and Janson, Cecez-Kecmanovic and Zupancic (2007) the issue is to reach the desired outcome for the phenomena, in this paper namely, to deter, detect, and prevent identity crime via information sharing. The umbrella for this collectiveness could be a committee, association or group.

---

**Figure 1. Sensemaking model of knowledge (left); and learning model in organisations (right)**
The learning model’s (see figure 1, right side diagram) learning loops are explained with examples relevant to sharing information to combat identity fraud in an organisation:

- **Single-loop learning**, “involves adaptive responses: measuring an organisation’s performance, comparing it with its stated goals and taking corrective action to close the gap” (Janson & Cecez-Kecmanovic & Zupancic 2007, pp. 6-7). For example, single-loop learning comprises adjusting a security system to make sure that the system meets privacy standards (legislation, protocols);

- **Double-loop learning** “involves evaluating and changing organisational goals, organisational strategies and mental maps” (Janson & Cecez-Kecmanovic & Zupancic 2007, pp. 6-7). For example, if a system is hacked with the loss of data, a firm is required to rethink its security procedures and develop new mental maps to allow the firm to change its security strategy through information sharing with others (levels 5 or 6 in figure 1); and

- **Triple loop learning** “occurs in response to a realisation that existing mental models and ways of organisational learning no longer suffice” (Janson & Cecez-Kecmanovic & Zupancic 2007, pp. 6-7) e.g., profiling to prevent identity crime (Jamieson & Winchester & Stephens & Smith 2008).

*Table 1: Participant Code, Category and Role Key (*Teleconference Participants)*

The research involves a mixed-method approach including: the use of industry-based pilot interview; and cross-sectional participant interviews (quotes are in *italics*, see table 1, for interviewee roles and category). In addition, we use secondary data ‘key word’ database searches for terms such as, information sharing, data matching, computer matching, identity, identity fraud, identity theft, and identity deception to build a better picture of the literature. Recordings were transcribed and transcripts coded using ‘key word themes’ in NVivo 2 (QSR International) qualitative analysis software. Interviewees were provided with transcripts so that they could retract any sensitive information or correct or add details from databases or other sources. Interview duration varied from 45 minutes for teleconferences to approximately 90 minutes for face-to-face interviews. Interviews were conducted (or supervised) by senior experienced academics, industry personnel, and an honours student. Ethical approval was sought and granted by the university ethics committee. A pilot interview was undertaken to test the survey instruments open-ended questions (which are not included here due to space constraints). The four main themes of the survey instrument were: What is Identity Fraud in Your Organisation; Managing Identity Fraud; Identity Fraud Reporting; and Identity Fraud Issues and

Proceedings ECIS 2009
Research. Participants selected were from organisations that issued or used proof of identity documents, personal identifying information or were highly targeted organisations (sectors) by identity fraud perpetrators e.g., Banks, Telecommunication organisations, Licensing or Welfare Agencies.

5 DISCUSSION: INFORMATION SHARING AND LEARNING

5.1 Organisational (Knowledge) Information Sharing

In Australia all financial institutions for bank account opening and government agencies for welfare eligibility are legally bound to identify their customers. Financial institutions are regulated under the Anti-Money Laundering and Counter-Terrorism Financing Act 2006 (similarly, section 326 USA PATRIOT Act 2001). Often protocols are drawn-up for the specific purpose of clarifying the process and types of information that may be exchanged. They are ‘dynamic’ agreements of no legal standing between various parties. Therefore, they are impacted by changes in legislation and guiding principles, and should be amended accordingly. The sharing and exchange of information is not something to be taken lightly, and it is fundamental to the success of any strategy to reduce identity and related crimes.

"Do not under-estimate the intelligence and innovation of the bad guys" (Participant 11). Identity fraud perpetrators have to-date managed to extract a huge economic and social cost of many billions of US dollars from the private and public sectors (Jamieson & Land & Stephens & Winchester 2008). Perpetrators obtain identity details by traditional, mechanical or digital identity replicating devices or via cyber space identity crime methods (Jamieson & Stephens & Winchester 2007a). One way to fight back against identity fraud perpetrators is to match information by sharing proof of identity details presented by the perpetrator to details of the real customer from other public and proprietary sources – especially for remote transactions. Any discrepancies will be: alerted, red flagged, and will require additional evidence of identity or face-to-face presentation. This identity corroboration occurring in the background is very effective and little different to customer service asking ‘non-wallet’ questions (e.g., your mothers’ maiden name) to match with previously supplied identity attributes. When customers supply their identity details, organisations are expected to hold this data under tight security and privacy regimes – often legally defined. There could be serious consequences for getting the identity of the suspected perpetrator wrong, including potential fines, court penalties or reputational loss. Often in the past data breaches have been ‘hushed up’ to protect the reputations of organisations. Now governments are legislating to protect consumers, for example, California's data breach laws.

Besides the common goal to catch identity fraud perpetrators, private organisations’ reasons for information and data sharing with public or other private organisations should be aligned to selfish motives of ‘profits’ (Gal-Or & Ghose 2005, Gordon & Loeb & Lucyshyn 2003). Otherwise these private organisations could be giving away their long-term sustainable competitive advantage (Alavi & Leidner 2001). Competition for these profits may lead to unscrupulous data resellers off-loading ‘dirty data’ (Marx & Reichman 1984). The use of dirty data in data matching processes might reveal a high number of ‘false’ (positives) potential perpetrators being questioned. The aim of identification of individuals through information sharing is to cut off perpetrators’ sources of funding.

The Australian Federal Privacy Act (1988) contains 11 Information Privacy Principles which apply to Commonwealth and Australian Capital Territory (ACT) government agencies. It also has 10 National Privacy Principles which apply to parts of the private sector and all health service providers. The Privacy Commissioner also has regulatory functions under some other laws: the Telecommunications Act 1997 (Commonwealth); National Health Act 1953 (Commonwealth); Data Matching Program (Assistance and Tax) Act 1990 (Commonwealth) - of the Australian Tax Office, Centrelink (a welfare agency) and the Department of Veteran's Affairs and the Crimes Act 1914 (Commonwealth). Our focus is on the Privacy Acts, the Datamatching Program (Assistance and Tax) Act 1990, and the protocols for the conduct of the data-matching program (the statutory data-matching guidelines). In
Australia, some government agencies are exempt from the Australian Privacy Act 1988 (Commonwealth), e.g., the Australian Crime Commission (Australian Crime Commission 2007). From 21 December 2001 the private sector amendments to the Privacy Act 1988 (the ‘Act’) came into force. Schedule 3 of the Act, applies to the private sector. The National Privacy Principles are in addition to existing legislation, guidelines which apply to the private sector. Part IIIA of the Act applies to credit providers and credit reporting agencies. The Credit Reporting Code of Conduct is also a binding law on credit providers and credit reporting agencies – organisations typically targeted by perpetrators. This Code was issued by the Privacy Commissioner (the ‘Commissioner’) under section 18A of the Act in 1991 and is complementary to Part IIIA of the Act. Three other significant areas which are monitored by the Commissioner which affect parts of the private sector are in relation to:
- the collection, storage, use and security of personal tax file numbers by organisations that are authorised or approved to record such information under taxation, assistance agency or superannuation law;
- the disclosure of personal information to law enforcement agencies under Part 13, Division 5 of the Telecommunications Act 1997 (Commonwealth), and
- the handling of personal information under the Anti-Money Laundering and Counter-Terrorism Legislation (2006). Under section 6E (1A) of the Privacy Act 1988 (Commonwealth) certain activities of some small businesses previously exempted are brought within coverage of the Act.

5.2 Inter-Organisational (Knowledge) Information Sharing

The difficulty in current business operations is that organisations, both private and public, are moving away from traditional face-to-face contact with customers to remote cyber space channels – Internet and mobile. “The downside of this situation is that identity fraud perpetrators use it to their advantage as well” (Participant 2:1). This is usually not a problem with genuine customers performing their normal tasks. However, a major problem for organisations is when identity fraud perpetrators use POI and PII that is not their own in the guise of a genuine current or potential customer to extract some illegal benefit or to avoid a cost or loss. It is well established from survey results that there are significant costs to the victim (customer and target entity) to re-establish their identity or situation to a comparable prior position (FDIC 2004). The costs do not only include money and time but also the sociological and psychological impact on them deciding that they can no longer be who they really were when they were born. This goes to the very core of an individual’s ‘identity’. There are many recent instances of ‘identity’ data security breaches where individuals have had their POI details stolen (Main & Robson 2001; Privacy Rights Clearinghouse 2008). Security breaches have occurred more frequently over the past five years with highly sensitive personal data lost or stolen, such as, personal identification numbers and driver’s licence details, or private information like ‘mother’s maiden name’ (Times Online 2007). One cause of this is the high portability of data storage devices e.g., laptops, etc.

One interviewee stated the need to move to alternative methodologies to verify a customer. For example, in less populated areas instances of using a local agent, the solicitor or the policeman or ask the customer to give a range of data about themselves. The details could be read from a driver’s licence, birth certificate, or passport. These are POI documents, with supporting databases that would give the organisation identity verification if the customer were in front of them. At issue now is the need for a way of validating the information provided back to the source of the documents, generally the government agency that issued it, to establish the documents as valid. A valid set of documents still does not tell the validating organisation, in ‘customer-not-present’ situations, that the remotely located person is in fact the person to whom the documents purport them to be. “For example, it could be the son-in-law who’s simply gone into the bedroom and lifted all this data. We need to be able to deal with our customers 24 hours 7 days, no matter what the location is. It’s about getting that veracity underneath the identity that’s the issue, not the documents per se” (Participant 2:1).

Some organisations stated that realistically, the data matching or information sharing tools, the front end tools in use, are not that effective. Examples quoted of front end tools in use, include: the Hunter
(Experian) style system; Decision Point, which is a product through Baycorp (a credit bureau); also a product called Fraud Check via Baycorp for fraud cheque style systems. “I think it’s fair to say, that as we get more sophisticated in the original analysis of facilities (products) we’re preventing more identity related fraud. We’ve now got reasonably sophisticated up front data matching capabilities.” (Participant 2:2). Similarly, Participant 3’s, long-term strategic solution in identity crime involves implementing software now and in the future. “With the Birth Deaths and Marriages systems currently in place, there has been a lot of lobbying with industry representatives, like the Bankers Association and through, the Provider Advisory Group, to push legislative change and get industry (sector) support. (This is) in terms of those state government bodies that are responsible for issuing identification documentation, to try and increase the security around those providers with access to verify the authenticity of those proof of identity documents. So you have to have rules - tell me your mother’s maiden name plus two others (secrets). The detection technology that we have in place for our products - be they electronic banking, cheques, credit cards, or applications – they do pick up a lot of identity fraud, but we just basically want to identify all fraud” (Participant 3:2). However, we need to be aware that it is unlikely technology will solve all the problems of sharing because tacit elements cannot be transmitted (Hislop 2002). Where knowledge is more explicit, sharing would be a lot more amenable with technology.

5.3 Intra- and Inter-Sector (Knowledge) Information Sharing

Participant 1:1, stated that an example of a measure gaining an advantage over perpetrators was “participation in a pilot with Bankers Association and a Licensing Authority Participant 2 and BDM” Often information is passed from the private sector to law agencies as part of a collaborative information sharing. “We do external reporting to XYZ organisation for cheque fraud, to the credit card schemes for credit card fraud, and we’ve also commenced to do some trialling of supplying some fraud data to another government agency (e.g., the Australian Crime Commission see figure 2) and we report fraud data to participant 10” (Participant 2:1). Organisations can also subscribe to commercial organisations that supply identity details to them. Other tools or systems in place by industry organisations check for the identity, verifying phone numbers against electronic White Pages, electoral roll data sets among others. Additional issues regarding data matching and information sharing were “things which are embedded into legacy style controls - checking of signatures on cheques. If the banks still did that, the cost to run that is the cost of control, one of the traditional controls. The cost of asking the wallet and non-wallet questions at the call centre is also a cost to control at a level of unauthorised – it’s also got privacy implications and is a fraud prevention control” (Participant 2:2).

In May 2006 the Australian Federal Government announced an increased focus on identity crime with the establishment of a national Document Verification Service that will allow for ‘blind’ inter-departmental cross-checking of documents (Wentworth Courier 2006). If there has been a hit on a person’s identity, by and large, it will not be captured by the credit reporting bureaus, which is a big problem for banks that use third party verification services. People are having their whole credit history basically altered or adulterated as a result of somebody helping themselves to their identity and perpetrators identity fraud. Government and taxpayers trust government agencies with delivering services, and there would be community revolt if information came out that showed inappropriate people were receiving more payments than they were entitled to. “We actually had a case where we waited until the individual accessed the false bank account and tapped him on the shoulder while he was at the ATM. The Australian Federal Police were there to make the arrest” (Participant 9:5).

Within the tax system identity fraud has been shown to affect the revenue collection, and goods and services tax fraud areas. For instance, the act of people falsely claiming input credits would be considered more fraud than identity fraud. If, on the other hand they are actually pretending to be some other entity in order to make the claim, then it becomes identity fraud. With the Higher Education Contribution Scheme, there is evidence that students are using one tax file number, and acquiring another separate tax file number after completion of their degree, thus, effectively setting
their education debt aside and permitting them to avoid paying down their debt. Other examples are income tax splitting, gaining employment whilst on welfare benefits, and a family tax benefit. This is referred to as ‘double-dipping’, basically an individual claims through the welfare system and through the taxation system; if the identity does not match between the welfare and the taxation systems they avoid detection. With the data matching processes implemented under various pieces of legislation, many identity fraud and fraud perpetrators are being caught. But the data matching is premised on data quality and if the data quality is ‘dirty’ (Marx & Reichman 1984) in the taxation system and in the private health funds, there is a problem. With most government benefits a customer needs a tax file number, so that even a slight change (in proof of identity) reduces the efficiency of the matching process and produces a low level of confidence in any matches detected. We can’t data match on everything. We can’t match data if evidence of wrong doing is not strong enough. In addition, we rely on the processes and documents of others. There is still the Privacy Commissioner who is quick to remind us that it is not mandatory in a lot of instances to quote your tax file number. Although there are some strong inducements like 50% tax rate penalty if a number is not supplied (Participant 11:1).

Immigration authorities around the world have a ‘person alert list’ and a ‘document alert list’. If the proof of identity (POI) document is stolen (identity theft), or altered, or totally fictitious (identity deception), it goes on an ‘alert’ and a risk rating algorithm would pick it up from that information and other sources and try and stop the use of the POI document. For the organisation, the problem is service versus compliance and integrity of the information and POI documents through the vetting process. The community has an expectation that the tax file number, drivers licence, passport are correct (no errors, duplicates, or false entries). Government agencies solve these POI database issues by matching records in the databases in Australia on identity details. Agencies look at the exceptions, for example, ages during matches with death, birth, citizenship and immigration records. In Australia, many citizens are registered in the Centrelink registry, in the tax system, and in the Health Insurance Commission. “The problem is we are now dealing with databases. Some are client-based registers; others have an event or a vehicle type of register. The three axes of data matching tend to be name, address and date of birth. In a perfect world we remove any privacy or that sort of problem; we could all do it by data matching or database security. We are certainly looking at data matching. Essentially, it is a virtual database of the population at any one time. It is not something one agency could do on its own. It is not a single issue, it is not a single agency issue and that is the problem. We couldn’t just swap identity details with any other agencies” (Participant 11:1).

The major issues restricting how entities would implement information sharing are particularly to do with privacy issues. “Which is why it’s important to recognise that the personal information isn’t being passed back to the bank, and that the banks, or whoever, don’t have unfettered access. They can’t have access to the systems themselves, they are just getting that sort of a yes, no answer. And that, of course, limits how much verification you can do. I think that’s the major issue. You could centralise data within government, probably much more easily. But again, the whole privacy issue can’t be cross matched ... all the data matching issues that come up in terms of privacy are obviously something that will have to be looked at” (Participant 10:1). The Australian Crime Commission have an identity fraud register (see figure 2, arrows show information flows), where the major banks and other organisations, including the commonwealth and international agencies, are providing information about identity fraud. This information has actually been compared to other entities databases and there have been a significant number of hits on people on the databases. “The banks can match up, not just whether it’s a fake birth certificate, but whether the person who holds it is dead. Extending that, obviously there are all sorts of issues about whether you could have that sort of access to Medicare information, passport and immigration” (Participant 10:1).

Figure 2 shows the Australian Crime Commission's an Australian Federal agency’s main Australian Criminal Intelligence Database and collaborative information sharing initiatives between regional countries (Pacific Islands Forum Secretariat 2004), and the Australian Commonwealth and state governments Identity Fraud Register. The Identity Fraud Register provides valuable intelligence to law enforcement by keeping a register of identities suspected of being fraudulent. The Australian Law
Enforcement Intelligence Net (ALEIN) “is a secure national extranet used by all Australian police services, the New Zealand Police, state Crime Commissions and a large number of government law enforcement agencies. ALEIN provides a dissemination capability for the Australian law enforcement community and enables cooperative intelligence sharing across jurisdictional boundaries. ALEIN provides real-time, secure intelligence communications between the ACC, police jurisdictions, and other law enforcement agencies across Australia” (Australian Crime Commission, ACC 2004, p. 31).

The police through the Australian Federal Police share information internationally through Interpol.

Figure 2. Australian Crime Commission Information Sharing Regime to Combat Identity Fraud

Information sharing interrelationships shown in Figure 2 also occurs in other government agencies (and they may interact with figure 2 databases). There are inhibitors on this sharing based on what is allowed under legislation. Entities have to work within these parameters. In Australia, driver licensing authorities have access to a national system, which allows authorities to look at licensing information from different states. In a government agency “cross-organisational participation and information sharing agreements do not exist holistically. Participant 8 has access to the Australian Electoral Commission, Participant (11), BDM, and Participant (7) databases but the information flow is one way for privacy reasons”. Similarly outside Australia, information sharing issues may be country specific, depending on what the other country’s privacy legislation and agreements with Australia or another jurisdiction are (see Fraud Prevention Expert Group 2007). In some cases it may actually be easier to share information, but in many other cases it is much more difficult because some countries may be unwilling to provide any information, unless they can see they can get a direct benefit out of it. “The international cooperation branch, that looks specifically at issues to do with countries overseas where Australia has an interest in getting cooperation on certain issues, on sharing information with those countries, and establishing formal systems and structures. It might be with memorandums of understanding or agreements with those countries that we’ll share information on certain issues” (Participant 7:1).

5.4 Organisational Learning

Organisational learning within participant interviewee’s organisations (Table 1, codes 1-11) was at the single-loop learning phase with respect to the identity crime phenomena. This was mainly due to identity crime within an organisation seldom seen as a problem from a whole-of-organisation perspective. It was often seen as a problem for the fraud department. Further interviews with the participant organisations to obtain additional organisational learning information may shed light on whether improvements have occurred in individual organisations. An important observation for the organisational learning model is when a new organisation (association, group, or committee) is set up to share information and learn from many other organisations with a purpose (or intent) to better understand a new phenomenon such as identity and related crimes. This reinforced our choice of lens.
6 CONCLUSIONS AND FURTHER RESEARCH

The sharing of identity attribute information within and across organisations or sectors has real value for those able to do so under current (Australian) privacy and related legislation. Information sharing has been proven to be an effective methodology to detect, deter and prevent identity and related crime perpetrators by many Australian organisations. As more identity fraud cases move through the judicial system the penalties perpetrators receive will act as a further deterrent to others. However, a substantial amount of privacy and related legislation enacted to protect individuals and entities identity attributes (sensitive information) may in some ways actually be helping perpetrators. This may hinder an organisation’s ability to collaborate through information (data) sharing, as the perpetrators hide behind privacy regimes. We applied the extended sensemaking model of knowledge management in organisations (Jamieson & Stephens & Winchester 2007b) and organisational learning model (Janson & Cecez-Kecmanovic & Zupanic 2007) to an intra- and inter-sector context, grounded from Australian based interviews. An example was also shown in Figure 2 highlighting the national and international effect of information sharing to mitigate identity fraud where perpetrators act across jurisdictions. This may create inter-jurisdictional problems or loopholes that perpetrators may exploit.

Interviewee feedback suggests we need to do more information (data) sharing via bilateral or multilateral communication and via linking and interrogating data sets or databases. A second finding is that the data to be matched or shared information needs to be free of errors as possible. Third, we need effective legislation that allows meaningful data sharing, where POI details (presented by the perpetrator) are matched to the bone fide customer details from other public and proprietary sources. Finally, organisational learning was mostly single-loop. Further interviews may detect learning (loop) improvements. These findings from our experts help to support an AC Nielsen poll finding that two-thirds of Australians were willing to sacrifice privacy and civil liberties for protection – especially against terrorists (Dodson 2006). Future research could use these models in different country settings.
